Kaspersky EDR Expert 8.3 Help
What's new
Fixed issues
About Kaspersky EDR Expert
- Distribution kit
- Hardware and software requirements
- Kaspersky Deployment Toolkit requirements
- Compatible applications and solutions
- Architecture of Kaspersky EDR Expert
- Basic concepts
  - Administration Server
  - Hierarchy of Administration Servers
  - Web Server
  - Network Agent
  - Administration groups
  - Managed device
  - Unassigned device
  - Administrator's workstation
  - Management web plug-in
  - Policies
  - Policy profiles
  - Tasks
  - Task scope
  - How local application settings relate to policies
  - Distribution point
  - Connection gateway
  - Core
  - Repository
  - Collector
  - Correlator
  - Events
  - Alerts
  - Incidents
  - Resources
  - Services
  - About Severity

About data provision
- About data provision
- Data provision in Kaspersky Unified Monitoring and Analysis Platform
- Data provision in Sandbox

Licensing
- About the End User License Agreement
- About the license key

- About the activation code
- About the key file
- Activating Kaspersky EDR Expert
- Viewing information about license keys in use
- Revoking consent with an End User License Agreement
- Renewing licenses for Kaspersky applications
- Using Kaspersky Marketplace to choose Kaspersky business solutions

Sizing calculations
- Calculations for Kaspersky EDR Expert components
- Calculations for Kaspersky EDR Expert 4-node deployment
- Calculations for Kaspersky EDR Expert 6-node deployment
- Calculations for high availability cluster configurations
- Calculations for Sandbox

Deployment of Kaspersky EDR Expert
- Single-node deployment on a standard Ubuntu Server 24.04 LTS virtual machine
- Single-node deployment on a standard Astra Linux Special Edition (operational update 1.8.2) virtual machine
- Multi-node deployment on standard Ubuntu Server 24.04 LTS virtual machines
- Multi-node deployment on standard Astra Linux Special Edition (operational update 1.8.2) virtual machines
- High availability configuration deployment on standard Ubuntu Server 24.04 LTS virtual machines
- High availability configuration deployment on standard Astra Linux Special Edition (operational update 1.8.2) virtual machines
- Hardening Guide
  - Managing infrastructure of Kaspersky EDR Expert
  - Connection safety
  - Accounts and authentication
  - Managing protection of Kaspersky EDR Expert
  - Managing protection of client devices
  - Event transfer to third-party systems
  - Configuring protection for managed applications
- Deployment schemes
  - Single-node deployment scheme
  - Multi-node deployment: 4-node profile scheme
  - Multi-node deployment: 6-node profile scheme
  - High availability deployment: 14-node profile scheme
  - Multi-site deployment
- Ports used by Kaspersky EDR Expert
  - Changing the port used to connect to the OSMP Console server
  - Changing the port used by Endpoint Agents to connect to the agentserver component
- Preparation work and deployment
  - Multi-node deployment: Preparing the administrator and target hosts
  - Single-node deployment: Preparing the administrator and target hosts
  - Preparing the hosts for installation of the KUMA services
  - Installing a database management system
  - Configuring the PostgreSQL or Postgres Pro server for working with Kaspersky EDR Expert
  - Preparing the KUMA inventory file for installing KUMA services outside the Kubernetes cluster
  - Multi-node deployment: Specifying the installation parameters
  - Single-node deployment: Specifying the installation parameters
  - Connecting Endpoint Agents through a proxy node

- Specifying the installation parameters by using the Configuration wizard
- Installing Kaspersky EDR Expert
- Configuring internet access for the target hosts
- Synchronizing time on machines
- Installing the KUMA services inside the Kubernetes cluster
- Installing KUMA services outside the Kubernetes cluster
- Deployment of multiple Kubernetes clusters and Kaspersky EDR Expert instances
- Installing and upgrading Kaspersky EDR Expert in an air-gapped environment
- Pre-check of infrastructure readiness for deployment
- Pre-installation integrity check of Kaspersky EDR Expert components
- Signing in to Kaspersky EDR Expert

Integration with Endpoint Agents

Sandbox preparation and installation

- Preparing IT infrastructure for the Sandbox installation
- Preparing a virtual machine for installing Sandbox
- Preparing an installation disk image
- Installing Sandbox
  - Step 1. Viewing the End User License Agreement and Privacy Policy
  - Step 2. Selecting a disk for installing Sandbox
  - Step 3. Configuring the minimum password length for the Sandbox administrator password
  - Step 4. Creating the Sandbox administrator account
  - Step 5. Configuring a management network interface
  - Step 6. Assigning a hostname and adding DNS server addresses
  - Step 7. Configuring a static network route

Integration with Sandbox

High-availability deployment of Kaspersky EDR Expert

- High-availability configuration of Kaspersky EDR Expert
- Restoring a failed node in the Kubernetes cluster

High-availability multi-site deployment of Kaspersky EDR Expert

- Multi-site deployment: Preparing the administrator and target hosts
- Multi-site deployment: Specifying the installation parameters
- Cross-datacenter multi-site deployment on standard Ubuntu Server 24.04 LTS virtual machines

Kaspersky EDR Expert maintenance

- Updating Kaspersky EDR Expert components
- Checking the integrity of installed Kaspersky EDR Expert components
- Changing the Kaspersky EDR Expert parameters without reinstalling
- Adding and deleting primary and worker nodes of the Kubernetes cluster
- Versioning the configuration file
- Uninstalling Kaspersky EDR Expert
- Manual uninstalling of Kaspersky EDR Expert components
- Reinstalling Kaspersky EDR Expert after a failed installation
- Reinstalling Kaspersky EDR Expert components
- Stopping the Kubernetes cluster nodes
- Using certificates for public Kaspersky EDR Expert services
- Calculation and changing of disk space for storing Administration Server data
- Viewing and changing disk space for KUMA Core and the Metrics service
- Viewing and changing the object storage size

Increasing the observability storage size
Rotation of Kubernetes cluster certificates
Rotation of Registry access credentials
Rotation of DBMS credentials and certificates
Adding hosts for installing the additional KUMA services
Replacing a host that uses KUMA storage
Working with Kaspersky EDR Expert deployed on virtual machines
Настройка модели статусов инцидентов
Demonstration deployment of Kaspersky EDR Expert
Preparing the administrator and target hosts
Specifying the installation parameters
Getting started
Initial setup of Kaspersky EDR Expert
Verifying correctness of the Kaspersky EDR Expert configuration
Using the threat monitoring, detection and hunting capabilities
Example of incident investigation with Kaspersky EDR Expert
Upgrading Kaspersky EDR Expert from version 8.2 to version 8.3
Migration to Kaspersky EDR Expert
About migration from Kaspersky Security Center Windows
Exporting group objects from Kaspersky Security Center Windows
Importing the export file to Kaspersky EDR Expert
Switching managed devices to be under management of Kaspersky EDR Expert
About migration from KEDR 7.1
Setting up and working with the SIEM component
KUMA services
Services tools
Getting service identifier
Stopping, starting, checking status of the service
Restarting the service
Deleting the service
Viewing the table of active queries
Partitions window
Searching for related events
Service resource sets
Creating a storage
ClickHouse cluster structure
ClickHouse cluster node settings
Cold storage of events
Removing cold storage disks
Disconnecting, archiving, and connecting partitions
Creating a set of resources for a storage
Creating a storage service in OSMP
Installing a storage in the OSMP network infrastructure
Backing up, restoring, and importing partitions
Scheduling partition backup
Manually backing up partitions

Importing partitions from an external OSMP instance
Restoring partitions from backup
Creating a collector
Starting the Collector Installation Wizard
Step 1. Connect event sources
Step 2. Transport
Step 3. Event parsing
Step 4. Filtering events
Step 5. Event aggregation
Step 6. Event enrichment
Step 7. Routing
Step 8. Setup validation
Installing a collector in a KUMA network infrastructure
Validating collector installation
Ensuring uninterrupted collector operation
Event stream control using rsyslog
Event stream control using nginx
Predefined collectors
Creating a correlator
Starting the Correlator Installation Wizard
Step 1. General correlator settings
Step 2. Global variables
Step 3. Correlation
Step 4. Enrichment
Step 5. Response
Step 6. Routing
Step 7. Setup validation
Installing a correlator in OSMP network infrastructure
Validating correlator installation
Creating a correlator-ng correlator
Configuring the correlator correlator-ng
Supported data types for correlator-ng
Correlation rule selectors and expressions
Attributes of the 'standard' correlation rule
Data functions in correlator-ng
Configuring event sources
Configuring receipt of Auditd events
Installing KUMA collector for receiving Auditd events
Configuring the event source server
Configuring receipt of KATA/EDR events
Configuring export of KATA/EDR events to KUMA
Creating KUMA collector for receiving KATA/EDR events
Installing KUMA collector for receiving KATA/EDR events
Integration with other solutions
Integration with Kaspersky Security Center
Configuring the data refresh interval for Kaspersky Security Center assets
Scheduled import of Kaspersky Security Center assets

- Manual import of Kaspersky Security Center assets
- Viewing the hierarchy of Kaspersky Security Center Servers
- Importing events from the Kaspersky Security Center database

Integration with Kaspersky CyberTrace
- Integrating CyberTrace indicator search
  - Configuring CyberTrace to receive and process requests
  - Creating event Enrichment rules
- Integrating CyberTrace interface

Connecting over LDAP
- Enabling and disabling LDAP integration
- Adding a tenant to the LDAP server integration list
- Creating an LDAP server connection
- Creating a copy of an LDAP server connection
- Changing an LDAP server connection
- Changing the data update frequency
- Changing the data storage period
- Starting account data update tasks
- Deleting an LDAP server connection

Kaspersky Industrial CyberSecurity for Networks integration
- Configuring integration in KICS for Networks
- Configuring integration in KUMA
- Enabling and disabling integration with KICS for Networks
- Changing the data update frequency
- Special considerations when importing asset information from KICS for Networks
- Changing the status of a KICS for Networks asset

Integration with Neurodat SIEM IM

Kaspersky Automated Security Awareness Platform
- Creating a token in KASAP and getting a link for API requests
- Configuring integration in KUMA
- Viewing information about the users from KASAP and changing learning groups

Sending notifications to Telegram
- Creating and configuring a Telegram bot
- Creating a script for sending notifications
- Configuring notifications in KUMA

UserGate integration
- Configuring integration in UserGate
- Preparing a script for integration with UserGate
- Configuring a response rule for integration with UserGate

Integration with Kaspersky Web Traffic Security
- Configuring integration in KWTS
- Preparing a script for integration with KWTS
- Configuring a response rule for integration with KWTS

Integration with Kaspersky Secure Mail Gateway
- Configuring integration in KSMG
- Preparing a script for integration with KSMG

Importing asset information from RedCheck

- Configuring receipt of Sendmail events
  - Configuring Sendmail logging
  - Configuring export of Sendmail events
- Configuring integration with an external SIEM system

Managing KUMA
- Configuring the KUMA Core
- Proxies
- Connecting to an SMTP server
- Working with Kaspersky Security Center tasks
  - Creating KUMA tasks in Kaspersky Security Center
  - Starting Kaspersky Security Center tasks manually
  - Starting Kaspersky Security Center tasks automatically
  - Checking the status of Kaspersky Security Center tasks
- KUMA logs
- KUMA notifications
- Editing a KUMA user profile
- Working with tenants

Managing certificates
- Downloading certificates
- Modifying the self-signed web interface certificate
- Reissuing internal CA certificates
- Reissuing a certificate for a specific service

Working with geographic data
- Geodata format
- Converting geographic data from MaxMind to IP2Location
- Importing and exporting geographic data
- Default mapping of geographic data

Working with the knowledge base
- Viewing package details
- Viewing resource details
- Installing and updating packages and resources

KUMA resources
- Operations with resources
  - Creating, renaming, moving, and deleting resource folders
  - Creating, duplicating, moving, editing, and deleting resources
  - Linking resources to services
  - Updating resources
    - Configuring a custom source using Kaspersky Update Utility
  - Exporting resources
  - Importing resources
  - Tag management
- Destinations
  - Destination, internal type
  - Nats-jetstream type
  - Tcp type
  - Udp type
  - Http type

- Diode type
- Kafka type
- File type
- Storage type
- Correlator type
- Predefined destinations

Normalizers

- Event parsing settings
- Extended event schema
  - Adding extended event schema fields
  - Editing extended event schema fields
  - Importing and exporting extended event schema fields
  - Deleting extended event schema fields
  - Using extended event schema fields in normalizers
- Generating regular expressions with KIRA
- Enrichment in the normalizer
- Conditions for sending data to an extra normalizer
- Supported event sources

Aggregation rules

Enrichment rules

Correlation rules

- Standard correlation rules
- Simple correlation rules
- Operational correlation rules
- Variables in correlators
  - Local variables in identical and unique fields
  - Local variables in selector
  - Local Variables in event enrichment
  - Local variables in active list enrichment
  - Properties of variables
  - Requirements for variables
  - Functions of variables
  - Declaring variables
- Predefined correlation rules
- Adding a temporary exclusion list for a correlation rule
- Sigma rules converter
  - Preparing a Sigma rule
  - Examples of supported Sigma rule conversions
- MITRE ATT&CK matrix coverage

Filters

Active lists

- Viewing the table of active lists
- Adding active list
- Viewing the settings of an active list
- Changing the settings of an active list
- Duplicating the settings of an active list
- Deleting an active list

Viewing records in the active list
Searching for records in the active list
Adding a record to an active list
Duplicating records in the active list
Changing a record in the active list
Deleting records from the active list
Import data to an active list
Exporting data from the active list
Predefined active lists
Dictionaries
Response rules
Response rules for Kaspersky Security Center
Response rules for a custom script
Response rules for KICS for Networks
Response rules for Kaspersky Endpoint Detection and Response
Active Directory response rules
Data collection and analysis rules
Virtual Administration Server
Connectors
Viewing connector settings
Adding a connector
Connector settings
kata/edr type
Secrets
Context tables
Viewing the list of context tables
Adding a context table
Viewing context table settings
Editing context table settings
Duplicating context table settings
Deleting a context table
Viewing context table records
Searching context table records
Adding a context table record
Editing a context table record
Deleting a context table record
Importing data into a context table
Exporting data from a context table
Building a hierarchy of OSMP instances
Connecting a child instance to the parent instance
Assigning a secondary Administration Server within the hierarchy of OSMP instances
Disconnecting a child instance from a parent instance
Distribution of the correlation rules in the hierarchy
Distributing global correlator configuration along with global correlation rules
Distributing global correlation rules for local use
Duplicating the inherited correlation rules for local use

- Viewing resources and services created in child OSMP instances
- Folder behavior when distributing resources in the hierarchy
- Combining OSMP instances into a hierarchy
- Reparing an instance hierarchy after certificate rotation

OSMP Console interface
- Changing the language of the OSMP Console interface
- Changing the OSMP Console home page
- Adding and removing bookmarks
- New KEDR navigation

Threat detection
- Working with alerts
  - About alerts
  - Alert data model
  - Viewing the alert table
  - Viewing alert details
  - Assigning alerts to analysts
  - Changing an alert status
  - Creating alerts manually
  - Linking alerts to incidents
  - Unlinking alerts from incidents
  - Linking events to alerts
  - Unlinking events from alerts
  - Searching for events related to an imported IOA alert
  - Working with alerts on the investigation graph
  - Adding an IOA rule to exclusions
  - Managing aggregation rules
    - Creating aggregation rules
    - Editing aggregation rules
    - Copying aggregation rules to another tenant
    - Deleting aggregation rules
- Working with incidents
  - About incidents
  - Incident data model
  - Creating incidents
  - Creating child incidents
  - Viewing the incident table
  - Viewing incident details
  - Assigning incidents to analysts
  - Changing an incident status
  - Changing an incident priority
  - Merging incidents
  - Exporting incidents to a file
  - Creating Managed Detection and Response incidents from EDR incidents
  - Segmentation rules
  - Copying segmentation rules to another tenant

- Managing Service Level Agreement (SLA)
  - Creating Service Level Agreement (SLA) entries
  - Deleting Service Level Agreement (SLA) entries
- Managing incident types
  - Viewing the incident types table
  - Creating incident types
  - Editing incident types
  - Deleting incident types
- Managing incident workflows
  - Viewing incident workflows table
  - Predefined incident workflows
  - Рабочий процесс по ГОСТ
  - Creating incident workflows
  - Editing incident workflows and statuses
  - Deleting incident workflows
- Managing incident effort
  - Adding effort for incidents
  - Editing effort for incidents
  - Deleting effort for incidents
  - Generating and exporting incident reports
- Configuring the retention period of alerts and incidents
- Viewing asset details
- Investigating and responding via remote terminal
  - Managing remote terminal connections
  - Performing response actions via remote terminal

Threat hunting

- Event data model
  - Process
  - File Create
  - File Modify
  - File Rename
  - File Read
  - File Delete
  - File Attributes Modify
  - File Creation Time Modify
  - File Hardlink Created
  - File Symlink Created
  - Module
  - Registry Create
  - Registry Delete
  - Registry Modify
  - Registry Rename
  - Registry Query
  - Registry Save
  - Connection
  - Port Listen
  - AMSI Scan

Connection Close

- Working with events
  - Granular access to events
  - Viewing the events table
  - Searching and filtering events
  - Manually creating SQL queries
  - Generating an SQL query using a builder
  - Generating an SQL query using KUMA SQL functions
    - Using the 'enrich' function set in SQL queries
    - Using the 'lookup' function set in SQL queries
  - Viewing event details
  - Saving and selecting events filter configuration
  - Filtering events by time range
  - Exporting events
  - Viewing audit events and configuring notifications
    - Audit events
- Retroscan
- Getting events table statistics

Threat response

- Response actions
  - Terminating processes
  - Moving files to quarantine
  - Performing the Add prevention rule and Delete prevention rule response actions
  - Managing a service
  - Getting files for further analysis
    - Getting a file
    - Getting a registry key
    - Getting NTFS metafiles
    - Getting forensics
    - Getting a disk image
    - Getting a memory dump
    - Getting a process memory dump
    - Getting a file from quarantine
  - Scanning devices for threats
    - YARA scan
    - IOC scan
  - Deleting a file
  - Responding through Active Directory
  - Enabling and disabling network isolation
  - Running a program
  - Viewing response history from alert or incident details
- Working with files obtained as a result of response actions
- Working with the table of prevention rules
  - Creating a prevention rule
  - Importing a prevention rule
- Working with the table of IOC rules
- Working with the table of YARA rules

Playbooks
- Response actions available in playbooks
- Viewing the playbooks table
- Creating playbooks
- Configuring playbook execution steps in visual editor
- Editing playbooks
- Customizing playbooks
- Viewing playbook properties
- Terminating playbooks
- Deleting playbooks
- Managing playbook versions
  - Comparing playbook versions
  - Restoring playbook versions
- Launching playbooks in test mode
- Launching playbooks and response actions
  - Launching playbooks manually
  - Launching playbooks for objects specified by users
  - Launching playbooks in the Training operation mode
- Configuring manual approval of response actions
- Approving playbooks or response actions
- Enrichment from playbook
- Viewing response history
- Predefined playbooks
  - [KL] P001 "Creation of executable files by office applications"
  - [KL] P002 "Windows Event Log was cleared"
  - [KL] P003 "Suspicious child process from wmiprvse.exe"
  - [KL] P004 "Sandbox Medium Detect"
  - [KL] P005 "Sandbox High Detect"
  - [KL] "Playbook for checking external IP addresses"
  - [KL] "Playbook for isolating a device where an infected file is detected"
  - [KL] "Playbook for isolating a device where an infected file is detected"
  - [KL][EDR] "Delete malicious files transferred to the host from alert"
  - [KL][EDR] "Delete malicious files transferred to the host from incident"
  - [KL][EDR] "Isolate host when Discovery activity is detected from alert"
  - [KL][EDR] "Isolate host when Discovery activity is detected from incident"
  - [KL][EDR] "Isolate host when Exfiltration activity is detected"
  - [KL][EDR] "Isolate host when reverse shell activity is detected from alert"
  - [KL][EDR] "Isolate host when reverse shell activity is detected from incident"
  - [KL][EDR] "Mitigate malicious activity from email attachments from alert"
  - [KL][EDR] "Mitigate malicious activity from email attachments from incident"
  - [KL][EDR] "Mitigate memory dumping activity from alert"
  - [KL][EDR] "Mitigate memory dumping activity from incident"
- Playbook trigger

- Playbook algorithm

  - Execution step parameters
    - Loop
    - Parallel
    - Decision
    - UpdateData
  - ResponseFunction parameters
- AI services
  - AI asset score and status
    - Installing the AI asset score and status service
    - Reissuing the AI service certificate
    - Settings of the AI asset score and status service
  - Configuring integration with KIRA using an LLM provider
  - Analyzing alerts and incidents with KIRA
    - Настройка интеграции с KIRA с использованием KSN
    - Analyzing using KIRA
    - Possible errors of the Analyze using KIRA task
  - Creating search queries in natural language by using KIRA
    - Creating search queries in natural language and converting them into SQL queries by using KIRA
    - Possible errors while creating a query in natural language
  - Configuring DLL Hijacking detection
  - Configuring Detection of Compromise Accounts
- Managing objects in repositories
  - Uploading files for scan
  - Scanning files in the File repository manually
  - Viewing scan status and results
  - Downloading files from Quarantine and File backups
  - Restoring files from quarantine
  - Deleting files from quarantine
  - About removing objects from the Quarantine, File backups, or Active threats repositories
- Managing assets
- Integration with other solutions
  - Integration with Kaspersky Managed Detection and Response
  - Integration with Kaspersky Security Network
    - Setting up access to KSN
    - Enabling and disabling participation in KSN and KPSN
    - Configuring the connection to a local reputation database of KPSN
    - Setting up sending detected objects to the KPSN denylist
    - Viewing Kaspersky Security Network Statement
  - Integration with Kaspersky Threat Intelligence Portal
  - Взаимодействие с НКЦКИ
    - Настройка интеграции с НКЦКИ
    - Просмотр таблицы инцидентов НКЦКИ
    - Просмотр сведений об инциденте НКЦКИ
    - Создание инцидента НКЦКИ
    - Передача инцидентов в НКЦКИ

Допустимые категории и типы инцидентов НКЦКИ
Статусы инцидента НКЦКИ
Managing Sandbox
Initial Sandbox setup
Configuring database updates for Sandbox
Sandbox network interfaces
Configuring DNS settings
Configuring a management network interface
Configuring Internet access for processed objects
Adding a static network route
Changing the Sandbox administrator account password
Sandbox authentication policies
Terminating inactive Sandbox sessions
Notifications about failed Sandbox authentication attempts
Making virtual machines ready for work
Uploading images to Storage
Importing a template
Creating a custom virtual machine template
Configuring the operating system and software
Creating a virtual machine
Installing a virtual machine
Downloading debug symbols
Configuring OSMP to use detection technologies
Updating anti-virus databases for Sandbox and Anti-Malware Engine
Creating a list of passwords for password-protected archives
Selecting operating systems for scanning objects in Sandbox
Creating custom Sandbox rules
Configuring sending of files from Endpoint Agents to Sandbox
About indicators of compromise, IOC files and IOC rules
Configuring IOC scanning on schedule
Importing IOC rules
Import YARA rules
Working with Open Single Management Platform
Configuring Administration Server
Configuring the Administration Server connection address
Configuring the OSMP Console connection to Administration Server
Configuring internet access settings
Certificates for work with Open Single Management Platform
About Open Single Management Platform certificates
Requirements for user certificates used in Open Single Management Platform
Reissuing the certificate for OSMP Console
Replacing certificate for OSMP Console
Converting a PFX certificate to the PEM format
Scenario: Specifying the custom Administration Server certificate
Replacing the Administration Server certificate by using the klsetsrvcert utility
Connecting Network Agents to Administration Server by using the klmover utility
Hierarchy of Administration Servers

- Creating a hierarchy of Administration Servers: adding a secondary Administration Server
- Viewing the list of secondary Administration Servers
- Managing virtual Administration Servers
  - Creating a virtual Administration Server
  - Enabling and disabling a virtual Administration Server
  - Assigning an administrator for a virtual Administration Server
  - Changing the Administration Server for client devices
  - Deleting a virtual Administration Server
- Configuring Administration Server connection events logging
- Setting the maximum number of events in the event repository
- Changing DBMS credentials
- Deleting a hierarchy of Administration Servers
- Access to public DNS servers
- Configuring the interface
- Encrypt communication with TLS

Discovering networked devices

- Scenario: Discovering networked devices
- Windows network polling
- IP range polling
- Domain controller polling
- Configuring a Samba domain controller
- Using VDI dynamic mode on client devices
  - Enabling VDI dynamic mode in the properties of an installation package for Network Agent
  - Moving devices from VDI to an administration group

Managing client devices

- Settings of a managed device
- Manually checking the connection between a client device and the Administration Server. klnagchk utility
- Creating administration groups
- Device moving rules
  - Creating device moving rules
  - Copying device moving rules
  - Conditions for a device moving rule
- Adding devices to an administration group manually
- Moving devices or clusters to an administration group manually
- About clusters and server arrays
- Properties of a cluster or server array
- Adjustment of distribution points and connection gateways
  - Standard configuration of distribution points: Single office
  - Standard configuration of distribution points: Multiple small remote offices
  - Calculating the number and configuration of distribution points
  - Assigning distribution points automatically
  - Assigning distribution points manually
  - Modifying the list of distribution points for an administration group
  - Enabling a push server
- About device statuses
- Configuring the switching of device statuses

- Device selections
  - Viewing the device list from a device selection
  - Creating a device selection
  - Configuring a device selection
  - Exporting the device list from a device selection
  - Removing devices from administration groups in a selection
- Device tags
  - Device tags
  - Creating a device tag
  - Renaming a device tag
  - Deleting a device tag
  - Viewing devices to which a tag is assigned
  - Viewing tags assigned to a device
  - Tagging a device manually
  - Removing an assigned tag from a device
  - Viewing rules for tagging devices automatically
  - Editing a rule for tagging devices automatically
  - Creating a rule for tagging devices automatically
  - Running rules for auto-tagging devices
  - Deleting a rule for tagging devices automatically
- Data encryption and protection
  - Viewing the list of encrypted drives
  - Viewing the list of encryption events
  - Creating and viewing encryption reports
  - Granting access to an encrypted drive in offline mode
  - Transmitting encryption keys between Administration Servers
- Changing the Administration Server for client devices
- Viewing and configuring the actions when devices show inactivity
- Remote access to managed devices
  - Remote access from a Linux-based device with OSMP Console to a Linux-based managed device
  - Remote access from a Linux-based device with OSMP Console to a Windows-based managed device
  - Remote access from a Windows-based device with OSMP Console to a Linux-based managed device
  - Remote access from a Windows-based device with OSMP Console to a Windows-based managed device

Managing assets

- Adding an asset category
- Configuring the table of assets
- Searching assets
- Exporting asset data
- Viewing asset details
- Adding assets
  - Adding asset information in OSMP
  - Importing asset information from Kaspersky Security Center
  - Importing asset information from KICS for Networks
  - Examples of asset field comparison during import
- Assigning a category to an asset
- Editing the parameters of assets
- Archiving assets

- Deleting assets
- Deleting an asset category
- Bulk deletion of assets
- Updating third-party applications and fixing vulnerabilities on Kaspersky Security Center assets
- Moving assets to a selected administration group
- Asset audit
  - Configuring an asset audit
  - Storing and searching asset audit events
  - Enabling and disabling an asset audit
- Custom asset fields
- Critical information infrastructure assets

Deploying Kaspersky applications

- Scenario: Kaspersky applications deployment
- Protection deployment wizard
  - Step 1. Starting Protection deployment wizard
  - Step 2. Selecting the installation package
  - Step 3. Selecting a method for distribution of key file or activation code
  - Step 4. Selecting Network Agent version
  - Step 5. Selecting devices
  - Step 6. Specifying the remote installation task settings
  - Step 7. Restart management
  - Step 8. Removing incompatible applications before installation
  - Step 9. Moving devices to Managed devices
  - Step 10. Selecting accounts to access devices
  - Step 11. Starting installation
- Adding management plug-ins for Kaspersky applications
- Removing management web plug-ins
- Viewing the list of components integrated in Open Single Management Platform
- Viewing names, parameters, and custom actions of Kaspersky EDR Expert components
- Downloading and creating installation packages for Kaspersky applications
- Creating installation packages from a file
- Creating stand-alone installation packages
- Changing the limit on the size of custom installation package data
- Installing Network Agent for Linux in silent mode (with an answer file)
- Preparing a device running Astra Linux in the closed software environment mode for installation of Network Agent
- Viewing the list of stand-alone installation packages
- Distributing installation packages to secondary Administration Servers
- Preparing a Linux device for installation of Network Agent
- Installing applications using a remote installation task
  - Installing an application remotely
  - Installing applications on secondary Administration Servers
- Specifying settings for remote installation on Unix devices
- Starting and stopping Kaspersky applications
- Replacing third-party security applications
- Removing applications or software updates remotely
- Preparing a device running SUSE Linux Enterprise Server 15 for installation of Network Agent
- Preparing a Windows device for remote installation

Configuring Kaspersky applications
Scenario: Configuring network protection
About device-centric and user-centric security management approaches
Policy setup and propagation: Device-centric approach
Policy setup and propagation: User-centric approach
About switching Network Agent to other Administration Servers
Creating a connection profile for out-of-office users
Policies and policy profiles
About policies and policy profiles
About lock and locked settings
Inheritance of policies and policy profiles
Hierarchy of policies
Policy profiles in a hierarchy of policies
How settings are implemented on a managed device
Managing policies
Viewing the list of policies

Kaspersky EDR Expert 8.3 Help

New features

- What's new in Kaspersky EDR Expert

Key features

- Managing alerts and security incidents
- Threat hunting tools
- Investigation graph
- Predefined and custom playbooks
- Manual threat response actions
- Dashboard and widgets

Compatibility and hardware and software requirements

- Hardware and software requirements
- Compatible applications and solutions
- Integration with other solutions

Getting started

- Deployment of Kaspersky EDR Expert
- Getting started
- Using the threat monitoring, detection and hunting capabilities
- Example of incident investigation with Kaspersky EDR Expert

Working with Open Single Management Platform

- Installing Kaspersky security applications on devices on a corporate network
- Remotely run scan and update tasks
- Managing the security policies of managed applications

What's new

Kaspersky EDR Expert (on-premises) 8.3 (hereinafter referred to as Kaspersky EDR Expert) introduces several new features and improvements:

- In the window with alert details and incident details, in the **Observables** section, you can search the table of observables by the data in the **Value** column.
- When an alert is added to or removed from an incident that has the **New** status, the incident priority is automatically reevaluated. The priority is set to the **Incident severity** value.
- New predefined playbooks are now available:
  - [KL][EDR] Mitigate malicious activity from email attachments from alert.
  - [KL][EDR] Mitigate malicious activity from email attachments from incident.
  - [KL][EDR]Mitigate memory dumping activity from alert.
  - [KL][EDR]Mitigate memory dumping activity from incident.
  - [KL][EDR] Isolate host when Discovery activity is detected from alert.
  - [KL][EDR] Isolate host when Discovery activity is detected from incident.
  - [KL][EDR] Isolate host when Exfiltration activity is detected.
  - [KL][EDR] Delete malicious files transferred to the host from alert.
  - [KL][EDR] Delete malicious files transferred to the host from incident.
  - [KL][EDR] Isolate host when reverse shell activity is detected from alert.
  - [KL][EDR] Isolate host when reverse shell activity is detected from incident.

Fixed issues

Tables below list issues found in previous Kaspersky EDR Expert versions and fixed in the current version.

List of fixed issues in Kaspersky EDR Expert 8.3

First affected version	Issue ID	Issue description
8.2	10563365	The **HTTP Streaming** connector is added.
8.2	10562746	When using the solution under the Kaspersky EDR Expert license, the `/xdr/api/v3/kuma/assets` endpoint correctly returns all resources available to the current user in the OSMP Console.
8.1	6962370	When migrating data from the secondary Administration Server of Kaspersky Security Center Windows to the primary Administration Server of Kaspersky EDR Expert, the Migration wizard does not finish the **Importing data** step. This issue occurs if you create a global task on the secondary Administration Server (for example, the *Install application remotely* task) and select only the **Kaspersky Security Center Administration Server** value for the **Managed applications to export** parameter in the Migration wizard.
8.2	10419559	When changing the `EventType` condition while editing an exclusion rule, the error *A rule with this name already exists* occurs.
8.2	10593484	After upgrading to version 8.2, resources, reports, and dashboard widgets are displayed correctly when using the solution under a Kaspersky EDR Expert license.
8.2	10624497, 10634081	Backup copies of Kaspersky EDR Expert data are created correctly.
8.2	10469536	The **Licenses** section correctly displays the limit on the number of accounts.
8.1	10687160	The home page selected by the user is displayed correctly.
8.1	10676575	Fixed the issue with the *Incorrect configuration of Kaspersky Next XDR Expert* error when logging in to the OSMP Console.
7.0	8690777	The launch of a third-party custom script by using a playbook is supported only on a Linux device.
8.1	10664457	Fixed the issue with increased memory usage when opening an incident card.
8.1	10663896	When a policy is changed, previously added devices are not displayed in the list of devices.
8.2	10644701	When a policy is changed, the added rule is saved correctly.
8.1	10536807	Policy settings for Kaspersky Endpoint Security for Windows 14.1 are changed correctly.
8.2	10442087	A Kaspersky Endpoint Security for Windows policy in OSMP is created correctly.
8.0	—	Migration of telemetry data from Kaspersky EDR Expert version 7.1 to version 8.0 without a Kaspersky Next XDR Expert license is performed correctly.
8.1	—	The **Live shell** button is displayed correctly without a Kaspersky Next XDR Expert license.

List of fixed issues in Kaspersky EDR Expert 8.2

First affected version	Issue ID	Issue description
8.1	10386561	Tenant request connection could not be canceled.
8.1	10317761	Loading process tree was delayed while using Threat hunting.

First affected version	Issue ID	Issue description
8.1	10063913	Requests to the `/api/v1/alerts` endpoint returned an `HTTP 500 Internal Server Error`.
8.1	10011047	For tenants created before upgrading to version 8.1, the IOC scanning schedule feature could appear as enabled in the interface, while scheduled IOC scanning was actually disabled.
8.1	6919635	After creating a new tenant, the alerts related to the tenant were sent to the server, but not displayed in the alert table.
8.1	6962370	When migrating data from the secondary Administration Server of Kaspersky Security Center Windows to the primary Administration Server of Kaspersky EDR Expert, the **Migration wizard** did not finish the Importing data step. This issue occurred if user created a global task on the secondary Administration Server (for example, the **Uninstall application remotely** task) and selected only the Kaspersky Security Center Administration Server value for the **Managed applications to export** parameter in the Migration wizard.
8.1	8690777	The launch of a third-party custom script by using a playbook was supported only on a Linux device.
8.0	9365692	Added instructions for connecting to the OSMP Console of a protected host if blocked by an antivirus.
8.1	9959974	The device properties window on the **Events** tab included the **Select all** option for deleting events. Using this option could delete all events from the Administration Server database, including events from other devices and the Administration Server events.
8.1	6646913	In the investigation graph, rearranging nodes was performed incorrectly.
8.1	6704698	The playbooks that contain response actions through Kaspersky Endpoint Security for Windows were displayed as available in the playbook list even though the Kaspersky Endpoint Security for Windows web plug-in is not installed in Kaspersky EDR Expert.
8.1	6810101	The Administration Server properties window contained settings for mobile devices, though Kaspersky EDR Expert did not support management of mobile devices.
8.1	7367358	After adding or deleting tenants in the **Tenants** section (**Settings** → **Tenants**), the changes to the tenant list were not synchronized with the tenant filter in the **Threat hunting** section.

List of fixed issues in Kaspersky EDR Expert 8.1

First affected version	Issue ID	Issue description
8.0	9577853	Fixed an issue where changing the host name for Agentserver and Updater in the configuration file was unavailable.
8.0	9652285 9680467 9666950	Fixed an issue where policies were not available after migrating data from Kaspersky Security Center Windows to Kaspersky EDR Expert 8.0.

About Kaspersky EDR Expert

Kaspersky EDR Expert is a robust cybersecurity solution that defends your corporate IT infrastructure against sophisticated cyberthreats, including those that cannot be detected by EPP applications installed on corporate assets. It provides full visibility, correlation, and automation; and leverages a diverse range of response tools and data sources, including endpoint assets, and network and cloud data. To protect your IT infrastructure effectively, Kaspersky EDR Expert analyzes the data from these sources to identify threats, create alerts for potential incidents, and provide the tools to respond to them. Kaspersky EDR Expert is backed by advanced analytics capabilities and a strong track record of security expertise.

This solution provides a unified detection and response process through integrated components and holistic scenarios in a single interface to improve the efficiency of security professionals.

The detection tools include:

- Threat hunting tools to proactively search for threats and vulnerabilities by analyzing events.
- Advanced threat detection and correlation: real-time correlation of events based on out-of-the-box correlation rules for different scenarios with MITRE ATT&CK matrix mapping, ability to create new rules and customize existing ones, and retrospective scans for detecting zero-day vulnerabilities.
- An investigation graph to visualize and facilitate an incident investigation and identify the root causes of the alert.
- Use of Kaspersky Threat Intelligence Portal to get the latest detailed threat intelligence, for example, about web addresses, domains, IP addresses, file hashes, statistical and behavioral data, and WHOIS and DNS data.

The response tools include:

- Manual response actions: asset isolation, run commands, create prevention rules, launch tasks on an asset, Kaspersky Threat Intelligence Portal reputation enrichment, and training assignments for users.
- Playbooks, both predefined and user-created, to automate typical response operations.

Kaspersky EDR Expert also takes advantage of the Open Single Management Platform component for asset management and the centralized run of security administration and maintenance tasks:

- Deploying Kaspersky applications on the assets in the corporate network.
- Remotely launching scan and update tasks.
- Sending objects to Sandbox that analyzes the behavior of those objects in virtual operating systems.
- Obtaining detailed information about asset protection.
- Configuring all the security components by using Kaspersky applications.

Kaspersky EDR Expert supports the hierarchy of tenants.

Kaspersky EDR Expert is integrated with Active Directory, includes APIs, and supports a wide range of integrations both with Kaspersky applications and third-party solutions for data obtaining and responding.

Distribution kit

The Kaspersky EDR Expert distribution kit includes the following files:

- The xdr-<build number>-<local>.tar archive that contains Kaspersky EDR Expert components, management web plug-ins, End User License Agreements for Kaspersky EDR Expert, KSN and KDT, and legal_notices.
- The bin.tar.gz: archive with the KDT utility, and templates of the configuration file and KUMA inventory file.
- The kes_linux_<version>_local_<build number>.tar archive that contains web plug-in for Kaspersky Endpoint Security for Linux.
- The kesmac_web_plugin_xdr_<build number>.tar archive that contains web plug-in for Kaspersky Endpoint Security for Mac.

The Kaspersky EDR Expert distribution kit also includes the following files for Sandbox deployment:

- Disk image (file with the iso extension) containing the installation files for the Ubuntu Server 22.04 operating system and for the Sandbox component.
- Archive (.tar.gz file) of the Sandbox component for creating an iso image based on Astra Linux Special Edition 1.8.1.
- Disk images (.iso files) of operating systems in which the Sandbox component runs files.
- Utility (.tar file) for creating an iso image based on Astra Linux Special Edition 1.8.1.

Hardware and software requirements

This article lists the software versions on which the solution has been tested and for which it is guaranteed to work correctly. The solution may also work with other software versions, but those configurations have not undergone a full testing cycle and are not included in the list of guaranteed-supported versions.

Hardware requirements for Kaspersky EDR Expert components and Sandbox

For the Kaspersky EDR Expert components and Sandbox hardware requirements, see the Sizing Guide.

Kaspersky EDR Expert software requirements

For hardware and software requirements of OSMP (including Kaspersky Next XDR Expert), refer to Kaspersky Next XDR Expert Help.

Operating system	64-bit versions of the following operating systems are supported: • Ubuntu Server 24.04 LTS • Ubuntu Server 26.04 LTS • Astra Linux Special Edition RUSB.10015-01 (operational update 1.8.5)
Runtime Environment	Python 3.8 or later
Database management system (DBMS)	PostgreSQL 17.9 64-bit PostgreSQL 18.4 64-bit Postgres Pro 18 Enterprise 64-bit (cluster Built-in High Availability) Corosync/Pacemaker is supported for all listed PostgreSQL versions
File system on the cluster nodes (controller and workers)	ext4 XFS

Software requirements for virtual platforms

You can deploy Kaspersky EDR Expert on the following virtual platforms:

- VMware ESXi 7.0.3
- Hyper-V for Windows Server 2022
- KVM-based platforms:
  - "Brest" 3.3 virtualization software
  - "RED Virtualization" 7.3
  - zVirt Node 4.5
- Nutanix 7.5
- Proxmox Virtual Environment 9.1, 9.2

You can deploy Sandbox on the following virtual platforms:

- VMware ESXi 7.0
- KVM-based platforms:
  - "Brest" 3.3 virtualization software
  - "RED Virtualization" 7.3
  - zVirt Node 4.2

To deploy Kaspersky EDR Expert components on a VMware ESXI virtual platform, you must install the current update package for the hypervisor.

If you want to deploy Kaspersky EDR Expert components on the Astra Linux operating system in a VMware ESXI hypervisor, you need to ensure that the server hardware you are using is compatible with the Astra Linux operating system. For a full list of supported server hardware, please refer to the Astra Linux developer website.

Hardware and software requirements for Endpoint Agents

You can find the hardware and software requirements for the application used as an Endpoint Agent in its documentation:

- Kaspersky Endpoint Security for Windows
- Kaspersky Endpoint Security for Linux
- Kaspersky Endpoint Security for Mac

Kaspersky Deployment Toolkit requirements

All Kaspersky EDR Expert components are installed by using the Kaspersky Deployment Toolkit utility (hereinafter referred to as KDT).

KDT has the following hardware and software requirements:

Specification	System requirements
Hardware	CPU: 4 cores, operating frequency of 2.5 GHz RAM: 8 GB Available disk space: at least 100 GB, including: • Docker data storage directory (default: `/var/lib/docker`): at least 60 GB • Temporary files directory for KDT (default: `/tmp`): at least 15 GB
System	64-bit versions of the following operating systems are supported: • Astra Linux Special Edition RUSB.10015-01 (operational update 1.8.5) • Ubuntu Server 24.04 LTS • Ubuntu Server 26.04 LTS

Compatible applications and solutions

Kaspersky EDR Expert 8.3 is compatible with the following applications and solutions:

- Kaspersky Security Center Linux 16.2, 16.3 (as secondary Administration Servers)
- Kaspersky Security Center Windows 14.2, 15.1 (as secondary Administration Servers)
- Kaspersky Endpoint Security for Windows 12.11
- Kaspersky Endpoint Security for Windows 12.12
- Kaspersky Endpoint Security for Windows 14.0
- Kaspersky Endpoint Security for Windows 14.1
- Kaspersky Endpoint Security for Linux 12.5

- Kaspersky Endpoint Security for Linux 12.4
- Kaspersky Endpoint Security for Mac 12.2.1
- Kaspersky Private Security Network 3.5
- Kaspersky Private Security Network 4.0.5
- Kaspersky Industrial CyberSecurity for Nodes 4.5
- Kaspersky Managed Detection and Response

Kaspersky EDR Expert 8.3 can be deployed based on OSMP component of the following versions:

- Open Single Management Platform 2.3

Kaspersky EDR Expert 8.3 is not compatible with Sandbox as part of the Kaspersky Anti Targeted Attack Platform 8.0.

Architecture of Kaspersky EDR Expert

This section provides a description of the Kaspersky EDR Expert components and their interaction.

Kaspersky EDR Expert components are:

- **Open Single Management Platform** that comprises the following parts:
  - **Open Single Management Platform** (OSMP). The technology basis on which Kaspersky EDR Expert is built. OSMP integrates all of the solution components and provides interaction between the components. OSMP is scalable and supports integration with both Kaspersky applications and third-party solutions.
  - **OSMP Console**. Provides a web interface for OSMP.
  - **Incident Response Platform**. An Open Single Management Platform component that allows you to create incidents automatically or manually, manage alert and incident life cycle, assign alerts and incidents to SOC analysts, and respond to the incidents automatically or manually.
  - **Administration Server** (also referred to as *Server*). The key component of endpoint protection of a client organization. Administration Server provides centralized deployment and management of endpoint protection through EPP-applications, and allows you to monitor the endpoint protection status.
  - **OSMP Scanner**. Manages objects scanning by using detection technologies such as Anti-Malware Engine, YARA and Sandbox.
  - **Agent server**. This component is responsible for interactions between OSMP and Endpoint Agents.
  - **KUMA** components:
    - KUMA Core. The central component of KUMA is responsible for storing and distributing configurations, as well as for the graphical interface for monitoring and managing the settings of KUMA components.
    - KUMA Collector. One or more collectors receive messages from event sources and parse, normalize, and, if required, filter and/or aggregate them.

- **KUMA Correlator**. Analyzes normalized events received from Collectors, performs the necessary actions with active lists, and creates alerts in accordance with the correlation rules.
- **Storage**. Contains normalized events and registered incidents.
- **Keeper**. Critical component of a ClickHouse cluster, responsible for coordinating data replication across the cluster.

- **Sandbox**

  Servers hosting the Sandbox component run virtual machines with images of operating systems. The Sandbox component starts objects in these operating systems and analyzes the behavior of the objects to detect malicious activity and signs of targeted attacks to the corporate IT infrastructure.

- **Endpoint Agents**

  Endpoint Agent is a software component installed on workstations and servers in the IT infrastructure of the organization.

  Depending on the computer operating system, one of the following applications can be used as an Endpoint Agent:

  - Kaspersky Endpoint Security for Windows
  - Kaspersky Endpoint Security for Linux
  - Kaspersky Endpoint Security for Mac

  Endpoint Agents continually monitor processes, active network connections, and files being modified, and send this monitoring data to OSMP.

The table below lists the components included with Kaspersky EDR Expert.

Kaspersky EDR Expert components

Component name	Description
`agentserver`	Component that allows performing response actions on assets through agent integration.
`asset-manager`	Component for centralized asset management.
`backup-operator`	Automated tool that manages data backup and recovery via Custom Resources and labels.
`bootstrap`	Basic execution environment that includes the Kubernetes cluster and infrastructure components for the function of Kaspersky EDR Expert.
`cp`	Communication platform that enables data exchange and interaction between system components.
`openbao-csi-provider`	Component that enables cluster access to external storage via the Container Storage Interface (CSI).
`database-cluster`	Set of database servers that work together for high availability and scalability.
`database-operator`	CloudNativePG Kubernetes controller for managing internal database connection configuration, database resources, secrets, and credential rotation.
`gateway`	Kubernetes cluster gateway.
`hierman`	Component that manages hierarchy operations.
`iam`	OSMP platform component that provides authentication and authorization.
`irp`	Component that automates alert and incident handling, and executes response actions.
`istio`	Service mesh for managing service communication in Kubernetes clusters.
`keswin_web_plugin_xdr`	Web plug-in for managing Kaspersky Endpoint Security for Windows within Kaspersky EDR Expert, supporting security policy configuration, incident monitoring, and platform component integration.
`ksb-facade`	Component that provides execution of actions by using mixins and deployment templates.

Component name	Description
ksc	Kaspersky Security Center Administration Server
ksn-proxy-facade	Component that manages KSN Proxy deployment via Porter, external KSN service integration, and statistics processing.
kuma-migrator	Component that automates migration of configurations, data, and settings between KUMA versions.
loadbalancer	Component that routes requests to containers or processes in the cluster, and provides auditing, authentication, and session synchronization across nodes.
nsqlookupd	Service that discovers NSQ producers and directs clients within the cluster.
nwc	OSMP Console.
objectstorage	Component for storing temporary playbook data, alert and incident files, and supporting the S3 API for external integrations.
observability	Component that provides centralized visibility into events, threats, and assets, and supports response automation through integration with the KUMA platform.
orchestra	Automation platform. A common component for orchestrating workflows and executing playbooks to support automated incident response and streamline security operations.
osmp-ksn-proxy	Component that transfers detection and alert statistics to KSN or KPSN via the KSN proxy API and routes data.
osmp-scanner	Component that scans files by using Anti-Malware, YARA, and Sandbox, sends them for analysis, and generates reports.
plugin-admin-agent	Component that manages Network Agent policies.
plugin-admin-server	Component that manages Administration Servers.
plugin-agent-server	Component that manages the features of Kaspersky Endpoint Detection and Response.
plugin-asset-management	Component that manages assets, including devices, users, and other resources.
plugin-enterprise	Component that integrates with other Kaspersky solutions and provides asset management, monitoring, response automation, and multitenancy support via web interface and API.
plugin-kata	Component that integrates with KATA/EDR for response actions, incident data enrichment, and high availability and scalability support.
plugin-kuma	Component that integrates KUMA features into Kaspersky EDR Expert.
plugin-osmp-scanner	Component that provides scanning interaction, integrates with Anti-Malware, YARA, and Sandbox, sends results to ObjectStorage, Proxy, and Disaster Recovery, and supports automatic and manual response actions.
plugin-public-api-token-settings	Component that manages API token settings via the public API to support authentication and authorization for Kaspersky EDR Expert components and external systems.
plugin-tenant-roles	Component that manages user and group role assignments within tenants and integrates with IAM for role model implementation and multitenancy support.
spp_web_plugin_xdr	Component that integrates with the Kaspersky Single Product Plugin to manage other Kaspersky applications through OSMP Console.
secrets-manager	Component that manages secrets, ensuring their secure storage and proper use during service deployment and configuration.
tenant-registry	Component that manages tenant lifecycle, identity data, and integration with Kaspersky Security Center servers and external systems.
plugin-kessw	Component for managing the Kaspersky Embedded Systems Security for Windows (KESS) within Kaspersky EDR Expert.
plugin-kes-linux	Component that manages Kaspersky Endpoint Security for Linux.
plugin-kesw	Component that manages Kaspersky Endpoint Security for Windows.
plugin-spp	Kaspersky Single Product Plugin for managing other Kaspersky products through the OSMP Console.

Basic concepts

This section explains basic concepts related to Kaspersky EDR Expert.

Administration Server

Kaspersky EDR Expert components enable remote management of Kaspersky applications installed on client devices.

Devices with the Administration Server component installed will be referred to as *Administration Servers* (also referred to as *Servers*). Administration Servers must be protected, including physical protection, against any unauthorized access.

Administration Server is installed on a device as a service with the following set of attributes:

- With the name `kladminserver_srv`
- Set to start automatically when the operating system starts
- With the `ksc` account or the user account selected during the installation of Administration Server

Refer to the following article for the full list of installation settings: Installing Open Single Management Platform.

Administration Server performs the following functions:

- Storage of the administration groups' structure
- Storage of information about the configuration of client devices
- Organization of repositories for application distribution packages
- Remote installation of applications to client devices and removal of applications
- Updating application databases and software modules of Kaspersky applications
- Management of policies and tasks on client devices
- Storage of information about events that have occurred on client devices
- Generation of reports on the operation of Kaspersky applications
- Deployment of license keys to client devices and storing information about the license keys
- Forwarding notifications about the progress of tasks (such as detection of viruses on a client device)

Naming Administration Servers in the application interface

In the interface of the OSMP Console, Administration Servers can have the following names:

- Name of the Administration Server device, for example: "*device_name*" or "Administration Server: *device_name*".
- IP address of the Administration Server device, for example: "*IP_address*" or "Administration Server: *IP_address*".
- Secondary Administration Servers and virtual Administration Servers have custom names that you specify when you connect a virtual or a secondary Administration Server to the primary Administration Server.
- If you use OSMP Console installed on a Linux device, the application displays the names of the Administration Servers that you specified as trusted in the response file.

You can connect to Administration Server by using OSMP Console.

Hierarchy of Administration Servers

Administration Servers can be arranged in a hierarchy. Each Administration Server can have several secondary Administration Servers (referred to as *secondary Servers*) on different nesting levels of the hierarchy. The root Administration Server can only act as a primary Server. The nesting level for secondary Servers is unrestricted. The administration groups of the primary Administration Server will then include the client devices of all secondary Administration Servers. Thus, isolated and independent sections of networks can be managed by different Administration Servers which are in turn managed by the primary Server.

In a hierarchy, a Linux-based Administration Server can work both as a primary Server and as a secondary Server. The primary Linux-based Server can manage both Linux-based and Windows-based secondary Servers. A primary Windows-based Server can manage a secondary Linux-based Server.

Virtual Administration Servers are a particular case of secondary Administration Servers.

The hierarchy of Administration Servers can be used to do the following:

- Decrease the load on Administration Server (compared to a single installed Administration Server for an entire network).
- Decrease intranet traffic and simplify work with remote offices. You do not have to establish connections between the primary Administration Server and all networked devices, which may be located, for example, in different regions. It is sufficient to install a secondary Administration Server in each network segment, distribute devices among administration groups of secondary Servers, and establish connections between the secondary Servers and the primary Server over fast communication channels.
- Distribute responsibilities among the anti-virus security administrators. All capabilities for centralized management and monitoring of the anti-virus security status in corporate networks remain available.
- Use Kaspersky EDR Expert by service providers. The service provider only needs to install Kaspersky EDR Expert and OSMP Console. To manage a large number of client devices of various organizations, a service provider can add secondary Administration Servers (including virtual Servers) to the hierarchy of Administration Servers.

Each device included in the hierarchy of administration groups can be connected to one Administration Server only. You must independently monitor the connection of devices to Administration Servers. Use the feature for device search in administration groups of different Servers based on network attributes.

Web Server

Kaspersky EDR Expert *Web Server* (hereinafter also referred to as *Web Server*) is a component of Kaspersky EDR Expert that is installed together with Administration Server. Web Server is designed for transmission, over a network, of stand-alone installation packages.

When you create a stand-alone installation package, it is automatically published on Web Server. The link for downloading the stand-alone package is displayed in the list of created stand-alone installation packages. If necessary, you can cancel publication of the stand-alone package or you can publish it on Web Server again. You can send the link to the user in any convenient way, such as by email. By using this link, the user can download the installation package to a local device.

Network Agent

Interaction between Administration Server and devices is performed by the *Network Agent* component of Kaspersky EDR Expert. Network Agent must be installed on all devices on which Kaspersky EDR Expert is used to manage Kaspersky applications.

A device that has Network Agent installed is called a *managed device* or *device*. You can download the installation package for Network Agent from the following sources:

- Administration Server storage (you must have Administration Server installed)
- Kaspersky website

Network Agent for Linux is installed on a device as a service, with the following set of attributes:

- The name "Kaspersky Network Agent"
- Set to start automatically when the operating system starts
- Using the root account

Network Agent for Windows is installed on a device as a service, with the following set of attributes:

- The name "Kaspersky Security Center Network Agent"
- Set to start automatically when the operating system starts
- Using the LocalSystem account

Network Agent for macOS is installed on a device as a service, with the following set of attributes:

- The name "com.kaspersky.klnagent.core"
- Set to start automatically when the operating system starts
- Using the root account

The names of the service processes:

- For Linux:
  - klnagent64.service (for a 64-bit operating system)
  - klnagent.service (for a 32-bit operating system)
- For Windows:
  - klnagent
- For macOS:
  - com.kaspersky.klnagent

By default, Network Agent is installed in the following locations:

- For Linux:
  - 32-bit systems: /opt/kaspersky/klnagent/
  - 64-bit systems: /opt/kaspersky/klnagent64/
- For Windows:
  - 32-bit systems: C:\Program Files\Kaspersky Lab\NetworkAgent
  - 64-bit systems: C:\Program Files (x86)\Kaspersky Lab\NetworkAgent

- For macOS:
  - 64-bit systems: /Library/Application Support/Kaspersky Lab/klnagent/Binaries/klnagent

For Windows devices, you can specify a different folder for the installation of Network Agent in the settings of the installation package. However, for Linux devices, Network Agent can only be installed in the default directory.

The Network Agent installation folder also contains utilities for managing and diagnosing the operation of Network Agent, such as the klmover and klnagchk utilities.

When you install Administration Server, the server version of Network Agent is automatically installed together with Administration Server. Nevertheless, to manage the Administration Server device as any other managed device, install Network Agent for Linux on the Administration Server device. In this case, Network Agent for Linux is installed and works independently from the server version of Network Agent that you installed together with Administration Server.

Network Agent synchronizes the managed device with the Administration Server. We recommend that you set the synchronization interval (also referred to as the *heartbeat*) to 15 minutes per 10,000 managed devices.

Administration groups

An *administration group* (hereinafter also referred to as *group*) is a logical set of managed devices combined on the basis of a specific trait for the purpose of managing the grouped devices as a single unit within Kaspersky EDR Expert.

All managed devices within an administration group are configured to do the following:

- Use the same application settings (which you can specify in group policies).
- Use a common operating mode for all applications through the creation of group tasks with specified settings. Examples of group tasks include creating and installing a common installation package, updating the application databases and modules, scanning the device on demand, and enabling real-time protection.

A managed device can belong to only one administration group.

You can create hierarchies that have any degree of nesting for Administration Servers and groups. A single hierarchy level can include secondary and virtual Administration Servers, groups, and managed devices. You can move devices from one group to another without physically moving them. For example, if a worker's position in the enterprise changes from that of accountant to developer, you can move this worker's device from the Accountants administration group to the Developers administration group. Thereafter, the device will automatically receive the application settings required for developers.

Managed device

A *managed device* is a device running Linux, Windows, or macOS and which has Network Agent installed. You can manage such devices by creating tasks and policies for applications installed on these devices. You can also receive reports from managed devices.

You can make a managed device function as a distribution point and as a connection gateway.

A device can be managed by only one Administration Server. The number of devices that can be managed by one Administration Server depends on configuration of the device that hosts the Administration Server and on DBMS restrictions.

Unassigned device

An *unassigned device* is a device on the network that has not been included in any administration group. You can perform some actions on unassigned devices, for example, move them to administration groups or install applications on them.

When a new device is discovered on your network, this device goes to the **Unassigned devices** administration group. You can configure rules for devices to be moved automatically to other administration groups after the devices are discovered.

Administrator's workstation

Devices on which OSMP Console Server is installed are referred to as *administrator's workstations*. Administrators can use these devices for centralized remote management of Kaspersky applications installed on client devices.

There are no restrictions on the number of administrator's workstations. From any administrator's workstation, you can manage administration groups of several Administration Servers on the network at once. You can connect an administrator's workstation to an Administration Server (physical or virtual) of any level of the hierarchy.

You can include an administrator's workstation in an administration group as a client device.

Within the administration groups of any Administration Server, the same device can function as an Administration Server client, an Administration Server, or an administrator's workstation.

Management web plug-in

A special component—the *management web plug-in*—is used for remote administration of Kaspersky software by means of OSMP Console. Hereinafter, a management web plug-in is also referred to as a *management plug-in*. A management plug-in is an interface between OSMP Console and a specific Kaspersky application. With a management plug-in, you can configure tasks and policies for the application.

The management plug-in provides the following:

- Interface for creating and editing application tasks and settings
- Interface for creating and editing policies and policy profiles for remote and centralized configuration of Kaspersky applications and devices
- Transmission of events generated by the application
- OSMP Console functions for displaying operational data and events of the application, and statistics relayed from client devices

Policies

A *policy* is a set of Kaspersky application settings that are applied to an administration group and its subgroups. You can install several Kaspersky applications on the devices of an administration group. Kaspersky EDR Expert provides a single policy for each Kaspersky application in an administration group. A policy has one of the following statuses:

The status of the policy

State	Description
Active	The current policy that is applied to the device. Only one policy may be active for a Kaspersky application in each administration group. Devices apply the settings values of an active policy for a Kaspersky application.
Inactive	A policy that is not currently applied to a device.
Out-of-office	If this option is selected, the policy becomes active when the device leaves the corporate network.

Policies function according to the following rules:

- Multiple policies with different values can be configured for a single application.
- Only one policy can be active for the current application.
- A policy can have child policies.

Generally, you can use policies as preparations for emergency situations, such as a virus attack. For example, if there is an attack via flash drives, you can activate a policy that blocks access to flash drives. In this case, the current active policy automatically becomes inactive.

In order to prevent maintaining multiple policies, for example, when different occasions assume changing of several settings only, you may use policy profiles.

A *policy profile* is a named subset of policy settings values that replaces the settings values of a policy. A policy profile affects the effective settings formation on a managed device. *Effective settings* are a set of policy settings, policy profile settings, and local application settings that are currently applied for the device.

Policy profiles function according to the following rules:

- A policy profile takes effect when a specific activation condition occurs.
- Policy profiles contain values of settings that differ from the policy settings.
- Activation of a policy profile changes the effective settings of the managed device.
- A policy can include a maximum of 100 policy profiles.

Policy profiles

Sometimes it may be necessary to create several instances of a single policy for different administration groups; you might also want to modify the settings of those policies centrally. These instances might differ by only one or two settings. For example, all the accountants in an enterprise work under the same policy—but senior accountants are allowed to use flash drives, while junior accountants are not. In this case, applying policies to devices only through the hierarchy of administration groups can be inconvenient.

To help you avoid creating several instances of a single policy, Kaspersky EDR Expert enables you to create *policy profiles*. Policy profiles are necessary if you want devices within a single administration group to run under different policy settings.

A policy profile is a named subset of policy settings. This subset is distributed on target devices together with the policy, supplementing it under a specific condition called the *profile activation condition*. Profiles only contain settings that differ from the "basic" policy, which is active on the managed device. Activation of a profile modifies the settings of the "basic" policy that were initially active on the device. The modified settings take values that have been specified in the profile.

Tasks

Kaspersky EDR Expert manages Kaspersky security applications installed on devices by creating and running *tasks*. Tasks are required for installing, launching, and stopping applications, scanning files, updating databases and software modules, and performing other actions on applications.

Tasks for a specific application can be created only if the management plug-in for that application is installed.

Tasks can be performed on the Administration Server and on devices.

The following tasks are performed on the Administration Server:

- Automatic distribution of reports
- Downloading of updates to the repository of the Administration Server
- Backup of Administration Server data
- Maintenance of the database

The following types of tasks are performed on devices:

- *Local tasks*—Tasks that are performed on a specific device

  Local tasks can be modified either by the administrator, by using Administration Console tools, or by the user of a remote device (for example, through the security application interface). If a local task has been modified simultaneously by the administrator and the user of a managed device, the changes made by the administrator will take effect because they have a higher priority.

- *Group tasks*—Tasks that are performed on all devices of a specific group

  Unless otherwise specified in the task properties, a group task also affects all subgroups of the selected group. A group task also affects (optionally) devices that have been connected to secondary and virtual Administration Servers deployed in the group or any of its subgroups.

- *Global tasks*—Tasks that are performed on a set of devices, regardless of whether they are included in any group

For each application, you can create any number of group tasks, global tasks, or local tasks.

You can make changes to the settings of tasks, view the progress of tasks, and copy, export, import, and delete tasks.

A task is started on a device only if the application for which the task was created is running.

Results of tasks are saved in the Syslog event log and the Kaspersky EDR Expert event log, both centrally on the Administration Server and locally on each device.

Do not include private data in task settings. For example, avoid specifying the domain administrator password.

Task scope

The *scope of a task* is the set of devices on which the task is performed. The types of scope are as follows:

- For a *local task*, the scope is the device itself.
- For an *Administration Server task*, the scope is the Administration Server.
- For a *group task*, the scope is the list of devices included in the group.

When creating a *global task*, you can use the following methods to specify its scope:

- Specifying certain devices manually.

  You can use an IP address (or IP range) or DNS name as the device address. You can also select networked devices detected by Administration Server.

- Importing a list of devices from a .txt file with the device addresses to be added (each address must be placed on an individual line).

  If you import a list of devices from a file or create a list manually, and if devices are identified by their names, the list can only contain devices for which information has already been entered into the Administration Server database. Moreover, the information must have been entered when those devices were connected or during device discovery.

- Specifying a device selection.

  Over time, the scope of a task changes as the set of devices included in the selection change. A selection of devices can be made on the basis of device attributes, including software installed on a device, and on the basis of tags assigned to devices. Device selection is the most flexible way to specify the scope of a task.

  Tasks for device selections are always run on a schedule by the Administration Server. These tasks cannot be run on devices that lack connection to the Administration Server. Tasks whose scope is specified by using other methods are run directly on devices and therefore do not depend on the device connection to the Administration Server.

  Tasks for device selections are not run on the local time of a device; instead, they are run on the local time of the Administration Server. Tasks whose scope is specified by using other methods are run on the local time of a device.

How local application settings relate to policies

You can use policies to set identical values of the application settings for all devices in a group.

The values of the settings that a policy specifies can be redefined for individual devices in a group by using local application settings. You can set only the values of settings that the policy allows to be modified, that is, the unlocked settings.

The value of a setting that the application uses on a client device is defined by the lock position (🔒) for that setting in the policy:

- If a setting modification is locked, the same value (defined in the policy) is used on all client devices.
- If a setting modification is unlocked, the application uses a local setting value on each client device instead of the value specified in the policy. The setting can then be changed in the local application settings.

This means that, when a task is run on a client device, the application applies settings that have been defined in two different ways:

- By task settings and local application settings, if the setting is not locked against changes in the policy.
- By the group policy, if the setting is locked against changes.

Local application settings are changed after the policy is first applied in accordance with the policy settings.

Distribution point

Distribution point (previously known as update agent) is a device with Network Agent installed that is used for update distribution, remote installation of applications, and retrieval of information about networked devices.

> The features and use cases of Network Agent installed on a device used as a distribution point vary depending on the operating system.

A distribution point can perform the following functions:

- Distribute updates and installation packages received from the Administration Server to client devices within the group (including distribution through multicasting using UDP). Updates can be received either from the Administration Server or from Kaspersky update servers. In the latter case, an update task must be created for the distribution point.

  Distribution points accelerate update distribution and free up Administration Server resources.

- Distribute policies and group tasks through multicasting using UDP.

- Act as a gateway for connection to the Administration Server for devices in an administration group.

  If a direct connection between managed devices within the group and the Administration Server cannot be established, you can use the distribution point as a connection gateway to the Administration Server for this group. In this case, managed devices connect to the connection gateway, which in turn connects to the Administration Server.

The presence of a distribution point that functions as connection gateway does not block the option of a direct connection between managed devices and the Administration Server. If the connection gateway is not available, but direct connection with the Administration Server is technically possible, managed devices are connected to the Administration Server directly.

- Poll the network to detect new devices and update information about existing ones. A distribution point can apply the same device discovery methods as the Administration Server.

- Perform remote installation of applications by Kaspersky and other software vendors, including installation on client devices without Network Agent.

  This feature allows you to remotely transfer Network Agent installation packages to client devices located on networks to which the Administration Server has no direct access.

- Act as a proxy server participating in Kaspersky Security Network (KSN).

  You can enable KSN proxy server on distribution point side to make the device act as a KSN proxy server. In this case, the KSN proxy service is run on the device.

Files are transmitted from the Administration Server to a distribution point over HTTP or, if SSL connection is enabled, over HTTPS. Using HTTP or HTTPS results in a higher level of performance, compared to SOAP, through cutting traffic.

Devices with Network Agent installed can be assigned distribution points either manually (by the administrator), or automatically (by the Administration Server). The full list of distribution points for specified administration groups is displayed in the report about the list of distribution points.

The scope of a distribution point is the administration group to which it has been assigned by the administrator, as well as its subgroups of all levels of embedding. If multiple distribution points have been assigned in the hierarchy of administration groups, Network Agent on the managed device connects to the nearest distribution point in the hierarchy.

If distribution points are assigned automatically by the Administration Server, it assigns them by broadcast domains, not by administration groups. This occurs when all broadcast domains are known. Network Agent exchanges messages with other Network Agents in the same subnet and then sends Administration Server information about itself and other Network Agents. Administration Server can use that information to group Network Agents by broadcast domains. Broadcast domains are known to Administration Server after more than 70% Network Agents in administration groups are polled. Administration Server polls broadcast domains every two hours. After distribution points are assigned by broadcast domains, they cannot be re-assigned by administration groups.

If the administrator manually assigns distribution points, they can be assigned to administration groups or network locations.

Network Agents with an active connection profile do not participate in broadcast domain detection.

Kaspersky EDR Expert assigns each Network Agent a unique IP multicast address that differs from every other address. This allows you to avoid network overload that might occur due to IP overlaps. IP multicast addresses that were assigned in previous versions of the application will not be changed.

If two or more distribution points are assigned to a single network area or to a single administration group, one of them becomes the active distribution point, and the rest become standby distribution points. The active distribution point downloads updates and installation packages directly from the Administration Server, while standby distribution points receive updates from the active distribution point only. In this case, files are downloaded once from the Administration Server and then are distributed among distribution points. If the active distribution point becomes unavailable for any reason, one of the standby distribution points becomes active. The Administration Server automatically assigns a distribution point to act as standby.

The distribution point status (*Active*/*Standby*) is displayed with a check box in the klnagchk report.

A distribution point requires at least 4 GB of free disk space. If the free disk space of the distribution point is less than 2 GB, Kaspersky EDR Expert creates a security issue with the *Warning* importance level. The security issue will be published in the device properties, in the **Security issues** section.

Running remote installation tasks on a device assigned as a distribution point requires additional free disk space. The volume of free disk space must exceed the total size of all installation packages to be installed.

Running any updating (patching) tasks and vulnerability fix tasks on a device assigned as a distribution point requires additional free disk space. The volume of free disk space must be at least twice the total size of all patches to be installed.

Devices functioning as distribution points must be protected, including physical protection, against any unauthorized access.

Connection gateway

A *connection gateway* is a Network Agent acting in a special mode. A connection gateway accepts connections from other Network Agents and tunnels them to the Administration Server through its own connection with the Server. Unlike an ordinary Network Agent, a connection gateway waits for connections from the Administration Server rather than establishes connections to the Administration Server.

A connection gateway can receive connections from up to 10,000 devices.

You have two options for using connection gateways:

- We recommend that you install a connection gateway in a demilitarized zone (DMZ). For other Network Agents installed on out-of-office devices, you need to specially configure a connection to Administration Server through the connection gateway.

  A connection gateway does not in any way modify or process data that is transmitted from Network Agents to Administration Server. Moreover, it does not write this data into any buffer and therefore cannot accept data from a Network Agent and later forward it to Administration Server. If Network Agent attempts to connect to Administration Server through the connection gateway, but the connection gateway cannot connect to Administration Server, Network Agent perceives this as if Administration Server is inaccessible. All data remains on Network Agent (not on the connection gateway).

  A connection gateway cannot connect to Administration Server through another connection gateway. It means that Network Agent cannot simultaneously be a connection gateway and use a connection gateway to connect to Administration Server.

All connection gateways are included in the list of distribution points in the Administration Server properties.

- You can also use connection gateways within the network. For example, automatically assigned distribution points also become connection gateways in their own scope. However, within an internal network, connection gateways do not provide considerable benefit. They reduce the number of network connections received by Administration Server, but do not reduce the volume of incoming data. Even without connection gateways, all devices could still connect to Administration Server.

Core

The *Core* is the central component of KUMA that serves as the foundation upon which all other services and components are built. The Core's console provides a graphical user interface that is intended for everyday use by operators/analysts and for configuring the entire system.

The Core allows you to:

- create and configure services, or components, of the program, as well as integrate the necessary software into the system;
- manage program services and user accounts in a centralized way;
- visualize statistical data on the program;
- Investigate security threats based on the received events.

Storage

A KUMA *storage* is used to store normalized events and ensure that KUMA can quickly and reliably access these events to extract analytical data. Access speed and high availability are made possible by the ClickHouse technology. This means that a *storage* is a ClickHouse cluster bound to a KUMA storage service. ClickHouse clusters can be supplemented with cold storage disks.

When choosing a ClickHouse cluster configuration, consider the specific event storage requirements of your organization. For more information, please refer to the ClickHouse documentation.

In repositories, you can create *spaces*. Spaces let you structure the data in the cluster and, for example, store events of a certain type together.

Collector

A *collector* is an application component that receives messages from event sources, processes them, and transmits them to a storage, correlator, and/or third-party services to identify alerts.

For each collector, you need to configure one connector and one normalizer. You can also configure an unlimited number of additional Normalizers, Filters, Enrichment rules, and Aggregation rules. For the collector to send normalized events to other services, you must add destinations. Normally, two destinations are used: a storage and a correlator.

The collector iterates over the following steps:

1. **Receive messages from event sources**

   To receive messages, you must configure an active or passive connector. A passive connector only listens for messages from an event source, while an active connector actively polls an event source, such as a database management system.

   Connectors can have different types. The choice of connector type depends on the transport protocol used for messaging. For example, if your event source sends messages over TCP, you must install a connector of the TCP type.

   The following connector types are available:

   - internal
   - tcp
   - udp
   - netflow
   - sflow
   - nats-jetstream
   - kafka
   - http
   - sql
   - file
   - diode
   - ftp
   - nfs
   - wmi
   - wec
   - snmp
   - elastic
   - etw

2. **Event parsing and normalization**

   Events received by the connector are processed using a normalizer and normalization rules set by the user. The choice of normalizer depends on the format of messages coming from the event source. For example, if your event source sends messages in the CEF format, you must select a normalizer of the CEF type.

   The following normalizers are available:

   - JSON

3. **Filtering of normalized events**

   You can configure filters that allow you to select the events that meet the specified conditions for further processing.

4. **Aggregate normalized events**

   You can configure aggregation rules to reduce the number of similar events that are transmitted to the storage and/or the correlator. Aggregation rules let you combine multiple events into one event. This can help reduce the load on the services responsible for further event processing, conserve storage space and the events per second (EPS) allowance of your license. For example, if you have many events for network connections between two IP addresses that use the same transport and application layer protocols, you can roll up such events for a certain period into one big event.

5. **Transferring normalized events**

   After all the processing stages are completed, the event is sent to configured destinations.

Correlator

The *Correlator* is a program component that analyzes normalized events. As part of the correlation process, an event can be correlated with information from active lists and/or dictionaries.

The data obtained by analysis is used to carry out the following tasks:

- Active lists content management.
- Sending correlation events to configured destinations

Events are correlated in real time.

The operating principle of the correlator is based on signature analysis of events. This means that every event is processed in accordance with the correlation rules set by the user. When the program detects a sequence of events that satisfies the conditions of the correlation rule, it creates a correlation event and sends it to the Storage. The correlation event can also be sent to the correlator for reanalysis, which allows you to customize the correlation rules so that they are triggered by the results of a previous analysis. Results of one correlation rule can be used by other correlation rules.

You can distribute correlation rules and the active lists they use among correlators, thereby balancing the load on services. In this arrangement, collectors will send normalized events to all available correlators.

A correlator iterates over the following steps:

1. **Get an event**

   The correlator receives a normalized event from a collector or another service.

2. **Apply correlation rules**

   You can configure correlation rules to trigger on a single event or a sequence of events. If correlation rules do not detect an alert, the event processing ends here.

3. **Respond to an alert**

You can specify actions that the program must perform when an alert is detected. The following actions are available in the program:

- Event enrichment
- Operations with active lists
- Sending notifications
- Saving a correlation event

4. **Send a correlation event**

   When the program detects a sequence of events that satisfies the conditions of the correlation rule, it creates a correlation event and sends it to the storage. At this point, the correlator is done processing the event.

Events

Events are information security events registered on the monitored elements of the organization's IT infrastructure. For example, events include login attempts, interactions with a database, and sensor information broadcasts. Each separate event may seem meaningless, but when considered together they form a bigger picture of network activities to help identify security threats. This is the core functionality of KUMA.

KUMA receives events from logs and restructures them by bringing data from heterogeneous sources to a uniform format (this process is called normalization). The events are then filtered, aggregated, and sent to the correlator service for analysis and to the storage service where they are retained. When KUMA recognizes a specific event or a sequence of events, it creates *correlation events*, which are also analyzed and retained. If an event or sequence of events indicates a potential security threat, KUMA creates an alert. This alert consists of a warning about the threat and all related data that should be investigated by a security officer.

Throughout their life cycle, events undergo conversions and may receive different names. Below is a description of a typical event life cycle:

The first steps are carried out in a collector.

1. Raw event. The original message received by KUMA from an event source using a Connector is called a *raw event*. This is an unprocessed message and it cannot be used yet by KUMA. To make it usable, it must be normalized to fit the KUMA data model. This happens at the next stage.

2. Normalized event. A normalizer transforms 'raw' event data in accordance with the KUMA data model. After this conversion, the original message becomes a *normalized event* and can be used by KUMA for analysis. From this point on, KUMA handles only normalized events. Raw events are no longer used, but they can be kept as a part of normalized events inside the `Raw` field.

   The program has the following normalizers:

   - JSON
   - CEF
   - Regexp
   - Syslog (as per RFC3164 and RFC5424)
   - CSV/TSV

- Key-value
- XML
- Netflow v5, v9, IPFIX (v10), sFlow v5
- SQL

At this point normalized events can already be used for analysis.

3. Event destination. After the Collector service have processed an event, it is ready to be used by other KUMA services and sent to the KUMA Correlator and/or Storage.

The next steps of the event life cycle are completed in the correlator.

The following event types are distinguished:

1. Base event. An event that has been normalized.
2. Aggregated event. When dealing with a large number of similar events, you can "merge" them into a single event to save processing time and resources. These act as base events and are processed in the same way, but In addition to all of the parameters of the parent events (the events that have been "merged"), an aggregated event has a counter that tells how many parent events it represents. Aggregated events also store the time when the first and last parent events were received.
3. Correlation event. When a sequence of events is detected that satisfies the conditions of a correlation rule, the program creates a *correlation event*. These events can be filtered, enriched, and aggregated. They can also be sent for storage or looped into the correlator pipeline.
4. Audit event. Audit events are created when certain security-related actions are completed in KUMA. These events are used to ensure system integrity. These events are automatically placed in a separate storage space and stored for at least 365 days.
5. Monitoring event. These events are used to track changes in the amount of data received by KUMA.

Alerts

In KUMA, an alert is created when a sequence of events is received that triggers a correlation rule. Correlation rules are created by KUMA analysts to check incoming events for possible security threats, so when a correlation rule is triggered, a warning about possible malicious activity is displayed. Security officers responsible for data protection must investigate these alerts and respond if necessary.

KUMA automatically assigns a severity level to each alert. This parameter shows how important or numerous are the processes that triggered the correlation rule. Alerts with higher severity should be dealt with first. The severity value is automatically updated when new correlation events are received, but a security officer can also set it manually. In this case, the alert severity is no longer automatically updated.

Related events are linked to the alerts, which allows enriching alerts with data from these events. KUMA also offers drill down functionality for alert investigations.

You can create incidents based on alerts.

Alert management in KUMA is described in this section.

Incidents

If the nature of the data received by KUMA or the generated correlation events and alerts indicate a possible attack or vulnerability, the symptoms of such an event can be combined into an *incident*. This allows security experts to analyze threat manifestations in a comprehensive manner and facilitates response.

You can assign a category, type, and severity to incidents, and assign incidents to data protection officers for processing.

Incidents can be exported to NCIRCC and MDR.

Resources

Resources are KUMA components that contain parameters for implementing various functions: for example, establishing a connection with a given web address or converting data in accordance with certain rules. These modular components are assembled into resource sets for services, which in turn are used to create KUMA services.

Services

Services are the main components of KUMA that work with events: receiving, processing, analyzing, and storing them. Each service consists of two parts that work together:

- One part of the service is created inside the KUMA Console based on the set of resources for services.
- The other part of the service is installed in the network infrastructure where KUMA is deployed, as one of KUMA components. The server part of a service can consist of multiple instances: for example, services of the same storage can be installed on multiple devices at once.

The two parts of a service are linked to each other by the service ID.

About Severity

Severity reflects the relative importance of security-sensitive activity detected by a KUMA correlator. It shows the order in which multiple alerts should be processed, and indicates whether senior security officers should be involved.

The correlator automatically assigns a severity value to correlation events and alerts based on correlation rule settings. The severity of an alert also depends on the assets related to the processed events because correlation rules take into account the severity of a related asset's category. If an alert or correlation event does not have any linked assets with a severity value, or if it does not have any linked assets at all, the alert or correlation event inherits the severity of the correlation rule that generated it. The severity of an alert or correlation event is always equal to or greater than the severity of the correlation rule that generated it.

The severity of an alert can be changed manually. A severity that has been manually modified is no longer automatically updated by correlation rules.

Possible severity values:

- Low
- Medium
- High
- Critical

About data provision

Kaspersky EDR Expert processes the following data:

- Open Single Management Platform
- Kaspersky Unified Monitoring and Analysis Platform
- Kaspersky Security Center Linux
- Sandbox
- Endpoint Agents

  For detailed information about data transmitted by Endpoint Agents, refer to the Online Help of the respective applications:

  - Kaspersky Endpoint Security for Windows 12.11
  - Kaspersky Endpoint Security for Windows 12.12
  - Kaspersky Endpoint Security for Linux
  - Kaspersky Endpoint Security for Mac

About data provision

Locally processed data

Kaspersky EDR Expert is designed to optimize threat detection, incident investigation, threat response (including automatic), and proactive threat hunting in real time.

Kaspersky EDR Expert performs the following main functions:

- Receiving, processing, and storing information security events
- Analyzing and correlating incoming data
- Incidents and alerts investigation, manual response.
- Automatic response by using the predefined and custom playbooks.
- Event-based threat hunting in real time.

To perform its main functions, Kaspersky EDR Expert can receive, store and process the following information:

- Information about the devices on which Kaspersky EDR Expert components are installed:
  - Device name, MAC address, operating system vendor, operating system build number, OS kernel version, required installed packages, account rights, service management tool type, and port status. This data is obtained by Kaspersky Deployment Toolkit during installation.
  - IPv4 address. This data is specified by the user in the Kaspersky Deployment Toolkit configuration file.
- Names of user accounts for access to devices on which Kaspersky EDR Expert components are installed, and SSH keys. This data is specified by the user in the Kaspersky Deployment Toolkit configuration file.
- Kaspersky EDR Expert account name and password. This data is specified by the user in the Kaspersky Deployment Toolkit configuration file.
- Database access data: IP/DNS name, port, user name, and password. This data is specified by the user in the Kaspersky Deployment Toolkit configuration file.
- KUMA inventory file and license keys. This data is specified by the user in the Kaspersky Deployment Toolkit configuration file.
- DNS zone. This data is specified by the user in the Kaspersky Deployment Toolkit configuration file.
- Certificates for secure connection of managed devices to the Open Single Management Platform components. This data is specified by the user in the Kaspersky Deployment Toolkit configuration file.
- Information is saved in the installation log, which is stored in the Kaspersky Deployment Toolkit database. The installation log of the initial infrastructure is saved to a file on the user's device. The installation log of the initial infrastructure is saved to a file on the user's device. The storage period is indefinite; the installation log file will be deleted when solution is uninstalled. User names and passwords are stored in encrypted form.
- Information about incident status models, including the predefined model.
- Information about incident types: incident type name, description and other general information.
- Information about user accounts: full name and email address. The user enters the data in the OSMP Console. The data is stored in the database until the user deletes it.
- Integration token data.
- Information about tenants: tenant name, parent tenant name, description. The user enters the data in the OSMP Console. The data is stored in the database until the user deletes it.
- Information about certificates: client certificates for applications acting as an Endpoint Agent, OSMP server certificate, KUMA collector server certificate.

- Information on devices in the organization's network.
    - OSMP receives the data when the relevant integration is configured. You can add assets in the following ways:
        - Import assets:
            - On demand from MaxPatrol VM.
            - On a schedule from Kaspersky Security Center Core and Kaspersky Industrial CyberSecurity for Networks.
        - Create assets manually through the OSMP Console or via the API.
    - OSMP stores the following information about devices:
        - Technical characteristics (general properties, OS, hardware details, and installed Kaspersky applications).
        - Detected vulnerabilities and device protection status.
        - Source-specific data.
        - Device categories and their criticality levels.
        - AI score and status.
- Alerts and incidents data:
    - Alert information: triggered rules, correspondence with the MITRE matrix, alert status, resolution, assigned operator or group, affected assets (devices and accounts), observables (IP, MD5, SHA256, URL, DNS domain or DNS name, user name, host name), involvement of CII devices in the alert, comments and change log, files. This information is generated in the OSMP Console automatically, based on correlation events obtained from Kaspersky Unified Monitoring and Analysis Platform.
        - Additional data is also stored depending on the alert type:
            - For alerts generated based on file scan results: names and hash values of scanned files; Anti-Malware and Sandbox decisions; information about local file actions and network activity triggered by the file during Sandbox analysis; a password-protected archive containing the scanned file object.
            - For alerts generated by TAA (IOA) rules by Kaspersky: information about triggered IOA rules, IOA rule descriptions, response recommendations, and possible causes of false positives (rule information is not provided by the user and is distributed by Kaspersky).
            - For alerts generated by IOC detection technology: names and severity of triggered IOC rules; objects detected during IOC device scanning, including IP addresses, DNS records, registry keys and values, routing table entries, process and file information, service details, and user name and ID.
            - For alerts generated by YARA detection technology: names and severity of triggered YARA rules; objects detected during YARA scanning of the device, including file and process information.

- Incident information: linked alerts, child incidents, triggered rules, correspondence with the MITRE matrix, incident status, resolution, assigned operator or group, affected assets (devices and accounts), observable (from the alert), involvement of CII devices in the incident (including comments on the investigation graph), change log, files, incident type, metrics for incident sorting, response, and resolution, details of the triggered IOA rule, including its name, description, response recommendations, and possible causes of false positives. This information is generated in the OSMP Console automatically in accordance with rules or manually by the user.

- Data on configuring the segmentation rules for generating incidents from alerts: the name and the rule triggering conditions, the template for the name of a new incident, a rule description, the rule launch priority, inheritance option, and inheritance scope. The user enters the data in the OSMP Console.

- Information about notification templates: template name, subject of the message, message body template, description of the template and the detection rules that send notifications when triggered, selected detection technologies to notify the user about, and the severity of alerts and incidents. The user enters the data in the OSMP Console.

- Expiration date settings for alerts and incidents.

- Incident investigation graph and process tree. OSMP stores the following user-defined information about the process trees built for events: the names of the created process trees and comments.

- Playbook data:

  - Playbook operational data, including data on response action parameters: name, description, tags, trigger, and algorithm. The user enters the data in the OSMP Console.

  - Data on the execution of response actions within a playbook: data from integrated systems, data from devices.

  - Full response history for all alerts and incidents, including response actions not associated with an alert or incident.

  The data listed above is stored in the database for three days and then deleted. This data is completely deleted when Kaspersky EDR Expert is uninstalled.

- Credentials for accessing shared resources. The credentials are stored in an encrypted form and are distributed to devices to support response actions, such as obtaining memory dumps and disk images.

- Information about files received from devices as a result of response actions or manually uploaded by users, including the file name or full path to the file, size, hash, tenant, source device or uploading user, description, scan status (Anti-Virus, YARA, Sandbox), and scan results.

- Information about prevention rules applied to devices. This includes the rule name, hash, tenant, the devices to which the rule applies, the rule status (enabled or disabled), and the option to notify the endpoint user when a file matching the prevention rule is executed.

- Information about YARA rules used for scanning on devices. This includes the rule name, tenant, description, and the file scanning option (enabled or disabled), which determines whether the rule is applied during server-side scanning of files obtained from devices or uploaded by users. The rules are stored as files in the OSMP object storage and are delivered to endpoints when the YARA scan response action is executed.

- Information about IOC rules used for scanning on devices. This includes the rule name, severity, tenant, and the scheduled scanning option (enabled or disabled). The rules are stored as files in the OSMP object storage and are delivered to endpoints when the IOC scan response action is executed. For scheduled scanning, the scan schedule is also delivered to endpoints, including the enable and disable option, scan start time, and maximum scan duration.

- File object scanning settings, including a catalog of commonly used client passwords for archive decryption and the update source for Asset Management and Sandbox databases. The settings are configured by the user in the OSMP Console.

- When KPSN is used in OSMP, the following data is processed: the name or IP address of the server where the KPSN API is deployed, as well as the certificate used to connect to the API.

- Integration settings data (both with Kaspersky solutions or services, and with third-party solutions that participate in Kaspersky EDR Expert scenarios):

  - Kaspersky Threat Intelligence Portal integration: API access token for connecting to Kaspersky Threat Intelligence Portal, cache retention period, whether the connection is through a proxy, or service type. The user enters the data in the OSMP Console.

  - KATA and KEDR integration: KATA and KEDR server address: IP address or host name, port, unique ID for connecting to KATA and KEDR, certificate file, and a private key for connecting to KATA and KEDR. The user enters the data in the OSMP Console.

  - Connection to the host where the custom script will be run: IP address or host name, port, user name and SSH key, and password or key. The user enters the data in the OSMP Console.

  - OSMP Administration Server integration: Administration Server name, full path to the Administration Server in the hierarchy. The user enters the data in the OSMP Console.

  - Kaspersky CyberTrace integration: IPv4 address or hostname and port through which Kaspersky CyberTrace is available, name, and password. The user enters the data in the OSMP Console.

  - Kaspersky Automated Security Awareness Platform (KASAP) integration: API access token for connecting to KASAP, KASAP portal URL, KASAP administrator email address, and whether the connection is through a proxy. The user enters the data in the OSMP Console.

  - Active Directory integration: addresses of domain controllers, user name and password for connecting to domain controllers, and certificate. The user enters the data in the OSMP Console.

  - External system integration (such as UserGate): account name and SSH key or password for remote access to the client device.

  - Kaspersky Sandbox integration: reference configurations of virtual machine operating systems on which the Sandbox is deployed, the Sandbox server IP address, the Sandbox server certificate, the server name displayed in the OSMP Console, and Sandbox rules for file analysis. The user enters the data in the OSMP Console.

- The IP address from which the user connects to the OSMP console is recorded automatically by the console and is stored until the retention period of object revisions that the user has edited expires.

- Information about the OSMP installation hierarchy configuration.

For detailed information about other data received, stored, and processed to perform the main functions of Kaspersky EDR Expert, refer to the application Help:

- Kaspersky Security Center 15.4 Linux

- Kaspersky Unified Monitoring and Analysis Platform

- Kaspersky EDR Expert

The above data is stored in the database until the user deletes it. Data related to an alert or incident is stored for the entire retention period of the alert or incident. All other data is stored indefinitely until the user deletes it or deletes the tenant to which the data is associated. This data is completely deleted when Kaspersky EDR Expert is uninstalled.

All data processed locally can be transferred to Kaspersky only through dump files, trace files, or log files of Kaspersky EDR Expert components, including log files created by installers and utilities. The dump files, trace files, or log files of Kaspersky EDR Expert components contain personal or confidential data. The dump files, trace files, or log files are stored on the devices in the clear. The dump files, trace files, or log files are not transferred to Kaspersky automatically, but an administrator may transfer those files to Kaspersky manually by request from Technical Support to resolve issues related to Kaspersky EDR Expert performance. Kaspersky protects all received data in accordance with applicable law and Kaspersky policies. Data is transmitted over secure communication channels. The default storage term for this information (rotation period) is 7 days.

Data transferred to AO Kaspersky Lab

By following links from the OSMP console to the Kaspersky EDR Expert Help, the user agrees to the automatic provision of the following data to Kaspersky: Kaspersky EDR Expert code, version of Kaspersky EDR Expert, localization of Kaspersky EDR Expert.

To assign a training course to an employee, Kaspersky EDR Expert sends the following data to Kaspersky Automated Security Awareness Platform (KASAP): the user's email address, KASAP user ID, and training group ID.

To fetch additional information for alerts, Kaspersky EDR Expert sends the following information to Threat Intelligence Portal: the type and value of observables from alerts, incidents, and information security events.

To obtain information about the assessment of a detected threat when following a link from an alert, incident, or event card, Kaspersky EDR Expert transfers the following data to the Kaspersky Threats service: decision name.

To receive incident detection and response services, Kaspersky EDR Expert transfers the following data to the Kaspersky Managed Detection and Response service:

- When integration with Kaspersky Managed Detection and Response is enabled, OSMP temporarily stores the following data until it is successfully transmitted, and then transfers it to the Kaspersky Managed Detection and Response infrastructure: the device identifier from which the rule-triggered event was received, the user identifier, and the Kaspersky Managed Detection and Response customer identifier.

- When using the Kaspersky Managed Detection and Response solution from OSMP, the following additional information from alerts is transferred to the Kaspersky Managed Detection and Response infrastructure: the names and hash values of scanned files; Anti-Malware and Sandbox detection results; information about local file actions and network activity generated by the file during Sandbox analysis; a password-protected archive containing the scanned file object; and events that triggered IOA rules, which may include file and application names on devices, registry key names and values, and user names.

- When using the Kaspersky Managed Detection and Response solution from OSMP, the following incident-related information is transferred to the Kaspersky Managed Detection and Response infrastructure at the user's request: the incident name, the date and time of creation and last update, information about triggered rules and associated MITRE tactics and techniques, the name of the operator assigned to the incident, the names and identifiers of affected devices, and events included in alerts. These events may include file names on customer devices, registry key names, application names, and user names.

  All of this data is transferred to Kaspersky Managed Detection and Response only after the user accepts the Kaspersky Managed Detection and Response Data Processing Agreement (DPA), which is confirmed when Kaspersky Managed Detection and Response is activated in the Kaspersky Managed Detection and Response interface.

To enhance information protection capabilities, Kaspersky EDR Expert transfers KSN statistical data generated during OSMP operation to the Kaspersky Security Network service. The scope of transferred data is specified in the KSN Statement, which is included in the application distribution package. Participation in KSN is optional and controlled by the OSMP user. Before transferring, KSN statistical data is temporarily cached on servers hosting OSMP components.

When using Kaspersky Private Security Network, KSN statistical data is cached on servers hosting OSMP components in the same scope as when using Kaspersky Security Network. If the Kaspersky Private Security Network server is located outside the organization, the cached KSN statistical data may be transferred outside the organization. The responsibility for ensuring the security of this data lies with the Kaspersky Private Security Network administrator.

Data provided to third parties

To fetch information about a MITRE tactic or technique when a user follows a link from an alert or incident card, Kaspersky EDR Expert sends the ID and type of the tactic or technique to the MITRE website.

To perform response actions through external systems (for example, UserGate) by executing third-party scripts on remote client devices, Kaspersky EDR Expert transfers the following information to external systems: the types and values of observed objects from alerts and incidents.

To check the reputation of files and URLs when following a link from an event card, Kaspersky EDR Expert transfers the following information to the VirusTotal service: the file hashes (FileMd5 and FileSha256); the remote host name (NetUrlHostname); the destination URI for HTTP requests (NetUri); the destination IPv4 or IPv6 address (NetDstIp); the URL requested in a DNS query (DnsResourceName); and the requested DNS server (DnsServerIp).

Data provision in Kaspersky Unified Monitoring and Analysis Platform

Data provided to third parties

KUMA functionality does not involve automatic provision of user data to third parties.

Locally processed data

Kaspersky Unified Monitoring and Analysis Platform (hereinafter KUMA or "program") is an integrated software solution that includes the following primary functions:

- Receiving, processing, and storing information security events
- Analyzing and correlating incoming data
- Searching in received events
- Creation of notifications upon detecting symptoms of information security threats.
- Creation of alerts and incidents for processing information security threats.
- Displaying information about the status of the customer's infrastructure on the dashboard and in reports.
- Monitoring event sources.
- Device (asset) management—viewing information about assets, searching, adding, editing, and deleting assets, exporting asset information to a CSV file.

To perform its primary functions, KUMA may receive, store and process the following information:

- Information about devices on the corporate network.

  The KUMA Core server receives data if the corresponding integration is configured. You can add assets to KUMA in the following ways:

  - Import assets:
    - On demand from MaxPatrol VM.
    - On a schedule from Open Single Management Platform and KICS for Networks.
  - Create assets manually through the web interface or via the API.

  KUMA stores the following device information:

  - Technical characteristics of the device.
  - Vulnerabilities, detected on an asset.
  - Information specific to the source of the asset.
- Additional technical attributes of devices on the corporate network that the user specifies to send an incident to NCIRCC: IP addresses, domain names, URIs, email address of the monitored object, attacked network service, and port/protocol.
- Information about the organization: name, tax ID, address, email address for sending notifications.

- Active Directory information about organizational units, domains, users, and groups obtained as a result of querying the Active Directory network.

  The KUMA Core server receives this information if the corresponding integration is configured. To ensure the security of the connection to the LDAP server, the user must enter the server URL, the Base DN, connection credentials, and certificate in the KUMA Console.

- Information for domain authentication of users in KUMA: root DN for searching access groups in the Active Directory directory service, URL of the domain controller, certificate (the root public key that the AD certificate is signed with), full path to the access group of users in AD (distinguished name).

- Information contained in events from configured sources

  In the collector, the event source is configured, KUMA events are generated and sent to other KUMA services. Sometimes events can arrive first at the agent service, which relays events from the source to the collector. In addition, you can configure saving the address or a hostname of the server that aggregates the events.

  Also, Endpoint Agents send to OSMP information about events in accordance with the event data model.

- Information required for the integration of KUMA with other applications (Kaspersky Threat Lookup, Kaspersky CyberTrace, Open Single Management Platform, Kaspersky Industrial CyberSecurity for Networks, Kaspersky Automated Security Awareness Platform, Kaspersky Endpoint Detection and Response, Security Orchestration, Automation and Response, AI services: AI asset score and status, Kaspersky Investigation and Response Assistant).

  It can include certificates, tokens, URLs or credentials for establishing a connection with the other application, or other data necessary for the basic functionality of KUMA, for example, email. The user enters this data in the KUMA Console

- Information about sources from which event receipt is configured.

  It can include the source name, host name, IP address, the monitoring policy assigned to the source. The monitoring policy specifies the email address of the person responsible, to whom a notification will be sent if the policy is violated.

- User accounts: name, username, email address. The user can view their profile data in the KUMA Console.

- User profile settings:

  - User role in KUMA. Users can see their assigned roles.

  - Localization language, notification settings, display of non-printable characters.

    The user enters this data in the KUMA interface.

  - List of asset categories in the **Assets** section, default dashboard, TV mode flag for the dashboard, SQL query for default events, default preset.

    The user specifies these settings in the corresponding sections of the KUMA Console.

- Data for domain authentication of users in KUMA:

  - Active Directory: root DN for searching access groups in the Active Directory directory service, URL of the domain controller, certificate (the root public key that the AD certificate is signed with), full path to the access group of users in AD (distinguished name).

  - Active Directory Federation Services: trusted party ID (KUMA ID in AD FS), URI for getting Connect metadata, URL for redirection from AD FS, and the AD FS server certificate.

  - FreeIPA: Base DN, URL, certificate (the public root key that was used to signed the FreeIPA certificate), custom integration credentials, connection credentials.

- Audit events

  KUMA automatically records audit events.

- KUMA log

  The user can enable extended logging in the KUMA Console. Log entries are stored on the user's device, no data is transmitted automatically.

- Information about the user accepting the terms and conditions of legal agreements with Kaspersky.

- Any information that the user enters in the KUMA interface.

The information listed above can find its way into KUMA in the following ways:

- The user enters information in the KUMA Console.

- KUMA services (agent or collector) receive data if the user has configured a connection to event sources.

- Through the KUMA REST API.

- Device information can be obtained using the utility from MaxPatrol VM.

The listed information is stored in the KUMA database (MongoDB, ClickHouse, SQLite). Passwords are stored in an encrypted form (the hash of the password is stored).

All of the information listed above can be transmitted to Kaspersky only in dump files, trace files, or log files of KUMA components, including log files created by the installer and utilities.

Dump files, trace files, and log files of KUMA components may contain personal and confidential information. Dump files, trace files, and log files are stored on the device in unencrypted form. Dump files, trace files, and log files are not automatically submitted to Kaspersky, but the administrator can manually submit this information to Kaspersky at the request of Technical Support to help troubleshoot KUMA problems.

Kaspersky uses the collected data in anonymized form and only for general statistical purposes. Summary statistics is generated from the received raw data automatically and does not contain any personal or other confidential information. When new data accumulates, older data is erased (once a year). Summary statistics is stored indefinitely.

Kaspersky protects all received data in accordance with applicable law and Kaspersky policies. Data is transmitted over secure communication channels.

Data provision in Sandbox

Data stored on the server with the Sandbox component:

- Scanned files: `/var/opt/kaspersky/sandbox/library/`.

- File scan results: `/var/opt/kaspersky/sandbox/library/` and `/tmp/`.

- Task settings: `/var/opt/kaspersky/sandbox/library/` and the Sandbox component database.

- Trace files: `/var/log/kaspersky/sandbox/`.

- Settings of the update source: `/var/opt/kaspersky/apt-updater`.

- Minimum password length settings: `/var/opt/kaspersky/apt-config-ram-common/validator.conf`.
- Virtual machines: `/vm`.
- Downloaded images of operating systems and applications in iso format: `/var/opt/kaspersky/sandbox/custom_images/iso`.

Licensing

This section covers the main aspects of Kaspersky EDR Expert licensing.

About the End User License Agreement

The End User License Agreement (License Agreement) is a binding agreement between you and AO Kaspersky Lab stipulating the terms on which you may use the application.

Carefully read the License Agreement before you start using the application.

You can familiarize yourself with the terms of the End User License Agreement in the following ways:

- During installation of Kaspersky EDR Expert.
- By reading the license.txt document. This document is included in the application distribution kit.

You accept the terms of the End User License Agreement by confirming that you agree with the End User License Agreement when installing the application. If you do not accept the terms of the License Agreement, cancel application installation and do not use the application.

About the license key

A *license key* is a sequence of bits that you can apply to activate and then use the application in accordance with the terms of the End User License Agreement. License keys are generated by Kaspersky specialists.

You can add a license key to the application using one of the following methods: by applying a *key file* or by entering an *activation code*. The license key is displayed in the application interface as a unique alphanumeric sequence after you add it to the application.

The license key may be blocked by Kaspersky in case the terms of the License Agreement have been violated. If the license key has been blocked, you need to add another one if you want to use the application.

A license key may be active or additional (or reserve).

An *active license key* is a license key that is currently used by the application. An active license key can be added for a trial or commercial license. The application cannot have more than one active license key.

An *additional (or reserve) license key* is a license key that entitles the user to use the application, but is not currently in use. The additional license key automatically becomes active when the license associated with the current active license key expires. An additional license key can be added only if an active license key has already been added.

A license key for a trial license can be added as an active license key. A license key for a trial license cannot be added as an additional license key.

About the activation code

An *activation code* is a unique sequence of 20 Latin letters and numbers. You have to enter an activation code in order to add a license key for activating Open Single Management Platform. You receive the activation code at the email address that you provided when you bought Open Single Management Platform or requested the trial version of Open Single Management Platform.

To activate the solution by using the activation code, you need internet access in order to connect to Kaspersky activation servers.

If you have lost your activation code after installing the solution, contact the Kaspersky partner from whom you purchased the license.

About the key file

A *key file* is a file with the .key extension provided to you by Kaspersky. Key files are designed to activate the application by adding a license key.

You receive a key file at the email address that you provided when you bought Open Single Management Platform or ordered the trial version of Open Single Management Platform.

You do not need to connect to Kaspersky activation servers in order to activate the application with a key file.

If the key file has been accidentally deleted, you can restore it. You may need a key file, for example, to register with Kaspersky CompanyAccount.

To restore the key file, you need to do one of the following:

- Contact the license seller.
- Get a key file on the Kaspersky website based on the available activation code.

Activating Kaspersky EDR Expert

After you install Kaspersky EDR Expert, you must perform the following steps:

- Activate the OSMP components.
- Activate the SIEM components.
- Activate the EPP applications installed on devices.

Activating OSMP components

To activate OSMP components:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **License keys** section.

3. Under **Current license**, click the **Select** button.

4. In the window that opens, select the license key that you want to use to activate OSMP components. If the license key is not listed, click the **Add new license key** button, and then specify a new license key.

5. If necessary, you can also add a reserve license key. To do this, under **Reserve license key**, click the **Select** button, and then select an existing license key or add a new one.

   > You cannot add a reserve license key if there is no active license key.

6. Click the **Save** button.

OSMP components are activated.

Activating SIEM components

SIEM components are enabled by activating KUMA.

To activate SIEM components:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

2. In the window that opens, go to **Other** → **License**.

3. Create a group of license keys for your license:

   a. Click the **Add license key** button.

   b. In the **Add group** pane, specify the name of the group of license keys.

   c. Click **Add**.

   The new group of license keys appears in the **All license keys** list.

4. Add your license key:

5. Click the name of the newly added group of license keys.

6. In the **Edit license group** pane, select an option based on whether you have an activation code or a key file:

   - To apply an activation code:

     a. Click **Activation code**.

     b. Enter your activation code in the **Activation code** field.

     c. Specify proxy if you are using Kaspersky EDR Expert in a closed infrastructure.

     d. Click **Upload**.

   - To apply a key file:

     a. Click **Key file**.

     b. Under **Active license key**, click the **Upload** button to upload your key file.

     c. You can also add a reserve license key by clicking the **Upload** button under **Reserve license key**. Note that you cannot add a reserve license key if there is no active license key.

7. Click **Add**.

SIEM components are activated.

Activating EPP applications

EPP applications must be activated with a separate Kaspersky EDR Expert license (Kaspersky Endpoint Detection and Response Expert (on-premises) Add-on).

The following applications are considered EPP applications:

- Kaspersky Endpoint Security for Windows
- Kaspersky Endpoint Security for Linux
- Kaspersky Endpoint Security for Mac

To activate EPP applications:

1. **Add a license key to the Administration Server repository**

   To add a license key to the Administration Server repository:

   1. In the main menu, go to **Operations** → **Licenses**.
   2. Click **Add**.
   3. Choose what you want to add:

      - **Add key file**

        Click the **Select key file** button and browse to the .key file that you want to add.

- **Enter activation code**

  Specify the activation code in the text field and click the **Send** button.

4. Click the **Save** button.

The license key is added to the Administration Server repository.

2. **Deploy a license key to client devices**

You can distribute a license key to client devices through the **Add key** task.

To distribute a license key to client devices:

1. In the main menu, go to **Asset management** → **Tasks**.
2. Click **Add**.

   The **New task wizard** starts. Proceed through the wizard by using the **Next** button.
3. In the **Application** drop-down list, select the application for which you want to add a license key.
4. In the **Task type** list, select the **Add key** task.
5. In the **Task name** field, specify the name of the new task.
6. Select the devices to which the task will be assigned.
7. At the **Selecting a license key** step of the wizard, click the **Add key** link to add the license key.
8. On the key adding pane, add the license key by using one of the following options:

   > You need to add the license key only if you did not add it to the Administration Server repository prior to creating the **Add key** task.

   - Select the **Enter activation code** option to enter an activation code, and then do the following:

     a. Specify the activation code, and then click the **Send** button.

     Information about the license key appears in the key adding pane.

     b. Click the **Save** button.

     > If you want to distribute the license key to managed devices automatically, enable the **Automatically distribute license key to managed devices** option.

     The key adding pane closes.

   - Select the **Add key file** option to add a key file, and then do the following:

     a. Click the **Select key file** button.

     b. In the window that opens, select a key file, and then click the **Open** button.

     Information about the license key appears in the license key adding pane.

c. Click the **Save** button.

> If you want to distribute the license key to managed devices automatically, enable the **Automatically distribute license key to managed devices** option.

The key adding pane closes.

9. Select the license key in the table of keys.
10. At the **License information** step of the wizard, clear the default **Use as a reserve key** check box if you want to replace the active license key.

    For example, this is needed when the organization changes, and another organization's key is required on the device; or if the key was reissued, and a new license expires earlier than the current license. To avoid errors, you have to clear the **Use as a reserve key** check box.

11. If at the **Finish task creation** step of the wizard, you enable the **Open task details when creation is complete** option, you can edit the default settings of the task.

    If you do not enable this option, the task is created with the default settings. You can modify the default settings later.

12. Click the **Finish** button.

    The wizard creates the task. If you enabled the **Open task details when creation is complete** option, the task properties window automatically opens. In this window, you can specify the general task settings and, if required, change the settings specified during task creation.

Alternatively, you can automatically distribute a license key to managed devices if it is stored in the Administration Server license key repository.

To distribute a license key to managed devices automatically:

1. In the main menu, go to **Operations** → **Licenses**.
2. Click the name of the license key that you want to distribute to devices automatically.
3. In the license key properties window that opens, select the **Automatically distribute license key to managed devices** check box.
4. Click the **Save** button.

The license key will be automatically distributed to all compatible devices.

After all components are activated, you can start to use Kaspersky EDR Expert.

Viewing information about license keys in use

To view active and reserve license keys:

1. In the main menu, go to **Settings** → **Tenants**.
2. In the **Tenants** section, click the Root tenant.

   The Root tenant's properties window opens.

3. Select the **Licenses** tab.

   The active and reserve license keys are displayed.

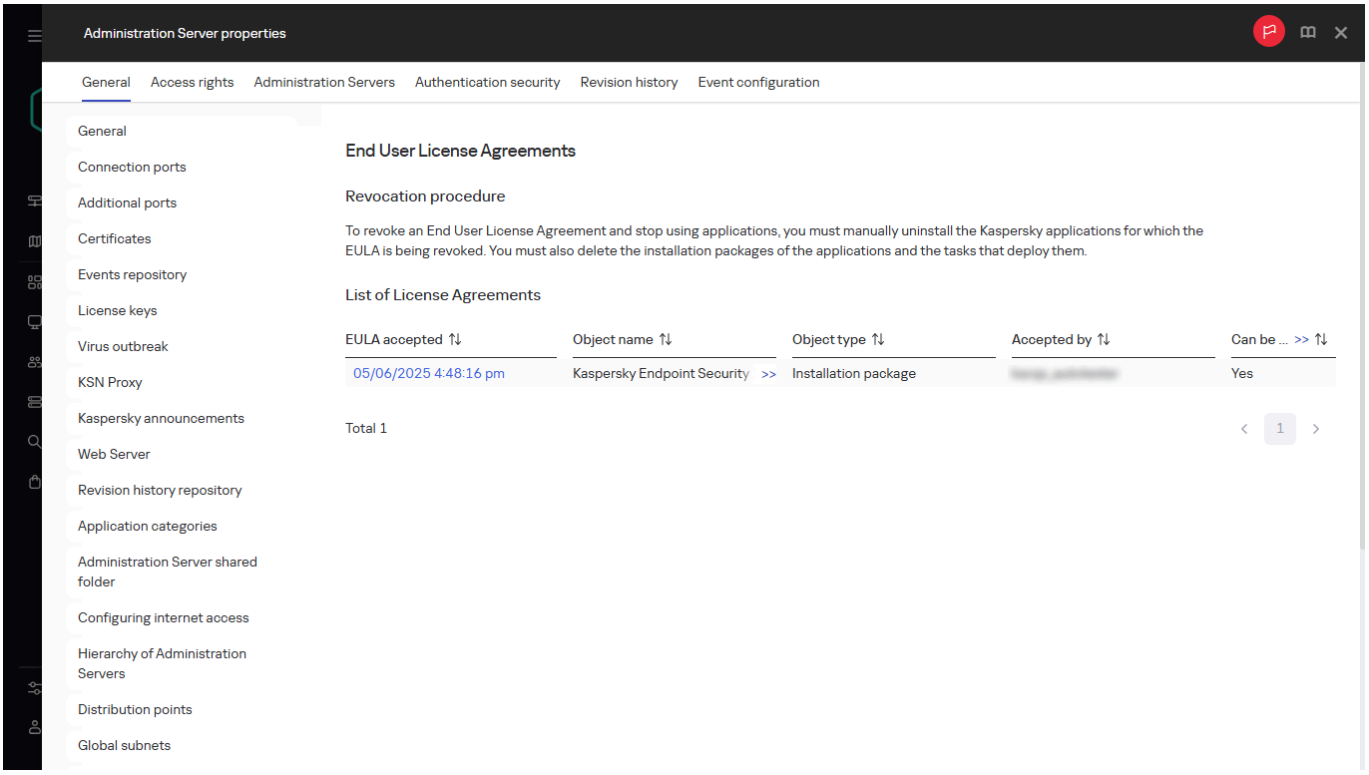
The displayed license key is applied to all child tenants of the root tenant. Specifying a separate license key for a child tenant is not available. The properties window for child tenants does not include the **Licenses** tab.

If the license keys limit is exceeded, a notification is shown, and the information about the license key shows a warning.

You can click the **Go to Administration Server** button to manage Kaspersky EDR Expert license keys.

On the **Licenses** tab, you can also view the list of licensed objects. To do this, click the ⓘ button.

The availability of the licensed object depends on the purchased license type.



Revoking consent with an End User License Agreement

If you decide to stop protecting some of your client devices, you can revoke the End User License Agreement (EULA) for any managed Kaspersky application. You must uninstall the selected application before revoking its EULA.

To revoke a EULA for managed Kaspersky applications:

1. Open the Administration Server properties window and on the **General** tab, select the **End User License Agreements** section.

   A list of EULAs—accepted upon creation of installation packages, at the seamless installation of updates, or upon deployment of Kaspersky Security for Mobile—is displayed.

The list of EULAs

2. In the list, select the EULA that you want to revoke.

You can view the following properties of the EULA:

- Date when the EULA was accepted
- Name of the user who accepted the EULA

3. Click the acceptance date of any EULA to open its properties window that displays the following data:

   - Name of the user who accepted the EULA
   - Date when the EULA was accepted
   - Unique identifier (UID) of the EULA
   - Full text of the EULA
   - List of objects (installation packages, seamless updates, mobile apps) linked to the EULA, and their respective names and types

4. In the lower part of the EULA properties window, click the **Revoke License Agreement** button.

   If there exist any objects (installation packages and their respective tasks) that prevent the EULA from being revoked, the corresponding notification is displayed. You cannot proceed with revocation until you delete these objects.

   In the window that opens, you are informed that you must first uninstall the Kaspersky application corresponding to the EULA.

5. Click the button to confirm revocation.

The EULA is revoked. It is no longer displayed in the list of License Agreements in the **End User License Agreements** section. The EULA properties window closes; the application is no longer installed.

Renewing licenses for Kaspersky applications

You can renew licenses for Kaspersky EDR Expert and included Kaspersky applications, such as Kaspersky Unified Monitoring and Analysis Platform. You can renew licenses that have expired or are going to expire within 30 days.

An email with an archive containing the new license keys will be sent to your email address after you purchase a new Kaspersky EDR Expert license.

To renew a license of Kaspersky EDR Expert:

1. Extract the new license keys from the archive sent to your email address.
2. Follow the steps described in Activating Kaspersky EDR Expert.

The license is renewed.

If you need to renew the licenses of the included Kaspersky applications, you must add new license keys to the web interfaces of these solutions.

For information on how to renew a Kaspersky Unified Monitoring and Analysis Platform license, see the Adding a license key to the program web interface section of the Kaspersky Unified Monitoring and Analysis Platform Help.

In OSMP Console, the notifications are displayed when a license is about to expire, according to the following schedule:

- 30 days before the expiration
- 7 days before the expiration
- 3 days before the expiration
- 24 hours before the expiration
- When a license has expired

Using Kaspersky Marketplace to choose Kaspersky business solutions

Marketplace is a section in the main menu that enables you to view the entire range of Kaspersky business solutions, select the ones you need, and proceed to the purchase at the Kaspersky website. You can use filters to view only those solutions that fit your organization and the requirements for your information security system. When you select a solution, Kaspersky EDR Expert redirects you to the related web page at the Kaspersky website to learn more about that solution. Each webpage enables you to proceed to the purchase or contains instructions on the purchase process.

In the **Marketplace** section, you can filter Kaspersky solutions by using the following criteria:

- Number of devices (endpoints, servers, and other types of assets) that you want to protect:
  - 50–250
  - 250–1000
  - More than 1000

- Maturity level of your organization's information security team:
  - **Foundations**

    This level is typical for enterprises that only have an IT team. The maximum possible number of threats is blocked automatically.
  - **Optimum**

    This level is typical for enterprises that have a specific IT security function within the IT team. At this level, companies require solutions that enable them to counter commodity threats and threats that circumvent existing preventive mechanisms.
  - **Expert**

    This level is typical for enterprises with complex and distributed IT environments. The IT security team is mature or the company has an SOC (Security Operations Center) team. The required solutions enable the companies to counter complex threats and targeted attacks.
- Types of assets that you want to protect:
  - **Endpoints**: workstations of employees, physical and virtual machines, embedded systems
  - **Servers**: physical and virtual servers
  - **Cloud**: public, private, or hybrid cloud environments; cloud services
  - **Network**: local area network, IT infrastructure
  - **Service**: security-related services provided by Kaspersky

To find and purchase a Kaspersky business solution:

1. In the main menu, go to **Marketplace**.

   By default, the section displays all available Kaspersky business solutions.
2. To view only those solutions that suit your organization, select the required values in the filters.
3. Click the solution that you want to purchase or you want to learn more about.

   You will be redirected to the solution webpage. You can follow the on-screen instructions to proceed to the purchase.

Sizing calculations

This section describes hardware requirements of single-node and multi-node deployment schemes for Kaspersky EDR Expert.

For hardware and software requirements of OSMP (including Kaspersky Next XDR Expert), refer to Kaspersky Next XDR Expert Help.

After selecting the deployment scenario that best fits your IT infrastructure, you can calculate the hardware requirements for the servers used to host Kaspersky EDR Expert components.

Minimum hardware requirements for small configurations with fewer than 1000 Endpoint Agents have been increased compared to previous versions of Kaspersky EDR Expert. The solution now requires at least nine CPU cores and 32 GB RAM.
For configurations with more than 1000 Endpoint Agents, hardware requirements have been reduced.
The single-node deployment scheme can be used for configurations with up to 20,000 Endpoint Agents.
The multi-node deployment scheme can be used for configurations with up to 30,000 Endpoint Agents.
For configurations with more than 30,000 Endpoint Agents, a *Hierarchy* deployment scheme must be used.

The hardware requirements are preliminary. For a more accurate estimate that takes into account all scenarios, contact Technical Support.

Calculations for Kaspersky EDR Expert components

When configuring virtual disks, Thick Provision must be selected as the disk type.

Hardware requirements for Kaspersky EDR Expert components

Hardware requirements for Kaspersky EDR Expert components depend on the following factors:

- Number of Endpoint Agent hosts:

  The Endpoint Agent component can be installed on workstations, terminal servers, file servers, or network attached storage (NAS).

  To determine the effective number of hosts with the Endpoint Agent component for estimating server load, use the following formula:

  ```
  K = A+3*B+3*C+20*D
  ```

  Where:

  - 'K' is the maximum number of hosts with the Endpoint Agent component.
  - 'A' is the number of workstations and terminal server users running Windows with the Endpoint Agent installed.
  - 'B' is the number of workstations and terminal server users running Linux with the Endpoint Agent installed.
  - 'C' is the number of workstations and terminal server users running macOS with the Endpoint Agent installed.
  - 'D' is the number of servers.

You can use SSD and HDD data storage devices. We recommend to use SSD.

Hardware requirements for Kaspersky EDR Expert components

Maximum number of hosts with Endpoint Agent	Minimum RAM (GB)	Minimum number of logical cores at 3 GHz	Minimum number of logical cores at 2.1 GHz, low frequency CPU	Disk subsystem (RAID 10)
1000	56	8	10	6x960 GB SSD or 6x1200 GB HDD
3000	64	10	14	10x960 GB SSD or 8x1200 GB HDD
5000	72	12	18	12x960 GB SSD or 10x1200 GB HDD
10,000	80	18	28	10x1920 GB SSD or 8x2400 GB HDD
15,000	96	24	36	8x3840 GB SSD or 12x2400 GB HDD
20,000	128	32	-	10x3840 GB SSD or 16x2400 GB HDD

When deploying Kaspersky EDR Expert on virtualization platforms, increase the number of logical cores according to the table below. All other hardware requirements for virtual servers are similar to those for physical servers, as listed in the table above.

Hardware requirements for Kaspersky EDR Expert components on virtualization platforms

Maximum number of hosts with an Endpoint Agent	Minimum RAM (GB)	Minimum number of logical cores on platform			Disk subsystem (GB)
		ESXi, Hyper-V	Other supported KVM-based platforms: Astra Brest, Red virtualization, zVirt	Other supported platforms with Spectre or Meltdown type vulnerability mitigations	
1000	56	8	10	12	2530
3000	64	10	14	16	3960
5000	68	14	18	20	5500
10,000	80	20	26	30	9240
15,000	92	28	36	40	12,980
20,000	124	34	44	52	17,270

The hardware requirements for Kaspersky EDR Expert components deployed on the Nutanix virtualization platform are outlined in the table below.

Hardware requirements for Kaspersky EDR Expert components on the Nutanix virtualization platform

Maximum number of hosts with Endpoint Agent	Minimum number of logical cores on platform		Minimum RAM (GB)	Disk subsystem (GB)
With vulnerability mitigations	Without vulnerability mitigations			
1000	12	10	64	2530
3000	16	14	72	3960
5000	20	18	80	5500
10,000	30	26	88	9240
15,000	40	36	104	12,980
20,000	52	44	136	17,270

The hardware requirements for Kaspersky EDR Expert components deployed on the Proxmox Virtual Environment virtualization platform are outlined in the table below.

Hardware requirements for Kaspersky EDR Expert components on the Proxmox Virtual Environment virtualization platform

Maximum number of hosts with Endpoint Agent	Minimum number of logical cores on platform		Minimum RAM (GB)	Disk subsystem (GB)
With vulnerability mitigations	Without vulnerability mitigations			
50	10	8	24	1870
100	10	8	24	1870
150	10	8	24	1980
250	10	9	24	1980
500	10	9	28	2200
750	11	10	32	2310
1000	12	10	56	2530
3000	16	14	64	4000
5000	20	18	68	5500
10,000	30	26	80	9240
15,000	40	36	92	12,980
20,000	52	44	124	17,270

The hardware requirements for Kaspersky EDR Expert components deployed on VMware ESXi and Microsoft Hyper-V virtualization platforms are listed in the table below. These requirements apply to deployments with 50 to 750 Endpoint Agents connected.

Hardware requirements for Kaspersky EDR Expert components on VMware ESXi or Microsoft Hyper-V virtualization platform with 50 to 750 Endpoint Agents

Maximum number of hosts with Endpoint Agent	Minimum number of logical cores on platform	Minimum RAM (GB)	Disk subsystem (GB)
50	6	24	1870
100	7	24	1870
150	7	24	1980
250	7	24	1980
500	7	28	2200
750	7	32	2310

The hardware requirements for Kaspersky EDR Expert components deployed on KVM-based virtualization platforms (such as Astra Brest, Red Virtualization, and zVirt) are listed in the table below. These requirements apply to deployments with 50 to 750 Endpoint Agents connected.

Hardware requirements for Kaspersky EDR Expert components on KVM-based virtualization platforms with 50 to 750 Endpoint Agents

Maximum number of hosts with Endpoint Agent	Minimum number of logical cores on platform		Minimum RAM (GB)	Disk subsystem (GB)
With vulnerability mitigations	Without vulnerability mitigations			
50	10	8	24	1870
100	10	8	24	1870
150	10	8	24	1980
250	10	9	24	1980
500	10	9	28	2200
750	11	10	32	2310

Minimum IOPS (input/output operations per second) for single-node deployment hardware and virtualization platforms are outlined in the table below.

IOPS for hardware and virtualization platforms

Maximum number of hosts with Endpoint Agent	Hardware-based IOPS	Virtualization-based IOPS
1000	500	500
3000	500	500
5000	700	1000
10,000	1000	1600
15,000	1200	1900
20,000	1400	2200

Communication channel requirements

Ensure that sufficient communication channel bandwidth is available between the Kaspersky EDR Expert server and each network segment, depending on the number of Endpoint Agent hosts in the segment. The table below shows the recommended communication channel bandwidth based on the number of Endpoint Agent hosts that do not automatically send files to Sandbox.

Communication channel bandwidth depending on the number of Endpoint Agent hosts that do not automatically send files to Sandbox

Maximum number of Endpoint Agent hosts	Required bandwidth of the communication channel reserved for Endpoint Agent hosts (Mbps)
10	2
50	4
100	6
1000	50
10,000	400

If the effective number of Endpoint Agent hosts exceeds 1000, use the following formula to calculate the required bandwidth:

```
40 Mbps*N : 1000
```

Where: `N` is the number of Endpoint Agent hosts.

Sizing limitations

- The hardware requirements are preliminary. For a more accurate estimate that takes into account all scenarios, contact Technical Support.
- Sizing is calculated for 30-day telemetry data storage.

Calculations for Kaspersky EDR Expert four-node deployment

For the multi-node Kaspersky EDR Expert deployment, you must have at least four servers. This article describes the deployment of Kaspersky EDR Expert on four nodes. The specifications of these servers depend on whether the Kaspersky EDR Expert components will be deployed on physical servers or virtual platforms.

Deploying Kaspersky EDR Expert components on physical servers

Requirements for servers

Maximum number of hosts with Endpoint Agent	Minimum RAM (GB)				Minimum number of logical cores			
	Controller node	Worker node 1	Worker node 2	Worker node 3	Controller node	Worker node 1	Worker node 2	Worker node 3
1000	8	24	24	40	6	6	4	6
3000	8	24	24	40	6	6	6	8
5000	8	24	24	40	6	8	6	8
10,000	8	24	24	48	6	10	8	10
15,000	8	32	24	56	6	12	10	12
20,000	8	56	32	64	6	16	10	12
30,000	8	112	40	72	6	20	14	16

You can use SSD and HDD data storage devices. We recommend to use SSD.

Requirements for disk space

Maximum number of hosts with Endpoint Agent	Disk subsystem			
Primary node (RAID 1)	Worker node 1 (RAID 10)	Worker node 2 (RAID 10)	Worker node 3 (RAID 10)	
1000	2x960 GB SSD or 2x600 GB HDD	4x960 GB SSD or 4x1200 GB HDD	4x960 GB SSD or 4x1200 GB HDD	4x960 GB SSD or 4x1200 GB HDD
3000	2x960 GB SSD or 2x600 GB HDD	6x960 GB SSD or 4x1200 GB HDD	4x960 GB SSD or 4x1200 GB HDD	4x960 GB SSD or 4x1200 GB HDD
5000	2x960 GB SSD or 2x600 GB HDD	8x960 GB SSD or 8x1200 GB HDD	4x960 GB SSD or 4x1200 GB HDD	4x960 GB SSD or 4x1200 GB HDD
10,000	2x960 GB SSD or 2x600 GB HDD	10x1920 GB SSD or 8x2400 GB HDD	4x960 GB SSD or 4x1200 GB HDD	4x960 GB SSD or 4x1200 GB HDD
15,000	2x960 GB SSD or 2x600 GB HDD	8x3840 GB SSD or 10x2400 GB HDD	4x960 GB SSD or 4x1200 GB HDD	4x960 GB SSD or 4x1200 GB HDD
20,000	2x960 GB SSD or 2x600 GB HDD	8x3840 GB SSD or 14x2400 GB HDD	4x960 GB SSD or 4x1200 GB HDD	6x960 GB SSD or 4x1200 GB HDD
30,000	2x960 GB SSD or 2x600 GB HDD	12x3840 GB SSD or 16x2400 GB HDD	4x960 GB SSD or 4x1200 GB HDD	8x960 GB SSD or 6x1200 GB HDD

Deploying Kaspersky EDR Expert components on virtualization platforms

Requirements for VMware ESXi and Microsoft Hyper-V

Maximum number of hosts with Endpoint Agent	Controller node		Worker node 1		Worker node 2		Worker node 3	
Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	
1000	8	6	24	6	24	6	40	8
3000	8	6	24	8	24	6	40	8
5000	8	6	24	8	24	6	40	8

Maximum number of hosts with Endpoint Agent	Controller node		Worker node 1		Worker node 2		Worker node 3	
10,000	8	6	24	12	24	8	48	10
15,000	8	6	32	14	24	10	52	12
20,000	8	6	56	16	32	12	60	14
30,000	8	6	116	22	40	14	72	18

Requirements for KVM-based Astra Brest, Red Virtualization, zVirt

Maximum number of hosts with Endpoint Agent	Controller node		Worker node 1		Worker node 2		Worker node 3	
Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	
1000	8	6	24	8	24	6	36	10
3000	8	6	24	10	24	8	40	10
5000	8	6	24	10	24	8	40	12
10,000	8	6	24	14	24	10	48	14
15,000	8	6	32	18	24	12	52	16
20,000	8	6	56	22	32	14	60	18
30,000	8	6	116	28	40	20	72	22

Requirements for Proxmox Virtual Environment and Nutanix

Maximum number of hosts with Endpoint Agent	Controller node		Worker node 1		Worker node 2		Worker node 3	
Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	Minimum RAM (GB)	Minimum number of logical cores	
1000	8	6	24	8	24	6	36	10
3000	8	6	24	10	24	8	40	10
5000	8	6	24	10	24	8	40	12
10,000	8	6	24	14	24	10	48	14
15,000	8	6	32	18	24	12	52	16
20,000	8	6	56	22	32	14	60	18
30,000	8	6	116	28	40	20	72	22

When using a platform with Spectre or Meltdown vulnerability mitigations, you must adjust the number of logical cores according to the table below.

Number of logical cores required for nodes with Spectre and Meltdown mitigations

Maximum number of hosts with Endpoint Agent	Minimum number of logical cores			
Controller node	Worker node 1	Worker node 2	Worker node 3	
1000	6	10	8	12
3000	6	10	8	12
5000	6	12	10	14
10,000	6	16	12	16
15,000	6	20	14	18

Maximum number of hosts with Endpoint Agent	Minimum number of logical cores			
20,000	6	24	18	20
30,000	6	34	22	26

Disk space requirements (all virtualization platforms, GB)

Maximum number of hosts with Endpoint Agent	Disk subsystem			
Controller node	Worker node 1	Worker node 2	Worker node 3	
1000	537	1210	1100	1870
3000	537	2640	1100	1870
5000	537	4179	1100	1870
10,000	537	7917	1100	1870
15,000	537	11,655	1100	1870
20,000	537	15,394	1100	2309
30,000	537	22,870	1100	3300

Sizing limitations

- The hardware requirements are preliminary. For a more accurate estimate that takes into account all scenarios, contact Technical Support.
- Sizing is calculated for 30-day telemetry data storage.

Calculations for Kaspersky EDR Expert 6-node deployment

For the multi-node Kaspersky EDR Expert deployment, you must have at least four servers. This article describes the deployment of Kaspersky EDR Expert on six nodes. The specifications of these servers depend on whether the Kaspersky EDR Expert components will be deployed on physical servers or virtual platforms.

Deploying Kaspersky EDR Expert components on physical servers

Requirements for servers

Maximum number of hosts with Endpoint Agent	Minimum RAM (GB)					Minimum number of logical cores				
	Controller node	3 worker nodes	Database node (PostgreSQL)	KUMA services node	2 KUMA storage nodes	Controller node	3 worker nodes	Database node (PostgreSQL)	KUMA services node	2x KUMA storage node
1000	8	24	16	32	No value	6	8	6	16	No value
3000	8	24	16	32	No value	6	10	6	16	No value
5000	8	24	16	32	No value	6	10	6	16	No value
10,000	8	24	16	32	No value	6	10	6	16	No value

Maximum number of hosts with Endpoint Agent	Minimum RAM (GB)					Minimum number of logical cores				
	Controller node	3 worker nodes	Database node (PostgresSQL)	KUMA services node	2 KUMA storage nodes	Controller node	3 worker nodes	Database node (PostgresSQL)	KUMA services node	2x KUMA storage node
15,000	8	24	24	32	No value	6	10	6	16	No value
20,000	8	24	24	56	No value	6	12	6	16	No value
30,000	8	32	32	32	64	6	14	8	16	24
50,000	8	32	48	48	96	6	16	12	16	32

You can use SSD and HDD data storage devices. We strongly recommend to use SSD.

Requirements for disk space

Maximum number of hosts with Endpoint Agent	Disk subsystem				
Primary node (RAID 1)	3x Worker node (RAID 10)	Database node (PostgresSQL, RAID 10)	KUMA services node (RAID 10)	2x KUMA storage node

50,000	537	1100	4728	1100	16,273

Sizing limitations

- The hardware requirements are preliminary. For a more accurate estimate that takes into account all scenarios, contact Technical Support.
- Sizing is calculated for 30-day telemetry data storage.

Calculations for high availability cluster configurations

For a high-availability deployment, you need the following servers:

- 3 controllers. For the high availability cluster configuration, the number of controller nodes can be one or three. Three controller nodes are recommended.
- 4 worker nodes
- 2 storage nodes
- 2 KUMA collector nodes
- 2 KUMA correlator nodes
- 3 database nodes (PostgresSQL)

The node characteristics are listed in the tables below.

Deployment on physical servers

Minimum RAM and number of logical cores

Maximum number of hosts with Endpoint Agent	Minimum RAM (GB)						Minimum number of logical co			
	3 controller nodes	4 worker nodes	3 database nodes (PostgresSQL)	2 KUMA collector nodes	2 KUMA correlator nodes	2 ClickHouse storage nodes	3 controller nodes	4 worker nodes	3 database nodes (PostgresSQL)	1 KUMA collector node
1000	8	24	16	16	16	64	6	8	6	8
3000	8	24	16	16	16	64	6	10	6	8
5000	8	24	16	16	16	64	6	10	6	8
10,000	8	24	16	16	16	64	6	10	6	8
15,000	8	24	24	16	16	64	6	10	6	8
20,000	8	24	24	24	16	96	6	12	6	8
30,000	8	32	32	24	16	128	6	14	8	8
50,000	8	32	48	40	16	256	6	16	12	14

You can use SSD and HDD data storage devices. We recommend to use SSD.

Required disk space

Maximum number of hosts with Endpoint Agent	Disk subsystem					
	3 controller nodes (RAID 1)	4 worker nodes (RAID 10)	3 database nodes (PostgresSQL) (RAID 10)	1 KUMA collector node (RAID 10)	1 KUMA correlator node	2 ClickHouse storage nodes

50,000	8	6	32	22	48	16	36	24	16	8	256

With active mitigation, it is necessary to adjust the number of logical cores as indicated in the table below.

Number of logical cores for active mitigation

Maximum number of hosts with Endpoint Agent	Minimum number of logical cores					
	3 controller nodes	4 worker nodes	3 database nodes (PostgresSQL)	1 KUMA collector node	1 KUMA correlator node	2 ClickHouse storage nodes
1000	6	14	6	8	8	24
3000	6	14	6	8	8	24
5000	6	16	6	8	8	24
10,000	6	16	6	8	8	24
15,000	6	18	8	8	8	24
20,000	6	18	8	10	8	32
30,000	6	22	12	14	8	32
50,000	6	26	18	22	8	48

Required disk space for virtualization platforms

Maximum number of hosts with Endpoint Agent	Disk subsystem					
	3 controller nodes	4 worker nodes	3 database nodes (PostgresSQL)	1 KUMA collector node	1 KUMA correlator node	2 ClickHouse storage nodes
1000	537	1100	1540	645	645	1100
3000	537	1100	1540	645	645	2309
5000	537	1100	1540	645	645	3519
10,000	537	1100	1540	645	645	6817

15,000	537	1100	1540	645	645	9896
20,000	537	1100	1980	645	645	13,085
30,000	537	1100	2860	645	645	19,462
50,000	537	1100	4728	645	645	32,216

Sizing limitations

- The hardware requirements are preliminary. For a more accurate estimate that takes into account all scenarios, contact Technical Support.
- Sizing is calculated for 30-day telemetry data storage.

Calculations for Sandbox

The hardware requirements for a server with the Sandbox component depend on the type and volume of processed traffic and on the permissible object scan time.

The hardware requirements are preliminary. For a more accurate estimate that takes into account all scenarios, contact Technical Support.

> The Sandbox component is not supported on AMD processors.

Number of physical servers with the Sandbox component required for scanning files

The number of physical servers hosting the Sandbox component depends on the number of connected Endpoint Agents (see table below).

Required number of physical servers with the Sandbox component

Maximum number of hosts with Endpoint Agent	Sending files for analysis from Endpoint Agent to Sandbox integration is disabled	Sending files for analysis from Endpoint Agent to Sandbox integration is enabled
1000	1	1
3000	1	2
5000	1	3
10,000	1	4
15,000	1	5

Hardware requirements for the server hosting the Sandbox component

A single Sandbox server with the default operating system is sufficient if Endpoint Agents do not automatically send files to the Sandbox.

When installing the Sandbox component on a VMware ESXi virtual machine with a 2.1 GHz CPU, you need seven times more virtual servers to achieve the same performance as a single physical server.

For virtual KVM-based platforms such as "Brest", "RED Virtualization", or zVirt Node, you need 13 times more virtual servers.

These estimates consider the need to maintain the configured object scan duration.

When installing the Sandbox component on the "Brest", "RED Virtualization", or zVirt Node KVM-based virtual platform with Spectre/Meltdown mitigations enabled, you require 19 times more servers. This estimate accounts for the need to configure the object scan duration.

Additional capacity may be required if you are using custom images for Sandbox servers.

To calculate the number of physical Sandbox servers required when using custom operating system images, you can use the following formula:

```
<number of files that need to be processed per hour in accordance with to user-defined Sandbox rules> * <number of custom operating system images> / 1000
```

To calculate the number of VMware ESXi virtual machines with the Sandbox component required when using custom operating system images, you can use the following formula:

```
<number of files that need to be processed per hour in accordance with to user-defined Sandbox rules> * <number of custom operating system images> / 142
```

When installing the Sandbox component on the "Brest" or zVirt Node KVM-based virtualization platforms, you can use the following formula to calculate the number of virtual machines required when using custom operating systems images:

```
<Number of physical servers with the Sandbox component> * 13
```

When installing the Sandbox component on the "RED Virtualization" platform, you can use the following formula to calculate the number of virtual machines required when using custom operating systems images:

```
<Number of physical servers with the Sandbox component> * 13
```

The estimation of the number of Sandbox servers is listed for servers with the following configuration:

- When installing the Sandbox component on a physical server:
  - Intel Xeon 16 Core (HT) at 2.6 GHz or higher.
  - 80 GB of RAM.

- 2 HDDs, 600 GB each, combined into a RAID 1 array.
- When installing the Sandbox component on a physical server with this configuration, you need to set the limit for the number of simultaneously running virtual machines to 48.

- When installing the Sandbox component on a virtual machine:
  - 15 vCPU at 2.1 GHz or higher.

    When installing the Sandbox component on "Brest", zVirt Node, or "RED Virtualization" KVM-based platforms, we recommend using Intel Ice Lake processors or later for optimal performance.
  - 32 GB of RAM.
  - 645 GB HDD.

    On the virtual machine:
    - Nested virtualization enabled.
    - High Latency Sensitivity settings are enabled (only when installing on a VMware ESXi virtual machine).
    - Entire RAM is reserved.
    - Entire CPU frequency is reserved.

  When installing the Sandbox component on a virtual machine with this configuration, you should set the limit for the number of simultaneously running virtual machines to 12.

If you plan to use custom operating system images, we recommend increasing the disk space to 600 GB or more.

Sizing limitations

The hardware requirements are preliminary. For a more accurate estimate that takes into account all scenarios, contact Technical Support.

Deployment of Kaspersky EDR Expert

Following this scenario, you can prepare your infrastructure for the deployment of Open Single Management Platform and all the required components for Kaspersky EDR Expert (including Kaspersky Endpoint Detection and Response functionality), prepare the configuration file containing the installation parameters, and deploy the solution by using the Kaspersky Deployment Toolkit utility (hereinafter referred to as KDT).

Before deploying the Open Single Management Platform and Kaspersky EDR Expert components, we recommend reading the Hardening Guide.

The deployment scenario proceeds in stages:

1. **Selecting the option for deploying Kaspersky EDR Expert**

   Select the configuration of Kaspersky EDR Expert that best suits your organization. You can choose deployment on one node, four nodes, six nodes, or 14 nodes (high-availability configuration).

2. **Downloading the distribution package with the Kaspersky EDR Expert components**

   The distribution package contains the following components:

   - Transport archive with the Kaspersky EDR Expert components and End User License Agreements for Kaspersky EDR Expert and KDT.

     The components are signed with RSA key and GOST R 34.11-2012 key. You can verify the authenticity and integrity of Kaspersky EDR Expert components.

   - Archive with the KDT utility, and templates of the configuration file and KUMA inventory file.

3. **Installing a database management system (DBMS)**

   For multi-node deployment, manually install the DBMS on the separated server that will not be included the Kubernetes cluster.

   For single-node deployment, manually install the DBMS on the target host before the Kaspersky EDR Expert deployment. In this case, the DBMS and Kaspersky EDR Expert components are installed on the same target host, but the DBMS is not included in the Kubernetes cluster.

4. **Preparing the administrator and target hosts**

   Based on the selected deployment scheme, define the number of target hosts on which you will deploy the Kubernetes cluster and the Kaspersky EDR Expert components included in this cluster. Prepare the selected administrator host and target hosts for deployment of Kaspersky EDR Expert.

   How-to instructions:

   - Multi-node deployment: Preparing the administrator and target hosts
   - Single-node deployment: Preparing the administrator and target hosts

5. **Preparing the KUMA hosts for installing KUMA services outside the Kubernetes cluster (optional)**

   KUMA services (collectors, correlators, and storages) can be installed entirely inside the Kubernetes cluster, entirely on separate hosts outside the cluster, or partially inside and partially outside the cluster.

   If you want to install KUMA services entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the cluster, prepare the KUMA target hosts for installing KUMA services.

   How-to instruction: Preparing KUMA hosts for installing KUMA service outside the Kubernetes cluster

6. **Preparing the KUMA inventory file for installing KUMA services outside the Kubernetes cluster (optional)**

   If you want to install KUMA services entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the cluster, prepare the KUMA inventory file in the YAML format. The KUMA inventory file contains parameters for installation of the KUMA services outside the Kubernetes cluster.

   How-to instruction: Preparing the KUMA inventory file for installing KUMA services outside the Kubernetes cluster

7. **Preparing the configuration file**

   Prepare the configuration file in the YAML format. The configuration file contains the list of target hosts for deployment and a set of installation parameters of the Kaspersky EDR Expert components.

   If you deploy Kaspersky EDR Expert on a single-node, use the configuration file that contains the installation parameters specific for single-node deployment.

   How-to instructions:

   - Multi-node deployment: Specifying the installation parameters
   - Single-node deployment: Specifying the installation parameters

   You can fill out the configuration file template manually; or use the Deployment wizard to specify the installation parameters that are required for the Kaspersky EDR Expert deployment, and then generate the configuration file.

   How-to instruction: Specifying the installation parameters by using the Deployment wizard

8. **Deployment of Kaspersky EDR Expert**

   Deploy Kaspersky EDR Expert by using KDT. KDT automatically deploys the Kubernetes cluster within which the Kaspersky EDR Expert components and other infrastructure components are installed.

   How-to: Installing Kaspersky EDR Expert

9. **Installing the KUMA services**

   Install the KUMA services (collectors, correlators, and storages).

   KUMA services can be installed entirely inside the Kubernetes cluster, entirely on separate hosts outside the cluster, or partially inside and partially outside the Kubernetes cluster.

   How-to instruction: Installing KUMA services outside the Kubernetes cluster

   How-to instruction: Installing KUMA services inside the Kubernetes cluster

10. **Adding a secondary Administration Server**

    A secondary Administration Server is required for further integration of Endpoint Agents.

    How-to instructions: Adding a secondary Administration Server

11. **Installing and integrating Endpoint Agents**

    Install Endpoint Agents according to Endpoint Agent documentation:

    - Kaspersky Endpoint Security for Windows
    - Kaspersky Endpoint Security for Linux
    - Kaspersky Endpoint Security for Mac

    Configure integration with Endpoint Agents.

12 **Installing and integrating Sandbox**

Install Sandbox, configure it, and then install virtual machines in it.

Configure integration with Sandbox.

Single-node deployment on a standard Ubuntu Server 24.04 LTS virtual machine

This section contains instructions for deploying a single-node Kaspersky EDR Expert instance on a standard Ubuntu Server 24.04 LTS virtual machine.

Hardware requirements for the cluster node

- 16 vCPU
- 32 GB of RAM
- 1 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

Hardware requirements must be calculated according to the sizing guide.

Checking free space in /var, /opt, and /tmp directories

Run the following commands:

```
df -h /var
```

At least 200 GB of free space must be available.

```
df -h /opt
```

At least 500 GB of free space must be available.

```
df -h /tmp
```

At least 50 GB of free space must be available.

Configuring a user account for deploying Kaspersky EDR Expert

1. Open /etc/sudoers:

```
sudo visudo
```

2. Add the following line to the end of the file:

```
{user} ALL=(ALL) NOPASSWD: ALL
```

Where `{user}` is the user account for deployment.

If you encounter the error "`user is not in sudoers file`", switch to a user with root privileges and run the following command:

```
echo "$USER ALL=(ALL) NOPASSWD: ALL" | sudo tee /etc/sudoers.d/$USER
```

3. Save (**Ctrl+S**), and then close the file (**Ctrl+X**).

4. Create SSH key:

```
ssh-keygen -t rsa -b 4096 -N ""
```

5. Copy the public key to the target host (in the case of single-node deployment, this is the same host from which you run the command):

```
ssh-copy-id <virtual_machine_IP>
```

Installing and configuring Docker

4.1 Docker installation

Docker versions 25 and later are supported.

4.1.1 Installation on Ubuntu 24:

```
sudo apt update && sudo apt install docker.io
```

4.1.2 **OR** Installation using official instructions:

1. Install the required packages:

```
sudo apt update && sudo apt install ca-certificates curl
```

2. Download Docker keyring:

```
sudo curl -fsSL https://download.docker.com/linux/ubuntu/gpg -o /etc/apt/keyrings/docker.asc && sudo chmod 0755
/etc/apt/keyrings/docker.asc
```

3. Add the Docker apt repository:

```
sudo tee /etc/apt/sources.list.d/docker.sources <<EOF
Types: deb
URIs: https://download.docker.com/linux/ubuntu
Suites: $(. /etc/os-release && echo "${UBUNTU_CODENAME:-$VERSION_CODENAME}")
Components: stable
Architectures: $(dpkg --print-architecture)
Signed-By: /etc/apt/keyrings/docker.asc
EOF
```

4. Update the repository cache and install Docker packages:

```
sudo apt update && sudo apt install docker-ce docker-ce-cli containerd.io docker-buildx-plugin docker-compose-plugin
```

4.2 Docker configuration

1. Add the current user to the `docker` group:

```
sudo usermod -aG docker $USER
```

2. Activate user membership in the `docker` group in the current session:

```
newgrp docker
```

Installing and configuring PostgreSQL

The following PostgreSQL versions are supported:

- PostgreSQL 15
- PostgreSQL 16
- PostgreSQL 17
- PostgreSQL 18

1. Install PostgreSQL:

```
sudo apt install -y postgresql-<version>
```

Where `<version>` is PostgreSQL version. For example, for PostgreSQL 16:

```
sudo apt install -y postgresql-16
```

If the required PostgreSQL version is not available in the connected repository, you must add the `PostgreSQL Apt` repository. For instructions, refer to PostgreSQL website.

2. Create a separate PostgreSQL superuser:

```
sudo -u postgres createuser --superuser xdr
```

3. Set a password for the user:

```
sudo -u postgres psql -c "ALTER USER xdr WITH PASSWORD 'your_password';"
```

4. Create a database with the same name as the user:

```
sudo -u postgres psql -c "CREATE DATABASE xdr OWNER xdr;"
```

5. Allow PostgreSQL access from any IP address:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/<version>/main/pg_hba.conf
```

Where <version> is PostgreSQL version. For example, for PostgreSQL 16:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/16/main/pg_hba.conf
```

6. Edit the following parameters in the PostgreSQL configuration file (/etc/postgresql/<version>/main/postgresql.conf), where <version> is PostgreSQL version. For example, for PostgreSQL 16: /etc/postgresql/16/main/postgresql.conf.

Commented (#) lines need to be uncommented.

```
listen_addresses = '*'
shared_buffers = 8192MB
max_stack_depth = 7MB
temp_buffers = 24MB
work_mem = 16MB
max_connections = 512
max_parallel_workers_per_gather = 0
maintenance_work_mem = 128MB
standard_conforming_strings = on
```

7. Restart PostgreSQL:

```
sudo systemctl restart postgresql
```

DNS configuration

On your DNS server, register the FQDN of the services to connect to OSMP services.

To get started quickly, add a wildcard A record in your DNS server that points to a free IP address (<ingress_ip>) in the same subnet as the cluster. The Kubernetes cluster gateway will listen on this IP address and route traffic to the appropriate services.

By default, OSMP services are available at the following addresses:

```
<ingress_ip> - admsrv.<ingress_domain>
<ingress_ip> - api.<ingress_domain>
<ingress_ip> - console.<ingress_domain>
<ingress_ip> - kuma.<ingress_domain>
<ingress_ip> - *.kuma.<ingress_domain>
<ingress_ip> - monitoring.<ingress_domain>
<ingress_ip> - agentserver.<ingress_domain>
<ingress_ip> - updater.<ingress_domain>
```

Unpacking the KDT utility

Run the following command to create a directory and unpack the KDT utility:

```
mkdir ./kdt && tar -xvf bin.tar.gz -C ./kdt
```

Configuring the system time to synchronize with the NTP server

1. Run the following commands:

   ```
   sudo apt update
   sudo apt install -y systemd-timesyncd
   sudo timedatectl set-ntp true
   sudo timedatectl set-timezone Europe/Moscow
   sudo timedatectl set-local-rtc 0
   timedatectl status
   ```

   The output will contain the line:

   ```
   System clock synchronized: yes
   ```

2. To check synchronization, run:

   ```
   date
   ```

   The output must contain current date and time.

Creating a configuration to run the installation

Show legend

- `10.0.0.100`—IP address of the host where deployment is performed (`<host_ip>`)
- `10.0.0.200`—IP address used for the wildcard A record in the DNS configuration step (`<ingress_ip>`)
- `user`—User account for deployment (`<user_name>`)

- `/home/user/.ssh/id_rsa`—Path to the SSH private key created during user configuration (`<ssh_key_path>`)
- `xdr.mydomain.com`—Domain for ingress (`<ingress_domain>`)

9.1 Specifying installation parameters using the Configuration wizard

1. Run the following command to start the Configuration wizard:

   ```
   ./bin/kdt wizard -k xdr-<program_version>.tar -o params.yaml
   ```

2. Enter the number of primary_nodes (minimum 1): `1`
3. Enter the IPv4 address of the 1st primary node: `10.0.0.100`
4. Enter the user name to connect to the 1st primary node: `user`
5. Enter the path to the SSH key to connect to the 1st primary node: `/home/user/.ssh/id_rsa`
6. Enter the number of worker_nodes (0 - single-node deployment, 3 or more - multi-node deployment): `0`
7. Enter `1` if loadbalancer is required, otherwise press **Enter**: press **Enter**
8. Enter the connection string for accessing the DBMS as follows: postgres://<dbms_username>:<password>@<fqdn>:<port>: `postgres://xdr:<your_password>@10.0.0.100:5432`
9. It is necessary to enter the IP address of the Kubernetes cluster gateway as follows: <ip_address>. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. Enter the IP address: `10.0.0.200`
10. It is necessary to create the Kaspersky EDR Expert user account. Enter the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters. Enter the password: `your_password`
11. Enter the path to the KUMA inventory file: `/dev/null`
12. Enter the path to the SSH key that is used for connection to the nodes with the KUMA services: `/home/user/.ssh/id_rsa`
13. Enter the path to the KUMA license file: `/dev/null`
14. It is necessary to enter the domain name for the public Kaspersky EDR Expert services. This domain name will be included in the domain names of Kaspersky EDR Expert services. For example, console.<domain name>. Enter the domain name: `xdr.mydomain.com`
15. Enter the path to the user certificate file and private key for public Kaspersky EDR Expert services (if you want to use a self-signed certificate, press **Enter** to skip this step): press **Enter**
16. Enter "Y" if extended incident lifecycle is required in your region: `N`

17. Enter the user name of the account used to view OSMP metrics using the Grafana tool. The user name cannot have less than 1 and more than 30 characters. The user name should start with a letter and can contain lowercase letters ('a' to 'z'), digits ('0' to '9'), and special characters (_ - .): `xdr`

18. Enter the password of the account used to view OSMP metrics through the Grafana tool. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters: `your_password`

9.2 Specifying installation parameters using the configuration file

The template of the configuration file (singlenode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility.

The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.

Symbols that must be replaced in the `psql_dsn` parameter value:

- Whitespace → `%20`
- ! → `%21`
- # → `%23`
- % → `%25`
- & → `%26`
- / → `%2F`
- : → `%3A`
- = → `%3D`
- ? → `%3F`
- @ → `%40`
- [→ `%5B`
-] → `%5D`

Refer to the PostgreSQL connection string article for details.

```

```

Installing Kaspersky EDR Expert

Run the following command:

```
./bin/kdt apply --accept-eula -k xdr-<program_version>.tar -i params.yaml
```

If the installation is successful, the following information will be displayed in the terminal:

```
INFO[0038] apply inventory ./conf.yaml
INFO[0039] preparing bootstrap_<ver>.tgz
INFO[0092] installing: bootstrap
INFO[0404] time: prepare 53.113895029s install 5m12.442326155s
INFO[0404] current installation is valid
INFO[0404] bundles will be published: 40
INFO[0536] bundles published 40
INFO[0536] bundles will be applied: 39
INFO[2450] apply done: 31m53.851140069s
INFO[2450] apply command completed successfully
INFO[2450] time: publish 2m11.679771805s install 31m53.930470045s
```

To check the installation, you need to go to the authorization page. To do this, enter the following in the search bar of the browser:

```
console.<ingress_domain>
```

Where `<ingress_domain>` is the FQDN from the step 6 of this procedure.

Single-node deployment on a standard Astra Linux Special Edition (operational update 1.8.2) virtual machine

This section contains instructions for deploying a single-node Kaspersky EDR Expert instance on a standard virtual machine with Astra Linux Special Edition RUSB.10015-01 (operational update 1.8.2) hardened version ("Voronezh") operating system.

Hardware requirements for the cluster node

- 16 vCPU
- 32 GB of RAM
- 1 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

Hardware requirements must be calculated according to the sizing guide.

Checking free space in /var, /opt, and /tmp directories

Run the following commands:

```
df -h /var
```

At least 200 GB of free space must be available.

```
df -h /opt
```

At least 500 GB of free space must be available.

```
df -h /tmp
```

At least 50 GB of free space must be available.

Installing python3-apt and curl

Run the following command:

```
sudo apt install python3-apt curl -y
```

Configuring a user account for deploying Kaspersky EDR Expert

1. Open /etc/sudoers:

   ```
   sudo visudo
   ```

2. Add the following line to the end of the file:

```
{user} ALL=(ALL) NOPASSWD: ALL
```

Where `{user}` is the user account for deployment.

If you encounter the error "`user is not in sudoers file`", switch to a user with root privileges and run the following command:

```
echo "$USER ALL=(ALL) NOPASSWD: ALL" | sudo tee /etc/sudoers.d/$USER
```

3. Save (**Ctrl+S**), and then close the file (**Ctrl+X**).

4. Create SSH key:

```
ssh-keygen -t rsa -b 4096 -N ""
```

5. Copy the public key to the target host (in the case of single-node deployment, this is the same host from which you run the command):

```
ssh-copy-id <virtual_machine_IP>
```

Installing and configuring Docker

5.1 Docker installation

Docker versions 25 and later are supported.

Run the following command:

```
sudo apt update && sudo apt install docker.io
```

5.2 Docker configuration

1. Add the current user to the `docker` group:

```
sudo usermod -aG docker $USER
```

2. Activate user membership in the `docker` group in the current session:

```
newgrp docker
```

Installing PostgreSQL and configuring DBMS host

A DBMS host is a DBMS instance that can be installed either outside of a Kubernetes cluster or inside a Kubernetes cluster.

Since Astra Linux SE 1.8.x repositories do not contain supported versions of PostgreSQL, we recommend to use a separate host outside the Kubernetes cluster with another operating sytem that has supported versions of PostgreSQL in its repositories (for example, Debian or Ubuntu).

If you install a DBMS instance inside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 20 vCPU
- 40 GB of RAM
- 2.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

If you install a DBMS instance outside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 10 vCPU
- 20 GB of RAM
- 1.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

The following PostgreSQL versions are supported:

- PostgreSQL 15
- PostgreSQL 16
- PostgreSQL 17
- PostgreSQL 18

1. Install PostgreSQL:

   ```
   sudo apt install -y postgresql-<version>
   ```

   Where <`version`> is PostgreSQL version. For example, for PostgreSQL 16:

   ```
   sudo apt install -y postgresql-16
   ```

2. Create a separate PostgreSQL superuser:

   ```
   sudo -u postgres createuser --superuser xdr
   ```

3. Set a password for the user:

   ```
   sudo -u postgres psql -c "ALTER USER xdr WITH PASSWORD 'your_password';"
   ```

4. Create a database with the same name as the user:

   ```
   sudo -u postgres psql -c "CREATE DATABASE xdr OWNER xdr;"
   ```

5. Allow PostgreSQL access from any IP address:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/<version>/main/pg_hba.conf
```

Where <version> is PostgreSQL version. For example, for PostgreSQL 16:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/16/main/pg_hba.conf
```

6. Edit the following parameters in the PostgreSQL configuration file (/etc/postgresql/<version>/main/postgresql.conf), where <version> is PostgreSQL version. For example, for PostgreSQL 16: /etc/postgresql/16/main/postgresql.conf.

Commented (#) lines need to be uncommented.

```
listen_addresses = '*'
shared_buffers = 8192MB
max_stack_depth = 7MB
temp_buffers = 24MB
work_mem = 16MB
max_connections = 512
max_parallel_workers_per_gather = 0
maintenance_work_mem = 128MB
standard_conforming_strings = on
```

7. Restart PostgreSQL:

```
sudo systemctl restart postgresql
```

8. Run the following commands to configure the system time to synchronize with the NTP server:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

9. To check synchronization, run:

```
date
```

The output must contain current date and time.

Unpacking the KDT utility

Run the following command to create a directory and unpack the KDT utility:

```
mkdir ./kdt && tar -xvf bin.tar.gz -C ./kdt
```

Disabling Mandatory Integrity Control mode, Closed Software Environment mode, and the ptrace capability

We recommend disabling the `ptrace` capability. For instructions, refer to Astra Linux documentation.

Disabling the Mandatory Integrity Control mode

Run the following command:

```
sudo astra-mic-control status
```

If the Mandatory Integrity Control mode is `enabled`, it is required to disable it. For instructions, refer to Astra Linux documentation.

Disabling the closed software environment mode in executable files

```
sudo astra-digsig-control status
```

If the closed software environment mode is enabled, it is required to disable it. For instructions, refer to Astra Linux documentation.

Configuring the system time to synchronize with the NTP server

1. Run the following commands:

   ```
   sudo apt update
   sudo apt install -y systemd-timesyncd
   sudo timedatectl set-ntp true
   sudo timedatectl set-timezone Europe/Moscow
   sudo timedatectl set-local-rtc 0
   timedatectl status
   ```

   The output will contain the line:

   ```
   System clock synchronized: yes
   ```

2. To check synchronization, run:

   ```
   date
   ```

   The output must contain current date and time.

DNS configuration

On your DNS server, register the FQDN of the services to connect to OSMP services.

To get started quickly, add a wildcard A record in your DNS server that points to a free IP address (`<ingress_ip>`) in the same subnet as the cluster. The Kubernetes cluster gateway will listen on this IP address and route traffic to the appropriate services.

By default, OSMP services are available at the following addresses:

```
<ingress_ip> - admsrv.<ingress_domain>
<ingress_ip> - api.<ingress_domain>
<ingress_ip> - console.<ingress_domain>
<ingress_ip> - kuma.<ingress_domain>
<ingress_ip> - *.kuma.<ingress_domain>
<ingress_ip> - monitoring.<ingress_domain>
<ingress_ip> - agentserver.<ingress_domain>
<ingress_ip> - updater.<ingress_domain>
```

Creating a configuration to run the installation

Show legend

- `10.0.0.100`—IP address of the host where deployment is performed (`<host_ip>`)
- `10.0.0.150`—IP address of the host where the DBMS instance is deployed (`<pg_ip>`)
- `10.0.0.200`—IP address used for the wildcard A record in the DNS configuration step (`<ingress_ip>`)
- `user`—User account for deployment (`<user_name>`)
- `/home/user/.ssh/id_rsa`—Path to the SSH private key created during user configuration (`<ssh_key_path>`)
- `xdr.mydomain.com`—Domain for ingress (`<ingress_domain>`)

11.1 Specifying installation parameters using the Configuration wizard

1. Run the following command to start the Configuration wizard:

   ```
   ./bin/kdt wizard -k xdr-<program_version>.tar -o params.yaml
   ```

2. Enter the number of primary_nodes (minimum 1): `1`
3. Enter the IPv4 address of the 1st primary node: `10.0.0.100`
4. Enter the user name to connect to the 1st primary node: `user`
5. Enter the path to the SSH key to connect to the 1st primary node: `/home/user/.ssh/id_rsa`
6. Enter the number of worker_nodes (0 - single-node deployment, 3 or more - multi-node deployment): `0`
7. Enter `1` if loadbalancer is required, otherwise press **`Enter`**: press **`Enter`**
8. Enter the connection string for accessing the DBMS as follows: postgres://<dbms_username>:<password>@<fqdn>:<port>: `postgres://xdr:<your_password>@10.0.0.100:5432`
9. It is necessary to enter the IP address of the Kubernetes cluster gateway as follows: <ip_address>. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. Enter the IP address: `10.0.0.200`

10. It is necessary to create the Kaspersky EDR Expert user account. Enter the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters. Enter the password: `your_password`

11. Enter the path to the KUMA inventory file: `/dev/null`

12. Enter the path to the SSH key that is used for connection to the nodes with the KUMA services: `/home/user/.ssh/id_rsa`

13. Enter the path to the KUMA license file: `/dev/null`

14. It is necessary to enter the domain name for the public Kaspersky EDR Expert services. This domain name will be included in the domain names of Kaspersky EDR Expert services. For example, console.<domain name>. Enter the domain name: `xdr.mydomain.com`

15. Enter the path to the user certificate file and private key for public Kaspersky EDR Expert services (if you want to use a self-signed certificate, press **Enter** to skip this step): press **Enter**

16. Enter "Y" if extended incident lifecycle is required in your region: `N`

17. Enter the user name of the account used to view OSMP metrics using the Grafana tool. The user name cannot have less than 1 and more than 30 characters. The user name should start with a letter and can contain lowercase letters ('a' to 'z'), digits ('0' to '9'), and special characters (_ - .): `xdr`

18. Enter the password of the account used to view OSMP metrics through the Grafana tool. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters: `your_password`

11.2 Specifying installation parameters using the configuration file

The template of the configuration file (singlenode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility.

The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.

Symbols that must be replaced in the `psql_dsn` parameter value:

- Whitespace → `%20`
- ! → `%21`
- # → `%23`
- % → `%25`
- & → `%26`
- / → `%2F`
- : → `%3A`
- = → `%3D`
- ? → `%3F`
- @ → `%40`
- [→ `%5B`
-] → `%5D`

Refer to the PostgreSQL connection string article for details.

```
schemaType: ParameterSet

```

Installing Kaspersky EDR Expert

Run the following command:

```
./bin/kdt apply --accept-eula -k xdr-<program_version>.tar -i params.yaml
```

If the installation is successful, the following information will be displayed in the terminal:

```
INFO[0038] apply inventory ./conf.yaml
INFO[0039] preparing bootstrap_<ver>.tgz
INFO[0092] installing: bootstrap
INFO[0404] time: prepare 53.113895029s install 5m12.442326155s
INFO[0404] current installation is valid
INFO[0404] bundles will be published: 40
INFO[0536] bundles published 40
INFO[0536] bundles will be applied: 39
INFO[2450] apply done: 31m53.851140069s
INFO[2450] apply command completed successfully
INFO[2450] time: publish 2m11.679771805s install 31m53.930470045s
```

To check the installation, you need to go to the authorization page. To do this, enter the following in the search bar of the browser:

```
console.<ingress_domain>
```

Where `<ingress_domain>` is the FQDN from the step 10 of this procedure.

Multi-node deployment on standard Ubuntu Server 24.04 LTS virtual machines

This section contains instructions for multi-node Kaspersky EDR Expert deployment on standard Ubuntu Server 24.04 LTS virtual machines.

Typical configuration of four virtual machines with minimum system requirements

- primary node: 4 vCPU, 8 GB of RAM, 500 GB of SSD*
- worker1, worker2, and worker3 nodes: 10 vCPU, 20 GB of RAM, 1 TB of SSD*

* Or any device with 8000 IOPS (input/output operations per second) in random access

> Hardware requirements must be calculated according to the sizing guide.

Configuring primary, worker1, worker2, and worker3 hosts

2.1 Configuring a user account for deploying Kaspersky EDR Expert

1. Open /etc/sudoers:

   ```
   sudo visudo
   ```

2. Add the following line to the end of the file:

   ```
   {user} ALL=(ALL) NOPASSWD: ALL
   ```

   Where `{user}` is the user account for deployment.

   If you encounter the error "`user is not in sudoers file`", switch to a user with root privileges and run the following command:

   ```
   echo "$USER ALL=(ALL) NOPASSWD: ALL" | sudo tee /etc/sudoers.d/$USER
   ```

3. Save (**Ctrl+S**), and then close the file (**Ctrl+X**).

2.2 Checking free space in /var, /opt, and /tmp directories

1. On the primary node, run the following commands:

   ```
   df -h /var
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /opt
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /tmp
   ```

   At least 50 GB of free space must be available.

2. On worker1-worker3 nodes, run the following commands:

   ```
   df -h /var
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /opt
   ```

   At least 700 GB of free space must be available.

   ```
   df -h /tmp
   ```

   At least 50 GB of free space must be available.

2.3 Ensuring there are no errors when synchronizing repositories

Run the following command:

```
sudo apt update
```

The command should return no errors.

2.4 Installing python3-apt and curl

Run the following command:

```
sudo apt install python3-apt curl -y
```

2.5 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

   The output will contain the line:

```
System clock synchronized: yes
```

2. If the `timedatectl` command returns `System clock synchronized: no`, run a network connectivity test:

```
ping google.com
```

3. If the test fails, in the /etc/systemd/resolved.conf file, uncomment the `` `DNS=` `` line and set it to `8.8.8.8`.

4. Run the following commands:

```
systemctl restart systemd-resolved
apt install chrony
sudo systemctl restart chronyd
sudo systemctl enable chronyd
chronyc sources -v
chronyc tracking
sudo apt install ntpsec-ntpdate
ntpdate -q time.google.com
sudo ntpdate -u time.google.com
timedatectl status
```

   The output will contain the line:

```
System clock synchronized: yes
```

5. To check synchronization, run:

```
date
```

   The output must contain current date and time.

Configuring DBMS host

A DBMS host is a DBMS instance that can be installed either outside of a Kubernetes cluster or inside a Kubernetes cluster.

If you install a DBMS instance inside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 20 vCPU
- 40 GB of RAM
- 2.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

If you install a DBMS instance outside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 10 vCPU
- 20 GB of RAM
- 1.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

The following PostgreSQL versions are supported:

- PostgreSQL 15
- PostgreSQL 16
- PostgreSQL 17
- PostgreSQL 18

3.1 Installing and configuring PostgreSQL

1. Install PostgreSQL:

   ```
   sudo apt install -y postgresql-<version>
   ```

   Where <`version`> is PostgreSQL version. For example, for PostgreSQL 16:

   ```
   sudo apt install -y postgresql-16
   ```

   If the required PostgreSQL version is not available in the connected repository, you must add the `PostgreSQL Apt` repository. For instructions, refer to PostgreSQL website.

2. Create a separate PostgreSQL superuser:

   ```
   sudo -u postgres createuser --superuser xdr
   ```

3. Set a password for the user:

   ```
   sudo -u postgres psql -c "ALTER USER xdr WITH PASSWORD 'your_password';"
   ```

4. Create a database with the same name as the user:

```
sudo -u postgres psql -c "CREATE DATABASE xdr OWNER xdr;"
```

5. Allow PostgreSQL access from any IP address:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/<version>/main/pg_hba.conf
```

   Where <version> is PostgreSQL version. For example, for PostgreSQL 16:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/16/main/pg_hba.conf
```

6. Edit the following parameters in the PostgreSQL configuration file (/etc/postgresql/<version>/main/postgresql.conf), where <version> is PostgreSQL version. For example, for PostgreSQL 16: /etc/postgresql/16/main/postgresql.conf.

   Commented (#) lines need to be uncommented.

```
listen_addresses = '*'
shared_buffers = 8192MB
max_stack_depth = 7MB
temp_buffers = 24MB
work_mem = 16MB
max_connections = 512
max_parallel_workers_per_gather = 0
maintenance_work_mem = 128MB
standard_conforming_strings = on
```

7. Restart PostgreSQL

```
sudo systemctl restart postgresql
```

3.2 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

   The output will contain the line:

```
System clock synchronized: yes
```

2. If the `timedatectl` command returns `System clock synchronized: no`, run a network connectivity test:

```
ping google.com
```

3. If the test fails, in the /etc/systemd/resolved.conf file, uncomment the `DNS=` line and set it to `8.8.8.8`.

4. Run the following commands:

```
systemctl restart systemd-resolved
apt install chrony
sudo systemctl restart chronyd
sudo systemctl enable chronyd
chronyc sources -v
chronyc tracking
sudo apt install ntpsec-ntpdate
ntpdate -q time.google.com
sudo ntpdate -u time.google.com
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

5. To check synchronization, run:

```
date
```

The output must contain current date and time.

Configuring administrator host

Administrator host is the host from which the KDT utility is run. Files from the distribution kit including the archive with the KDT utility, must be located on the administrator host. This host may be part of the Kubernetes cluster created by the KDT utility during deploy, or it may remain outside the cluster. If the administrator host is not included in the cluster, it is used solely to deploy and manage the Kubernetes cluster and OSMP. If the administrator host is included in the cluster, in addition it also serves as a target host on which OSMP components are run.

4.1 Unpacking the KDT utility

Run the following command to create a directory and unpack the KDT utility:

```
mkdir ./kdt && tar -xvf bin.tar.gz -C ./kdt
```

4.2 Docker installation

Docker versions 25 and later are supported.

4.2.1 Installation on Ubuntu 24:

```
sudo apt update && sudo apt install docker.io
```

4.2.2 **OR** Installation using official instructions:

1. Install the required packages:

```
sudo apt update && sudo apt install ca-certificates curl
```

2. Download Docker keyring:

```
sudo curl -fsSL https://download.docker.com/linux/ubuntu/gpg -o /etc/apt/keyrings/docker.asc && sudo chmod 0755
/etc/apt/keyrings/docker.asc
```

3. Add the Docker apt repository:

```
sudo tee /etc/apt/sources.list.d/docker.sources <<EOF
Types: deb
URIs: https://download.docker.com/linux/ubuntu
Suites: $(. /etc/os-release && echo "${UBUNTU_CODENAME:-$VERSION_CODENAME}")
Components: stable
Architectures: $(dpkg --print-architecture)
Signed-By: /etc/apt/keyrings/docker.asc
EOF
```

4. Update the repository cache and install Docker packages:

```
sudo apt update && sudo apt install docker-ce docker-ce-cli containerd.io docker-buildx-plugin docker-compose-
plugin
```

4.3 Docker configuration

1. Add the current user to the `docker` group:

```
sudo usermod -aG docker $USER
```

2. Activate user membership in the `docker` group in the current session:

```
newgrp docker
```

4.4 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

2. If the `timedatectl` command returns `System clock synchronized: no`, run a network connectivity test:

```
ping google.com
```

3. If the test fails, in the /etc/systemd/resolved.conf file, uncomment the `DNS=` line and set it to `8.8.8.8`.

4. Run the following commands:

```
systemctl restart systemd-resolved
apt install chrony
sudo systemctl restart chronyd
sudo systemctl enable chronyd
chronyc sources -v
chronyc tracking
sudo apt install ntpsec-ntpdate
ntpdate -q time.google.com
sudo ntpdate -u time.google.com
timedatectl status
```

   The output will contain the line:

```
System clock synchronized: yes
```

5. To check synchronization, run:

```
date
```

   The output must contain current date and time.

4.5 Checking free space in the /tmp directory

Execute the following command:

```
df -h /tmp
```

At least 50 GB of free space must be available.

If you do not have enough free space in the /tmp directory, specify the path to another directory:

```
export TMPDIR=<new_directory>/tmp
```

Or allocate the required free space:

```
echo 'tmpfs /tmp tmpfs defaults,size=50G 0 0' | sudo tee -a /etc/fstab
```

After allocating the required space, reboot the host or remount the partition.

4.6 Configuring an SSH connection between administrator host and primary, worker1, worker2, and worker3 nodes

1. Create SSH key:

```
ssh-keygen -t rsa -b 4096 -N ""
```

2. Copy the key to each target host one-by-one:

```
ssh-copy-id {user}@{primary_ip}
ssh-copy-id {user}@{worker1_ip}
ssh-copy-id {user}@{worker2_ip}
ssh-copy-id {user}@{worker3_ip}
```

Where `{user}` is the user account for Kaspersky EDR Expert deployment created during target host configuration.

4.7 DNS configuration

On your DNS server, register the FQDN of the services to connect to OSMP services (`<ingress_domain>`).

To get started quickly, add a wildcard A record in your DNS server that points to a free IP address (`<ingress_ip>`) in the same subnet as the cluster. The Kubernetes cluster gateway will listen on this IP address and route traffic to the appropriate services.

By default, OSMP services are available at the following addresses:

```
<ingress_ip> - admsrv.<ingress_domain>
<ingress_ip> - api.<ingress_domain>
<ingress_ip> - console.<ingress_domain>
<ingress_ip> - kuma.<ingress_domain>
<ingress_ip> - *.kuma.<ingress_domain>
<ingress_ip> - monitoring.<ingress_domain>
<ingress_ip> - agentserver.<ingress_domain>
<ingress_ip> - updater.<ingress_domain>
```

4.8 Creating a configuration to run the installation

Legend

- `10.0.0.100`—IP address of the primary node (`<primary_ip>`)
- `10.0.0.101`—IP address of the worker1 node (`<worker1_ip>`)
- `10.0.0.102`—IP address of the worker2 node (`<worker2_ip>`)
- `10.0.0.103`—IP address of the worker3 node (`<worker3_ip>`)
- `10.0.0.150`—IP address of the DBMS host (`<DB_ip>`)
- `10.0.0.200`—IP address used for the wildcard A record in the DNS configuration step (`<ingress_ip>`)
- `user`—User account for deployment (`<user_name>`)
- `/home/user/.ssh/id_rsa`—Path to the SSH key created during SSH connection configuration on the administrator host (`<ssh_key_path>`)
- `xdr.mydomain.com`—Domain for ingress (`<ingress_domain>`)

4.8.1 Specifying installation parameters using the Configuration wizard

1. Run the following command to start the Configuration wizard:

   ```
   ./bin/kdt wizard -k xdr-<program_version>.tar -o params.yaml
   ```

2. Enter the number of primary_nodes (minimum 1): `1`
3. Enter the IPv4 address of the 1st primary node: `10.0.0.100`
4. Enter the user name to connect to the 1st primary node: `user`
5. Enter the path to the SSH key to connect to the 1st primary node: `/home/user/.ssh/id_rsa`
6. Enter the number of worker_nodes (0 - single-node deployment, 3 or more - multi-node deployment): `3`
7. Enter the IPv4 address of the 1st worker node: `10.0.0.101`
8. Enter the user name to connect to the 1st worker node: `user`
9. Enter the path to the SSH key to connect to the 1st worker node: `/home/user/.ssh/id_rsa`
10. Enter the IPv4 address of the 2nd worker node: `10.0.0.102`
11. Enter the user name to connect to the 2nd worker node: `user`
12. Enter the path to the SSH key to connect to the 2nd worker node: `/home/user/.ssh/id_rsa`
13. Enter the IPv4 address of the 3rd worker node: `10.0.0.103`
14. Enter the user name to connect to the 3rd worker node: `user`
15. Enter the path to the SSH key to connect to the 3rd worker node: `/home/user/.ssh/id_rsa`
16. Enter 1 if loadbalancer is required, otherwise press **`Enter`**: press **`Enter`**
17. Enter the connection string for accessing the DBMS as follows: postgres://<dbms_username>:<password>@<fqdn>:<port>: `postgres://xdr:<your_password>@10.0.0.150:5432`
18. It is necessary to enter the IP address of the Kubernetes cluster gateway as follows: <ip_address>. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. Enter the IP address: `10.0.0.200`
19. It is necessary to create the Kaspersky EDR Expert user account. Enter the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters. Enter the password: `your_password`
20. Enter the path to the KUMA inventory file: `/dev/null`
21. Enter the path to the SSH key that is used for connection to the nodes with the KUMA services: `/home/user/.ssh/id_rsa`
22. Enter the path to the KUMA license file: `/dev/null`

23. It is necessary to enter the domain name for the public Kaspersky EDR Expert services. This domain name will be included in the domain names of Kaspersky EDR Expert services. For example, console.<domain name>. Enter the domain name: `xdr.mydomain.com`

24. Enter the path to the user certificate file and private key for public Kaspersky EDR Expert services (if you want to use a self-signed certificate, press **Enter** to skip this step): press **Enter**

25. Enter "Y" if extended incident lifecycle is required in your region: `N`

26. Enter the user name of the account used to view OSMP metrics using the Grafana tool. The user name cannot have less than 1 and more than 30 characters. The user name should start with a letter and can contain lowercase letters ('a' to 'z'), digits ('0' to '9'), and special characters (_ - .): `xdr`

27. Enter the password of the account used to view OSMP metrics through the Grafana tool. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters: `your_password`

4.8.2 Specifying installation parameters using the configuration file

The template of the configuration file (multinode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility.

The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.

Symbols that must be replaced in the `psql_dsn` parameter value:

- Whitespace → `%20`
- ! → `%21`
- # → `%23`
- % → `%25`
- & → `%26`
- / → `%2F`
- : → `%3A`
- = → `%3D`
- ? → `%3F`
- @ → `%40`
- [→ `%5B`
-] → `%5D`

Refer to the PostgreSQL connection string article for details.

```
schemaType: ParameterSet

```

Installing Kaspersky EDR Expert

Run the following command:

```
./bin/kdt apply --accept-eula -k xdr-<program_version>.tar -i params.yaml
```

If the installation is successful, the following information will be displayed in the terminal:

```
INFO[0038] apply inventory ./conf.yaml
INFO[0039] preparing bootstrap_<ver>.tgz
INFO[0092] installing: bootstrap
INFO[0404] time: prepare 53.113895029s install 5m12.442326155s
INFO[0404] current installation is valid
INFO[0404] bundles will be published: 40
INFO[0536] bundles published 40
INFO[0536] bundles will be applied: 39
INFO[2450] apply done: 31m53.851140069s
INFO[2450] apply command completed successfully
INFO[2450] time: publish 2m11.679771805s install 31m53.930470045s
```

To check the installation, you need to go to the authorization page. To do this, enter the following in the search bar of the browser:

```
console.<ingress_domain>
```

Where `<ingress_domain>` is the FQDN from the step 4.6 of this procedure.

Multi-node deployment on standard Astra Linux Special Edition (operational update 1.8.2) virtual machines

This section contains instructions for multi-node Kaspersky EDR Expert deployment on standard virtual machines with Astra Linux Special Edition RUSB.10015-01 (operational update 1.8.2) hardened version ("Voronezh") operating system.

Typical configuration of four virtual machines with minimum system requirements

- primary node: 4 vCPU, 8 GB of RAM, 500 GB of SSD*
- worker1, worker2, and worker3 nodes: 10 vCPU, 20 GB of RAM, 1 TB of SSD*

* Or any device with 8000 IOPS (input/output operations per second) in random access

> Hardware requirements must be calculated according to the sizing guide.

Configuring primary, worker1, worker2, and worker3 hosts

2.1 Configuring a user account for deploying Kaspersky EDR Expert

1. Open /etc/sudoers:

   ```
   sudo visudo
   ```

2. Add the following line to the end of the file:

   ```
   {user} ALL=(ALL) NOPASSWD: ALL
   ```

   Where `{user}` is the user account for deployment.

   If you encounter the error "`user is not in sudoers file`", switch to a user with root privileges and run the following command:

   ```
   echo "$USER ALL=(ALL) NOPASSWD: ALL" | sudo tee /etc/sudoers.d/$USER
   ```

3. Save (**Ctrl+S**), and then close the file (**Ctrl+X**).

2.2 Checking free space in /var, /opt, and /tmp directories

1. On the primary node, run the following commands:

   ```
   df -h /var
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /opt
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /tmp
   ```

   At least 50 GB of free space must be available.

2. On worker1-worker4 nodes, run the following commands:

   ```
   df -h /var
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /opt
   ```

   At least 700 GB of free space must be available.

   ```
   df -h /tmp
   ```

   At least 50 GB of free space must be available.

2.3 Ensuring there are no errors when synchronizing repositories

Run the following command:

```
sudo apt update
```

The command should return no errors.

2.4 Installing python3-apt and curl

Run the following command:

```
sudo apt install python3-apt curl -y
```

2.5 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

   The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

   The output must contain current date and time.

2.6 Disabling Mandatory Integrity Control mode, Closed Software Environment mode, and the ptrace capability

We recommend disabling the `ptrace` capability. For instructions, refer to Astra Linux documentation.

Disabling the Mandatory Integrity Control mode

Run the following command:

```
sudo astra-mic-control status
```

If the Mandatory Integrity Control mode is `enabled`, it is required to disable it. For instructions, refer to Astra Linux documentation.

Disabling the closed software environment mode in executable files

```
sudo astra-digsig-control status
```

If the closed software environment mode is enabled, it is required to disable it. For instructions, refer to Astra Linux documentation.

Configuring DBMS host

A DBMS host is a DBMS instance that can be installed either outside of a Kubernetes cluster or inside a Kubernetes cluster.

Since Astra Linux SE 1.8.x repositories do not contain supported versions of PostgreSQL, we recommend to use a separate host outside the Kubernetes cluster with another operating sytem that has supported versions of PostgreSQL in its repositories (for example, Debian or Ubuntu).

If you install a DBMS instance inside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 20 vCPU
- 40 GB of RAM
- 2.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

If you install a DBMS instance outside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 10 vCPU
- 20 GB of RAM
- 1.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

The following PostgreSQL versions are supported:

- PostgreSQL 15
- PostgreSQL 16
- PostgreSQL 17
- PostgreSQL 18

3.1 Installing and configuring PostgreSQL

1. Install PostgreSQL:

   ```
   sudo apt install -y postgresql-<version>
   ```

   Where <`version`> is PostgreSQL version. For example, for PostgreSQL 16:

   ```
   sudo apt install -y postgresql-16
   ```

2. Create a separate PostgreSQL superuser:

   ```
   sudo -u postgres createuser --superuser xdr
   ```

3. Set a password for the user:

   ```
   sudo -u postgres psql -c "ALTER USER xdr WITH PASSWORD 'your_password';"
   ```

4. Create a database with the same name as the user:

   ```
   sudo -u postgres psql -c "CREATE DATABASE xdr OWNER xdr;"
   ```

5. Allow PostgreSQL access from any IP address:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/<version>/main/pg_hba.conf
```

Where <version> is PostgreSQL version. For example, for PostgreSQL 16:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/16/main/pg_hba.conf
```

6. Edit the following parameters in the PostgreSQL configuration file (/etc/postgresql/<version>/main/postgresql.conf), where <version> is PostgreSQL version. For example, for PostgreSQL 16: /etc/postgresql/16/main/postgresql.conf.

Commented (#) lines need to be uncommented.

```
listen_addresses = '*'
shared_buffers = 8192MB
max_stack_depth = 7MB
temp_buffers = 24MB
work_mem = 16MB
max_connections = 512
max_parallel_workers_per_gather = 0
maintenance_work_mem = 128MB
standard_conforming_strings = on
```

7. Restart PostgreSQL

```
sudo systemctl restart postgresql
```

3.2 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

The output must contain current date and time.

Configuring administrator host

Administrator host is the host from which the KDT utility is run. Files from the distribution kit including the archive with the KDT utility, must be located on the administrator host. This host may be part of the Kubernetes cluster created by the KDT utility during deploy, or it may remain outside the cluster. If the administrator host is not included in the cluster, it is used solely to deploy and manage the Kubernetes cluster and OSMP. If the administrator host is included in the cluster, in addition it also serves as a target host on which OSMP components are run.

4.1 Unpacking the KDT utility

Run the following command to create a directory and unpack the KDT utility:

```
mkdir ./kdt && tar -xvf bin.tar.gz -C ./kdt
```

4.2 Disabling Mandatory Integrity Control and Closed Software Environment modes

We recommend disabling the `ptrace` capability. For instructions, refer to Astra Linux documentation.

Disabling the Mandatory Integrity Control mode

Run the following command:

```
sudo astra-mic-control status
```

If the Mandatory Integrity Control mode is `enabled`, it is required to disable it. For instructions, refer to Astra Linux documentation.

Disabling the closed software environment mode in executable files

```
sudo astra-digsig-control status
```

If the closed software environment mode is enabled, it is required to disable it. For instructions, refer to Astra Linux documentation.

4.3 Docker installation

Docker versions 25 and later are supported.

Run the following command:

```
sudo apt update && sudo apt install docker.io
```

4.4 Docker configuration

1. Add the current user to the `docker` group:

   ```
   sudo usermod -aG docker $USER
   ```

2. Activate user membership in the `docker` group in the current session:

```
newgrp docker
```

4.5 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

The output must contain current date and time.

4.6 Checking free space in the /tmp directory

Run the following command:

```
df -h /tmp
```

At least 50 GB of free space must be available.

If you do not have enough free space in the /tmp directory, specify the path to another directory:

```
export TMPDIR=<new_directory>/tmp
```

Or allocate the required free space:

```
echo 'tmpfs /tmp tmpfs defaults,size=50G 0 0' | sudo tee -a /etc/fstab
```

After allocating the required space, reboot the host or remount the partition.

4.7 Configuring an SSH connection between administrator host and primary, worker1, worker2, and worker3 nodes

1. Create SSH key:

```
ssh-keygen -t rsa -b 4096 -N ""
```

2. Copy the key to each target host one-by-one:

```
ssh-copy-id {user}@{primary_ip}
ssh-copy-id {user}@{worker1_ip}
ssh-copy-id {user}@{worker2_ip}
ssh-copy-id {user}@{worker3_ip}
```

Where `{user}` is the user account for Kaspersky EDR Expert deployment created during target host configuration.

4.8 DNS configuration

On your DNS server, register the FQDN of the services to connect to OSMP services (`<ingress_domain>`).

To get started quickly, add a wildcard A record in your DNS server that points to a free IP address (`<ingress_ip>`) in the same subnet as the cluster. The Kubernetes cluster gateway will listen on this IP address and route traffic to the appropriate services.

By default, OSMP services are available at the following addresses:

```
<ingress_ip> - admsrv.<ingress_domain>
<ingress_ip> - api.<ingress_domain>
<ingress_ip> - console.<ingress_domain>
<ingress_ip> - kuma.<ingress_domain>
<ingress_ip> - *.kuma.<ingress_domain>
<ingress_ip> - monitoring.<ingress_domain>
<ingress_ip> - agentserver.<ingress_domain>
<ingress_ip> - updater.<ingress_domain>
```

4.9 Creating a configuration to run the installation

Legend

- `10.0.0.100`—IP address of the primary node (`<primary_ip>`)
- `10.0.0.101`—IP address of the worker1 node (`<worker1_ip>`)
- `10.0.0.102`—IP address of the worker2 node (`<worker2_ip>`)
- `10.0.0.103`—IP address of the worker3 node (`<worker3_ip>`)
- `10.0.0.150`—IP address of the DBMS host (`<DB_ip>`)
- `10.0.0.200`—IP address used for the wildcard A record in the DNS configuration step (`<ingress_ip>`)
- `user`—User account for deployment (`<user_name>`)
- `/home/user/.ssh/id_rsa`—Path to the SSH key created during SSH connection configuration on the administrator host (`<ssh_key_path>`)
- `xdr.mydomain.com`—Domain for ingress (`<ingress_domain>`)

4.9.1 Specifying installation parameters using the Configuration wizard

1. Run the following command to start the Configuration wizard:

   ```
   ./bin/kdt wizard -k xdr-<program_version>.tar -o params.yaml
   ```

2. Enter the number of primary_nodes (minimum 1): `1`
3. Enter the IPv4 address of the 1st primary node: `10.0.0.100`
4. Enter the user name to connect to the 1st primary node: `user`
5. Enter the path to the SSH key to connect to the 1st primary node: `/home/user/.ssh/id_rsa`
6. Enter the number of worker_nodes (0 - single-node deployment, 3 or more - multi-node deployment): `3`
7. Enter the IPv4 address of the 1st worker node: `10.0.0.101`
8. Enter the user name to connect to the 1st worker node: `user`
9. Enter the path to the SSH key to connect to the 1st worker node: `/home/user/.ssh/id_rsa`
10. Enter the IPv4 address of the 2nd worker node: `10.0.0.102`
11. Enter the user name to connect to the 2nd worker node: `user`
12. Enter the path to the SSH key to connect to the 2nd worker node: `/home/user/.ssh/id_rsa`
13. Enter the IPv4 address of the 3rd worker node: `10.0.0.103`
14. Enter the user name to connect to the 3rd worker node: `user`
15. Enter the path to the SSH key to connect to the 3rd worker node: `/home/user/.ssh/id_rsa`
16. Enter 1 if loadbalancer is required, otherwise press **`Enter`**: press **`Enter`**
17. Enter the connection string for accessing the DBMS as follows: postgres://<dbms_username>:<password>@<fqdn>:<port>: `postgres://xdr:<your_password>@10.0.0.150:5432`
18. It is necessary to enter the IP address of the Kubernetes cluster gateway as follows: <ip_address>. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. Enter the IP address: `10.0.0.200`
19. It is necessary to create the Kaspersky EDR Expert user account. Enter the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters. Enter the password: `your_password`
20. Enter the path to the KUMA inventory file: `/dev/null`
21. Enter the path to the SSH key that is used for connection to the nodes with the KUMA services: `/home/user/.ssh/id_rsa`
22. Enter the path to the KUMA license file: `/dev/null`

23. It is necessary to enter the domain name for the public Kaspersky EDR Expert services. This domain name will be included in the domain names of Kaspersky EDR Expert services. For example, console.<domain name>. Enter the domain name: `xdr.mydomain.com`

24. Enter the path to the user certificate file and private key for public Kaspersky EDR Expert services (if you want to use a self-signed certificate, press **Enter** to skip this step): press **Enter**

25. Enter "Y" if extended incident lifecycle is required in your region: `N`

26. Enter the user name of the account used to view OSMP metrics using the Grafana tool. The user name cannot have less than 1 and more than 30 characters. The user name should start with a letter and can contain lowercase letters ('a' to 'z'), digits ('0' to '9'), and special characters (_ - .): `xdr`

27. Enter the password of the account used to view OSMP metrics through the Grafana tool. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters: `your_password`

4.9.2 Specifying installation parameters using the configuration file

The template of the configuration file (multinode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility.

The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.

Symbols that must be replaced in the `psql_dsn` parameter value:

- Whitespace → `%20`
- ! → `%21`
- # → `%23`
- % → `%25`
- & → `%26`
- / → `%2F`
- : → `%3A`
- = → `%3D`
- ? → `%3F`
- @ → `%40`
- [→ `%5B`
-] → `%5D`

Refer to the PostgreSQL connection string article for details.

```

```

Installing Kaspersky EDR Expert

Run the following command:

```
./bin/kdt apply --accept-eula -k xdr-<program_version>.tar -i params.yaml
```

If the installation is successful, the following information will be displayed in the terminal:

```
INFO[0038] apply inventory ./conf.yaml
INFO[0039] preparing bootstrap_<ver>.tgz
INFO[0092] installing: bootstrap
INFO[0404] time: prepare 53.113895029s install 5m12.442326155s
INFO[0404] current installation is valid
INFO[0404] bundles will be published: 40
INFO[0536] bundles published 40
INFO[0536] bundles will be applied: 39
INFO[2450] apply done: 31m53.851140069s
INFO[2450] apply command completed successfully
INFO[2450] time: publish 2m11.679771805s install 31m53.930470045s
```

To check the installation, you need to go to the authorization page. To do this, enter the following in the search bar of the browser:

```
console.<ingress_domain>
```

Where `<ingress_domain>` is the FQDN from the step 4.8 of this procedure.

High availability configuration deployment on standard Ubuntu Server 24.04 LTS virtual machines

This section contains instructions for multi-node Kaspersky EDR Expert deployment on standard Ubuntu Server 24.04 LTS virtual machines.

Typical configuration of seven virtual machines with minimum system requirements

- primary1, primary2, and primary3 nodes: 4 vCPU, 8 GB of RAM, 500 GB of SSD*
- worker1, worker2, worker3, and worker4 nodes: 10 vCPU, 20 GB of RAM, 1 TB of SSD*

* Or any device with 8000 IOPS (input/output operations per second) in random access

> Hardware requirements must be calculated according to the sizing guide.

Configuring primary1, primary2, primary3, worker1, worker2, worker3, and worker4 hosts

2.1 Configuring a user account for deploying Kaspersky EDR Expert

1. Open /etc/sudoers:

   ```
   sudo visudo
   ```

2. Add the following line to the end of the file:

   ```
   {user} ALL=(ALL) NOPASSWD: ALL
   ```

   Where `{user}` is the user account for deployment.

   If you encounter the error "`user is not in sudoers file`", switch to a user with root privileges and run the following command:

   ```
   echo "$USER ALL=(ALL) NOPASSWD: ALL" | sudo tee /etc/sudoers.d/$USER
   ```

3. Save (**Ctrl+S**), and then close the file (**Ctrl+X**).

2.2 Checking free space in /var, /opt, and /tmp directories

1. On primary1-primary3 nodes, run the following commands:

   ```
   df -h /var
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /opt
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /tmp
   ```

   At least 50 GB of free space must be available.

2. On worker1-worker4 nodes, run the following commands:

   ```
   df -h /var
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /opt
   ```

   At least 700 GB of free space must be available.

   ```
   df -h /tmp
   ```

   At least 50 GB of free space must be available.

2.3 Ensuring there are no errors when synchronizing repositories

Run the following command:

```
sudo apt update
```

The command should return no errors.

2.4 Installing python3-apt and curl

Run the following command:

```
sudo apt install python3-apt curl -y
```

2.5 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

   ```
   sudo apt update
   sudo apt install -y systemd-timesyncd
   sudo timedatectl set-ntp true
   sudo timedatectl set-timezone Europe/Moscow
   sudo timedatectl set-local-rtc 0
   timedatectl status
   ```

   The output will contain the line:

   ```
   System clock synchronized: yes
   ```

2. To check synchronization, run:

   ```
   date
   ```

   The output must contain current date and time.

Configuring DBMS host

A DBMS host is a DBMS instance that can be installed either outside of a Kubernetes cluster or inside a Kubernetes cluster.

If you install a DBMS instance inside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 20 vCPU
- 40 GB of RAM
- 2.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

If you install a DBMS instance outside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 10 vCPU
- 20 GB of RAM
- 1.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

The following PostgreSQL versions are supported:

- PostgreSQL 15
- PostgreSQL 16
- PostgreSQL 17
- PostgreSQL 18

3.1 Installing and configuring PostgreSQL

1. Install PostgreSQL:

   ```
   sudo apt install -y postgresql-<version>
   ```

   Where <version> is PostgreSQL version. For example, for PostgreSQL 16:

   ```
   sudo apt install -y postgresql-16
   ```

   If the required PostgreSQL version is not available in the connected repository, you must add the PostgreSQL Apt repository. For instructions, refer to PostgreSQL website.

2. Create a separate PostgreSQL superuser:

   ```
   sudo -u postgres createuser --superuser xdr
   ```

3. Set a password for the user:

   ```
   sudo -u postgres psql -c "ALTER USER xdr WITH PASSWORD 'your_password';"
   ```

4. Create a database with the same name as the user:

   ```
   sudo -u postgres psql -c "CREATE DATABASE xdr OWNER xdr;"
   ```

5. Allow PostgreSQL access from any IP address:

   ```
   echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/<version>/main/pg_hba.conf
   ```

   Where <version> is PostgreSQL version. For example, for PostgreSQL 16:

   ```
   echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/16/main/pg_hba.conf
   ```

6. Edit the following parameters in the PostgreSQL configuration file (/etc/postgresql/<version>/main/postgresql.conf), where <version> is PostgreSQL version. For example, for PostgreSQL 16: /etc/postgresql/16/main/postgresql.conf.

   Commented (#) lines need to be uncommented.

   ```
   listen_addresses = '*'
   shared_buffers = 8192MB
   max_stack_depth = 7MB
   temp_buffers = 24MB
   work_mem = 16MB
   max_connections = 512
   max_parallel_workers_per_gather = 0
   maintenance_work_mem = 128MB
   standard_conforming_strings = on
   ```

7. Restart PostgreSQL

```
sudo systemctl restart postgresql
```

3.2 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

The output must contain current date and time.

Configuring administrator host

Administrator host is the host from which the KDT utility is run. Files from the distribution kit including the archive with the KDT utility, must be located on the administrator host. This host may be part of the Kubernetes cluster created by the KDT utility during deploy, or it may remain outside the cluster. If the administrator host is not included in the cluster, it is used solely to deploy and manage the Kubernetes cluster and OSMP. If the administrator host is included in the cluster, in addition it also serves as a target host on which OSMP components are run.

4.1 Unpacking the KDT utility

Run the following command to create a directory and unpack the KDT utility:

```
mkdir ./kdt && tar -xvf bin.tar.gz -C ./kdt
```

4.2 Docker installation

Docker versions 25 and later are supported.

4.2.1 Installation on Ubuntu 24:

```
sudo apt update && sudo apt install docker.io
```

4.2.2 **OR** Installation using official instructions:

1. Install the required packages:

```
sudo apt update && sudo apt install ca-certificates curl
```

2. Download Docker keyring:

```
sudo curl -fsSL https://download.docker.com/linux/ubuntu/gpg -o /etc/apt/keyrings/docker.asc && sudo chmod 0755
/etc/apt/keyrings/docker.asc
```

3. Add the Docker apt repository:

```
sudo tee /etc/apt/sources.list.d/docker.sources <<EOF
Types: deb
URIs: https://download.docker.com/linux/ubuntu
Suites: $(. /etc/os-release && echo "${UBUNTU_CODENAME:-$VERSION_CODENAME}")
Components: stable
Architectures: $(dpkg --print-architecture)
Signed-By: /etc/apt/keyrings/docker.asc
EOF
```

4. Update the repository cache and install Docker packages:

```
sudo apt update && sudo apt install docker-ce docker-ce-cli containerd.io docker-buildx-plugin docker-compose-
plugin
```

4.3 Docker configuration

1. Add the current user to the `docker` group:

```
sudo usermod -aG docker $USER
```

2. Activate user membership in the `docker` group in the current session:

```
newgrp docker
```

4.4 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

The output must contain current date and time.

4.5 Checking free space in the /tmp directory

Execute the following command:

```
df -h /tmp
```

At least 50 GB of free space must be available.

If you do not have enough free space in the /tmp directory, specify the path to another directory:

```
export TMPDIR=<new_directory>/tmp
```

Or allocate the required free space:

```
echo 'tmpfs /tmp tmpfs defaults,size=50G 0 0' | sudo tee -a /etc/fstab
```

After allocating the required space, reboot the host or remount the partition.

4.6 Configuring an SSH connection between administrator host and primary1, primary2, primary3, worker1, worker2, worker3, and worker4 nodes

1. Create SSH key:

```
ssh-keygen -t rsa -b 4096 -N ""
```

2. Copy the key to each target host one-by-one:

```
ssh-copy-id {user}@{primary1_ip}
ssh-copy-id {user}@{primary2_ip}
ssh-copy-id {user}@{primary3_ip}
ssh-copy-id {user}@{worker1_ip}
ssh-copy-id {user}@{worker2_ip}
ssh-copy-id {user}@{worker3_ip}
ssh-copy-id {user}@{worker4_ip}
```

Where `{user}` is the user account for Kaspersky EDR Expert deployment created during target host configuration.

4.7 DNS configuration

On your DNS server, register the FQDN of the services to connect to OSMP services (`<ingress_domain>`).

To get started quickly, add a wildcard A record in your DNS server that points to a free IP address (`<ingress_ip>`) in the same subnet as the cluster. The Kubernetes cluster gateway will listen on this IP address and route traffic to the appropriate services.

By default, OSMP services are available at the following addresses:

```
<ingress_ip> - admsrv.<ingress_domain>
<ingress_ip> - api.<ingress_domain>
<ingress_ip> - console.<ingress_domain>
<ingress_ip> - kuma.<ingress_domain>
<ingress_ip> - *.kuma.<ingress_domain>
<ingress_ip> - monitoring.<ingress_domain>
<ingress_ip> - agentserver.<ingress_domain>
<ingress_ip> - updater.<ingress_domain>
```

4.8 Creating a configuration to run the installation

Legend

- `10.0.0.110`—IP address of the primary node (`<primary1_ip>`)
- `10.0.0.120`—IP address of the primary node (`<primary2_ip>`)
- `10.0.0.130`—IP address of the primary node (`<primary3_ip>`)
- `10.0.0.101`—IP address of the worker1 node (`<worker1_ip>`)
- `10.0.0.102`—IP address of the worker2 node (`<worker2_ip>`)
- `10.0.0.103`—IP address of the worker3 node (`<worker3_ip>`)
- `10.0.0.104`—IP address of the worker4 node (`<worker4_ip>`)
- `10.0.0.150`—IP address of the DBMS host (`<DB_ip>`)
- `10.0.0.200`—IP address used for the wildcard A record in the DNS configuration step (`<ingress_ip>`)
- `user`—User account for deployment (`<user_name>`)
- `/home/user/.ssh/id_rsa`—Path to the SSH key created during SSH connection configuration on the administrator host (`<ssh_key_path>`)
- `xdr.mydomain.com`—Domain for ingress (`<ingress_domain>`)

4.8.1 Specifying installation parameters using the Configuration wizard

1. Run the following command to start the Configuration wizard:

   ```
   ./bin/kdt wizard -k xdr-<version>.tar -o params.yaml
   ```

2. Enter the number of primary_nodes (minimum 1): `3`
3. Enter the IPv4 address of the 1st primary node: `10.0.0.110`
4. Enter the user name to connect to the 1st primary node: `user`
5. Enter the path to the SSH key to connect to the 1st primary node: `/home/user/.ssh/id_rsa`
6. Enter the IPv4 address of the 2nd primary node: `10.0.0.120`

7. Enter the user name to connect to the 2nd primary node: `user`
8. Enter the path to the SSH key to connect to the 2nd worker node: `/home/user/.ssh/id_rsa`
9. Enter the IPv4 address of the 3rd primary node: `10.0.0.130`
10. Enter the user name to connect to the 3rd primary node: `user`
11. Enter the path to the SSH key to connect to the 3rd primary node: `/home/user/.ssh/id_rsa`
12. Enter the number of worker_nodes (0 - single-node deployment, 3 or more - multi-node deployment): `4`
13. Enter the IPv4 address of the 1st worker node: `10.0.0.101`
14. Enter the user name to connect to the 1st worker node: `user`
15. Enter the path to the SSH key to connect to the 1st worker node: `/home/user/.ssh/id_rsa`
16. Enter the IPv4 address of the 2nd worker node: `10.0.0.102`
17. Enter the user name to connect to the 2nd worker node: `user`
18. Enter the path to the SSH key to connect to the 2nd worker node: `/home/user/.ssh/id_rsa`
19. Enter the IPv4 address of the 3rd worker node: `10.0.0.103`
20. Enter the user name to connect to the 3rd worker node: `user`
21. Enter the path to the SSH key to connect to the 3rd worker node: `/home/user/.ssh/id_rsa`
22. Enter the IPv4 address of the 4th worker node: `10.0.0.104`
23. Enter the user name to connect to the 4th worker node: `user`
24. Enter the path to the SSH key to connect to the 4th worker node: `/home/user/.ssh/id_rsa`
25. Enter 1 if loadbalancer is required, otherwise press **Enter**: press **Enter**
26. Enter the connection string for accessing the DBMS as follows: postgres://<dbms_username>:<password>@<fqdn>:<port>: `postgres://xdr:<your_password>@10.0.0.150:5432`
27. It is necessary to enter the IP address of the Kubernetes cluster gateway as follows: <ip_address>. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. Enter the IP address: `10.0.0.200`
28. It is necessary to create the Kaspersky EDR Expert user account. Enter the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters. Enter the password: `your_password`
29. Enter the path to the KUMA inventory file: `/dev/null`
30. Enter the path to the SSH key that is used for connection to the nodes with the KUMA services: `/home/user/.ssh/id_rsa`

31. Enter the path to the KUMA license file: `/dev/null`

32. It is necessary to enter the domain name for the public Kaspersky EDR Expert services. This domain name will be included in the domain names of Kaspersky EDR Expert services. For example, console.<domain name>. Enter the domain name: `xdr.mydomain.com`

33. Enter the path to the user certificate file and private key for public Kaspersky EDR Expert services (if you want to use a self-signed certificate, press **Enter** to skip this step): press **Enter**

34. Enter "Y" if extended incident lifecycle is required in your region: `N`

35. Enter the user name of the account used to view OSMP metrics using the Grafana tool. The user name cannot have less than 1 and more than 30 characters. The user name should start with a letter and can contain lowercase letters ('a' to 'z'), digits ('0' to '9'), and special characters (_ - .): `xdr`

36. Enter the password of the account used to view OSMP metrics through the Grafana tool. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters: `your_password`

4.8.2 Specifying installation parameters using the configuration file

The template of the configuration file (multinode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility.

The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.

Symbols that must be replaced in the `psql_dsn` parameter value:

- Whitespace → `%20`
- ! → `%21`
- # → `%23`
- % → `%25`
- & → `%26`
- / → `%2F`
- : → `%3A`
- = → `%3D`
- ? → `%3F`
- @ → `%40`
- [→ `%5B`
-] → `%5D`

Refer to the PostgreSQL connection string article for details.

```

```

Installing Kaspersky EDR Expert

Run the following command:

```
./bin/kdt apply --accept-eula -k xdr-<program_version>.tar -i params.yaml
```

If the installation is successful, the following information will be displayed in the terminal:

```
INFO[0038] apply inventory ./conf.yaml
INFO[0039] preparing bootstrap_<ver>.tgz
INFO[0092] installing: bootstrap
INFO[0404] time: prepare 53.113895029s install 5m12.442326155s
INFO[0404] current installation is valid
INFO[0404] bundles will be published: 40
INFO[0536] bundles published 40
INFO[0536] bundles will be applied: 39
INFO[2450] apply done: 31m53.851140069s
INFO[2450] apply command completed successfully
INFO[2450] time: publish 2m11.679771805s install 31m53.930470045s
```

To check the installation, you need to go to the authorization page. To do this, enter the following in the search bar of the browser:

```
console.<ingress_domain>
```

Where `<ingress_domain>` is the FQDN from the step 4.6 of this procedure.

High availability configuration deployment on standard Astra Linux Special Edition (operational update 1.8.2) virtual machines

This section contains instructions for multi-node Kaspersky EDR Expert deployment on standard virtual machines with Astra Linux Special Edition RUSB.10015-01 (operational update 1.8.2) hardened version ("Voronezh") operating system.

Typical configuration of seven virtual machines with minimum system requirements

- primary1, primary2, and primary3 nodes: 4 vCPU, 8 GB of RAM, 500 GB of SSD*
- worker1, worker2, worker3, and worker4 nodes: 10 vCPU, 20 GB of RAM, 1 TB of SSD*

* Or any device with 8000 IOPS (input/output operations per second) in random access

> Hardware requirements must be calculated according to the sizing guide.

Configuring primary1, primary2, primary3, worker1, worker2, worker3, and worker4 hosts

2.1 Configuring a user account for deploying Kaspersky EDR Expert

1. Open /etc/sudoers:

```
sudo visudo
```

2. Add the following line to the end of the file:

```
{user} ALL=(ALL) NOPASSWD: ALL
```

Where `{user}` is the user account for deployment.

If you encounter the error "`user is not in sudoers file`", switch to a user with root privileges and run the following command:

```
echo "$USER ALL=(ALL) NOPASSWD: ALL" | sudo tee /etc/sudoers.d/$USER
```

3. Save (**Ctrl+S**), and then close the file (**Ctrl+X**).

2.2 Checking free space in /var, /opt, and /tmp directories

1. On primary1-primary3 nodes, run the following commands:

```
df -h /var
```

At least 200 GB of free space must be available.

```
df -h /opt
```

At least 200 GB of free space must be available.

```
df -h /tmp
```

At least 50 GB of free space must be available.

2. On worker1-worker4 nodes, run the following commands:

```
df -h /var
```

At least 200 GB of free space must be available.

```
df -h /opt
```

At least 700 GB of free space must be available.

```
df -h /tmp
```

At least 50 GB of free space must be available.

2.3 Ensuring there are no errors when synchronizing repositories

Run the following command:

```
sudo apt update
```

The command should return no errors.

2.4 Installing python3-apt and curl

Run the following command:

```
sudo apt install python3-apt curl -y
```

2.5 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

   ```
   sudo apt update
   sudo apt install -y systemd-timesyncd
   sudo timedatectl set-ntp true
   sudo timedatectl set-timezone Europe/Moscow
   sudo timedatectl set-local-rtc 0
   timedatectl status
   ```

   The output will contain the line:

   ```
   System clock synchronized: yes
   ```

2. To check synchronization, run:

   ```
   date
   ```

   The output must contain current date and time.

2.6 Disabling Mandatory Integrity Control mode, Closed Software Environment mode, and the ptrace capability

We recommend disabling the `ptrace` capability. For instructions, refer to Astra Linux documentation.

Disabling the Mandatory Integrity Control mode

Run the following command:

```
sudo astra-mic-control status
```

If the Mandatory Integrity Control mode is `enabled`, it is required to disable it. For instructions, refer to Astra Linux documentation.

Disabling the closed software environment mode in executable files

```
sudo astra-digsig-control status
```

If the closed software environment mode is enabled, it is required to disable it. For instructions, refer to Astra Linux documentation.

Configuring DBMS host

A DBMS host is a DBMS instance that can be installed either outside of a Kubernetes cluster or inside a Kubernetes cluster.

Since Astra Linux SE 1.8.x repositories do not contain supported versions of PostgreSQL, we recommend to use a separate host outside the Kubernetes cluster with another operating sytem that has supported versions of PostgreSQL in its repositories (for example, Debian or Ubuntu).

If you install a DBMS instance inside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 20 vCPU
- 40 GB of RAM
- 2.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

If you install a DBMS instance outside a Kubernetes cluster, you must increase the sizing of the target host on which the DBMS instance will be installed to the following:

- 10 vCPU
- 20 GB of RAM
- 1.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

The following PostgreSQL versions are supported:

- PostgreSQL 15
- PostgreSQL 16
- PostgreSQL 17
- PostgreSQL 18

3.1 Installing and configuring PostgreSQL

1. Install PostgreSQL:

   ```
   sudo apt install -y postgresql-<version>
   ```

   Where <`version`> is PostgreSQL version. For example, for PostgreSQL 16:

   ```
   sudo apt install -y postgresql-16
   ```

2. Create a separate PostgreSQL superuser:

   ```
   sudo -u postgres createuser --superuser xdr
   ```

3. Set a password for the user:

```
sudo -u postgres psql -c "ALTER USER xdr WITH PASSWORD 'your_password';"
```

4. Create a database with the same name as the user:

```
sudo -u postgres psql -c "CREATE DATABASE xdr OWNER xdr;"
```

5. Allow PostgreSQL access from any IP address:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/<version>/main/pg_hba.conf
```

Where <version> is PostgreSQL version. For example, for PostgreSQL 16:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/16/main/pg_hba.conf
```

6. Edit the following parameters in the PostgreSQL configuration file (/etc/postgresql/<version>/main/postgresql.conf), where <version> is PostgreSQL version. For example, for PostgreSQL 16: /etc/postgresql/16/main/postgresql.conf.

Commented (#) lines need to be uncommented.

```
listen_addresses = '*'
shared_buffers = 8192MB
max_stack_depth = 7MB
temp_buffers = 24MB
work_mem = 16MB
max_connections = 512
max_parallel_workers_per_gather = 0
maintenance_work_mem = 128MB
standard_conforming_strings = on
```

7. Restart PostgreSQL

```
sudo systemctl restart postgresql
```

3.2 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

The output must contain current date and time.

Configuring administrator host

Administrator host is the host from which the KDT utility is run. Files from the distribution kit including the archive with the KDT utility, must be located on the administrator host. This host may be part of the Kubernetes cluster created by the KDT utility during deploy, or it may remain outside the cluster. If the administrator host is not included in the cluster, it is used solely to deploy and manage the Kubernetes cluster and OSMP. If the administrator host is included in the cluster, in addition it also serves as a target host on which OSMP components are run.

4.1 Unpacking the KDT utility

Run the following command to create a directory and unpack the KDT utility:

```
mkdir ./kdt && tar -xvf bin.tar.gz -C ./kdt
```

4.2 Disabling Mandatory Integrity Control and Closed Software Environment modes

We recommend disabling the `ptrace` capability. For instructions, refer to Astra Linux documentation.

Disabling the Mandatory Integrity Control mode

Run the following command:

```
sudo astra-mic-control status
```

If the Mandatory Integrity Control mode is `enabled`, it is required to disable it. For instructions, refer to Astra Linux documentation.

Disabling the closed software environment mode in executable files

```
sudo astra-digsig-control status
```

If the closed software environment mode is enabled, it is required to disable it. For instructions, refer to Astra Linux documentation.

4.3 Docker installation

Docker versions 25 and later are supported.

Run the following command:

```
sudo apt update && sudo apt install docker.io
```

4.4 Docker configuration

1. Add the current user to the `docker` group:

```
sudo usermod -aG docker $USER
```

2. Activate user membership in the `docker` group in the current session:

```
newgrp docker
```

4.5 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

   The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

   The output must contain current date and time.

4.6 Checking free space in the /tmp directory

Run the following command:

```
df -h /tmp
```

At least 50 GB of free space must be available.

If you do not have enough free space in the /tmp directory, specify the path to another directory:

```
export TMPDIR=<new_directory>/tmp
```

Or allocate the required free space:

```
echo 'tmpfs /tmp tmpfs defaults,size=50G 0 0' | sudo tee -a /etc/fstab
```

After allocating the required space, reboot the host or remount the partition.

4.7 Configuring an SSH connection between administrator host and primary1, primary2, primary3, worker1, worker2, worker3, and worker4 nodes

1. Create SSH key:

```
ssh-keygen -t rsa -b 4096 -N ""
```

2. Copy the key to each target host one-by-one:

```
ssh-copy-id {user}@{primary1_ip}
ssh-copy-id {user}@{primary2_ip}
ssh-copy-id {user}@{primary3_ip}
ssh-copy-id {user}@{worker1_ip}
ssh-copy-id {user}@{worker2_ip}
ssh-copy-id {user}@{worker3_ip}
ssh-copy-id {user}@{worker4_ip}
```

Where `{user}` is the user account for Kaspersky EDR Expert deployment created during target host configuration.

4.8 DNS configuration

On your DNS server, register the FQDN of the services to connect to OSMP services (`<ingress_domain>`).

To get started quickly, add a wildcard A record in your DNS server that points to a free IP address (`<ingress_ip>`) in the same subnet as the cluster. The Kubernetes cluster gateway will listen on this IP address and route traffic to the appropriate services.

By default, OSMP services are available at the following addresses:

```
<ingress_ip> - admsrv.<ingress_domain>
<ingress_ip> - api.<ingress_domain>
<ingress_ip> - console.<ingress_domain>
<ingress_ip> - kuma.<ingress_domain>
<ingress_ip> - *.kuma.<ingress_domain>
<ingress_ip> - monitoring.<ingress_domain>
<ingress_ip> - agentserver.<ingress_domain>
<ingress_ip> - updater.<ingress_domain>
```

4.9 Creating a configuration to run the installation

Legend

- `10.0.0.110`—IP address of the primary node (`<primary1_ip>`)
- `10.0.0.120`—IP address of the primary node (`<primary2_ip>`)
- `10.0.0.130`—IP address of the primary node (`<primary3_ip>`)
- `10.0.0.101`—IP address of the worker1 node (`<worker1_ip>`)
- `10.0.0.102`—IP address of the worker2 node (`<worker2_ip>`)
- `10.0.0.103`—IP address of the worker3 node (`<worker3_ip>`)
- `10.0.0.104`—IP address of the worker4 node (`<worker4_ip>`)

- `10.0.0.150`—IP address of the DBMS host (`<DB_ip>`)
- `10.0.0.200`—IP address used for the wildcard A record in the DNS configuration step (`<ingress_ip>`)
- `user`—User account for deployment (`<user_name>`)
- `/home/user/.ssh/id_rsa`—Path to the SSH key created during SSH connection configuration on the administrator host (`<ssh_key_path>`)
- `xdr.mydomain.com`—Domain for ingress (`<ingress_domain>`)

4.9.1 Specifying installation parameters using the Configuration wizard

1. Run the following command to start the Configuration wizard:

   ```
   ./bin/kdt wizard -k xdr-<version>.tar -o params.yaml
   ```

2. Enter the number of primary_nodes (minimum 1): `3`
3. Enter the IPv4 address of the 1st primary node: `10.0.0.110`
4. Enter the user name to connect to the 1st primary node: `user`
5. Enter the path to the SSH key to connect to the 1st primary node: `/home/user/.ssh/id_rsa`
6. Enter the IPv4 address of the 2nd primary node: `10.0.0.120`
7. Enter the user name to connect to the 2nd primary node: `user`
8. Enter the path to the SSH key to connect to the 2nd worker node: `/home/user/.ssh/id_rsa`
9. Enter the IPv4 address of the 3rd primary node: `10.0.0.130`
10. Enter the user name to connect to the 3rd primary node: `user`
11. Enter the path to the SSH key to connect to the 3rd primary node: `/home/user/.ssh/id_rsa`
12. Enter the number of worker_nodes (0 - single-node deployment, 3 or more - multi-node deployment): `4`
13. Enter the IPv4 address of the 1st worker node: `10.0.0.101`
14. Enter the user name to connect to the 1st worker node: `user`
15. Enter the path to the SSH key to connect to the 1st worker node: `/home/user/.ssh/id_rsa`
16. Enter the IPv4 address of the 2nd worker node: `10.0.0.102`
17. Enter the user name to connect to the 2nd worker node: `user`
18. Enter the path to the SSH key to connect to the 2nd worker node: `/home/user/.ssh/id_rsa`
19. Enter the IPv4 address of the 3rd worker node: `10.0.0.103`
20. Enter the user name to connect to the 3rd worker node: `user`

21. Enter the path to the SSH key to connect to the 3rd worker node: `/home/user/.ssh/id_rsa`

22. Enter the IPv4 address of the 4th worker node: `10.0.0.104`

23. Enter the user name to connect to the 4th worker node: `user`

24. Enter the path to the SSH key to connect to the 4th worker node: `/home/user/.ssh/id_rsa`

25. Enter 1 if loadbalancer is required, otherwise press **Enter**: press **Enter**

26. Enter the connection string for accessing the DBMS as follows: postgres://<dbms_username>:<password>@<fqdn>:<port>: `postgres://xdr:<your_password>@10.0.0.150:5432`

27. It is necessary to enter the IP address of the Kubernetes cluster gateway as follows: <ip_address>. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. Enter the IP address: `10.0.0.200`

28. It is necessary to create the Kaspersky EDR Expert user account. Enter the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters. Enter the password: `your_password`

29. Enter the path to the KUMA inventory file: `/dev/null`

30. Enter the path to the SSH key that is used for connection to the nodes with the KUMA services: `/home/user/.ssh/id_rsa`

31. Enter the path to the KUMA license file: `/dev/null`

32. It is necessary to enter the domain name for the public Kaspersky EDR Expert services. This domain name will be included in the domain names of Kaspersky EDR Expert services. For example, console.<domain name>. Enter the domain name: `xdr.mydomain.com`

33. Enter the path to the user certificate file and private key for public Kaspersky EDR Expert services (if you want to use a self-signed certificate, press **Enter** to skip this step): press **Enter**

34. Enter "Y" if extended incident lifecycle is required in your region: `N`

35. Enter the user name of the account used to view OSMP metrics using the Grafana tool. The user name cannot have less than 1 and more than 30 characters. The user name should start with a letter and can contain lowercase letters ('a' to 'z'), digits ('0' to '9'), and special characters (_ - .): `xdr`

36. Enter the password of the account used to view OSMP metrics through the Grafana tool. The password cannot have less than 8 and more than 256 characters. The password must contain uppercase letters, lowercase letters, numbers, and special characters: `your_password`

4.9.2 Specifying installation parameters using the configuration file

The template of the configuration file (multinode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility.

The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.

Symbols that must be replaced in the `psql_dsn` parameter value:

- Whitespace → `%20`
- ! → `%21`
- # → `%23`
- % → `%25`
- & → `%26`
- / → `%2F`
- : → `%3A`
- = → `%3D`
- ? → `%3F`
- @ → `%40`
- [→ `%5B`
-] → `%5D`

Refer to the PostgreSQL connection string article for details.

```

Installing Kaspersky EDR Expert

Run the following command:

```
./bin/kdt apply --accept-eula -k xdr-<program_version>.tar -i params.yaml
```

If the installation is successful, the following information will be displayed in the terminal:

```
INFO[0038] apply inventory ./conf.yaml
INFO[0039] preparing bootstrap_<ver>.tgz
INFO[0092] installing: bootstrap
INFO[0404] time: prepare 53.113895029s install 5m12.442326155s
INFO[0404] current installation is valid
INFO[0404] bundles will be published: 40
INFO[0536] bundles published 40
INFO[0536] bundles will be applied: 39
INFO[2450] apply done: 31m53.851140069s
INFO[2450] apply command completed successfully
INFO[2450] time: publish 2m11.679771805s install 31m53.930470045s
```

To check the installation, you need to go to the authorization page. To do this, enter the following in the search bar of the browser:

```
console.<ingress_domain>
```

Where `<ingress_domain>` is the FQDN from the step 4.8 of this procedure.

Hardening Guide

The Hardening Guide is intended for professionals who deploy and administer Kaspersky EDR Expert, as well as for those who provide technical support to organizations that use Kaspersky EDR Expert.

The Hardening Guide describes recommendations and features of configuring Kaspersky EDR Expert and its components, aimed to reduce the risks of its compromise.

The Hardening Guide contains the following information:

- Preparing the infrastructure for the Kaspersky EDR Expert deployment
- Configuring a secure connection to Kaspersky EDR Expert
- Configuring accounts to access Kaspersky EDR Expert
- Managing protection of Kaspersky EDR Expert
- Managing protection of client devices
- Configuring protection for managed applications
- Transferring information to third-party applications

Before you start to deploy Kaspersky EDR Expert, we recommend reading the Hardening Guide.

Managing infrastructure of Kaspersky EDR Expert

This article describes the general principle of using the minimum required number of applications for the function of the operating system and Kaspersky EDR Expert. This section also describes the principle of least privilege, which boils down to the concept of Zero Trust.

Managing operating system accounts

To work with a Kubernetes cluster by using KDT, we recommend creating a separate user with minimal privileges. The optimal way is to implement management of user accounts of the operating system by using LDAP, with the ability to revoke user rights through LDAP. For the specific implementation of user revocation and blocking, see the user/administrator guide in your LDAP solution. We recommend using a password of at least 18 characters or a passphrase with any delimiters of at least 4 words to authenticate the user. You can also use a physical means of authentication (for example, token).

For more information, refer to OpenLDAP Software documentation.

Example

Distribution package	User creation command	Minimum set of groups/privileges
Ubuntu / Debian / Astra / Atlant	`useradd "$1" --shell /bin/bash --create-home --password "$(openssl passwd -1 "$2")"`	`usermod -aG sudo,root "$1"` Adding to the `sudo` group allows user to execute `sudo` without a password.

We also recommend protecting the user home directory and all nested directories in such a way that only the user has access to them. Other users and the user group must not have rights to the home directory.

Example

In this example, an `example_user` user has a document directory located at `~/Documents`. By default (when creating a user via `useradd/adduser` and `umask 022` commands), directories are created with permissions `755`. To ensure that only this user has access to the root folder and all subfolders, the `umask` is changed to `077` and the permissions are explicitly set to `700`. Below is an example of commands that can be used to verify that the permissions are already set correctly (only the owner has access).

To show permissions, owner, and group of a directory:
`stat -c "%A %U %G" /home/example_user/Documents`
Expected command output if permissions are granted correctly:
`drwx------ example_user example_user`
If the permissions do not meet the requirements, set the permissions to `700` for the root directory and all subdirectories:
`chmod -R 700 /home/example_user/Documents`
Ensure the owner is the correct user:
`chown -R example_user:example_user /home/example_user/Documents`

We recommend not granting the execute permission for the .ssh, .kube, .config, and .kdt directories, and all the contained files in these directories in the user's home directory.

Example

Display permissions for the most sensitive directories –show the mode, owner, and path for each of the specified directories:

```
find ~/Documents -type d \( -name .ssh -o -name .kube -o -name .config -o -name .kdt \) \

-exec stat -c "%A %U %G %n" {} \;
```

Expected command output:

```
drwx------ example_user example_user /home/example_user/Documents/.ssh

drwx------ example_user example_user /home/example_user/Documents/.kube

drwx------ example_user example_user /home/example_user/Documents/.config

drwx------ example_user example_user /home/example_user/Documents/.kdt
```

`drwx------` represents permissions `700`: only the owner can read, write, and execute (in the case of directories, "execute" is the permission to enter a directory, but not to run software).

If extra execute bits are detected, remove them from files:

```
find ~/Documents -type f \( -path "*/.ssh/*" -o -path "*/.kube/*" -o -path "*/.config/*"
-o -path "*/.kdt/*" \) -exec chmod a-x {} \;
```

If necessary, set stricter permissions (for example, `600`):

```
find ~/Documents -type f \( -path "*/.ssh/*" -o -path "*/.kube/*" -o -path "*/.config/*"
-o -path "*/.kdt/*" \) -exec chmod 600 {} \;
```

Package management of the operating system

We recommend using the minimum set of applications required for the function of KDT and Kaspersky EDR Expert. For example, you do not need to use a graphical user interface for working in the Kubernetes cluster, so we recommend not installing graphical packages. If packages are installed, we recommend removing these packages, including graphical servers such as Xorg or Wayland.

We recommend regularly installing security updates for the system software and the Linux kernel. We also recommend enabling automatic updates as follows:

- For operating systems with the apt package manager:

  /etc/apt/apt.conf.d/50unattended-upgrades

  ```
  Unattended-Upgrade::Allowed-Origins {
   "${distro_id}:${distro_codename}-security";

   "${distro_id}ESMApps:${distro_codename}-apps-security";
   "${distro_id}ESM:${distro_codename}-infra-security";
  };
  ```

- For operating systems with the rpm, dnf, and yum package managers:

  /etc/dnf/automatic.conf

  ```
  [commands]
  # What kind of upgrade to perform:
  # default = all available upgrades
  # security = only the security upgrades
  upgrade_type = default

  # Whether updates should be downloaded when they are available, by
  # dnf-automatic.timer. notifyonly.timer, download.timer and
  # install.timer override this setting.
  download_updates = yes

  # Whether updates should be applied when they are available, by
  # dnf-automatic.timer. notifyonly.timer, download.timer and
  # install.timer override this setting.
  apply_updates = no
  ```

Operating system security settings

The Linux kernel security settings can be enabled in the `/etc/sysctl.conf` file or by using the `sysctl` command. The recommended Linux kernel security settings are listed in the `/etc/sysctl.conf` file snippet:

/etc/sysctl.conf

```
# Disable execshield
kernel.randomize_va_space=2
# Enable IP spoofing protection
net.ipv4.conf.all.rp_filter=1
net.ipv4.conf.default.rp_filter=1
# Ignore broadcast network requests
net.ipv4.icmp_echo_ignore_broadcasts=1
net.ipv4.icmp_ignore_bogus_error_responses=1
# Enable logging of network spoofing packages
net.ipv4.conf.all.log_martians=1
# Hide the kernel pointers
kernel.kptr_restrict=1
```

```
# Restrict access to the kernel logs
kernel.dmesg_restrict = 1
# Prohibit the kernel profiling for unprivileged users
kernel.perf_event_paranoid=3
# Increasing the ASLR entropy bits
vm.mmap_rnd_bits=32
vm.mmap_rnd_compat_bits=16
```

We recommend restricting access to the PID. This will reduce the possibility of one user tracking the processes of another user. You can restrict access to the PID while mounting the `/proc` file system, for example, by adding the following line to the `/etc/fstab` file:

```
proc /proc proc nosuid,nodev,noexec,hidepid=2,gid=proc 0 0
```

If the operating system processes are managed by using the `systemd` system, the `systemd-logind` service can still monitor the processes of other users. In order for user sessions to work correctly in the `systemd` system, you need to create the `/etc/systemd/system/systemd-logind.service.d/hidepid.conf` file, and then add the following lines to it:

```
[Service]
SupplementaryGroups=proc
```

Since some systems may not have the `proc` group, we recommend adding the `proc` group in advance.

We recommend turning off the **ctrl**+**alt**+**del** key combination, to prevent an unexpected reboot of the operating system by using the `systemctl mask ctrl-alt-del.target` command.

We recommend prohibiting authentication of privileged users (root users) to establish a remote user connection.

Example

Below is a set of commands that simultaneously prevent root from logging in over the network and exclude it from LDAP authentication.

```
# 1. SSH

sudo sed -i 's/^#\?PermitRootLogin .*/PermitRootLogin no/' /etc/ssh/sshd_config

sudo systemctl restart sshd

# 2. Local account

sudo passwd -l root

sudo usermod -s /usr/sbin/nologin root

# 3. Example of LDAP bind, the file path may differ

LDAP_CONF="/etc/ksc/ldap_connection.json"

if [ -f "$LDAP_CONF" ]; then

sudo jq '.ldap.bindDn = "cn=admin,dc=example,dc=com"' "$LDAP_CONF" | sudo tee
"$LDAP_CONF" > /dev/null
```

```
sudo systemctl restart ksc-orchestrator

fi

# 4. Sudo without NOPASSWD

sudo sed -i '/^root.*NOPASSWD/d' /etc/sudoers
```

We recommend using a firewall to limit network activity. For more information about the ports and protocols used, refer to Ports used by Kaspersky EDR Expert.

Example

Action	ufw (Ubuntu/Debian)	firewalld (RHEL/CentOS)	iptables
Check status	ufw status	firewall-cmd --list-all	iptables -L -n
Check port	ss -tuln | grep 443	ss -tuln | grep 443	ss -tuln | grep 443
External audit	nc -zv IP 443	nc -zv IP 443	nc -zv IP 443
Open port	ufw allow 443/tcp	firewall-cmd --add-port=443/tcp --permanent + --reload	iptables -A INPUT -p tcp --dport 443 -j ACCEPT
Close port	ufw deny 443/tcp	firewall-cmd --remove-port=443/tcp --permanent + --reload	iptables -A INPUT -p tcp --dport 443 -j DROP
Save rules	Auto	Auto	iptables-save > /etc/iptables/rules.v4

We recommend enabling `auditd`, to simplify the investigation of security incidents. For more information about enabling telemetry redirection, refer to Setting up receiving Auditd events.

We recommend regularly backing up the following configurations and data directories:

- Administration host: `~/kdt`
- Target hosts: `/etc/k0s/`, `/var/lib/k0s`

Also we recommend encrypting these backups.

Hardening guides for various operating systems and for DBMS

If you need to configure the security settings of your operating system and software, you can use the recommendations provided by Center for Internet Security (CIS).

If you use the Astra Linux operating system, refer to the security recommendations that can be applied to your Astra Linux version.

If you need to configure security settings of PostgreSQL, use the server administration recommendations from the official PostgreSQL documentation.

Connection safety

Strict TLS settings

We recommend using TLS protocol version 1.2 and later, and restricting or prohibiting insecure encryption algorithms.

You can configure encryption protocols (TLS) used by Administration Server. Please note that at the time of the release of a version of Kaspersky EDR Expert, the encryption protocol settings are configured by default to ensure secure data transfer.

Restricting access to the Kaspersky EDR Expert database

We recommend restricting access to the Kaspersky EDR Expert database. For example, grant access only from devices with Kaspersky EDR Expert deployed. This reduces the likelihood of the Kaspersky EDR Expert database being compromised due to known vulnerabilities.

You can configure the parameters according to the operating instructions of the used database, as well as provide closed ports on firewalls.

Accounts and authentication

Using two-step verification with Kaspersky EDR Expert

Kaspersky EDR Expert provides two-step verification for users, based on the RFC 6238 standard (TOTP: Time-Based One-Time Password algorithm).

When two-step verification is enabled for your own account, every time you log in to Kaspersky EDR Expert through a browser, you enter your user name, password, and an additional single-use security code. To receive a single-use security code, you must install an authenticator app on your computer or your mobile device.

There are both software and hardware authenticators (tokens) that support the RFC 6238 standard. For example, software authenticators include Google Authenticator, Microsoft Authenticator, FreeOTP.

We strongly do not recommend installing the authenticator app on the same device from which the connection to Kaspersky EDR Expert is established. You can install an authenticator app on your mobile device.

Using two-factor authentication for an operating system

We recommend using multi-factor authentication (MFA) on devices with Kaspersky EDR Expert deployed, by using a token, a smart card, or other method (if possible).

Prohibition on saving the administrator password

If you use Kaspersky EDR Expert through a browser, we do not recommend saving the administrator password in the browser installed on the user device.

Authentication of an internal user account

By default, the password of an internal user account of Kaspersky EDR Expert must comply with the following rules:

- The password must be 10 to 256 characters long.
- The password must contain characters from at least three of the groups listed below:
  - Uppercase letters (A–Z)
  - Lowercase letters (a-z)
  - Numbers (0–9)
  - Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)
- The password must not contain any whitespaces, Unicode characters, or the combination of "." and "@", when "." is placed before "@".

By default, the maximum number of allowed password entry attempts is 3. This number is fixed and cannot be changed.

The user can enter an invalid password a limited number of times. After the limit is reached, the user account is blocked for one hour.

Restricting the assignment of the Main administrator role

The user is assigned the Main Administrator role in the access control list (ACL) of Kaspersky EDR Expert. We do not recommend assigning the Main administrator role to a large number of users.

Configuring access rights to application features

We recommend using flexible configuration of access rights to the features of Kaspersky EDR Expert for each user or group of users.

Role-based access control allows the creation of standard user roles with a predefined set of rights and the assignment of those roles to users depending on their scope of duties.

The main advantages of the role-based access control model:

- Ease of administration
- Role hierarchy
- Least privilege approach
- Segregation of duties

You can assign built-in roles to certain employees based on their positions, or create completely new roles.

While configuring roles, pay attention to the privileges associated with changing the protection state of the device with Kaspersky EDR Expert and remote installation of third-party software:

- Managing administration groups.
- Operations with Administration Server
- Remote installation
- Changing the parameters for storing events and sending notifications.

  This privilege allows you to set notifications that run a script or an executable module on the device with OSMP when an event occurs.

Separate account for remote installation of applications

In addition to the basic differentiation of access rights, we recommend restricting the remote installation of applications for all accounts (except for the Main administrator or another specialized account).

We recommend using a separate account for remote installation of applications. You can assign a role or permissions to the separate account.

Regular audit of all users and users' actions

We recommend conducting a regular audit of all users on devices with Kaspersky EDR Expert deployed. This allows you to respond to certain types of security threats associated with the possible compromise of a device.

Also, you can track the users' actions, such as connecting to and disconnecting from Administration Server, connecting to Administration Server with an error, and objects modification (for objects that support revision management).

Managing protection of Kaspersky EDR Expert

Selecting protection software of Kaspersky EDR Expert

Depending on the type of the Kaspersky EDR Expert deployment and the general protection strategy, select the application to protect devices with Kaspersky EDR Expert deployed and the administrator host.

If you deploy Kaspersky EDR Expert on dedicated devices, we recommend selecting the Kaspersky Endpoint Security application to protect devices with Kaspersky EDR Expert deployed and the administrator host. This allows applying all available technologies to protect these devices, including behavioral analysis modules.

If Kaspersky EDR Expert is deployed on devices that exists in the infrastructure and has previously been used for other tasks, we recommend considering the following protection software:

- Kaspersky Industrial CyberSecurity for Nodes. We recommend installing this application on devices that are included in an industrial network. Kaspersky Industrial CyberSecurity for Nodes is an application that has certificates of compatibility with various manufacturers of industrial software.
- Recommended security applications. If Kaspersky EDR Expert is deployed on devices with other software, we recommend taking into account the recommendations from that software vendor on the compatibility of security applications (there may already be recommendations for selecting a security solution, and you may need to configure the trusted zone).

Protection modules

If there are no special recommendations from the vendor of the third-party software installed on the same devices as Kaspersky EDR Expert, we recommend activating and configuring all available protection modules (after checking the operation of these protection modules for a certain time).

Configuring the firewall of devices with Kaspersky EDR Expert

On devices with Kaspersky EDR Expert deployed, we recommend configuring the firewall to restrict the number of devices from which administrators can connect to Kaspersky EDR Expert through a browser.

By default,

Kaspersky EDR Expert uses port 443 to log in through a browser. We recommend restricting the number of devices from which Kaspersky EDR Expert can be managed by using this port.

Managing protection of client devices

Restricting of adding license keys to installation packages

Installation packages can be published through Web Server, which is included in Kaspersky EDR Expert. If you add a license key to the installation package that is published on Web Server, the license key will be available for all users to read.

To avoid compromising the license key, we do not recommend adding license keys to installation packages.

We recommend using automatic distribution of license keys to managed devices, deployment through the *Add license key* task for a managed application, and adding an activation code or a key file manually to the devices.

Automatic rules for moving devices between administration groups

We recommend restricting the use of automatic rules for moving devices between administration groups.

If you use automatic rules for moving devices, this may lead to propagation of policies that provide more privileges to the moved device than the device has before relocation.

Also, moving a client device to another administration group may lead to propagation of policy settings. These policy settings may be undesirable for distribution to guest and untrusted devices.

This recommendation does not apply for one-time initial allocation of devices to administration groups.

Security requirements for distribution points and connection gateways

Devices with Network Agent installed can act as a distribution point and perform the following functions:

- Distribute updates and installation packages received from Kaspersky EDR Expert to client devices within the group.
- Perform remote installation of third-party software and Kaspersky applications on client devices.
- Poll the network to detect new devices and update information about existing ones. The distribution point can use the same methods of device detection as Kaspersky EDR Expert.

Placing distribution points on the organization's network used for:

- Reducing the load on Kaspersky EDR Expert
- Traffic optimization
- Providing Kaspersky EDR Expert with access to devices in hard-to-reach parts of the network

Taking into account the available capabilities, we recommend protecting devices that act as distribution points from any type of unauthorized access (including physically).

Restricting automatic assignment of distribution points

To simplify administration and keep the network operability, we recommend using automatic assignment of distribution points. However, for industrial networks and small networks, we recommend that you avoid assigning distribution points automatically, since, for example, the private information of the accounts used for pushing remote installation tasks, can be transferred to distribution points by means of the operating system.

For industrial networks and small networks, you can manually assign devices to act as distribution points.

You can also view the Report on activity of distribution points.

Event transfer to third-party systems

This section describes the specifics of transferring security issues found on client devices to third-party systems.

Monitoring and reporting

For timely response to security issues, we recommend configuring the monitoring and reporting features.

Export of events to SIEM systems

For fast detection of security issues before significant damage occurs, we recommend using event export in a SIEM system.

Email notifications of audit events

For timely response to emergencies, we recommend configuring Administration Server to send notifications about the audit events, critical events, failure events, and warnings that it publishes.

Since these events are intra-system events, a small number of them can be expected, which is quite applicable for mailing.

Configuring protection for managed applications

Managed application policies

We recommend creating a policy for each type of the used applications and for all components of Kaspersky EDR Expert (Network Agent, Kaspersky Endpoint Security for Windows, Kaspersky Endpoint Agent, and others). This policy must be applied to all managed devices (the root administration group) or to a separate group to which new managed devices are automatically moved according to the configured movement rules.

Specifying the password for disabling protection and uninstalling the application

We strongly recommend enabling password protection to prevent intruders from disabling or uninstalling Kaspersky security applications. On platforms where password protection is supported, you can set the password, for example, for Kaspersky Endpoint Security, Network Agent, and other Kaspersky applications. After you enable password protection, we recommend locking the corresponding settings by closing the "lock."

Using Kaspersky Security Network

In all policies of managed applications and in the Kaspersky EDR Expert properties, we recommend enabling the use of Kaspersky Security Network (KSN) and accepting the KSN Statement. When you update Kaspersky EDR Expert, you can accept the updated KSN Statement. In some cases, when the use of cloud services is prohibited by law or other regulations, you can disable KSN.

Regular scan of managed devices

For all device groups, we recommend creating a task that periodically runs a full scan of devices.

Discovering new devices

We recommend properly configuring device discovery settings: set up integration with domain controllers and specify IP address ranges for discovering new devices.

For security purposes, you can use the default administration group that includes all new devices and the default policies affecting this group.

Deployment schemes

There are two options for deploying Kaspersky EDR Expert (including Kaspersky Endpoint Detection and Response functionality): on multiple nodes or on a single node within a Kubernetes cluster. Before you start, we recommend that you familiarize yourself with the available deployment schemes, and then choose the one that best meets your organization's requirements. You can also refer to the sizing guide, which outlines hardware requirements and recommends deployment options based on the number of devices in your organization.

Depending on the deployment option you choose, the following hosts may be required for Kaspersky EDR Expert to function properly:

- **Administrator device**

  The administrator host is a physical or virtual machine that is used to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. Since KDT runs on the administrator host, this host must meet the requirements for KDT.

  If the administrator host is not included in the cluster, it will be used only to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. If the administrator host is included in the cluster, it will also act as a target host that is used for operation of Kaspersky EDR Expert components. In this case, the host must meet the requirements for target hosts.

- **Target hosts**

  Target hosts are the physical or virtual machines that are used to deploy Kaspersky EDR Expert. The following target hosts are used:

  - Target hosts for installing the Kaspersky EDR Expert components inside the cluster

    The hosts that are included in the Kubernetes cluster and between which the workload is distributed. The target hosts must meet the requirements for the selected deployment option (multi-node or single node deployment).

    The KUMA services (collectors, correlators, and storages) can be installed entirely inside the cluster, entirely on separate hosts outside the cluster, or partially inside and partially outside the Kubernetes cluster. In this case, hosts must meet the hardware, software, and installation requirements that are necessary for installing the KUMA services.

    You can use one of the target hosts as the administrator host to run the Kaspersky EDR Expert deployment. In this case, this host must also meet the requirements for KDT.

  - KUMA target hosts for installing the KUMA services (optional)

    The KUMA services (collectors, correlators, and storages) can be installed on target hosts on separate hosts outside the cluster. The number of KUMA target hosts depends on the amount of events that Kaspersky EDR Expert has to process.

    KUMA target hosts must meet the hardware, software, and installation requirements that are necessary for installing the KUMA services.

- **DBMS host (multi-node deployment only)**

  The host for installing the DBMS is a separate server located outside the Kubernetes cluster. This host must meet the requirements for the database node.

Multi-node deployment

In the multi-node deployment, Kaspersky EDR Expert components are installed across several worker nodes in the Kubernetes cluster. If one node fails, the cluster can restore component operation on another node.

In this configuration, you need at least five hosts:

- One host for the DBMS
- Four target hosts for the Kubernetes cluster and Kaspersky EDR Expert components:
  - One host serving as both the administrator and a target host
  - Three target hosts

  If you want to use the administrator host located outside the cluster, you need to allocate one additional host for deployment.

  In order to install KUMA services outside the cluster, you must allocate at least one additional KUMA target host.

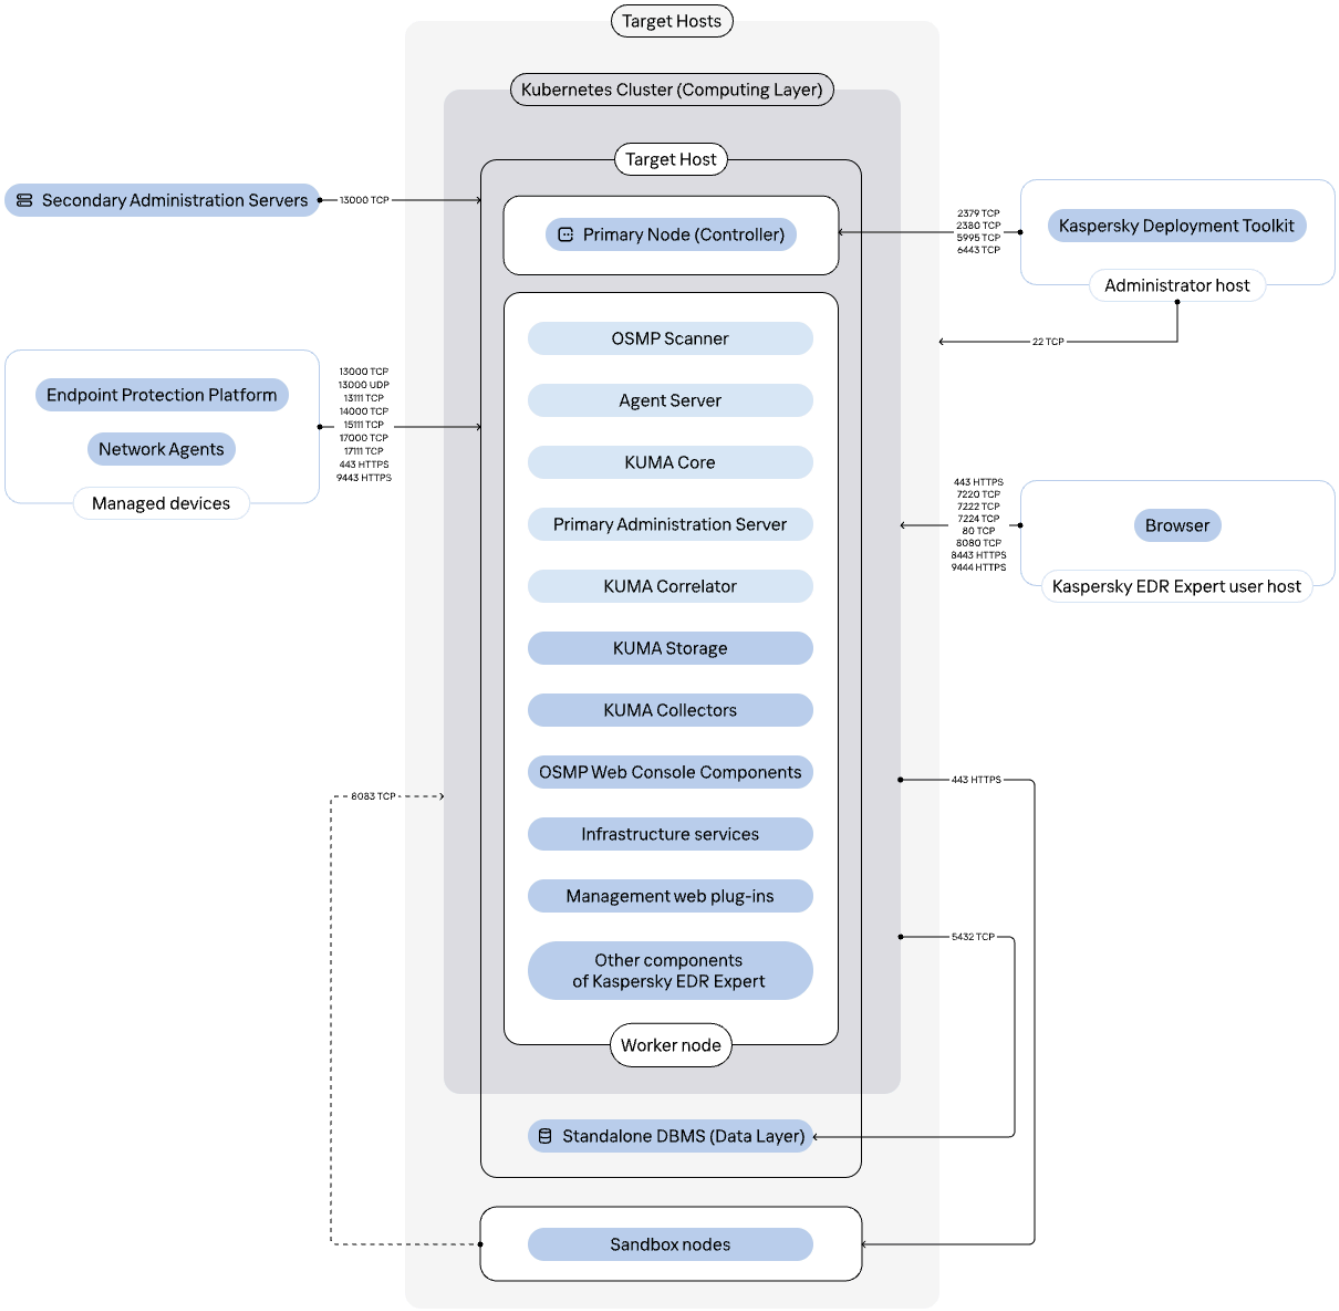
Single-node deployment

In the single-node deployment, all Kaspersky EDR Expert components are installed on a single node within the Kubernetes cluster. This option is suitable for solutions that require fewer computing resources.

In this configuration, at least one target host is required to install the Kubernetes cluster, KasperskyEDR Expert components, and the DBMS. This host serves both as the administrator and target host. If you prefer to use an administrator host located outside the cluster, you must allocate an additional host for deployment.

If you want to install KUMA services outside the cluster, at least one additional KUMA target host must be allocated.

In this configuration, the DBMS does not require a separate node. However. it should be installed manually on the target host prior to deploying Kaspersky EDR Expert.



Deploying the hierarchy of single nodes

In a hierarchical deployment, multiple single nodes are deployed. Once all single nodes are deployed, one node is selected as a parent instance. Typically, the most powerful node becomes the parent, based on calculations. The remaining nodes are then connected to the parent instance.

To calculate the resources required for deployment, contact Technical Support.

Single-node deployment scheme

The figure below illustrates the Kaspersky EDR Expert deployment scheme for a single node configuration.

Single-node deployment scheme of Kaspersky EDR Expert

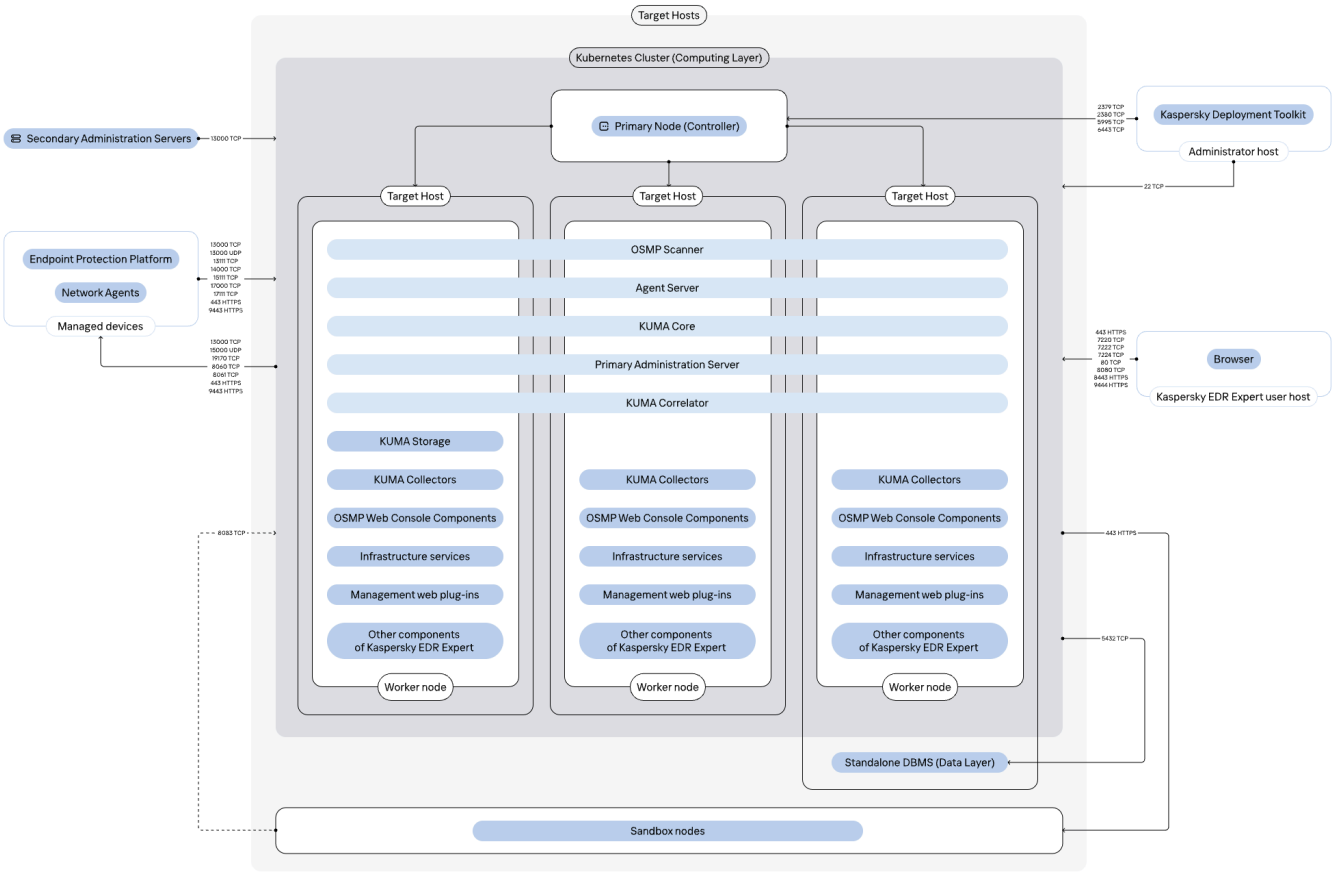
The single-node deployment scheme of Kaspersky EDR Expert includes the following main components:

- **Administrator host**. On this host, an administrator uses the Kaspersky Deployment Toolkit (KDT) to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. This host can either be part of the Kubernetes cluster created by KDT during deployment, or may remain separate.

- **Agent server**. This component is responsible for communication between OSMP and Endpoint Agents.

- **Kubernetes cluster**. In a single-node deployment, the Kubernetes cluster consists of a single host that acts as both the controller node (also referred to as primary node during deployment) and a worker node.
- **Standalone DBMS**. A database management system (DBMS) is required for the correct operation of Kaspersky EDR Expert components. The administrator installs the DBMS on the same physical host as the Kubernetes worker node. The DBMS must not be deployed within the Kubernetes cluster; it operates as an independent service outside the orchestration platform.
- **KUMA Core**. Central component of SIEM (KUMA) that serves as the foundation for all other services and components.
- **KUMA Collector**. SIEM (KUMA) component that receives messages from event sources, processes them, and transmits them to KUMA Storage and KUMA Correlator.
- **KUMA Correlator**. SIEM (KUMA) component that analyzes normalized events.
- **KUMA Storage**. SIEM (KUMA) component used to store normalized events, enabling quick and continuous access for analytical processing.
- **OSMP Scanner**. Component that scans files by using Anti-Malware Engine, YARA, and Sandbox; sends files for analysis and generates reports.
- **Sandbox nodes**. A Sandbox node consists of one or more servers running Sandbox components and provides dedicated compute resource s for an isolated runtime environment and supporting services. This node analyzes files, links, URLs, and other objects entering the protected system. Sandbox nodes operate independently of the Kubernetes cluster.

  The number of Sandbox servers may vary depending on workload requirements.
- **Management web plug-in**. Component used for remote administration of Kaspersky software through OSMP Console.
- **Kaspersky EDR Expert user host**. A user device used to sign in to the OSMP Console.
- **Secondary Administration Servers** (optional). These servers are used to create a Server hierarchy.
- **Managed devices**. Client devices protected by Kaspersky EDR Expert. Each managed device has Network Agent and an EPP application installed.
- **Infrastructure services and other Kaspersky EDR Expert components**. The solution also consists of additional components that provide centralized asset management, data exchange, hierarchy building, authentication and authorization, as well as other functions, such as action auditing, security policy management, and update distribution.



Ports

The deployment scheme does not include all ports required for successful installation and operation. For the full list of ports, refer to the Ports used by Kaspersky EDR Expert section.

Multi-node deployment: 4-node profile scheme

The 4-node deployment profile is intended for environments with constrained hardware resources and for maintaining infrastructure parity with previous deployments. The 4-node architecture strikes a balance between hardware requirements and ensures the completion of all key functional tasks. This deployment minimizes infrastructure costs while maintaining full compatibility with target services. The figure below illustrates the multi-node deployment scheme of Kaspersky EDR Expert.

For installations with high computational loads, the 6-node deployment is recommended.

Multi-node deployment scheme of Kaspersky EDR Expert

The multi-node deployment scheme of Kaspersky EDR Expert includes the following main components:

- **Administrator host**. On this host, an administrator uses Kaspersky Deployment Toolkit to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. This host can either be included in the Kubernetes cluster created by KDT during deployment, or it may remain separate.

- **Agent server**. This component is responsible for interactions between OSMP and Endpoint Agents.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **Kubernetes cluster**. A Kubernetes cluster includes the controller node (also referred to as primary node during deployment) and at least three worker nodes. The number of primary and worker nodes may vary depending on deployment requirements. The diagram illustrates an example distribution of Kaspersky EDR Expert components across worker nodes (actual distribution may vary).

  Standalone DBMS. A database management system (DBMS) is required for the correct operation of Kaspersky EDR Expert components. The administrator installs the DBMS on the same physical host as the Kubernetes worker node. The DBMS must not be included in the Kubernetes cluster; it operates as an independent service managed outside the orchestration platform.

- **KUMA Core**. The central component of SIEM (KUMA), which serves as the foundation for all other services and components.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **KUMA Collector**. SIEM (KUMA) component that receives messages from event sources, processes them, and transmits them to KUMA Storage and KUMA Correlator.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may differ and the number of replicas may vary.

- **KUMA Correlator**. SIEM (KUMA) component that analyzes normalized events.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

- **KUMA Storage**. SIEM (KUMA) component used to store normalized events, enabling continuous and efficient access for analytical processing.

- **OSMP Scanner**. Component that scans files by using Anti-Malware Engine, YARA, and Sandbox; sends files for analysis and generates reports.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **Sandbox nodes**. A Sandbox node consists of one or more servers running Sandbox components and provides dedicated compute resource s for an isolated runtime environment and supporting services. These nodes analyze files, links, URLs, and other objects entering the protected system. Sandbox nodes operate independently of the Kubernetes cluster.

  The number of Sandbox servers may vary depending on the workload.

- **Management web plug-in**. Component used for remote administration of Kaspersky software through OSMP Console.

  These components are deployed on all cluster nodes.

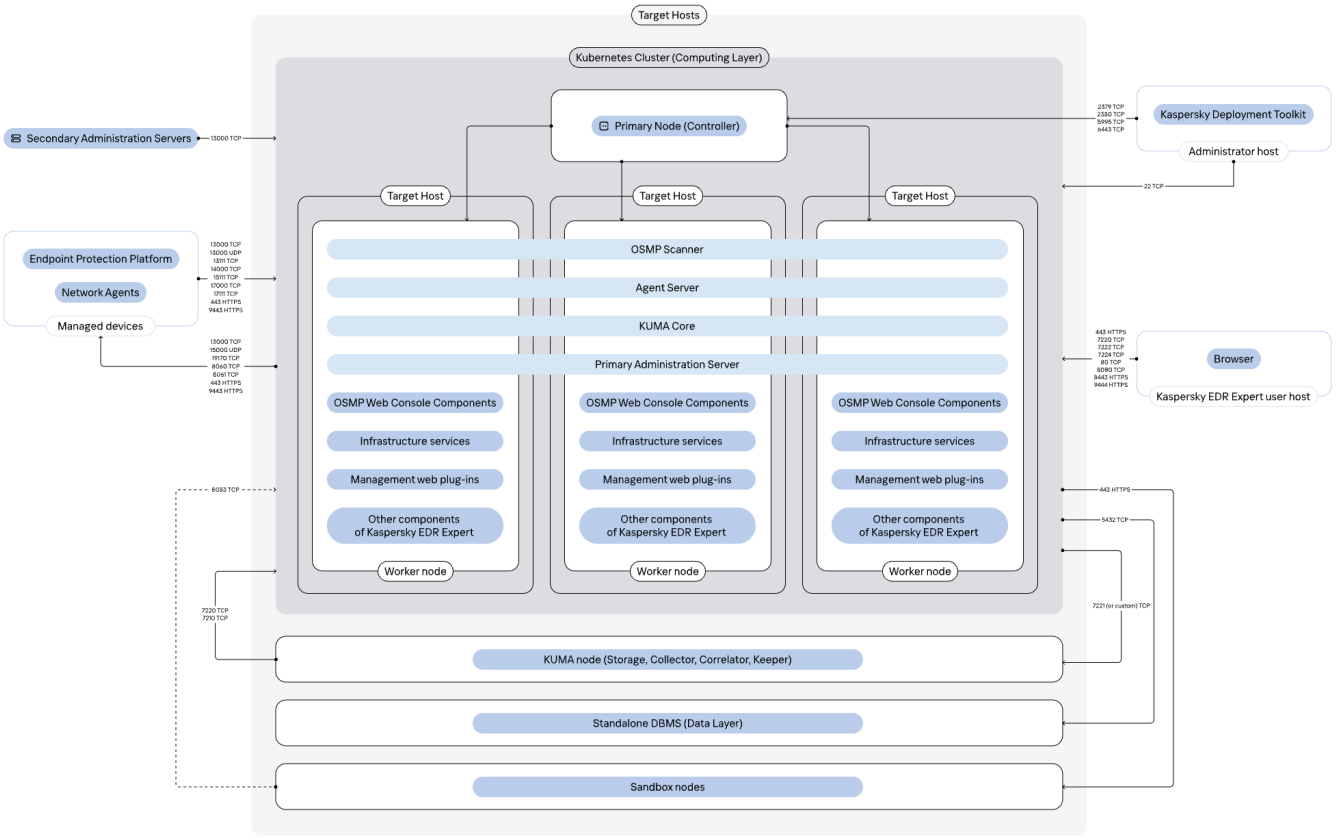
- **Kaspersky EDR Expert user host**. A user device used to sign in to the OSMP Console.

- **Secondary Administration Servers** (optional). These servers are used to create a Server hierarchy.

- **Managed devices**. Client devices protected by Kaspersky EDR Expert. Each managed device has Network Agent and an EPP application installed.

- **Infrastructure services and other Kaspersky EDR Expert components**. The solution also includes additional components that provide centralized asset management, data exchange, hierarchy building, authentication and authorization. Other functions include action auditing, security policy management, and update distribution.

Ports



The deployment scheme does not include all ports required for successful installation and operation. For the full list of ports, refer to the Ports used by Kaspersky EDR Expert section.

Multi-node deployment: 6-node profile scheme

The 6-node deployment profile is intended for environments with high computational demands and stringent data processing performance requirements. The 6-node architecture is optimized for maximum performance through service segregation and isolation of intensive disk I/O.

A key feature of this profile is the externalization of SIEM (KUMA) services outside the Kubernetes cluster to dedicated physical or virtual servers. This approach eliminates resource contention between components and guarantees stable, predictable system operation under high load.

The figure below illustrates the 6-node deployment scheme of Kaspersky EDR Expert.

Multi-node deployment scheme of Kaspersky EDR Expert

The multi-node deployment scheme of Kaspersky EDR Expert includes the following main components:

- **Administrator host**. On this host, an administrator uses Kaspersky Deployment Toolkit to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. This host can either be included in the Kubernetes cluster created by KDT during deployment, or it may remain separate.

- **Agent server**. This component is responsible for interactions between OSMP and Endpoint Agents.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **Kubernetes cluster**. A Kubernetes cluster includes the controller node (also referred to as primary node during deployment) and at least three worker nodes. The number of primary and worker nodes may vary depending on deployment requirements. The diagram illustrates an example distribution of Kaspersky EDR Expert components across worker nodes (actual distribution may vary).

  Standalone DBMS. A database management system (DBMS) is required for the correct operation of Kaspersky EDR Expert components. The administrator installs the DBMS on the same physical host as the Kubernetes worker node. The DBMS must not be included in the Kubernetes cluster; it operates as an independent service managed outside the orchestration platform.

- **KUMA Core**. The central component of SIEM (KUMA), which serves as the foundation for all other services and components.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **KUMA Collector**. SIEM (KUMA) component that receives messages from event sources, processes them, and forwards them to KUMA Storage and KUMA Correlator.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may differ and the number of replicas may vary.

- **KUMA Correlator**. SIEM (KUMA) component that analyzes normalized events.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

- **KUMA Storage**. SIEM (KUMA) component used to store normalized events, enabling continuous and efficient access for analytical processing.

- **OSMP Scanner**. Component that scans files by using Anti-Malware Engine, YARA, and Sandbox; sends files for analysis and generates reports.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **Sandbox nodes**. A Sandbox node consists of one or more servers running Sandbox components and provides dedicated compute resource s for an isolated runtime environment and supporting services. These nodes analyze files, links, URLs, and other objects entering the protected system. Sandbox nodes operate independently of the Kubernetes cluster.

  The number of Sandbox servers may vary depending on the workload.

- **Management web plug-in**. Component used for remote administration of Kaspersky software through OSMP Console.

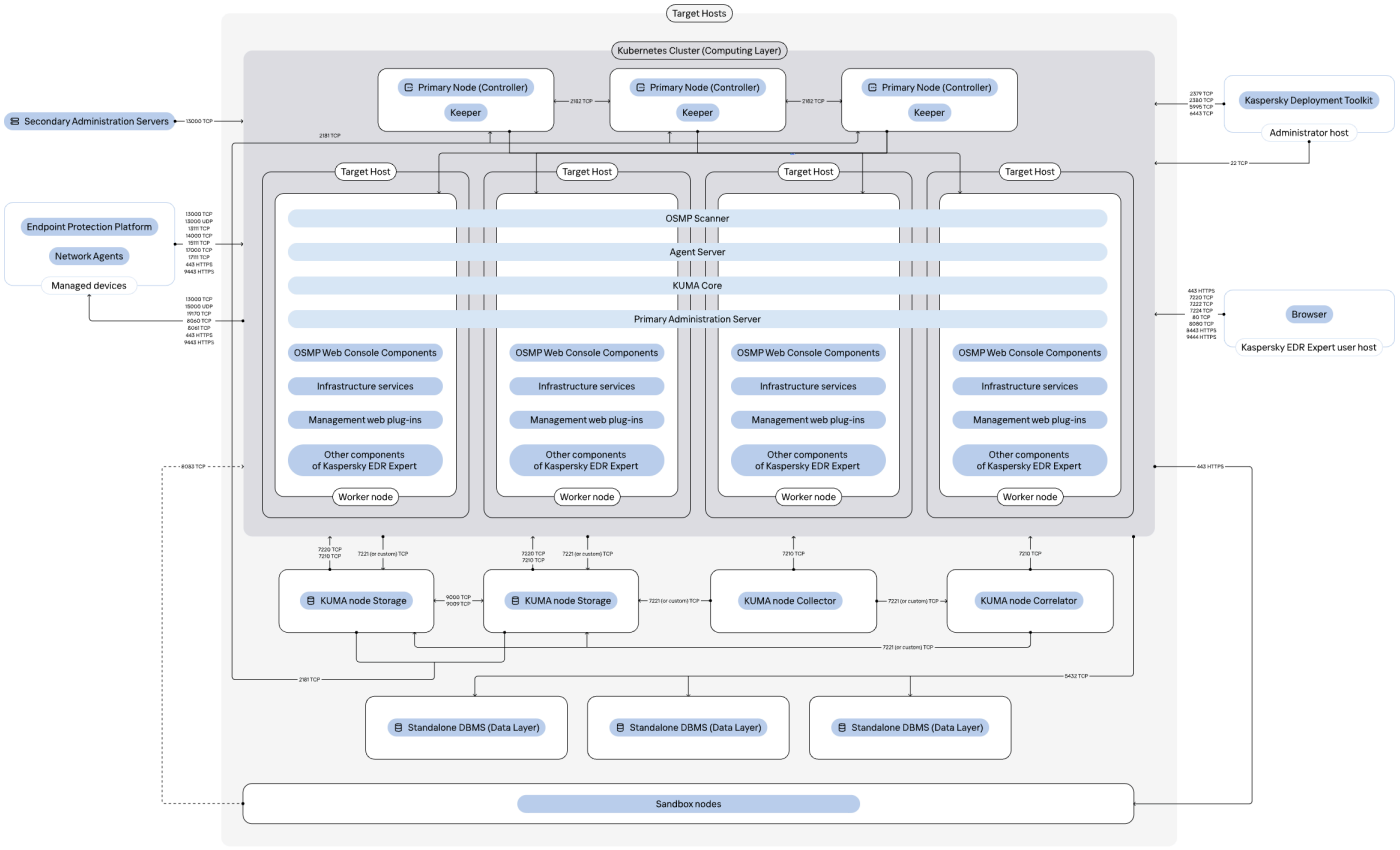
  These components are deployed on all cluster nodes.

- **Kaspersky EDR Expert user host**. A user device used to sign in to the OSMP Console.

- **Secondary Administration Servers** (optional). These servers are used to create a Server hierarchy.

- **Managed devices**. Client devices protected by Kaspersky EDR Expert. Each managed device has Network Agent and an EPP application installed.

- **Infrastructure services and other Kaspersky EDR Expert components**. The solution also includes additional components that provide centralized asset management, data exchange, hierarchy building, authentication and authorization. Other functions include action auditing, security policy management, and update distribution.



Ports

The deployment scheme does not include all ports required for successful installation and operation. For the full list of ports, refer to the Ports used by Kaspersky EDR Expert section.

High availability deployment: 14-node profile scheme

The high availability deployment scheme is intended for systems that require continuous operation and fault tolerance. This architecture is based on the principle of duplicating all critical components, which guarantees that in the event of a server failure, its functions are automatically transferred to a redundant node.

The figure below illustrates the 14-node deployment scheme of Kaspersky EDR Expert.

High availability deployment scheme of Kaspersky EDR Expert

The high availability deployment scheme of Kaspersky EDR Expert includes the following main components:

- **Administrator host**. On this host, an administrator uses Kaspersky Deployment Toolkit to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. This host can either be included in the Kubernetes cluster created by KDT during deployment, or it may remain separate.

- **Agent server**. This component is responsible for interactions between OSMP and Endpoint Agents.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **Kubernetes cluster**. A Kubernetes cluster includes the controller node (also referred to as primary node during deployment) and at least three worker nodes. The number of primary and worker nodes may vary depending on deployment requirements. The diagram illustrates an example distribution of Kaspersky EDR Expert components across worker nodes (actual distribution may vary).

  Standalone DBMS. A database management system (DBMS) is required for the correct operation of Kaspersky EDR Expert components. The administrator installs the DBMS on the same physical host as the Kubernetes worker node. The DBMS must not be included in the Kubernetes cluster; it operates as an independent service managed outside the orchestration platform.

- **KUMA Core**. The central component of SIEM (KUMA), which serves as the foundation for all other services and components.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **KUMA Collector**. SIEM (KUMA) component that receives messages from event sources, processes them, and forwards them to KUMA Storage and KUMA Correlator.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may differ and the number of replicas may vary.

- **KUMA Correlator**. SIEM (KUMA) component that analyzes normalized events.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

- **KUMA Storage**. SIEM (KUMA) component used to store normalized events, enabling continuous and efficient access for analytical processing.

- **OSMP Scanner**. Component that scans files by using Anti-Malware Engine, YARA, and Sandbox; sends files for analysis and generates reports.

  The component distribution shown in the diagram above is for illustrative purposes only. The actual distribution across worker nodes may vary.

  This component is deployed on one of the worker nodes without node affinity. The Kubernetes scheduler selects a worker node based on available resources.

- **Sandbox nodes**. A Sandbox node consists of one or more servers running Sandbox components and provides dedicated compute resource s for an isolated runtime environment and supporting services. These nodes analyze files, links, URLs, and other objects entering the protected system. Sandbox nodes operate independently of the Kubernetes cluster.

  The number of Sandbox servers may vary depending on the workload.

- **Management web plug-in**. Component used for remote administration of Kaspersky software through OSMP Console.

  These components are deployed on all cluster nodes.

- **Kaspersky EDR Expert user host**. A user device used to sign in to the OSMP Console.

- **Secondary Administration Servers** (optional). These servers are used to create a Server hierarchy.

- **Managed devices**. Client devices protected by Kaspersky EDR Expert. Each managed device has Network Agent and an EPP application installed.

- **Infrastructure services and other Kaspersky EDR Expert components**. The solution also includes additional components that provide centralized asset management, data exchange, hierarchy building, authentication and authorization. Other functions include action auditing, security policy management, and update distribution.

Ports

The deployment scheme does not include all ports required for successful installation and operation. For the full list of ports, refer to the Ports used by Kaspersky EDR Expert section.

Multi-site deployment

The diagram below shows the conceptual architecture of a distributed deployment of the platform in several data centers, with KUMA services deployed outside the Kubernetes cluster.

KUMA services (collectors, correlators, and storages) can be installed entirely inside the cluster on worker nodes, entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the Kubernetes cluster. In the diagram, KUMA services are deployed outside the Kubernetes cluster.

Multi-site deployment scheme of Kaspersky EDR Expert

The multi-site deployment scheme of Kaspersky EDR Expert includes the following main components:

- **Kubernetes cluster**. The Kubernetes cluster includes 3 control nodes (at least 1 per data center) and 9 worker nodes (at least 3 per data center).
- **DBMS**. A database management system (DBMS) is required for the correct operation of Kaspersky EDR Expert components. The DBMS is deployed in one of the supported high-availability configurations. The DBMS may not be deployed in a Kubernetes cluster.
- **KUMA Collector**. SIEM (KUMA) component that receives messages from event sources, processes them, and forwards them to KUMA Storage and KUMA Correlator.
- **KUMA Correlator**. SIEM (KUMA) component that analyzes normalized events.
- **KUMA Storage**. SIEM (KUMA) component used to store normalized events, enabling continuous and efficient access for analytical processing.
- **Sandbox nodes**. A Sandbox node consists of one or more servers running Sandbox components and provides dedicated compute resource s for an isolated runtime environment and supporting services. These nodes analyze files, links, URLs, and other objects entering the protected system. Sandbox nodes operate independently of the Kubernetes cluster.

  When deploying across multiple data centers, three Sandbox devices are required (at least one node per data center).
- **Managed devices**. Client devices protected by Kaspersky EDR Expert. Each managed device has Network Agent and an EPP application installed.
- **Infrastructure services and other Kaspersky EDR Expert components**. The solution also includes additional components that provide centralized asset management, data exchange, hierarchy building, authentication and authorization. Other functions include action auditing, security policy management, and update distribution.
- **High-availability load balancer**. Distributes incoming traffic between cluster nodes located in multiple data centers.

Ports

The deployment scheme does not include all ports required for successful installation and operation. For the full list of ports, refer to the Ports used by Kaspersky EDR Expert section.

Ports used by Kaspersky EDR Expert

For correct interaction between the administrator host and target hosts, you must provide connection access from the administrator host to the target hosts by the ports listed in the table below. These ports cannot be changed.

For interaction between the administrator host and hosts that are used for the installation of the KUMA services and are located outside the Kubernetes cluster, you must provide access only by TCP 22 port.

Ports used for interaction between the administrator host and target hosts

Port	Protocol	Direction	Source	Destination	Port purpose
22	TCP	Inbound	Administrator device	Target hosts	Providing the SSH connection from the administrator host to the target hosts. Providing the SSH connection from the administrator host to the hosts that are used for the installation of the external KUMA services.
2379, 2380	TCP	Inbound	Administrator device	Target host (primary node)	Connection to the Kubernetes storage (ETCD).
5995	TCP	Inbound	Administrator device	Target host (primary node)	Connection to the Docker registry.
6443	TCP	Inbound	Administrator device	Target host (primary node)	Connection to the Kubernetes API.

For properly work of the Kaspersky EDR Expert components, the target hosts must be located in the same broadcast domain.

The table below contains the ports that must be opened on the firewalls of all target hosts of the cluster. These ports cannot be changed.

If you use the firewalld or UFW firewall on your target hosts, the KDT opens the required ports on the firewalls automatically. Otherwise, you can open the listed ports manually before you deploy Kaspersky EDR Expert.

Required ports used by the Kaspersky EDR Expert components

Port	Protocol	Direction	Source	Destination	Port purpose
80, 8080	TCP (HTTP)	Inbound	Browser	Target hosts of the cluster	Receiving connections from browser. Redirecting to the 443 TCP (HTTPS) port.
443, 8443	TCP (HTTPS)	Inbound	Browser	Target hosts of the cluster	Receiving connections from browser. Receiving connections to the Administration Server over OpenAPI. Used to automate scenarios for working with the Administration Server.
13000	TCP	Inbound	Network Agent or secondary Administration Server	Target hosts of the cluster	Receiving connections from Network Agents and secondary Administration Servers.
13000	UDP	Inbound	Network Agent	Target hosts of the cluster	Receiving information about devices that were turned off from Network Agents.
14000	TCP	Inbound	Network Agent	Target hosts of the cluster	Receiving connections from Network Agents.
17000	TCP	Inbound	Managed devices	Target hosts of the cluster	Receiving connections for application activation from managed devices (except for mobile devices).
19170	TCP (HTTPS)	Outbound	Target hosts of the cluster	Managed devices	Remote access to managed devices by using OSMP Console.
7210	TCP	Inbound	KUMA target hosts	Target hosts of the cluster	Receiving of the KUMA configuration from the KUMA Core server.

Port	Protocol	Direction	Source	Destination	Port purpose
7220	TCP	Inbound	Browser	Target hosts of the cluster	Receiving connections from browser.
7222	TCP	Inbound	Browser	Target hosts of the cluster	Reversing proxy in the CyberTrace system.
7224	TCP	Inbound	Browser	Target hosts of the cluster	Callbacks for Identity and Access Manager (IAM).

The table below contains the ports that are not opened by default on the firewalls during the Kaspersky EDR Expert deployment. These ports cannot be changed.

If you need to perform actions listed in the **Port purpose** column of the table below, you can open the corresponding ports on the firewalls of all target hosts manually.

Optional ports on the firewall used by the Kaspersky EDR Expert components

Port	Protocol	Direction	Source	Destination	Port purpose
8060	TCP	Outbound	Target hosts of the cluster	Managed devices	Transmitting published installation packages to managed devices.
8061	TCP	Outbound	Target hosts of the cluster	Managed devices	Transmitting published installation packages to managed devices.
8083	HTTP	Inbound	Sandbox	Target hosts of the cluster	Updating anti-virus databases in Sandbox.
13111	TCP	Inbound	Managed devices	Target hosts of the cluster	Receiving requests from managed devices to KSN proxy server.
15111	UDP	Inbound	Managed devices	Target hosts of the cluster	Receiving requests from managed devices to KSN proxy server.
17111	TCP	Inbound	Managed devices	Target hosts of the cluster	Receiving requests from managed devices to KSN proxy server.
5432	TCP	Inbound	DBMS (PostgreSQL)	Target hosts of the cluster	Interaction with the DBMS (PostgreSQL). This port is used only if you perform the demonstration deployment and install the DBMS on the target host inside the Kubernetes cluster.

The table below contains the ports that must be opened on the firewalls of the hosts that interact with Sandbox.

Ports used for interaction with Sandbox

Port	Protocol	Direction	Source	Destination	Port purpose
22	TCP	Inbound	Administrator device	Sandbox node	Connecting to the Sandbox server over SSH.
443	TCP	Inbound	OSMP	Target component on the Sandbox node	Incoming connections from OSMP components.
8443	TCP	Inbound	Browser	Target component on the Sandbox node	Access to the Sandbox web interface.
80 or 443	TCP	Outbound	Target component on the Sandbox node	Target update server	Getting updates from Kaspersky update servers.
Any	Any	Outbound and corresponding inbound	Target component on the Sandbox node	Target resource on the internet	Access to the internet for analyzing the network behavior of processed objects.

The table below contains the ports that must be opened for functioning of the Kubernetes cluster and infrastructure components. These ports cannot be changed.

If you use the firewalld or UFW firewall on your target hosts, the KDT opens the required ports on the firewalls automatically. Otherwise, you can open the listed ports manually before you deploy Kaspersky EDR Expert.

Ports used by the Kubernetes cluster and infrastructure components

Port	Protocol	Node
80	TCP	Control node
443	TCP	Control node
10250	TCP	Control node
9443	TCP	Control node
6443	TCP	Control node
8132	TCP	Control node
5995	TCP	Control node
80	TCP	Worker node
443	TCP	Worker node
179	TCP	Worker node
10250	TCP	Worker node
10255	TCP	Worker node
9443	TCP	Worker node
6443	TCP	Worker node
9500	TCP	Worker node
9501	TCP	Worker node
9502	TCP	Worker node
9503	TCP	Worker node
8500	TCP	Worker node
8501	TCP	Worker node
3260	TCP	Worker node
8000	TCP	Worker node
8002	TCP	Worker node
2049	TCP	Worker node
3370	TCP	Worker node
179	UDP	Worker node
51820	UDP	Worker node
51821	UDP	Worker node

For correct work of the KUMA services that are not included in a Kubernetes cluster, you must open the ports listed in the table below. The table below shows the default network ports values. These ports automatically open during the KUMA installation.

Ports used for the interaction with the external KUMA services

Port	Protocol	Direction	Source	Destination	Port purpose
8123	HTTPS	Inbound	Storage service	ClickHouse cluster node	Writing and receiving normalized events in the ClickHouse cluster.
9009	HTTPS	Inbound/Outbound	ClickHouse cluster replica	ClickHouse cluster replica	Internal communication between ClickHouse cluster replicas for transferring data of the cluster.
2181	TCP	Inbound	ClickHouse cluster nodes	ClickHouse keeper replication coordination service	Receiving and writing of replication metadata by replicas of ClickHouse servers.
2182	TCP	Inbound/Outbound	ClickHouse keeper replication coordination service	ClickHouse keeper replication coordination service	Internal communication between replication coordination services to reach a quorum.

Port	Protocol	Direction	Source	Destination	Port purpose
8001	TCP	Inbound	Victoria Metrics	ClickHouse server	Receiving ClickHouse server operation metrics.
9000	TCP	Inbound	ClickHouse client	ClickHouse cluster node	Writing and receiving data in the ClickHouse cluster.

If you create an additional KUMA service (collector, correlator or storage) on a server, you need to manually open a port that corresponds to the created service on the server. You can use port TCP 7221 or other port used for service installation.

If the out of the box example services are used, the following ports automatically open during the Kaspersky EDR Expert deployment:

- 7230 TCP
- 7231 TCP
- 7232 TCP
- 7233 TCP
- 7234 TCP
- 7235 TCP
- 7236 TCP
- 5140 TCP
- 5140 UDP
- 5141 TCP
- 5144 UDP
- 5150 UDP

Changing the port used to connect to the OSMP Console server

The same node and the same port (443) are used by default both when an administrator connects via a browser to the OSMP Console server and when Endpoint Agents connect to the agentserver component, though different FQDNs are used for each. If necessary, two different ports for these components can be configured either during installation of Kaspersky EDR Expert, or after the solution is already installed.

To change the required port, you must have access to the administrator host where the KDT utility is located.

The procedures for changing the OSMP Console port have the following limitations:

- If you specify an invalid value as the port number (out of range, invalid characters, or empty value), the solution installation fails.
- After changing the port, always specify the new port number in the browser's address bar when connecting to OSMP Console.

To change the OSMP Console port when Kaspersky EDR Expert is installed:

1. Choose a new port number in the range 1–65535.
2. If a firewall or other network access restriction tools are used, configure these tools to ensure that the selected port is accessible.
3. Run the following command to change the port:

   ```
   ./kdt invoke foreach -a setConsolePort --param console_port="<port_number>"
   ```

   where `<port_number>` is replaced with the port number you selected.

   If the command is completed successfully, the current OSMP Console connection sessions are terminated.
4. Reconnect to the OSMP Console server. To do this, in the browser's address bar, enter the Web Console service FQDN specified in the configuration file and the new port number.

The port for connecting to OSMP Console has been changed. The default port 443 no longer accepts connections to OSMP Console.

To change the OSMP Console port during the installation of Kaspersky EDR Expert:

1. Choose a new port number in the range 1–65535.
2. Specify the new port number in the configuration file.

   To do so, add the installation parameter for the new OSMP Console port in the configuration file, and then specify the selected port number as follows:

   ```
   parameters:
    - name: console_port
    source:
    value: "<port_number>"
   ```

   where:

   - `console_port` specifies the new port number.
   - `<port_number>` is replaced with the port number you have selected.
3. If a firewall or other network access restriction tools are used, configure these tools to ensure that the selected port is accessible.
4. Install Kaspersky EDR Expert.

   For more information, refer to the Deployment of Kaspersky EDR Expert section.

5. After a successful installation, connect to the OSMP Console server.

   To do so, in the browser's address bar, enter the Web Console service FQDN and the new port number specified in the configuration file.

The port for connecting to OSMP Console has been changed. The default port (443) is no longer used to connect to OSMP Console.

Changing the port used by Endpoint Agents to connect to the agentserver component

The same node and the same port (443) are used by default both when an administrator connects via a browser to the OSMP Console server and when Endpoint Agents connect to the agentserver component, though different FQDNs are used for each. If necessary, two different ports for these components can be configured either during installation of Kaspersky EDR Expert, or after the solution is already installed.

To change the required port, you must have access to the administrator host where the KDT utility is located, as well as rights to modify the Endpoint Agents policy.

The procedures for changing the port that Endpoint Agents use have a limitation. If you specify an invalid value as the port number (out of range, invalid characters, or empty value), the command for changing the port fails in the first procedure. In the second procedure, the installation of the solution fails.

To change the port used by Endpoint Agents when Kaspersky EDR Expert is installed:

1. Choose a new port number in the range 1–65535.

2. If a firewall or other network access restriction tools are used, configure these tools to ensure that the selected port is accessible.

3. Run the following commands to change the port used by Endpoint Agents for connecting to the agentserver component (first command) and the port used for sending the telemetry (second command):

   ```
   ./kdt invoke foreach -a changeAgentServerSmpPort --param as_smp_port="<port_number>"
   ```

   ```
   ./kdt invoke foreach -a setKumaTelemetryPort --param kuma_gateway_telemetry_listener_port="<port_number>"
   ```

   where `<port_number>` is replaced with the port number you selected.

   If the commands are completed successfully, the current connection sessions between Endpoint Agents and the agentserver component are terminated. The agentserver component no longer receives data from Endpoint Agents.

4. If data from Endpoint Agents is routed through a proxy node, do the following:

   a. In the Nginx configuration file, specify the new port number in the string `listen <port_number> ssl http2;`

   b. Restart Nginx to apply the changes in the configuration file by running the command `nginx -s reload`.

5. In the main menu of OSMP Console, go to **Asset management** → **Policies**.

6. Click the necessary endpoint security application policy in the list and go to **Application settings → Built-in Agents Configuration → Endpoint Detection and Response Expert (on-premises) → Connection to response servers**.

7. Under **Connection settings**, select the check box next to the server, and then click the **Delete** button.

   The required server with the old port is deleted.

8. Click the **Add** button in the pane, and then click the **Select server** button.

9. In the window that opens, select the server with new port, and then confirm the action.

The port used by Endpoint Agents to connect to the agentserver component has been changed. The agentserver component begins to receive data from Endpoint Agents by using the new port. Once the policy is applied to Endpoint Agents, they will reconnect to the OSMP components via the new port. The default port (443) is no longer used to connect to the agentserver component.

To change the port used by Endpoint Agents during the installation of Kaspersky EDR Expert:

1. Choose a new port number in the range 1–65535.

2. In the configuration file, specify the new port used by Endpoint Agents for connecting to the agentserver component and the port used for sending the telemetry.

   To do so, add the installation parameters for the new ports in the configuration file as follows:

```
parameters:
- name: as_smp_port
 source:
 value: "<port_number>"
- name: kuma_gateway_telemetry_listener_port
 source:
 value: "<port_number>"
```

   where:

   - `as_smp_port` specifies the new port number used by Endpoint Agents.
   - `kuma_gateway_telemetry_listener_port` specifies the new port number used for sending the telemetry.
   - `<port_number>` is replaced with the port number you have selected.

3. If a firewall or other network access restriction tools are used, configure these tools to ensure that the selected port is accessible.

4. Install Kaspersky EDR Expert.

   For more information, refer to the Deployment of Kaspersky EDR Expert section.

5. If data from Endpoint Agents is routed through a proxy node, do the following:

   a. In the Nginx configuration file, specify the new port number in the string `listen <port_number> ssl http2;`

   b. Restart Nginx to apply the changes in the configuration file by running the command `nginx -s reload`.

   The port used by Endpoint Agents has been changed. The agentserver component begins to receive data from Endpoint Agents by using the new port. The default port 443 cannot be used to connect to the agentserver component.

Preparation work and deployment

This section describes how to prepare the infrastructure for the Kaspersky EDR Expert deployment, set the installation parameters that are specific for the multi-node or single-node deployment, as well as how to use the Deployment wizard to generate the configuration file.

You will find out how to install Kaspersky EDR Expert according to the multi-node and single-node deployment schemes. Also, this section contains information on how to deploy multiple Kubernetes clusters with Kaspersky EDR Expert instances and switch between them by using KDT.

Multi-node deployment: Preparing the administrator and target hosts

Preparing for a multi-node deployment includes configuring the administrator and target hosts. After preparing hosts and specifying the configuration file, you will be able to deploy Kaspersky EDR Expert on target hosts by using KDT.

Preparing the administrator host

You first need to prepare a device that will act as the administrator host from which KDT will launch. This host can be either included in the Kubernetes cluster that is created by KDT during the deployment or not. If the administrator host is not included in the cluster, it will be used only to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. If the administrator host is included in the cluster, it will also act as a target host that is used for operation of Kaspersky EDR Expert components.

> All virtual CPUs assigned to the administrator host must reside on a single NUMA node. When configuring the virtual machine for the administrator host on the hypervisor, ensure that CPU and memory resources are allocated from the same NUMA node. This prevents cross-node memory access, which can cause memory allocation failures during installation.

To prepare the administrator host:

1. Make sure that the hardware and software on the administrator host meet the requirements.

   If the administrator host is not included in the Kubernetes cluster, use the KDT requirements.

If the administrator host is included in the cluster, use the hardware requirements for the multi-node deployment and the software requirements for OSMP.

2. Allocate at least 15 GB of free space in the temporary files directory (`/tmp`) for KDT.

   To find out how much space is available in the `/tmp` directory, run the following command:

   ```
   df -h /tmp
   ```

   If you do not have enough free space in this directory, run the following command to specify the path to another directory:

   ```
   export TMPDIR=<new_directory>/tmp
   ```

3. Install the package for Docker version 23 or later. Do not install unofficial distributions of Docker packages from the operating system maintainer repositories.

   The disk partition for Docker data storage (by default, `/var/lib/docker`) must have at least 60 GB of available space.

4. Perform the post-installation steps to configure the administration host for proper functioning with Docker:

   ```
   sudo groupadd docker
   sudo usermod -aG docker $USER
   newgrp docker
   sudo systemctl enable docker.service
   sudo systemctl enable containerd.service
   sudo systemctl status docker.service
   ```

   Make sure the Docker service is in the **Active** status.

   If a key cannot be downloaded automatically, download it manually:

   1. Open the https://download.docker.com/linux/ubuntu/gpg link in your browser to save the key as docker.asc.

   2. Run the following command:

      ```
      sudo mv docker.asc /etc/apt/keyrings/docker.asc
      ```

5. For the administrator host that will be included in the cluster, perform additional preparatory steps:

   a. Since the device will act as the administrator and target host, make sure that it meets the requirements for multi-node deployment.

   b. Make sure that the cgroup v2 technology is supported on the administrator host.

      a. Since the device will act as the administrator and target host, make sure that it meets the requirements for the single-node deployment (because the demonstration and single-node deployment have a similar deployment scheme).

      b. Make sure that the cgroup v2 technology is supported on the administrator host.

         The cgroup v2 technology is supported for the Linux kernel version 2.6.24 or later.

      c. Install the uidmap package on the administrator host.

         Check that the /etc/subgid and /etc/subuid files contain the user account under which KDT will be launched. To do this, you can run the following command:

         ```
         getsubids USER
         ```

If this command does not return a result, you must add the user account to the /etc/subgid and /etc/subuid files manually in the following format:

`<username>:<min_subid>:<range_length>`

where

- `<username>`—Username of the account under which KDT will be launched.
- `<min_subid>`—Minimum subuid value.
- `<range_length>`—Number of subuids allocated for the user `<username>`.

Preparing the target hosts

The *target hosts* are physical or virtual machines that are used to deploy Kaspersky EDR Expert and included in the Kubernetes cluster. The Kaspersky EDR Expert components work on these hosts.

> One of the target hosts can be used as the administrator host. In this case, you must prepare this host as the administrator host, as described in the previous procedure, and then prepare the target host.

A minimum cluster configuration for the multi-node deployment includes four nodes:

- One primary node

  The primary node is intended for managing the cluster, storing metadata, and distributing the workload.

- Three worker nodes

  The worker nodes are intended for performing the workload of the Kaspersky EDR Expert components.

  The number of primary and worker nodes in the cluster may vary. For optimal workload distribution between nodes, it is recommended to use nodes with approximately the same performance.

  KUMA services (collectors, correlators, and storages) can be installed entirely inside the cluster on worker nodes, entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the Kubernetes cluster.

  If you have multiple primary nodes, a load balancer is required to distribute incoming requests across the primary nodes and ensure an even workload. If you want to use an external load balancer, allocate a separate host outside the Kubernetes cluster and specify its parameters in the configuration file. If you do not want to use an external load balancer, a worker node will act as the load balancer.

To prepare the target hosts:

1. Make sure that the hardware and software on the target hosts meet the requirements for multi-node deployment, and the target hosts are located in the same broadcast domain.

   If KUMA services are installed inside the cluster, target hosts must meet the hardware, software, and installation requirements that are necessary for installing the KUMA services.

   > For proper functioning of Kaspersky EDR Expert, the Linux kernel version must be 5.15.0.107 or later on the target hosts with the Ubuntu family of operating systems.

Docker must not be installed on the target hosts, except the target host that will be used as the administrator host. KDT will install all necessary software and dependencies during the deployment.

2. Ensure that the filesystem mounted at `/var` has at least 700 GB of free space on each target host.

   To find out how much space is available in the `/var` directory, run the following command:

   ```
   df -h /var
   ```

3. Check that the sudo package is installed on each target host:

   ```
   apt list --installed | grep sudo
   ```

   The command output should list packages with the specified package name, for example:

   ```
   sudo/noble-updates,noble-security,now 1.9.15p5-3ubuntu5.24.04.2 amd64 [installed]
   ```

   Install the sudo package, if this package is not already installed:

   ```
   apt install sudo
   ```

4. For the Debian family of operating systems, install the UFW package:

   ```
   apt install ufw
   ```

5. On each target host, configure the /etc/environment file. If your organization's infrastructure uses a proxy server to access the internet, configure the internet access by using the proxy server on the target hosts.

6. If the primary worker node uses the UFW, allow IP forwarding. In the `/etc/default/ufw` file, set `DEFAULT_FORWARD_POLICY` to `ACCEPT`.

7. Provide access to the package repository that stores the following packages required for Kaspersky EDR Expert:

   - nfs-common
   - cron
   - tar
   - open-iscsi
   - python3-cffi-backend
   - python3-cryptography
   - systemd
   - cryptsetup-bin
   - cryptsetup
   - netcat-traditional
   - containerd

   KDT will try to install these packages during the deployment from the package repository. You can also install these packages manually.

8. Ensure that the python3-apt and libnfs packages are installed on each target node:

   ```
   apt list --installed | grep <package_name>
   ```

   The command output should list packages with the specified package name, for example:

   ```
   libnfs14/noble,now 5.0.2-1build1 amd64 [installed,automatic]
   ```

   ```
   libnfsidmap1/noble-updates,now 1:2.6.4-3ubuntu5.1 amd64 [installed,automatic]
   ```

   The python3-apt and libnfs packages are not installed during the deployment from the package repository by using KDT. You must install these packages manually, if they are not already installed. The libnfs package version 12 and later is used.

   ```
   sudo apt install <package_name>
   ```

9. For the primary nodes, ensure that the curl package is installed.

   The curl package is not installed during the deployment from the package repository by using KDT. You must install this package manually, if it is not already installed.

10. Make sure configuration files do not contain any unavailable repositories: running the `apt update` command should return no errors.

11. Disable ARP spoofing protection on the hypervisor or network infrastructure for the target hosts.

12. Reserve static IP addresses for the target hosts and the Kubernetes cluster gateway.

    The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. The gateway IP address is an IPv4 address (for example, 10.80.23.182). It is specified in the configuration file (the `ingress_ip` parameter).

    Make sure that the target hosts, the Kubernetes cluster gateway, and the DBMS host are located in the same broadcast domain.

    > The Kubernetes cluster gateway and target hosts require IPv4 addressing. If your environment requires IPv6 connectivity, configure the operating systems on the target hosts and the Kubernetes cluster gateway to route IPv6 traffic through an IPv6 gateway (NAT64) or an IPv6 tunnel. This configuration keeps the cluster running on IPv4 while providing interoperability with IPv6 networks.

13. On your DNS server, register the service FQDNs to connect to the Kaspersky EDR Expert services.

    By default, the Kaspersky EDR Expert services are available at the following addresses:

    - <console_host>.<smp_domain>—Access to the OSMP Console interface.
    - <ksc_host>.<smp_domain>—Interaction with Administration Server.
    - <kuma_host>.<smp_domain>—Access to the SIEM component.
    - <api_host>.<smp_domain>—Access to the Kaspersky EDR Expert API.
    - <monitoring_host>.<smp_domain>—Access to OSMP metrics.

      Where <console_host>, <ksc_host>, <kuma_host>, and <api_host>, and <monitoring_host> are service host names, <smp_domain> is a service domain name. These parameters are parts of the service FQDNs, which you can specify in the configuration file. If you do not specify custom values of service host names, the default values are used: `console_host`—"`console`", `ksc_host`—"`admsrv`", `kuma_host`—"`kuma`", `api_host`—"`api`", `monitoring_host`—"`monitoring`".

The listed service FQDNs must be resolved to the IP address of the Kubernetes cluster. For example, if the Kubernetes cluster address is 10.80.23.182, service FQDNs are resolved to the IP address as follows:

- <console_host>.<smp_domain>—10.80.23.182
- <ksc_host>.<smp_domain>—10.80.23.182
- <kuma_host>.<smp_domain>—10.80.23.182
- <api_host>.<smp_domain>—10.80.23.182
- <monitoring_host>.<smp_domain>—10.80.23.182

14. On each target host, create the accounts that will be used for the Kaspersky EDR Expert deployment.

    These accounts are used for the SSH connection and must be able to elevate privileges (sudo) without entering a password. To do this, add the created user accounts to the `/etc/sudoers` file.

    a. Run the following commands:

    ```
    sudo useradd -m -s /bin/bash sshuser
    sudo usermod -aG sudo sshuser
    ```

    b. Open the /etc/sudoers file by using the following command:

    ```
    sudo visudo
    ```

    c. At the end of the file, add the following line:

    ```
    sshuser ALL=(ALL) NOPASSWD: ALL
    ```

    where `sshuser` is the name of the created user.

    d. Run the following command:

    ```
    sudo systemctl restart ssh
    ```

15. Configure the SSH connection between the administrator and target hosts:

    a. On the administrator host, run the following command to generate SSH keys by using the ssh-keygen utility without a passphrase:

    ```
    ssh-keygen -t rsa
    ```

    b. Copy the public key to the target host (for example, to the `/home/sshuser/.ssh` directory) by using the ssh-copy-id utility:

    ```
    ssh-copy-id sshuser@<target_host_IP>
    ```

    If you use a target host as the administrator host, you must copy the public key to it, too.

    Public key creation example

    To create a public key, run the following command:

    ```
    ssh-keygen -t rsa
    ssh-copy-id sshuser@<target_host_IP>
    ```

16. For proper function of the Kaspersky EDR Expert components, provide network access between the target hosts and open the required ports on the firewall of the administrator and target hosts, if necessary.

17. Configure time synchronization over Network Time Protocol (NTP) on the administrator and target hosts.

18. If necessary, prepare user certificates for working with Kaspersky EDR Expert public services.

    You can use one intermediate certificate that is issued off the organization's root certificate or leaf certificates for each of the services. The prepared user certificates will be used instead of self-signed certificates.

Single-node deployment: Preparing the administrator and target hosts

Preparing for a single-node deployment includes configuring the administrator and target hosts. In the single-node configuration, the Kubernetes cluster and Kaspersky EDR Expert components are installed on one target host. After preparing the target host and specifying the configuration file, you will be able to deploy Kaspersky EDR Expert on the target host by using KDT.

Preparing the administrator host

You first need to prepare a device that will act as the administrator host from which KDT will launch. This host can be either included in the Kubernetes cluster that is created by KDT during the deployment or not. If the administrator host is not included in the cluster, it will be used only to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. If the administrator host is included in the cluster, it will also act as a target host that is used for operation of Kaspersky EDR Expert components. In this case, only one host will be used for deployment and operation of the solution.

> All virtual CPUs assigned to the administrator host must reside on a single NUMA node. When configuring the virtual machine for the administrator host on the hypervisor, ensure that CPU and memory resources are allocated from the same NUMA node. This prevents cross-node memory access, which can cause memory allocation failures during installation.

To prepare the administrator host:

1. Make sure that the hardware and software on the administrator host meet the requirements.

   If the administrator host is not included in the Kubernetes cluster, use the KDT requirements.

   If the administrator host is included in the cluster, use the hardware requirements for the single-node deployment and the software requirements for OSMP.

2. Allocate at least 15 GB of free space in the temporary files directory (`/tmp`) for KDT.

   To find out how much space is available in the `/tmp` directory, run the following command:

   ```
   df -h /tmp
   ```

   If you do not have enough free space in this directory, run the following command to specify the path to another directory:

   ```
   export TMPDIR=<new_directory>/tmp
   ```

3. Install Docker.

   Docker versions 25 and later are supported.

   The disk partition for Docker data storage (by default, `/var/lib/docker`) must have at least 60 GB of available space.

Docker installation on Ubuntu Server 24.04 LTS

Below is an example of installing Docker on a standard Ubuntu Server 24.04 LTS virtual machine.

Installation on Ubuntu 24.04 LTS

Run the following command:

```
sudo apt update && sudo apt install docker.io
```

OR Installation using official instructions

Run the following commands:

1. Install the required packages:

   ```
   sudo apt update && sudo apt install ca-certificates curl
   ```

2. Download Docker keyring:

   ```
   sudo curl -fsSL https://download.docker.com/linux/ubuntu/gpg -o /etc/apt/keyrings/docker.asc && sudo chmod
   0755 /etc/apt/keyrings/docker.asc
   ```

3. Add the Docker apt repository:

   ```
   sudo tee /etc/apt/sources.list.d/docker.sources <<EOF
   Types: deb
   URIs: https://download.docker.com/linux/ubuntu
   Suites: $(. /etc/os-release && echo "${UBUNTU_CODENAME:-$VERSION_CODENAME}")
   Components: stable
   Architectures: $(dpkg --print-architecture)
   Signed-By: /etc/apt/keyrings/docker.asc
   EOF
   ```

4. Update the repository cache and install Docker packages:

   ```
   sudo apt update && sudo apt install docker-ce docker-ce-cli containerd.io docker-buildx-plugin docker-
   compose-plugin
   ```

4. Perform the following post-installation steps to configure the administration host for proper functioning with Docker:

```
sudo groupadd docker
sudo usermod -aG docker $USER
newgrp docker
sudo systemctl enable docker.service
sudo systemctl enable containerd.service
sudo systemctl status docker.service
```

Run the following command to make sure the Docker service is active:

```
sudo systemctl status docker
```

If a key cannot be downloaded automatically, download it manually:

1. Open the https://download.docker.com/linux/ubuntu/gpg link in your browser to save the key as docker.asc.
2. Run the following command:

   ```
   sudo mv docker.asc /etc/apt/keyrings/docker.asc
   ```

5. For the administrator host that will be included in the cluster, perform additional preparatory steps:

   a. Since the device will act as the administrator and target host, make sure that it meets the requirements for the single-node deployment.

   b. Make sure that the cgroup v2 technology is supported on the administrator host (the `/sys/fs/cgroup/cgroup.controllers` file is present).

Preparing the target host

The target host is a physical or virtual machine that is used to deploy Kaspersky EDR Expert and included in the Kubernetes cluster. The target host manages the Kubernetes cluster and the Kaspersky EDR Expert components that work on this host, and stores metadata.

A minimum cluster configuration for the single-node deployment includes one target host, which acts as the primary and worker nodes. On this primary worker node, the Kubernetes cluster and Kaspersky EDR Expert components are installed.

The KUMA services (collectors, correlators, and storages) can be installed entirely inside the cluster on the primary worker node, entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the Kubernetes cluster.

If you want to run the Kaspersky EDR Expert deployment from the target host, you must prepare this host as the administrator host, as described in the previous procedure, and then prepare the target host.

To prepare the target host:

1. Make sure that the hardware and software on the target host meet the requirements for the single-node deployment.

   If KUMA services are to be installed outside the cluster, the target host must meet the hardware, software, and installation requirements for installing the KUMA services.

   Since the DBMS will be installed on the target host, you also need to make sure that the target host meets the requirements for the DBMS.

For proper functioning of Kaspersky EDR Expert, the Linux kernel version must be 5.15.0.107 or later on the target host with the Ubuntu family operating systems.

Do not install Docker on the target host unless the target host will be used as the administrator host. KDT will install all necessary software and dependencies during the deployment.

2. Ensure that the filesystem mounted at `/var` has at least 360 GB of free space on the target host.

   To find out how much space is available in the `/var` directory, run the following command:

   ```
   df -h /var
   ```

3. Configure the /etc/environment file. If your organization's infrastructure uses a proxy server to access the internet, configure the internet access by using the proxy server on the target hosts.

4. Check that the sudo package is installed:

   ```
   apt list --installed | grep sudo
   ```

   The command output should list packages with the specified package name, for example:

   ```
   sudo/noble-updates,noble-security,now 1.9.15p5-3ubuntu5.24.04.2 amd64 [installed]
   ```

   Install the sudo package, if this package is not already installed:

   ```
   apt install sudo
   ```

5. For the Debian family of operating systems, install the UFW package:

   ```
   apt install ufw
   ```

6. If the primary worker node uses the UFW, allow IP forwarding. In the `/etc/default/ufw` file, set `DEFAULT_FORWARD_POLICY` to `ACCEPT`.

7. Provide access to the package repository that stores the following packages required for Kaspersky EDR Expert:

   - nfs-common
   - cron
   - tar
   - open-iscsi
   - python3-cffi-backend
   - python3-cryptography
   - systemd
   - cryptsetup-bin
   - cryptsetup
   - netcat-traditional
   - containerd

KDT will try to install these packages during the deployment from the package repository. You can also install these packages manually.

8. Ensure that the python3-apt, curl, and libnfs packages are installed on the primary worker node:

   ```
   apt list --installed | grep <package_name>
   ```

   The command output should list packages with the specified package name, for example:

   ```
   libnfs14/noble,now 5.0.2-1build1 amd64 [installed,automatic]
   ```

   ```
   libnfsidmap1/noble-updates,now 1:2.6.4-3ubuntu5.1 amd64 [installed,automatic]
   ```

   The python3-apt, curl, and libnfs packages are not installed during the deployment from the package repository by using KDT. You must install these packages manually, if they are not already installed. The libnfs package version 12 and later is used.

   ```
   sudo apt install <package_name>
   ```

9. Make sure configuration files do not contain any unavailable repositories: running the `apt update` command should return no errors.

10. Disable ARP spoofing protection on the hypervisor or network infrastructure for the target hosts.

11. Reserve static IP addresses for the target host and for the Kubernetes cluster gateway.

    The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. The gateway IP address is an IPv4 address (for example, 10.80.23.182). It is specified in the configuration file (the `ingress_ip` parameter). The static IP address specified in the `ingress_ip` parameter must be reserved in advance in the DNS system and remain free, that is, not assigned to any server.

    Make sure that the target host and the Kubernetes cluster gateway are located in the same broadcast domain.

    > The Kubernetes cluster gateway and target hosts require IPv4 addressing. If your environment requires IPv6 connectivity, configure the operating systems on the target hosts and the Kubernetes cluster gateway to route IPv6 traffic through an IPv6 gateway (NAT64) or an IPv6 tunnel. This configuration keeps the cluster running on IPv4 while providing interoperability with IPv6 networks.

12. On your DNS server, register the service FQDNs to connect to the Kaspersky EDR Expert services.

    By default, the Kaspersky EDR Expert services are available at the following addresses:

    - <console_host>.<smp_domain>—Access to the OSMP Console interface.
    - <ksc_host>.<smp_domain>—Interaction with Administration Server.
    - <kuma_host>.<smp_domain>—Access to the SIEM component.
    - <api_host>.<smp_domain>—Access to the Kaspersky EDR Expert API.
    - <monitoring_host>.<smp_domain>—Access to OSMP metrics.

      Where <console_host>, <ksc_host>, <kuma_host>, and <api_host>, and <monitoring_host> are service host names, <smp_domain> is a service domain name. These parameters are parts of the service FQDNs, which you can specify in the configuration file. If you do not specify custom values of service host names, the default values are used: `console_host`—`"console"`, `ksc_host`—`"admsrv"`, `kuma_host`—`"kuma"`, `api_host`—`"api"`, `monitoring_host`—`"monitoring"`.

The listed service FQDNs must be resolved to the IP address of the Kubernetes cluster. For example, if the Kubernetes cluster address is 10.80.23.182, service FQDNs are resolved to the IP address as follows:

- <console_host>.<smp_domain>—10.80.23.182
- <ksc_host>.<smp_domain>—10.80.23.182
- <kuma_host>.<smp_domain>—10.80.23.182
- <api_host>.<smp_domain>—10.80.23.182
- <monitoring_host>.<smp_domain>—10.80.23.182

When installing the DBMS, you must also reserve a separate free static IP address, which will be specified in the `pg_ip` parameter and used to access PostgreSQL.

13. Create one user account (for example, `sshuser`) that will be used for the Kaspersky EDR Expert deployment. This account is used for the SSH connection and must be able to elevate privileges (sudo) without entering a password. To do this, add the created user accounts to the `/etc/sudoers` file.

    a. Run the following commands:

    ```
    # create user sshuser
    sudo useradd -m -s /bin/bash sshuser
    # specify password for user sshuser
    sudo passwd sshuser
    # add user sshuser to sudo group
    sudo usermod -aG sudo sshuser
    ```

    b. Open the /etc/sudoers file by using the following command:

    ```
    sudo visudo
    ```

    c. Add the following line to the end of the section `# Allow members of group sudo to execute any command`:

    ```
    # grant privileges to user sshuser to elevate privileges (sudo) without entering a password
    sshuser ALL=(ALL) NOPASSWD: ALL
    ```

    Here, `sshuser` is the name of the created user.

    d. Save and close the /etc/sudoers file.

    e. Run the following command:

    ```
    sudo systemctl restart ssh # restart ssh
    ```

14. Configure the SSH connection between the administrator and target hosts:

    a. On the administrator host, run the following command to generate SSH keys by using the ssh-keygen utility without a passphrase:

    ```
    ssh-keygen -t rsa
    ```

b. Copy the public key to the target host (for example, to the `/home/sshuser/.ssh` directory) by using the ssh-copy-id utility:

`ssh-copy-id sshuser@<target_host_IP>`

If you use a target host as the administrator host, you must copy the public key to it, too.

Public key creation example

To create a public key, run the following command:

```
ssh-keygen -t rsa
ssh-copy-id sshuser@<target_host_IP>
```

15. For proper function of the Kaspersky EDR Expert components, open the required ports on the firewall of the administrator and target hosts, if necessary.

16. Configure time synchronization over Network Time Protocol (NTP) on the administrator and target hosts.

17. If necessary, prepare user certificates for working with Kaspersky EDR Expert public services.

    You can use one intermediate certificate that is issued off the organization's root certificate or leaf certificates for each of the services. The prepared user certificates will be used instead of self-signed certificates.

Preparing the hosts for installation of the KUMA services

The KUMA services (collectors, correlators, and storages) are installed on the KUMA target hosts that are located outside the Kubernetes cluster.

Access to KUMA services is performed by using the KUMA target host FQDNs. The administrator host must be able to access the KUMA target hosts by its FQDNs.

If you plan to use multiple tenants in your infrastructure, create a separate collector for each tenant.

To prepare the KUMA target hosts for installation of the KUMA services:

1. Ensure that the hardware, software, and installation requirements are met.

2. Specify the host names.

   You must specify the FQDN, for example: kuma1.example.com.

   We do not recommend changing the KUMA host name after installation. This will make it impossible to verify the authenticity of certificates and will disrupt the network communication between the application components.

3. Run the following commands:

   `hostname -f`

   `hostnamectl status`

   Compare the output of the `hostname -f` command and the value of the `Static hostname` field in the `hostnamectl status` command output. These values must match the FQDN of the device.

4. Configure the SSH connection between the administrator host and KUMA target hosts.

   Use the SSH keys created for the target hosts. Copy the public key to the KUMA target hosts by using the ssh-copy-id utility.

5. Register the KUMA target hosts in your organization's DNS zone, to allow host names to be translated to IP addresses.

6. Ensure time synchronization over Network Time Protocol (NTP) is configured on all KUMA target hosts. The KUMA services (collectors, correlators, and storages) are installed on the KUMA target hosts that are located outside the Kubernetes cluster.

The hosts are ready for installation of the KUMA services.

Installing a database management system

Kaspersky EDR Expert supports PostgreSQL or Postgres Pro database management systems (DBMS). For the full list of supported DBMSs, refer to the Hardware and software requirements.

Each of the following Kaspersky EDR Expert components requires a database:

- Administration Server
- Automation Platform
- Incident Response Platform (IRP)
- Identity and Access Manager (IAM)

Each of the components must have a separate database within the same instance of DBMS. The DBMS instance must be installed outside the Kubernetes cluster on a separate server. We recommend that you install the DBMS instance outside the Kubernetes cluster.

For the DBMS installation, KDT requires a privileged DBMS account that has permissions to create databases and other DBMS accounts. KDT uses the default DBMS account with superuser permissions, or another DBMS account with the same permissions, to create the databases and other DBMS accounts required for the Kaspersky EDR Expert components.

For the multi-node deployment, you must manually install the DBMS on the separated server that will not be included the Kubernetes cluster.

For single-node deployment, manually install the DBMS on the target host before the Kaspersky EDR Expert deployment. In this case, the DBMS and Kaspersky EDR Expert components are installed on the same target host, but the DBMS is not included in the Kubernetes cluster.

For information about how to install the selected DBMS, refer to its documentation.

PostgreSQL installation command example

To install PostgreSQL, run the following commands:

```
sudo apt install -y postgresql-<version>
sudo systemctl start postgresql
sudo systemctl enable postgresql
```

Where <version> is one of supported PostgreSQL versions.

After you install the DBMS, you need to configure the DBMS server parameters to ensure proper operation of the DBMS with Open Single Management Platform.

Configuring the PostgreSQL or Postgres Pro server for working with Kaspersky EDR Expert

To successfully configure PostgreSQL or Postgres Pro server for working with Administration Server, you must use the default server parameters except for the server parameters specified in this article.

Kaspersky EDR Expert supports PostgreSQL or Postgres Pro database management systems (DBMS). For the full list of supported DBMSs, refer to the Hardware and software requirements. Consider configuring the DBMS server parameters to optimize the DBMS work with Administration Server. Compliance of the DBMS server parameters with the recommended values is one of the prerequisites for installing Kaspersky EDR Expert, The compliance of parameters is verified using KDT.

Find the DBMS configuration file:

- The default path to the PostgreSQL configuration file is: `/etc/postgresql/<VERSION>/main/postgresql.conf`
- The default path to the Postgres Pro configuration file is: `/var/lib/pgpro/std-<VERSION>/data/postgresql.conf`

If there is no configuration file at the default path, run the following commands to find the correct path:

```
sudo su - postgres
psql -c 'SHOW config_file'
```

The command response will contain the path to the configuration file.

Then log out from the `postgres` user by running the following command:

```
exit
```

Recommended parameters for PostgreSQL and Postgres Pro DBMS for work with Administration Server:

- `listen_addresses = '*'`

  Specifies IP interfaces that Administration Server will listen to. For security purposes, configure firewall to allow access to port 5432 only for trusted IP addresses.

- `max_connections = 512`

  This is a minimum recommended value, you can specify a larger one. If you use a cluster Postgres DBMS, specify the `max_connections` parameter for all DBMS servers as well as in the cluster configuration.

- `shared_buffers = N`

  N = 25%–40% of the RAM value of the device where the DBMS is installed, but not less than 3 GB.

- `temp_buffers = 24MB`

- `work_mem = 16MB`

- `maintenance_work_mem = 128MB`

- `max_stack_depth = N`

  If the DBMS is installed on a Linux device, then N = maximum stack size minus the 1 MB safety margin. To obtain the maximum stack size value in KB, execute the '`ulimit -s`' command.

  If the DBMS is installed on a Windows device, then leave the default value 2 MB.

- `max_parallel_workers_per_gather = 0`

- `standard_conforming_strings = on`

If you use Postgres Pro 15.7 or Postgres Pro 15.7.1, disable the `enable_compound_index_stats` parameter:

```
enable_compound_index_stats = off
```

Reload configuration or restart the DBMS server after updating the configuration file.

For detailed information about PostgreSQL and Postgres Pro server parameters and on how to specify the parameters, refer to the corresponding DBMS documentation.

Specify authentication entries for nodes in the pg_hba.conf configuration file. You can find it in the same path, where postgresql.conf is located.

- In the `"# "local" is for Unix domain socket connections only"` section, for `local`, in the `METHOD` column, change the value to `trust`

- In the `"IPv4 local connections"` section, for `host`, in the `ADDRESS` column, change the value to `0.0.0.0/0`

- Run the following command to apply the changes without restarting the database server:

  ```
  sudo -u postgres psql -c "SELECT pg_reload_conf();"
  ```

Specify the password for the `postgres` user:

1. Run the following commands:

   ```
   sudo su - postgres
   psql
   ```

   The command output should be as follows:

   ```
   psql (15.12)
   Type "help" for help.
   postgres=#
   ```

2. After `postgres=#`, enter `\password`:

   ```
   postgres=# \password
   ```

3. Enter and repeat the password:

   ```
   Enter new password for user "postgres"
   Enter it again:
   ```

4. To log out of a user `postgres`:

   ```
   postgres=# exit
   ```

Kaspersky EDR Expert components require PostgrSQL superuser credentials in `parameters.psql_dsn` as the `value`. Specify postgres credentials in the deployment configuration file. For more information, see Single-node deployment: Specifying the installation parameters or Multi-node deployment: Specifying the installation parameters sections depending on your deployment schema.

Checking the database connection

To check the database connection:

1. Make sure the Postgres service is running:

   ```
   systemctl list-unit-files | grep postgres
   ```

   Example output:

   ```
   postgrespro-std-17.service enabled enabled
   ```

2. Restart the Postgres service:

   ```
   systemctl restart <Postgres_service>
   ```

   Where <`Postgres_service`> is the Postgres service name obtained at step 1 of this procedure.

3. Run `psql` to check the connection:

   ```
   psql -h <fqdn> -U postgres -d postgres
   ```

   Enter the password specified earlier:

   ```
   Password for user postgres:
   ```

   Example output:

   ```
   psql (17.4)
   Type "help" for help.
   ```

4. Enter `exit`:

```
postgres=# exit
```

Highly available cluster support

Highly available PostgreSQL clusters are supported with the following settings:

- Replication type: Synchronous
- Minimum number of nodes: 3.
- Maximum number of nodes: 15.

Set the `psql_dsn` parameter as follows: `postgres://<dbms_username>:<password>@<fqdn1>:<port>,<fqdn2>:<port>,<fqdn3>:<port>`

When using a Postgres Highly Available cluster version 14 or later as the database, the database user must have the `pg_read_all_stats` privilege. You can grant this privilege by running the following command:

```
GRANT pg_read_all_stats TO "dbms_username";
```

Where `dbms_username` is the name of a privileged internal DBMS account.

Specify the following parameter in the configuration file (`/etc/postgresql/< VERSION >/main/postgresql.conf`):

```
log_hostname = 1
```

Corosync/Pacemaker support

To use Corosync/Pacemaker, set the `psql_dsn` parameter with a virtual IP address of the DBMS cluster as follows:

```
psql_dsn=postgres://postgres:pass!@<virtual ip>:<port>
```

Preparing the KUMA inventory file for installing KUMA services outside the Kubernetes cluster

The KUMA inventory file is a file in the YAML format that contains installation parameters for deployment of the KUMA services that are not included in the Kubernetes cluster. The path to the KUMA inventory file is included in the configuration file that is used by Kaspersky Deployment Toolkit for the Kaspersky EDR Expert deployment.

The templates of the KUMA inventory file are located in the distribution package. If you want to install the KUMA services (storage, collector, and correlator) on one host, use the single.inventory.yml file. To install the services on several hosts in the network infrastructure, use the distributed.inventory.yml file.

We recommend backing up the KUMA inventory file that you used to install the KUMA services. You can use it to remove KUMA.

To prepare the KUMA inventory file,

Open the KUMA inventory file template located in the distribution package, and then edit the variables in the inventory file.

The KUMA inventory file contains the following blocks:

- `all` block

  The `all` block contains the variables that are applied to all hosts specified in the inventory file. The variables are located in the `vars` section.

- `kuma` block

  The `kuma` block contains the variables that are applied to hosts on which the KUMA services will be installed. These hosts are listed in the `kuma` block in the `children` section. The variables are located in the `vars` section.

The following table lists possible variables, their descriptions, possible values, and blocks of the KUMA inventory file where these variables can be located.

List of possible variables in the vars section

Variable	Description	Possible values	Block
Variables located in the `vars` section of the `all` and `kuma` blocks			
`ansible_connection`	Method used to connect to the KUMA service hosts.	• `ssh`—Connection to the target hosts via SSH is established. • `local`—No connection to the target hosts is established. To provide the correct installation of the KUMA services, in the `all` block, set the `ansible_connection` variable to `local`. In the `kuma` block, you must specify the `ansible_connection` variable and set `ansible_connection` to `ssh` to provide the connection to the hosts on which the KUMA services are installed via SSH.	• `all` • `kuma`
`ansible_user`	User name used to connect to KUMA service hosts to install external KUMA services.	If the root user is blocked on the target hosts, specify a user name that has the right to establish SSH connections and elevate privileges by using su or sudo. To provide the correct installation of the KUMA services, in the `all` block, set the `ansible_user` variable to `nonroot`. In the `kuma` block, you must override the `ansible_user` variable and set `ansible_user` to the username of the account that can connect to remote hosts via SSH, to prepare them for the installation of the KUMA services.	• `all` • `kuma`
`ansible_become`	Variable used to indicate the need to increase the privileges of the user account that is used to install KUMA components.	• `false`—If the `ansible_user` value is `root`. • `true`—If the `ansible_user` value is not `root`.	`kuma`

ansible_become_method	Method used for increasing the privileges of the user account that is used to install KUMA components.	su or sudo if the ansible_user value is not root.	kuma
Variables located in the children section of the kuma block			
kuma_utils	Group of hosts used for storing the service files and utilities of KUMA. A host can be included in the kuma_utils group and in the kuma_collector, kuma_correlator, or kuma_storage group at the same time. The kuma_utils group can contain multiple hosts. During the Kaspersky EDR Expert deployment, on the hosts that are included in kuma_utils, the following files are copied to the /opt/kaspersky/kuma/utils/ directory: • kuma is an executable file with which the KUMA services are installed. • LEGAL_NOTICES is a file with information about third-party code. • kuma-ptvm.tar.gz is a utility for integration with MaxPatrol. • ootb-content is an archive with out of the box resources for the KUMA services.	The group of hosts contains the ansible_host variable that specifies the unique host FQDN and IP address.	kuma
kuma_collector	Group of KUMA collector hosts. This group can contain multiple hosts.	The group of KUMA collector hosts contains the ansible_host variable that specifies the unique host FQDN and IP address.	kuma
kuma_correlator	Group of KUMA correlator hosts. This group can contain multiple hosts.	The group of KUMA correlator hosts contains the ansible_host variable that specifies the unique host FQDN and IP address.	kuma
kuma_storage	Group of KUMA storage hosts. This group can contain multiple hosts.	The group of KUMA storage hosts contains the ansible_host variable that specifies the unique host FQDN and IP address.	kuma

```

Multi-node deployment: Specifying the installation parameters

The configuration file is a file in the YAML format and contains a set of installation parameters for the Kaspersky EDR Expert components.

> The installation parameters listed in the tables below are required for the multi-node deployment of Kaspersky EDR Expert. To deploy Kaspersky EDR Expert on a single node, use the configuration file that contains installation parameters specific for the single node deployment.

The template of the configuration file (multinode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility. You can fill out the configuration file template manually; or use the Deployment wizard to specify the installation parameters that are required for the Kaspersky EDR Expert deployment, and then generate the configuration file.

Not all of the parameters listed below are included in the configuration file template. This template contains only those parameters that must be specified before Kaspersky EDR Expert deployment. Remaining parameters are set to default values, and they are not included in the template. You can manually add these parameters to the configuration file to override its values. Parameter values must follow the rules described below. During the Kaspersky EDR Expert deployment, KDT checks whether the required installation parameters are specified correctly. If the required parameters in the configuration file are missing or invalid, the deployment will be interrupted.

Sample of the configuration file for the multi-node deployment of Kaspersky EDR Expert

# Parameters for the Kaspersky EDR deployment
parameters:
  # The connection string for access to the DBMS that is installed and configured on a
  separate server.
  # user_db—The user name of a privileged internal DBMS account. This account is granted
  permissions to create databases and other DBMS accounts.
  # password_db—The password of the privileged internal DBMS account.
  # fqdn_db:port_db is the fully qualified domain name and connection port of the
  separate server on which the DBMS is installed.
  # The 'psql_dsn' parameter value must comply with the URI format. If the connection URI
  includes symbols with special meaning in any of its parts, it must be encoded with
  percent-encoding.
  - name: psql_dsn
    source:
      value: "postgres://postgres:password@dbms.example.com:1234"
  # IP address of the Kubernetes cluster gateway
  # The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR
  components installed inside the Kubernetes cluster.
  # The gateway must be included in the same subnet as all cluster nodes.
  - name: ingress_ip
    source:
      value: 10.80.23.182
  # Path to the SSH private key for connection to the control node and worker nodes using
  KDT. The SSH private key is located on the administrator host.
  # The parameter value must be a Linux file path or Base64-encoded file content.
  - name: ssh_pk
    source:
      path: /root/.ssh/id_rsa
  # Password of the Kaspersky EDR user account that will be created during the
  installation.
  # The password must be 10 to 256 characters long.
  # It can contain only ASCII characters: upper or lower case letters (A–Z, a–z),
  numerals (0–9), and special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \
  ` ~ " ( ) ;).
  # The password must not contain either whitespaces or ".@".
  - name: admin_password
    source:
      value: "password"
  # Amount of disk space for the operation of KUMA Core, in gigabytes.
  # Specified as "<amount>Gi". Default value is 512Gi.
```

```
# If the 'low_resources' setting is set to true, the 'core_disk_request' setting is
ignored and 4Gi is allocated.
- name: core_disk_request
  source:
    value: 512Gi
# Path to the KUMA inventory file that contains the installation parameters for
deployment of the KUMA services. This file is located on the administrator host.
# The parameter value must be a Linux file path or Base64-encoded file content.
- name: inventory
  source:
    value: "/home/user/inventory.yml"
# Path to the Kaspersky Endpoint Detection and Response license key. This file is
located on the administrator host.
# The parameter value must be a Linux file path or Base64-encoded file content.
- name: license
  source:
    value: "/home/user/license.key"
# Domain name. The parameter value must satisfy the naming requirements for domains up
to the fourth level.
# The service host name and domain name are parts of FQDNs of the Kaspersky EDR
services.
# Default values of service host names: nwc_host—"console", flow_host—"console",
hydra_host—"console", login_host—"console", ksc_host—"admsrv", console_host—"console",
api_host—"api", kuma_host—"kuma", monitoring_host—"monitoring".
# Custom device names can be specified in the configuration file.
# Example: console.smp.local is the FQDN of the service that provides access to the
OSMP Console. This FQDN consists of the 'console_host' and 'smp_domain' parameter
values.
- name: smp_domain
  source:
    value: "smp.local"
# List of host names of the Kaspersky EDR services for which a self-signed or user
certificate must be generated.
# The parameter value must be a list of host names, separated by spaces. If custom host
names are not specified, the default host names are used.
- name: pki_host_list
  source:
    value: "admsrv api console kuma monitoring"
- name: autodeploy_plan
  source:
    value: "edr"
# The user name of the account used to view OSMP metrics through the Grafana tool.
# The user name must be 1 to 30 characters long.
# It can contain lowercase letters ('a' to 'z'), digits ('0' to '9'), and special
characters (_ - .).
# A user name must begin with a letter and may not contain spaces or the "@" character.
- name: grafana_admin_user
  source:
    value: "grafana_admin_user"
# The password of the account used to view OSMP metrics through the Grafana tool.
# The password must be 8 to 256 characters long.
# It can contain only ASCII characters: upper or lower case letters (A–Z, a–z),
numerals (0–9), and special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \
` ~ " ( ) ;).
- name: grafana_admin_password
  source:
    value: "grafana_admin_password"
```

For correct function of KDT with the configuration file, add an empty line at the end of the file.

The `nodes` section of the configuration file contains installation parameters for each target host of the Kubernetes cluster. These parameters are listed in the table below.

Nodes section

Parameter name	Required	Description
`desc`	Yes	The node name. The value must comply with the following rules: • The node name must be 1 to 63 characters long. • The node name can contain the following characters: • Uppercase ASCII letters (A–Z) • Lowercase ASCII letters (a–z) • Numbers (0–9) • Hyphen (-) All cluster nodes must have unique names. This requirement is one of the prerequisites for the installation of Kaspersky EDR Expert and is verified by KDT.
`type`	Yes	The node type. Possible parameter values: • `primary` • `worker` • `loadbalancer`
`host`	Yes	The IP address of the node. All nodes must be included in the same subnet as the Kubernetes cluster gateway. Nodes require IPv4 addressing. KDT automatically disables IPv6 on the cluster nodes. If you have multiple primary nodes, a load balancer is required to distribute incoming requests across the primary nodes and ensure an even workload. If you want to use an external load balancer, allocate a separate host outside the cluster and specify its parameters in the configuration file. If you do not want to use an external load balancer, worker nodes will act as the load balancer.
`kuma_role`	No	The KUMA service that you can specify for installation on the worker node. You can specify one, multiple, or no KUMA services. The `kuma_roles` parameter is considered when the KUMA service installing in the Kubernetes cluster by using the OSMP Console. If the node where you plan to install the KUMA service is overloaded, the cluster will select another, less busy node for the service installation. Set the `inventory` parameter to `/dev/null`. It is not allowed to place storages created from the same KUMA resource on the same worker node. This rule ensures the required level of fault tolerance. Possible parameter values: • `core`—KUMA Core • `metrics`—KUMA metrics • `collector`—Collector • `correlator`—Correlator • `storage`—Storage The parameter value is specified as a list of strings containing KUMA roles. For example: `kuma_roles: ["core","metrics","collector"]`

Parameter name	Required	Description
`user`	Yes	The user name of the account created on the target host and used for connection to the node by KDT. The value must comply with the following rules: • The user name must be 1 to 31 characters long. • The user name can contain the following characters: • Lowercase letters (a–z) • Numbers (0–9) • Underscore (_), hyphen (-)
`password`	No	The password for connecting to the node. Can be used instead of the SSH key specified by the `ssh_pk` parameter.

Other installation parameters are listed in the `parameters` section of the configuration file and are described in the table below.

Parameters section

Parameter name	Required	Description

`psql_dsn`	Yes	The connection string for accessing the DBMS that is installed and configured outside the Kubernetes cluster.
		Specify this parameter as follows:
		`psql_dsn=postgres://<dbms_username>:<password>@<fqdn>:<port>`
		where:
		• `dbms_username` —The user name of a privileged internal DBMS account. This account is granted permissions to create databases and other DBMS accounts. By using this privileged DBMS account, the databases and other DBMS accounts required for the Kaspersky EDR Expert components will be created during the deployment.
		• `password` —The password of the privileged internal DBMS account.
		• `fqdn:port` —The FQDN and connection port of the target host on which the DBMS is installed.
		To use a highly available cluster, specify this parameter as follows:
		`psql_dsn=postgres://<dbms_username>:<password>@<fqdn1>:<port>,<fqdn2>:<port>,<fqdn3>:<port>`
		To use Corosync/Pacemaker, specify this parameter with a virtual IP as follows:
		`psql_dsn=postgres://postgres:pass!@<virtual ip>:<port>`
		The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.
		Symbols that must be replaced in the `psql_dsn` parameter value:
		• Whitespace → `%20`
		• ! → `%21`
		• # → `%23`
		• % → `%25`
		• & → `%26`
		• / → `%2F`
		• : → `%3A`
		• = → `%3D`
		• ? → `%3F`
		• @ → `%40`
		• [→ `%5B`
		•] → `%5D`
		Refer to the PostgreSQL connection string article for details.

`nwc-language`	Yes	The language of the OSMP Console interface is specified by default. After installation, you can change the OSMP Console language. Possible parameter values: • `enUS` (default value) • `ruRu` The default value is used if you do not specify this parameter in the configuration file.

Parameter name	Required	Description
`ingress_ip`	Yes	The reserved static IPv4 address of the Kubernetes cluster gateway. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. The gateway must be included in the same subnet as the primary and worker nodes.
`ssh_pk`	Yes	The path to the private part of the SSH key located on the administrator host and used for connection to the primary worker node and nodes with the KUMA services (collectors, correlators, and storages) by using KDT. The parameter value must be a Linux file path or Base64-encoded file content.
`admin_password`	Yes	The `admin_password` parameter specifies the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The default user name of this account is "admin." The Main administrator role is assigned to this user account. The password must comply with the following rules: • The user password cannot have fewer than 10 or more than 256 characters. • The password must contain characters from at least three of the groups listed below: • Uppercase letters (A–Z) • Lowercase letters (a–z) • Numbers (0–9) • Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;) • The password must not contain any whitespaces, or the ".@" combination. When you specify the `admin_password` parameter value manually (not by the Deployment wizard), make sure that this value meets the YAML standard requirements for values in strings: • The parameter value containing special characters must be enclosed in single quotes. • Any single quote ' inside the parameter value must be doubled to escape this single quote. Example: the user account password `Any_pass%1234'5678"90` must be specified as the value `'Any_pass%1234''5678"90'` of the `admin_password` parameter.
`low_resources`	No	The parameter indicating that Kaspersky EDR Expert is installed on the target host with limited computing resources. Set the `low_resources` parameter to `false` for multi-node deployment. Possible parameter values: • `true` —Installation with limited computing resources (for single-node deployment) • `false` —Standard installation (default value)
`core_disk_request`	Yes	The parameter that specifies the amount of disk space for the operation of KUMA Core. If you do not specify the `core_disk_request` parameter and the `low_resources` parameter is set to `false` or is not specified, the default amount of disk space for the operation of KUMA Core is 100 GB. If you do not specify the `core_disk_request` parameter and the `low_resources` parameter is set to `true`, the default amount of disk space for the operation of KUMA Core is 4 GB. You can change the `core_disk_request` parameter later, after the application deployment.
`metrics_disk_request`	Yes	The parameter that specifies the amount of disk space for the operation of the Metrics service. If you do not specify the `metrics_disk_request` parameter and the `low_resources` parameter is set to `false` or is not specified, the default amount of disk space for the operation of the Metrics service is 80 GB. If you do not specify the `metrics_disk_request` parameter and the `low_resources` parameter is set to `true`, the default amount of disk space for the operation of the Metrics service is 4 GB. You can change the `metrics_disk_request` parameter later, after the application deployment.

Parameter name	Required	Description
`inventory`	Yes	The path to the KUMA inventory file located on the administrator host. The inventory file contains installation parameters for deployment of the KUMA services that are not included in the Kubernetes cluster. The parameter value must be a Linux file path or Base64-encoded file content. If all KUMA services will be installed inside the cluster, set the `inventory` parameter to `/dev/null`.
`host_inventory`	No	The path to the additional KUMA inventory file located on the administrator host. This file contains the installation parameters used to partially add or remove hosts with the KUMA services. The parameter value must be a Linux file path or Base64-encoded file content. If you perform an initial deployment of Kaspersky EDR Expert or run a custom action that requires configuration file, leave the default parameter value (`/dev/null`).
`license`	No	The path to the KUMA license key located on the administrator host. The parameter value must be a Linux file path or Base64-encoded file content. You can upload the license key or specify the activation code once you log in to OSMP after deployment is complete.

`nwc_host`
`flow_host`
`hydra_host`
`login_host`
`ksc_host`
`console_host`
`api_host`
`kuma_host`
`monitoring_host`
`xdr_edr_ingress_host`
	Yes	The host name that is used in the FQDNs of the public Kaspersky EDR Expert services. The service host name and domain name (the `smp_domain` parameter value) are parts of the service FQDN.
		If custom host names are not specified, the following default host names are used:
		• `nwc_host—"console"`
		• `flow_host—"console"`
		• `hydra_host—"console"`
		• `login_host—"console"`
		• `ksc_host—"admsrv"`
		• `console_host—"console"`
		• `api_host—"api"`
		• `kuma_host—"kuma"`
		• `monitoring_host—"monitoring"`
		• `xdr_edr_ingress_host—"agentserver"`

`smp_domain`	Yes	The domain name that is used in the FQDNs of the public Kaspersky EDR Expert services. The parameter value must satisfy the naming requirements for domains up to the fourth level. The service host name and domain name are parts of the service FQDN. For example, if the value of the `console_host` variable is `console`, and the value of the `smp_domain` variable is `smp.local`, then the full name of the service that provides access to the OSMP Console is `console.smp.local`.
`pki_host_list`	Yes	The list of host names of the public Kaspersky EDR Expert services for which a self-signed or user certificate is to be generated. The parameter value must be a list of host names, separated by spaces.
`intermediate_enabled`	No	The parameter that indicates whether to use the custom intermediate certificate instead of the self-signed certificates for the public Kaspersky EDR Expert services. Possible parameter values: • `true`—Use custom intermediate certificate. • `false`—Use self-signed certificates (default value).
`intermediate_bundle`	No	The path to the custom intermediate certificate used to work with public Kaspersky EDR Expert services. Specify this parameter if the `intermediate_enabled` parameter is set to `true`. The parameter value must be a Linux file path or Base64-encoded file content. The validity period for the custom intermediate certificate must be 399 days or more.

`admsrv_bundle`
`api_bundle`
`console_bundle`
`kuma_bundle`
`monitoring_bundle`
	No	The paths to the custom leaf certificates used to work with the corresponding public Kaspersky EDR Expert services: `<admsrv_host>.<smp_domain>`, `<api_host>.<smp_domain>`, `<kuma_host>.<smp_domain>`, `<monitoring_host>.<smp_domain>`, and `<console_host>.<smp_domain>`. The parameter values must be a Linux file path or Base64-encoded file content.
		If you want to specify the custom leaf certificates, set the `intermediate_enabled` parameter to `false` and do not specify the `intermediate_bundle` parameter and the `pki_host_list` parameter.

Parameter name	Required	Description
`ksc_state_size`	Yes	The amount of free disk space allocated to store the Administration Server data (updates, installation packages, and other internal service data). Measured in gigabytes, specified as "<amount>Gi". The required amount of free disk space depends on the number of managed devices and other parameters, and can be calculated. The default value is 30 GB. This value is used if you do not specify this parameter in the configuration file.
`prometheus_size`	Yes	The amount of free disk space allocated to store metrics. Measured in gigabytes, specified as "<amount>GB". The minimum recommended and default value is 5 GB. The default value is used if you do not specify this parameter in the configuration file.
`grafana_admin_user`	No	The user name of the account used to view OSMP metrics through the Grafana tool. The value must comply with the following rules: • The user name must be 1 to 30 characters long. • The user name can contain the following characters: • Lowercase letters (a–z) • Numbers (0–9) • Special characters (_ - .) • The user name must start with a letter. • The user name must not contain either whitespaces or the "@" symbol.
`grafana_admin_password`	No	The password of the account used to view OSMP metrics through the Grafana tool. The password must comply with the following rules: • The user password cannot have fewer than 8 or more than 256 characters. • The password must contain characters from the groups listed below: • Uppercase letters (A–Z) • Lowercase letters (a–z) • Numbers (0–9) • Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)
`loki_size`	Yes	The amount of free disk space allocated to store OSMP logs. Measured in gigabytes, specified as "<amount>Gi". The minimum recommended and default value is 40 GB. The default value is used if you do not specify this parameter in the configuration file.
`loki_retention_period`	Yes	The storage period of OSMP logs after which logs are automatically removed. The default value is 72 hours (set the parameter value in the configuration file as "<time in hours>h". For example, "72h"). The default value is used if you do not specify this parameter in the configuration file.
`file_storage_cp`	No	The amount of free disk space allocated to store data of the component for working with response actions. Measured in gigabytes, specified as "<amount>Gi". The minimum recommended value is 20 GB.
`psql_tls_off`	No	The parameter that indicates whether to encrypt the traffic between the Kaspersky EDR Expert components and the DBMS by using the TLS protocol. If the DBMS is installed outside the cluster, TLS encryption is disabled by default (the default value is `true`). Possible parameter values: • `true` —Do not encrypt the traffic (default value). • `false` —Encrypt the traffic.
`psql_trusted_cas`	No	The path to the PEM file that can contain the TLS certificate of the DBMS server or a root certificate from which the TLS server certificate can be issued. The parameter value must be a Linux file path or Base64-encoded file content. Specify the `psql_trusted_cas` parameter if the DBMS will be installed and configured on a separate server and traffic encryption is enabled (`psql_tls_off` is set to `false`).

Parameter name	Required	Description
`proxy_enabled`	No	The parameter that indicates whether to use the proxy server to connect the Kaspersky EDR Expert components to the internet. If the host on which Kaspersky EDR Expert is installed has internet access, you can also provide internet access for the operation of Kaspersky EDR Expert components (for example, Administration Server) and for specific integrations, both Kaspersky and third-party. To establish the proxy connection, you must also specify the proxy server parameters in the Administration Server properties. Possible parameter values: • `true` —Proxy server is used. • `false` —Proxy server is not used (default value).
`proxy_addresses`	No	The IP address of the proxy server. If the proxy server uses multiple IP addresses, specify these addresses separated by a space (for example, "`0.0.0.0 0.0.0.1 0.0.0.2`"). Specify this parameter if the `proxy_enabled` parameter is set to `true`.
`proxy_port`	No	The number of the port through which the proxy connection will be established. Specify this parameter if the `proxy_enabled` parameter is set to `true`.
`console_port`	No	The parameter that specifies the customized number of the port used to connect to the OSMP console server. The default value is 443.
`as_smp_port`	No	The parameter that specifies the customized number of the port used by Endpoint Agents to connect to the agentserver component. The default value is 443.
`kuma_gateway_telemetry_listener_port`	No	The parameter that specifies the customized number of the port used for sending the telemetry. The default value is 443.
`trace_level`	No	The verbosity level of Administration Server trace files. Traces are written during the Administration Server operation. The default value is 0, no traces are written. Possible parameter values: 0–5. The higher the parameter value, the more detailed the trace details.
`ansible_extra_flags`	No	The verbosity level of logs of the KUMA Core and KUMA services deployment that is performed by KDT. Possible parameter values: • `-v` • `-vv` • `-vvv` • `-vvvv` As the number of "v" letters in the flag increases, logs become more detailed. If this parameter is not specified in the configuration file, the standard component installation logs are saved.
`incident_attachments_max_count_limit`	No	The number of files that you can attach to the incident. The default value is `100`.
`incident_attachments_max_size_limit`	No	The total size of files attached to the incident. Measured in bytes. Specified without units of measurement. The default value is `26214400`.
`ignore_precheck`	No	The parameter indicating whether to check the hardware, software, and network configuration of the Kubernetes cluster nodes for compliance with the prerequisites for installing the solution before the deployment. Possible parameter values: • `true` —Skip the pre-checks. • `false` —Perform the pre-checks (default value).
`airgap_mode`	No	The parameter indicating whether to perform the APT package manager pre-check and update the package cache. This allows deploying Kaspersky EDR Expert in an air-gapped environment. Possible parameter values: • `true` —Skip the pre-check and the package cache update. • `false` —Perform the pre-check and update the package cache (default value).
`grafana_smtp_host`	No	SMTP server address for Grafana, used to send email notifications about Kubernetes cluster health events. Specify this parameter in the `<host>:<port>` format, for example, `localhost:25`.
`grafana_smtp_user`	No	User name for authentication on the SMTP server.
`grafana_smtp_password`	No	Password for authentication on the SMTP server.

Parameter name	Required	Description
`grafana_smtp_bundle`	No	File containing the X.509 certificate chain used for verifying TLS connection to the SMTP server.
`grafana_smtp_skip_verify`	No	The parameter that indicates whether to skip TLS certificate verification of the SMTP server. Possible parameter values: • `true` —Skip TLS certificate verification. • `false` —Perform TLS certificate verification (default value).
`grafana_smtp_from_address`	No	Email address of the sender, which will appear in the From field when sending email notifications.
`grafana_smtp_from_name`	No	Display name of the sender in email notifications.
`grafana_smtp_ehlo_identity`	No	Identifier used in the EHLO command when connecting to the SMTP server.
`grafana_starttls_policy`	No	Policy for using STARTTLS when connecting to the SMTP server. Possible parameter values: • `OpportunisticStartTLS` —Use STARTTLS if the SMTP server supports it; otherwise, connect to the SMPT server without encryption. • `MandatoryStartTLS` —Require STARTTLS; fail if the SMTP server does not support it. • `NoStartTLS` —Do not use STARTTLS; connect to the SMPT server without encryption. • `empty` —Use STARTTLS if the SMTP server supports it; otherwise, connect to the SMPT server without encryption (default value).
`grafana_smtp_enable_tracing`	No	The parameter that indicates whether to enable SMTP connection tracing for debugging email sending. Possible parameter values: • `true` —Enable SMTP connection tracing. • `false` —Disable SMTP connection tracing (default value).
`autodeploy_plan`	No	The parameter that indicates whether to deploy the KUMA services for Kaspersky EDR or for Kaspersky NGFW. Possible parameter values: • `edr` —Deploy the KUMA services for OSMP and for Kaspersky EDR inside the Kubernetes cluster (default value). • `ngfw` —Deploy the KUMA services for OSMP and for Kaspersky NGFW inside the Kubernetes cluster. Additionally, the predefined collector **[OOTB] Kaspersky NGFW** will be installed on the first host from the host list specified in the `kuma_collector` parameter of the KUMA inventory file. • `none` —Do not deploy the KUMA services for Kaspersky EDR or Kaspersky NGFW. Use this value for Kaspersky EDR Expert deployment without KUMA services for Kaspersky EDR and Kaspersky NGFW or for Kaspersky EDR Expert restoration from a backup. If you use the `edr` or `ngfw` values for Kaspersky EDR Expert restoration, this may lead to conflicts between the deployed services and the services stored in a backup.
`tokenhub_access_token`	No	The lifetime of an access token. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`1h10m`" or "`2h`". The minimum possible value is `5m` and the maximum is `2h`. The default value is `1h`. This value is used if you do not specify this parameter in the configuration file. You can change the `tokenhub_access_token` parameter later, after the application deployment.
`tokenhub_refresh_token`	No	The lifetime of a refresh token that is used for getting a new access token. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`24h`" or "`1240h30m`". The minimum possible value is `12h` and the maximum is `4320h`. The default value is `24h`. This value is used if you do not specify this parameter in the configuration file. You can change the `tokenhub_refresh_token` parameter later, after the application deployment.

Parameter name	Required	Description
`credentials_session_ttl`	No	The maximum single sign-on session idle time. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`24h`" or "`1h30m`". The minimum possible value is `5m` and the maximum is `96h`. The default value is `1h`. This value is used if you do not specify this parameter in the configuration file. You can change the `credentials_session_ttl` parameter later, after the application deployment.

Single-node deployment: Specifying the installation parameters

The configuration file used to deploy Kaspersky EDR Expert on a single node contains the installation parameters that are required both for the multi-node and single-node deployment. Also, this configuration file contains parameters specific only for the single-node deployment (`openbao_ha_mode`, `openbao_standalone`, and `default_class_replica_count`).

The template of the configuration file (singlenode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility. You can fill out the configuration file template manually; or use the Deployment wizard to specify the installation parameters that are required for the Kaspersky EDR Expert deployment, and then generate the configuration file.

Not all of the parameters listed below are included in the configuration file template. This template contains only those parameters that must be specified before Kaspersky EDR Expert deployment. Remaining parameters are set to default values, and they are not included in the template. You can manually add these parameters to the configuration file to override its values. Parameter values must follow the rules described below. During the Kaspersky EDR Expert deployment, KDT checks whether the required installation parameters are specified correctly. If the required parameters in the configuration file are missing or invalid, the deployment will be interrupted.

Sample of the configuration file for the single-node deployment of Kaspersky EDR Expert

```
schemaType: ParameterSet
schemaVersion: 1.0.1
namespace: ""
name: bootstrap
project: xdr
# Node on which the Kubernetes cluster and Kaspersky EDR will be deployed
nodes:
  # Primary/worker node settings.
    # The node name. The value must be 1 to 63 characters long.
    # The node name can contain only ASCII characters: letters (a-z; A-Z), numbers (0-9),
    and hyphen (-).
  - desc: cdt-1
    # The node type.
    # For single-node deployment, set "type" to "primary-worker". In this case, the target
    host will act as the primary and worker nodes.
    type: primary-worker
    # The IP address of the node.
    # The primary worker node must be included in the same subnet as the Kubernetes
    cluster gateway.

      ssh:
```

```
      # User account name.
      # A user account is created on the target device and is used by KDT for connection
      to the node.
      # The user name must be 1 to 31 characters long.
      # A user name can contain only ASCII characters: letters (a–z; A–Z), numbers (0–
      9), and hyphen (-).
      user: root
      # The password for connecting to the node. Can be used instead of the SSH key
      specified by the ssh_pk parameter.
      # password: pass
# Parameters for the Kaspersky EDR deployment
parameters:
  # The connection string for access to the DBMS that is installed and configured on a
  separate server.
  # user_db—The user name of a privileged internal DBMS account. This account is granted
  permissions to create databases and other DBMS accounts.
  # password_db—The password of the privileged internal DBMS account.
  # fqdn_db:port_db is the fully qualified domain name and connection port of the
  separate server on which the DBMS is installed.
  # The 'psql_dsn' parameter value must comply with the URI format. If the connection URI
  includes symbols with special meaning in any of its parts, it must be encoded with
  percent-encoding.
  - name: psql_dsn
    source:
      value: "postgres://postgres:password@dbms.example.com:1234"
  # IP address of the Kubernetes cluster gateway
  # The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR
  components installed inside the Kubernetes cluster.
  # The gateway must be included in the same subnet as the primary worker node.
  - name: ingress_ip
    source:
      value: 10.80.23.182
  # Path to the SSH private key for connection to the primary worker node by KDT. The SSH
  private key is located on the administrator host.
  # The parameter value must be a Linux file path or Base64-encoded file content.
  - name: ssh_pk
    source:
      path: /root/.ssh/id_rsa
  # Password of the Kaspersky EDR user account that will be created during the
  installation.
  # The password must be 10 to 256 characters long.
  # It can contain only ASCII characters: upper or lower case letters (A–Z, a–z),
  numerals (0–9), and special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \
  ` ~ " ( ) ;).
  # The password must not contain either whitespaces or ".@".
  - name: admin_password
    source:
      value: ""
  # The parameter indicating that Kaspersky EDR is installed on the target host with
  limited computing resources.
  # For the single-node deployment, set the 'low_resources' parameter to "true" so that
  Kaspersky Symphony EDR components will require less memory and CPU resources.
  # Also, if you enable this parameter, 4 GB of free disk space will be allocated to
  install KUMA Core on the target host.
  - name: low_resources
    source:
      value: "true"
```

```
# The number of disk volumes that are used to store the service data of Kaspersky EDR
components and KDT.
# For the single-node deployment, set the parameter value to "1".
- name: default_class_replica_count
  source:
    value: "1"
# The parameter that indicates whether to run the secret storage in the High
Availability (HA) mode.
# For the single-node deployment, set the parameter value to "false".
- name: openbao_ha_mode
  source:
    value: "false"
# The parameter that indicates whether to run the secret storage in the standalone
mode.
# For the single-node deployment, set the parameter value to "true".
- name: openbao_standalone
  source:
    value: "true"
# Path to the KUMA inventory file that contains installation settings for KUMA service
deployment. This file is located on the administrator host.
# The parameter value must be a Linux file path or Base64-encoded file content.
- name: inventory
  source:
    value: "/home/user/inventory.yml"
# Path to the Kaspersky Endpoint Detection and Response license key. This file is
located on the administrator host.
# The parameter value must be a Linux file path or Base64-encoded file content.
- name: license
  source:
    value: "/home/user/license.key"
# Domain name. The parameter value must meet the requirements for second-level domain
naming.
# The service host name and domain name are parts of FQDNs of the Kaspersky EDR
services.
# Default values of service host names: nwc_host—"console", flow_host—"console",
hydra_host—"console", login_host—"console", ksc_host—"admsrv", console_host—"console",
api_host—"api", kuma_host—"kuma", monitoring_host—"monitoring".
# Custom device names can be specified in the configuration file.
# Example: console.smp.local is the FQDN of the service that provides access to the
OSMP Console. This FQDN consists of the 'console_host' and 'smp_domain' parameter
values.
- name: smp_domain
  source:
    value: "smp.local"
# List of host names of the Kaspersky EDR services for which a self-signed or user
certificate must be generated.
# The parameter value must be a list of host names, separated by spaces. If custom host
names are not specified, the default host names are used.
- name: pki_host_list
  source:
    value: "admsrv api console kuma monitoring"
- name: autodeploy_plan
  source:
    value: "edr"
# The user name of the account used to view OSMP metrics through the Grafana tool.
# The user name must be 1 to 30 characters long.
# It can contain lowercase letters ('a' to 'z'), digits ('0' to '9'), and special
characters (_ - .).
```

```
# A user name must begin with a letter and may not contain spaces or the "@" character.
- name: grafana_admin_user
  source:
    value: "grafana_admin_user"
# The password of the account used to view OSMP metrics through the Grafana tool.
# The password must be 8 to 256 characters long.
# It can contain only ASCII characters: upper or lower case letters (A-Z, a-z),
numerals (0-9), and special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \
` ~ " ( ) ;).
- name: grafana_admin_password
  source:
    value: "grafana_admin_password"
```

For correct function of KDT with the configuration file, add an empty line at the end of the file.

The `nodes` section of the configuration file contains the target host parameters that are listed in the table below.

Nodes section

Parameter name	Required	Description
`desc`	Yes	The node name. The value must comply with the following rules: • The node name must be 1 to 63 characters long. • The node name can contain the following characters: • Uppercase ASCII letters (A–Z) • Lowercase ASCII letters (a–z) • Numbers (0–9) • Hyphen (-) All cluster nodes must have unique names. This requirement is one of the prerequisites for the installation of Kaspersky EDR Expert and is verified by KDT.
`type`	Yes	The node type. For the target host, set the `type` parameter to `primary-worker` to enable the **single-node deployment**. In this case, the target host will act as the primary and worker nodes.
`host`	Yes	The IP address of the node. The primary worker node must be included in the same subnet as the Kubernetes cluster gateway. The node requires IPv4 addressing. KDT automatically disables IPv6 on the cluster nodes.
`kuma_role`	No	The KUMA service that you can specify for installation on the worker node. KUMA services (collectors, correlators, and storages) can be installed entirely inside the cluster on worker nodes, entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the Kubernetes cluster. If all KUMA services will be installed inside the cluster, set the `inventory` parameter to `/dev/null`. For **single-node deployment**, leave this parameter empty, because all services will be installed on a single node.
`user`	Yes	The user name of the account created on the target host and used for connection to the node by KDT. The value must comply with the following rules: • The user name must be 1 to 31 characters long. • The user name can contain the following characters: • Lowercase letters (a–z) • Numbers (0–9) • Underscore (_), hyphen (-)
`password`	No	The password for connecting to the node. Can be used instead of the SSH key specified by the `ssh_pk` parameter.

Other installation parameters are listed in the `parameters` section of the configuration file and are described in the table below.

Parameters section

Parameter name	Required	Description

`psql_dsn`	Yes	The connection string for accessing the DBMS that is installed and configured outside the Kubernetes cluster.
		Specify this parameter as follows:
		`psql_dsn=postgres://<dbms_username>:<password>@<fqdn>:<port>`
		where:
		• `dbms_username` —The user name of a privileged internal DBMS account. This account is granted permissions to create databases and other DBMS accounts. By using this privileged DBMS account, the databases and other DBMS accounts required for the Kaspersky EDR Expert components will be created during the deployment.
		• `password` —The password of the privileged internal DBMS account.
		• `fqdn:port` —The FQDN and connection port of the target host on which the DBMS is installed.
		If your DBMS is installed on the same host as a Kubernetes cluster node, do not use `localhost` or `127.0.0.1` as the DBMS address in the `psql_dsn` parameter. Use the host's IP address that is reachable over the cluster network (not a loopback address).
		To use a highly available cluster, specify this parameter as follows:
		`psql_dsn=postgres://<dbms_username>:<password>@<fqdn1>:<port>,<fqdn2>:<port>,<fqdn3>:<port>`
		To use Corosync/Pacemaker, specify this parameter with a virtual IP as follows:
		`psql_dsn=postgres://postgres:pass!@<virtual ip>:<port>`
		The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.
		Symbols that must be replaced in the `psql_dsn` parameter value:
		• Whitespace → `%20`
		• ! → `%21`
		• # → `%23`
		• % → `%25`
		• & → `%26`
		• / → `%2F`
		• : → `%3A`
		• = → `%3D`
		• ? → `%3F`
		• @ → `%40`
		• [→ `%5B`
		•] → `%5D`
		Refer to the PostgreSQL connection string article for details.

`nwc-language`	Yes	The language of the OSMP Console interface is specified by default. After installation, you can change the OSMP Console language. Possible parameter values: • `enUS` (default value) • `ruRu` The default value is used if you do not specify this parameter in the configuration file.
`ingress_ip`	Yes	The reserved static IPv4 address of the Kubernetes cluster gateway. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. The gateway must be included in the same subnet as the primary worker node. The Kubernetes cluster gateway requires IPv4 addressing. KDT automatically disables IPv6 on the cluster nodes. The value of this parameter cannot be the IP address of the same host on which the deployment is being performed.
`ssh_pk`	Yes	The path to the private part of the SSH key located on the administrator host and used for connection to the primary worker node and nodes with the KUMA services (collectors, correlators, and storages) by using KDT. The parameter value must be a Linux file path or Base64-encoded file content.

Parameter name	Required	Description
admin_password	Yes	The admin_password parameter specifies the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The default user name of this account is "admin." The Main administrator role is assigned to this user account. The password must comply with the following rules: • The user password cannot have fewer than 10 or more than 256 characters. • The password must contain characters from at least three of the groups listed below: • Uppercase letters (A–Z) • Lowercase letters (a–z) • Numbers (0–9) • Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;) • The password must not contain any whitespaces, or the ".@" combination. When you specify the admin_password parameter value manually (not by the Deployment wizard), make sure that this value meets the YAML standard requirements for values in strings: • The parameter value containing special characters must be enclosed in single quotes. • Any single quote ' inside the parameter value must be doubled to escape this single quote. Example: the user account password Any_pass%1234'5678"90 must be specified as the value 'Any_pass%1234''5678"90' of the admin_password parameter.
low_resources	Yes	The parameter indicating that Kaspersky EDR Expert is installed on the target host with limited computing resources. Possible parameter values: • true—Installation with limited computing resources (for single-node deployment) • false—Standard installation For the **single-node deployment**, set the low_resources parameter to true so that Kaspersky EDR Expert components will require less memory and CPU resources. Also, if you enable this parameter, 4 GB of free disk space will be allocated to install KUMA Core on the target host.
openbao_ha_mode	Yes	The parameter that indicates whether to run the secret storage in the High Availability (HA) mode. Possible parameter values: • true • false For the **single-node deployment**, set the openbao_ha_mode parameter to false.
openbao_standalone	Yes	The parameter that indicates whether to run the secret storage in the standalone mode. Possible parameter values: • true • false For the **single-node deployment**, set the openbao_standalone parameter value to true.
default_class_replica_count	Yes	The number of disk volumes that are used to store the service data of Kaspersky EDR Expert components and KDT. The default value is 3. For the **single-node deployment**, set the default_class_replica_count parameter value to 1.
core_disk_request	Yes	The parameter that specifies the amount of disk space for the operation of KUMA Core. If you do not specify the core_disk_request parameter and the low_resources parameter is set to false or is not specified, the default amount of disk space for the operation of KUMA Core is 100 GB. If you do not specify the core_disk_request parameter and the low_resources parameter is set to true, the default amount of disk space for the operation of KUMA Core is 4 GB. You can change the core_disk_request parameter later, after the application deployment.

Parameter name	Required	Description
`metrics_disk_request`	Yes	The parameter that specifies the amount of disk space for the operation of the Metrics service. If you do not specify the `metrics_disk_request` parameter and the `low_resources` parameter is set to `false` or is not specified, the default amount of disk space for the operation of the Metrics service is 80 GB. If you do not specify the `metrics_disk_request` parameter and the `low_resources` parameter is set to `true`, the default amount of disk space for the operation of the Metrics service is 4 GB. You can change the `metrics_disk_request` parameter later, after the application deployment.
`inventory`	Yes	The path to the KUMA inventory file located on the administrator host. The inventory file contains installation parameters for deployment of the KUMA services that are not included in the Kubernetes cluster. The parameter value must be a Linux file path or Base64-encoded file content. If all KUMA services will be installed inside the cluster, set the `inventory` parameter to `/dev/null`.
`host_inventory`	No	The path to the additional KUMA inventory file located on the administrator host. This file contains the installation parameters used to partially add or remove hosts with the KUMA services. The parameter value must be a Linux file path or Base64-encoded file content. If you perform an initial deployment of Kaspersky EDR Expert or run a custom action that requires configuration file, leave the default parameter value (`/dev/null`).
`license`	No	The path to the KUMA license key located on the administrator host. The parameter value must be a Linux file path or Base64-encoded file content. You can upload the license key or specify the activation code once you log in to OSMP after deployment is complete.

`nwc_host`
`flow_host`
`hydra_host`
`login_host`
`ksc_host`
`console_host`
`api_host`
`kuma_host`
`monitoring_host`
`xdr_edr_ingress_host`
	Yes	The host name that is used in the FQDNs of the public Kaspersky EDR Expert services. The service host name and domain name (the `smp_domain` parameter value) are parts of the service FQDN.
		If custom host names are not specified, the following default host names are used:
		• `nwc_host—"console"`
		• `flow_host—"console"`
		• `hydra_host—"console"`
		• `login_host—"console"`
		• `ksc_host—"admsrv"`
		• `console_host—"console"`
		• `api_host—"api"`
		• `kuma_host—"kuma"`
		• `monitoring_host—"monitoring"`
		• `xdr_edr_ingress_host—"agentserver"`

`smp_domain`	Yes	The domain name that is used in the FQDNs of the public Kaspersky EDR Expert services. The parameter value must satisfy the naming requirements for domains up to the fourth level. The service host name and domain name are parts of the service FQDN. For example, if the value of the `console_host` variable is `console`, and the value of the `smp_domain` variable is `smp.local`, then the full name of the service that provides access to the OSMP Console is `console.smp.local`.
`pki_host_list`	Yes	The list of host names of the public Kaspersky EDR Expert services for which a self-signed or custom certificate is to be generated. The parameter value must be a list of host names, separated by spaces.
`intermediate_enabled`	No	The parameter that indicates whether to use the custom intermediate certificate instead of the self-signed certificates for the public Kaspersky EDR Expert services. Possible parameter values: • `true`—Use custom intermediate certificate. • `false`—Use self-signed certificates (default value).

Parameter name	Required	Description
`intermediate_bundle`	No	The path to the custom intermediate certificate used to work with public Kaspersky EDR Expert services. Specify this parameter if the `intermediate_enabled` parameter is set to `true`. The parameter value must be a Linux file path or Base64-encoded file content. The validity period for the custom intermediate certificate must be 399 days or more.

`admsrv_bundle`
`api_bundle`
`console_bundle`
`kuma_bundle`
`monitoring_bundle`
	No	The paths to the custom leaf certificates used to work with the corresponding public Kaspersky EDR Expert services: `<admsrv_host>.<smp_domain>`, `<api_host>.<smp_domain>`, `<kuma_host>.<smp_domain>`, `<monitoring_host>.<smp_domain>`, and `<console_host>.<smp_domain>`. The parameter values must be a Linux file path or Base64-encoded file content.
		If you want to specify the custom leaf certificates, set the `intermediate_enabled` parameter to `false` and do not specify the `intermediate_bundle` parameter and the `pki_host_list` parameter.

`ksc_state_size`	Yes	The amount of free disk space allocated to store the Administration Server data (updates, installation packages, and other internal service data). Measured in gigabytes, specified as "<amount>Gi". The required amount of free disk space depends on the number of managed devices and other parameters, and can be calculated. The default value is 30 GB. This value is used if you do not specify this parameter in the configuration file.
`prometheus_size`	Yes	The amount of free disk space allocated to store metrics. Measured in gigabytes, specified as "<amount>GB". The minimum recommended and default value is 5 GB. The default value is used if you do not specify this parameter in the configuration file.
`grafana_admin_user`	No	The user name of the account used to view OSMP metrics through the Grafana tool. The value must comply with the following rules: • The user name must be 1 to 30 characters long. • The user name can contain the following characters: • Lowercase letters (a–z) • Numbers (0–9) • Special characters (_ - .) • The user name must start with a letter. • The user name must not contain either whitespaces or the "@" symbol.
`grafana_admin_password`	No	The password of the account used to view OSMP metrics through the Grafana tool. The password must comply with the following rules: • The user password cannot have fewer than 8 or more than 256 characters. • The password must contain characters from the groups listed below: • Uppercase letters (A–Z) • Lowercase letters (a–z) • Numbers (0–9) • Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)
`loki_size`	Yes	The amount of free disk space allocated to store OSMP logs. Measured in gigabytes, specified as "<amount>Gi". The minimum recommended and default value is 40 GB. The default value is used if you do not specify this parameter in the configuration file.
`loki_retention_period`	Yes	The storage period of OSMP logs after which logs are automatically removed. The default value is 72 hours (set the parameter value in the configuration file as "<time in hours>h". For example, "72h"). The default value is used if you do not specify this parameter in the configuration file.
`file_storage_cp`	No	The amount of free disk space allocated to store data of the component for working with response actions. Measured in gigabytes, specified as "<amount>Gi". The minimum recommended value is 20 GB.

Parameter name	Required	Description
`psql_tls_off`	No	The parameter that indicates whether to encrypt the traffic between the Kaspersky EDR Expert components and the DBMS by using the TLS protocol. If the DBMS is installed outside the cluster, TLS encryption is disabled by default (the default value is `true`). Possible parameter values: • `true`—Do not encrypt the traffic (default value). • `false`—Encrypt the traffic.
`psql_trusted_cas`	No	The path to the PEM file that can contain the TLS certificate of the DBMS server or a root certificate from which the TLS server certificate can be issued. The parameter value must be a Linux file path or Base64-encoded file content. Specify the `psql_trusted_cas` parameter if the DBMS will be installed and configured on a separate server and traffic encryption is enabled (`psql_tls_off` is set to `false`).
`proxy_enabled`	No	The parameter that indicates whether to use the proxy server to connect the Kaspersky EDR Expert components to the internet. If the host on which Kaspersky EDR Expert is installed has internet access, you can also provide internet access for the operation of Kaspersky EDR Expert components (for example, Administration Server) and for specific integrations, both Kaspersky and third-party. To establish the proxy connection, you must also specify the proxy server parameters in the Administration Server properties. Possible parameter values: • `true`—Proxy server is used. • `false`—Proxy server is not used (default value).
`proxy_addresses`	No	The IP address of the proxy server. If the proxy server uses multiple IP addresses, specify these addresses separated by a space (for example, "`0.0.0.0 0.0.0.1 0.0.0.2`"). Specify this parameter if the `proxy_enabled` parameter is set to `true`.
`proxy_port`	No	The number of the port through which the proxy connection will be established. Specify this parameter if the `proxy_enabled` parameter is set to `true`.
`console_port`	No	The parameter that specifies the customized number of the port used to connect to the OSMP console server. The default value is 443.
`as_smp_port`	No	The parameter that specifies the customized number of the port used by Endpoint Agents to connect to the agentserver component. The default value is 443.
`kuma_gateway_telemetry_listener_port`	No	The parameter that specifies the customized number of the port used for sending the telemetry. The default value is 443.
`trace_level`	No	The verbosity level of Administration Server trace files. Traces are written during the Administration Server operation. The default value is 0, no traces are written. Possible parameter values: 0–5. The higher the parameter value, the more detailed the trace details.
`ansible_extra_flags`	No	The verbosity level of logs of the KUMA Core and KUMA services deployment that is performed by KDT. Possible parameter values: • `-v` • `-vv` • `-vvv` • `-vvvv` As the number of "v" letters in the flag increases, logs become more detailed. If this parameter is not specified in the configuration file, the standard component installation logs are saved.
`incident_attachments_max_count_limit`	No	The number of files that you can attach to the incident. The default value is `100`.
`incident_attachments_max_size_limit`	No	The total size of files attached to the incident. Measured in bytes. Specified without units of measurement. The default value is `26214400`.

Parameter name	Required	Description
`ignore_precheck`	No	The parameter indicating whether to check the hardware, software, and network configuration of the Kubernetes cluster nodes for compliance with the prerequisites for installing the solution before the deployment. Possible parameter values: • `true` —Skip the pre-checks. • `false` —Perform the pre-checks (default value).
`airgap_mode`	No	The parameter indicating whether to perform the APT package manager pre-check and update the package cache. This allows deploying Kaspersky EDR Expert in an air-gapped environment. Possible parameter values: • `true` —Skip the pre-check and the package cache update. • `false` —Perform the pre-check and update the package cache (default value).
`grafana_smtp_host`	No	SMTP server address for Grafana, used to send email notifications about Kubernetes cluster health events. Specify this parameter in the `<host>:<port>` format, for example, `localhost:25`.
`grafana_smtp_user`	No	User name for authentication on the SMTP server.
`grafana_smtp_password`	No	Password for authentication on the SMTP server.
`grafana_smtp_bundle`	No	File containing the X.509 certificate chain used for verifying TLS connection to the SMTP server.
`grafana_smtp_skip_verify`	No	The parameter that indicates whether to skip TLS certificate verification of the SMTP server. Possible parameter values: • `true` —Skip TLS certificate verification. • `false` —Perform TLS certificate verification (default value).
`grafana_smtp_from_address`	No	Email address of the sender, which will appear in the From field when sending email notifications.
`grafana_smtp_from_name`	No	Display name of the sender in email notifications.
`grafana_smtp_ehlo_identity`	No	Identifier used in the EHLO command when connecting to the SMTP server.
`grafana_starttls_policy`	No	Policy for using STARTTLS when connecting to the SMTP server. Possible parameter values: • `OpportunisticStartTLS` —Use STARTTLS if the SMTP server supports it; otherwise, connect to the SMPT server without encryption. • `MandatoryStartTLS` —Require STARTTLS; fail if the SMTP server does not support it. • `NoStartTLS` —Do not use STARTTLS; connect to the SMPT server without encryption. • `empty` —Use STARTTLS if the SMTP server supports it; otherwise, connect to the SMPT server without encryption (default value).
`grafana_smtp_enable_tracing`	No	The parameter that indicates whether to enable SMTP connection tracing for debugging email sending. Possible parameter values: • `true` —Enable SMTP connection tracing. • `false` —Disable SMTP connection tracing (default value).

Parameter name	Required	Description
`autodeploy_plan`	No	The parameter that indicates whether to deploy the KUMA services for Kaspersky EDR or for Kaspersky NGFW. Possible parameter values: • `edr`—Deploy the KUMA services for OSMP and for Kaspersky EDR inside the Kubernetes cluster (default value). • `ngfw`—Deploy the KUMA services for OSMP and for Kaspersky NGFW inside the Kubernetes cluster. Additionally, the predefined collector **[OOTB] Kaspersky NGFW** will be installed on the first host from the host list specified in the `kuma_collector` parameter of the KUMA inventory file. • `none`—Do not deploy the KUMA services for Kaspersky EDR or Kaspersky NGFW. Use this value for Kaspersky EDR Expert deployment without KUMA services for Kaspersky EDR and Kaspersky NGFW or for Kaspersky EDR Expert restoration from a backup. If you use the `edr` or `ngfw` values for Kaspersky EDR Expert restoration, this may lead to conflicts between the deployed services and the services stored in a backup.
`tokenhub_access_token`	No	The lifetime of an access token. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`1h10m`" or "`2h`". The minimum possible value is `5m` and the maximum is `2h`. The default value is `1h`. This value is used if you do not specify this parameter in the configuration file. You can change the `tokenhub_access_token` parameter later, after the application deployment.
`tokenhub_refresh_token`	No	The lifetime of a refresh token that is used for getting a new access token. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`24h`" or "`1240h30m`". The minimum possible value is `12h` and the maximum is `4320h`. The default value is `24h`. This value is used if you do not specify this parameter in the configuration file. You can change the `tokenhub_refresh_token` parameter later, after the application deployment.
`credentials_session_ttl`	No	The maximum single sign-on session idle time. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`24h`" or "`1h30m`". The minimum possible value is `5m` and the maximum is `96h`. The default value is `1h`. This value is used if you do not specify this parameter in the configuration file. You can change the `credentials_session_ttl` parameter later, after the application deployment.

Connecting Endpoint Agents through a proxy node

This section describes a deployment scenario for Kaspersky EDR Expert Endpoint Agents and the servers to which they transfer data when located across different networks. This approach simplifies network configuration, while ensuring reliable connectivity between Endpoint Agents and servers.

In this scenario, data from Endpoint Agents is routed through an intermediate proxy node. This allows for a single network connection between the proxy node and the solution, rather than establishing multiple connections from each Endpoint Agent to the solution. This approach can be applied to both single-node and multi-node deployments of Kaspersky EDR Expert.

The section describes setting up an Nginx proxy server on a Linux device. You may use a different proxy server with mTLS Passthrough support and a different operating system if needed.

This scenario uses example FQDNs of the public Kaspersky EDR Expert services specified during the solution deployment (`<agentserver>.<smp_domain>`, `<ksc_host>.<smp_domain>`, and `<kuma_host>.<smp_domain>`), file paths, and directory paths. You should replace these with values that match your infrastructure.

If you changed the port used by Endpoint Agents to connect to the agentserver component, you should also specify the new port number in the Nginx configuration file.

Deployment stages

Deployment with configuration of proxying data from Endpoint Agents through an intermediate proxy node involves several stages:

1. **Installing and configuring Nginx**

   Install Nginx proxy server on a server located in the same network (subnet) where the Endpoint Agents are located.

   1. Run the following commands:

      ```
      sudo apt update
      sudo apt install nginx-full
      ```

   2. Ensure that the `stream`, `stream_ssl`, and `stream_ssl_preread` modules are included in Nginx and loaded:

      ```
      nginx -V 2>&1 | grep -E 'stream|stream_ssl|stream_ssl_preread
      ```

      The command output must include the `stream`, `stream_ssl`, and `stream_ssl_preread` modules.

      Nginx proxy server with the `stream`, `stream_ssl`, and `stream_ssl_preread` modules is installed on the server.

   3. Ensure that the Nginx configuration file (by default, /etc/nginx/nginx.conf) contains a `stream {}` block, and in this block, the `stream.d` directory connection is configured. If the `stream` block is missing, add this block at the same level as the `http {}` block:

      ```
      /etc/nginx/nginx.conf
      ...
      http {
       ...
      }

      stream {
       include /etc/nginx/stream.d/*.conf;
      }
      ```

   4. Create or edit the Nginx configuration file in the CONF format in the /etc/nginx/stream.d/ directory according to the template below.

      If the /etc/nginx/stream.d/ directory does not exist, create it.

      Path and name of the Nginx configuration file: /etc/nginx/stream.d/asproxy.conf.

      Template variables (use values corresponding to your infrastructure):

FQDN host names of the public Kaspersky EDR Expert services with which Endpoint Agent communicates:

- `<agentserver>.<smp_domain>` – FQDN of the component that allows performing response actions on assets through agent integration.
- `in.<some_symbols>.<kuma_host>.<smp_domain>` – FQDN of the target backend server for telemetry.

  How to obtain the server address

  1. In the main menu, go to **Monitoring → Resources & services → Work with services → Active services**.
  2. In the list of services, find the **[OOTB] Kaspersky EDR** service, select it and click **Deploy** in the menu.
  3. In the opened window, copy the server address from the **API gateway URL** field.

     The server name should follow this format: `in.blh4zjhm4edckdt8qyprkpm2b.kuma_host.smp_domain`.
- `<ksc_host>.<smp_domain>` – FQDN of the target backend server for agent management. It can be FQDN of the OSMP component for Endpoint Agent management or FQDN of the secondary KSC server.

IP addresses:

- `<ingress_ip>` – IP address of the OSMP cluster ingress.
- `<ksc_ip>` – IP address of the secondary OSMP or KSC server (if it is used).

There are three ways to connect Endpoint Agents:

- Via policy. In this case, configure proxying for communication between Endpoint Agent and server on the Nginx proxy server: specify `<ksc_host>.<smp_domain>` and TCP 13000, TCP 14000, and TCP 13292 ports.

  Example

```
# ----- SNI → upstream -------------------------------------------------
map_hash_bucket_size 256;

map $ssl_preread_server_name $upstream_osmp {
 hostnames;
 <agentserver>.<smp_domain> osmp-ingress;
 in.<some_symbols>.<kuma_host>.<smp_domain> osmp-ingress;
 <ksc_host>.<smp_domain> ksc_ingress;
 default deny-backend;
}

# ----- Backends-------------------------------------------------------
upstream osmp-ingress {
 server <ingress_ip>:443;
}
upstream ksc-ingress {
 server <ingress_ip>:13000;
 server <ingress_ip>:14000;
 server <ingress_ip>:13292;
}
upstream deny-backend {
 server 127.0.0.1:1;
}

# ----- Logging--------------------------------------------------------
log_format basic '$remote_addr [$time_local] '
 '$protocol $status $bytes_sent $bytes_received '
 '$session_time "$upstream_addr" '
 'sni="$ssl_preread_server_name" '
```

```
 '"$upstream_connect_time"';
access_log /var/log/nginx/passthrough_access.log basic;
error_log /var/log/nginx/passthrough_error.log notice;

# ----- Timeouts----------------------------------------
preread_timeout 10s;
proxy_connect_timeout 5s;
proxy_timeout 30s;

# ----- Server (port 443) ------------------------------------------
server {
 listen 443; # regular TCP-port, no TLS termination
 listen 13000;
 listen 14000;
 listen 13292;
 ssl_preread on; # reads only ClientHello
 proxy_pass $upstream_osmp; # var from map
}
```

- Via policy in the secondary OSMP or KSC server. In this case, configure proxying for communication between Endpoint Agent and server on the Nginx proxy server: specify `<ksc_host>.<smp_domain>` and TCP 13000, TCP 14000, and TCP 13292 ports.

  Example

```
# ----- SNI → upstream ---------------------------------------------------
map_hash_bucket_size 256;

map $ssl_preread_server_name $upstream_osmp {
 hostnames;
 <agentserver>.<smp_domain> osmp-ingress;
 in.<some_symbols>.<kuma_host>.<smp_domain> osmp-ingress;
 <ksc_host>.<smp_domain> ksc_ingress;
 default deny-backend;
}

# ----- Backends---------------------------------------------------------
upstream osmp-ingress {
 server <ingress_ip>:443;
}
upstream ksc-ingress {
 server <ksc_ip>:13000;
 server <ksc_ip>:14000;
 server <ksc_ip>:13292;
}
upstream deny-backend {
 server 127.0.0.1:1;
}

# ----- Logging----------------------------------------------------------
log_format basic '$remote_addr [$time_local] '
 '$protocol $status $bytes_sent $bytes_received '
 '$session_time "$upstream_addr" '
 'sni="$ssl_preread_server_name" '
 '"$upstream_connect_time"';
access_log /var/log/nginx/passthrough_access.log basic;
error_log /var/log/nginx/passthrough_error.log notice;

# ----- Timeouts----------------------------------------
preread_timeout 10s;
proxy_connect_timeout 5s;
proxy_timeout 30s;

# ----- Server (port 443) ------------------------------------------
server {
 listen 443; # regular TCP-port, no TLS termination
 listen 13000;
 listen 14000;
 listen 13292;
 ssl_preread on; # reads only ClientHello
 proxy_pass $upstream_osmp; # var from map
}
```

- Locally. In this case, `<ksc_host>.<smp_domain>` and TCP ports on the Nginx proxy server do not need to be configured. For more information, see step 3 of this scenario.

Example

```
# ----- SNI → upstream -------------------------------------------------
map_hash_bucket_size 256;

map $ssl_preread_server_name $upstream_osmp {
 hostnames;
 <agentserver>.<smp_domain> osmp-ingress;
 in.<some_symbols>.<kuma_host>.<smp_domain> osmp-ingress;
 default deny-backend;
}

# ----- Backends-------------------------------------------------------
upstream osmp-ingress {
 server <ingress_ip>:443;
}

upstream deny-backend {
 server 127.0.0.1:1;
}

# ----- Logging--------------------------------------------------------
log_format basic '$remote_addr [$time_local] '
 '$protocol $status $bytes_sent $bytes_received '
 '$session_time "$upstream_addr" '
 'sni="$ssl_preread_server_name" '
 '"$upstream_connect_time"';
access_log /var/log/nginx/passthrough_access.log basic;
error_log /var/log/nginx/passthrough_error.log notice;

# ----- Timeouts-------------------------------------------
preread_timeout 10s;
proxy_connect_timeout 5s;
proxy_timeout 30s;

# ----- Server (port 443) ---------------------------------------------
server {
 listen 443; # regular TCP-port, no TLS termination
 ssl_preread on; # reads only ClientHello
 proxy_pass $upstream_osmp; # var from map
}
```

5. Check the Nginx configuration:

   ```
   nginx -t
   ```

   Command output when the test is successful:

   ```
   nginx: the configuration file /etc/nginx/nginx.conf syntax is ok
   nginx: configuration file /etc/nginx/nginx.conf test is successful
   ```

6. Restart Nginx to apply the changes in the configuration file:

   ```
   nginx -s reload
   ```

Installed Nginx proxy server is configured for Endpoint Agent data proxying.

2 Configuring network connectivity between the Nginx proxy node and Kaspersky EDR Expert

1. Configure network connectivity. Ensure that network settings (firewall, routing) allow outgoing connections from the proxy node to the OSMP platform and secondary OSMP or KSC server over the TCP 13000, TCP 14000, TCP 13292, and TCP 443 ports.

2. Configure the network so that requests from Endpoint Agent nodes to `<smp_domain>` are routed to the proxy node.

3 Configuring Kaspersky Endpoint Security for Windows Endpoint Agents to work through a proxy node

1. Configure network connectivity. Ensure that network settings (firewall, routing) allow outgoing connections from the Endpoint Agents to the proxy node over the TCP 13000, TCP 14000, TCP 13292, and TCP 443 ports.
2. Download the following OSMP certificates:
   - certificate.pem – response server certificate
   - certificate.pfx – Endpoint Agent certificate
   - [OOTB] Kaspersky EDR – telemetry server certificate
3. Copy certificate files to the server where Endpoint Agent is installed (C:\Users\TestUser\ in the example in this section).
4. Open the command prompt `cmd.exe` with administrator rights.
5. Navigate to the directory containing the executable file of Endpoint Agent and run the following command:

```
./avp.com EDREXPERTONPREM `
/SET /mode=EDRExpertOnPrem `
/servers=<agentserver>.<smp_domain>:443 `
/server-certificate=C:\Users\TestUser\certificate.pem `
/client-certificate=C:\Users\TestUser\certificate.pfx `
/client-certificate-password=client certificate password`
/telemetry-servers=in.blh4zjhm4edckdt8qyprkpm2b.<kuma_host>.<smp_domain>:443 `
/telemetry-server-certificate='C:\Users\TestUser\[OOTB] Kaspersky EDR' `
/telemetry-client-certificate=C:\Users\TestUser\certificate.pfx `
/telemetry-client-certificate-password=client certificate password
```

6. Start Kaspersky EDR Expert if the solution is not already started:

```
./avp.com start EDREXPERTONPREM
```

For more information on configuring an Endpoint Agent using the command line, see the Kaspersky Endpoint Security documentation.

Specifying the installation parameters by using the Configuration wizard

For the multi-node and single-node Kaspersky EDR Expert deployment, you have to prepare a configuration file that contains the installation parameters of the Kaspersky EDR Expert components. The Configuration wizard allows you to specify the installation parameters that are required to deploy Kaspersky EDR Expert, and then generate the resulting configuration file. Optional installation parameters have default values, and they are not to be specified in the Configuration wizard. You can manually add these parameters to the configuration file to override their default values.

Prerequisites

Before specifying the installation parameters by using the Configuration wizard, you must install a database management system on a separate server that is located outside the Kubernetes cluster, perform all preparatory steps necessary for the administrator, target hosts (depending on the multi-node or single-node deployment option), and KUMA hosts.

Process

To specify the installation parameters by using the Configuration wizard:

1. Unpack the bin.tar.gz: archive with the KDT utility on the administrator host by using the following command:

   `tar -xvzf bin.tar.gz`

2. On the administrator host where the KDT utility is located, run the Configuration wizard by using the following command:

   `./bin/kdt wizard -k <path_to_transport_archive> -o <path_to_configuration_file>`

   where:

   - `<path_to_transport_archive>` is the path to the transport archive.
   - `<path_to_configuration_file>` is the path where you want to save the configuration file and the configuration file name.

   The Configuration wizard prompts you to specify the installation parameters. The list of the installation parameters that are specific for the multi-node and single-node deployment differs.

   If you do not have the Write permissions on the specified directory or a file with the same name is located in this directory, an error occurs and the wizard terminates.

3. Enter the number of primary nodes.

   Possible values:

   - 1—Single-node deployment or multi-node deployment.
   - 2 or more—Multi-node deployment.

   The Kubernetes cluster can have multiple primary nodes only in the case of a multi-node deployment.

4. Enter the IPv4 address of a primary node (or a target node, if you will perform the single-node deployment). This value corresponds to the `host` parameter of the configuration file.

   This node must be included in the same subnet as the Kubernetes cluster gateway.

5. Enter the user name of the account used for connection to the primary node by KDT (the `user` parameter of the configuration file).

The value must comply with the following rules:

- The user name must be 1 to 31 characters long.
- The user name can contain the following characters:
  - Lowercase letters (a–z)
  - Numbers (0–9)
  - Underscore (_), hyphen (-)

6. Enter the path to the private part (without .pub extension in filename) of the SSH key, which is located on the administrator host and is used for connection to the primary node by KDT (the `ssh_pk` parameter of the configuration file).

   The parameter value must be a Linux file path or Base64-encoded file content.

7. Enter the number of worker nodes.

   Possible values:

   - 0—Single-node deployment. In this case, steps 8–10 will be skipped.
   - 3 or more—Multi-node deployment.

   This step defines the option of deploying Kaspersky EDR Expert. If you want to perform single-node deployment, the following parameters specific for this deployment option will take the default values:

   - `type—primary-worker`
   - `low_resources—true`
   - `openbao_ha_mode—false`
   - `openbao_standalone—true`
   - `default_class_replica_count—1`

8. For each worker node, enter the IPv4 address (the `host` parameter of the configuration file).

   All nodes must be included in the same subnet as the Kubernetes cluster gateway.

9. For each worker node, enter the user name used for connection to the worker node by KDT (the `user` parameter of the configuration file).

   The value must comply with the following rules:

   - The user name must be 1 to 31 characters long.
   - The user name can contain the following characters:
     - Lowercase letters (a–z)
     - Numbers (0–9)
     - Underscore (_), hyphen (-)

10. For each worker node, enter the path to the SSH key, which is located on the administrator host and is used for connection to the worker nodes by KDT (the `ssh_pk` parameter of the configuration file).

    The parameter value must be a Linux file path or Base64-encoded file content.

11. Specify whether the load balancing is required:

    - 1—If you have multiple primary nodes and an external load balancer is required.
    - 0—If you have multiple primary nodes but you do not want to use an external load balancer. In this case, worker nodes will act as the load balancer.
    - Press **Enter** to skip this step. In this case, steps 12–14 will be skipped.

12. Enter the IPv4 address of an external load balancer. This value corresponds to the `host` parameter of the configuration file.

13. Enter the user name of the account used for connection to the external load balancer by KDT (the `user` parameter of the configuration file).

    The value must comply with the following rules:

    - The user name must be 1 to 31 characters long.
    - The user name can contain the following characters:
        - Lowercase letters (a–z)
        - Numbers (0–9)
        - Underscore (_), hyphen (-)

14. For each balancer node enter the path to the SSH key, which is located on the administrator host and is used for connection to the worker nodes by KDT (the `ssh_pk` parameter of the configuration file).

    The parameter value must be a Linux file path or Base64-encoded file content.

15. Enter the connection string for accessing the DBMS that is installed and configured on a separate server (the `psql_dsn` parameter of the configuration file).

    Specify this parameter as follows: `postgres://<dbms_username>:<password>@<fqdn>:<port>`

    where:

    - `dbms_username`—The user name of a privileged internal DBMS account. This account is granted permissions to create databases and other DBMS accounts. By using this privileged DBMS account, the databases and other DBMS accounts required for the Kaspersky EDR Expert components will be created during the deployment.
    - `password`—The password of the privileged internal DBMS account.
    - `fqdn:port`—The FQDN and connection port of the target host on which the DBMS is installed.

    To use a highly available cluster, specify this parameter as follows:
    `psql_dsn=postgres://<dbms_username>:<password>@<fqdn1>:<port>,<fqdn2>:<port>,<fqdn3>:<port>`

    The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.

Symbols that must be replaced in the `psql_dsn` parameter value:

- Whitespace → `%20`
- ! → %21
- % → %25
- & → %26
- / → %2F
- : → %3A
- = → %3D
- ? → %3F
- @ → %40
- [→ %5B
-] → %5D

Refer to the PostgreSQL connection string article for details.

> The Configuration wizard specifies the installation parameters only for the deployment option with the DBMS installed on a separate server that is located outside the Kubernetes cluster.

16. Enter the IPv4 address of the Kubernetes cluster gateway (the `ingress_ip` parameter of the configuration file).

    The gateway must be included in the same subnet as all cluster nodes.

17. Enter the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation (the `admin_password` parameter of the configuration file).

    The default user name of this account is "admin." The Main administrator role is assigned to this user account.

    The password must comply with the following rules:

    - The user password cannot have fewer than 10 or more than 256 characters.
    - The password must contain characters from at least three of the groups listed below:
        - Uppercase letters (A–Z)
        - Lowercase letters (a–z)
        - Numbers (0–9)
        - Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)
    - The password must not contain any whitespaces, or the ".@" combination.

When you specify the `admin_password` parameter value manually (not by the Configuration wizard), make sure that this value meets the YAML standard requirements for values in strings:

- The parameter value containing special characters must be enclosed in single quotes.
- Any single quote ' inside the parameter value must be doubled to escape this single quote.

Example: the user account password `Any_pass%1234'5678"90` must be specified as the value `'Any_pass%1234''5678"90'` of the `admin_password` parameter.

18. Enter the path to the KUMA inventory file located on the administrator host (the `inventory` parameter of the configuration file).

    The KUMA inventory file contains the installation parameters for deployment of the KUMA services that are not included in the Kubernetes cluster. The parameter value must be a Linux file path or Base64-encoded file content.

    If KUMA services are installed in the Kubernetes cluster, specify the path `/dev/null`.

19. Enter the path to the private part of the SSH key located on the administrator host and used for connection to the worker node and nodes with the KUMA services (collectors, correlators, and storages) by using KDT (the `ssh_pk` parameter of the configuration file).

    The parameter value must be a Linux file path or Base64-encoded file content.

20. Enter the path to the LICENSE file of KUMA Core (the `license` parameter of the configuration file).

    The parameter value must be a Linux file path or Base64-encoded file content.

21. Enter the domain name that is used in the FQDNs of the public Kaspersky EDR Expert services (the `smp_domain` parameter of the configuration file).

    The parameter value must satisfy the naming requirements for domains up to the fourth level.

22. Enter the path to the user certificates used to work with the public Kaspersky EDR Expert services (the `intermediate_bundle` parameter of the configuration file).

    The parameter value must be a Linux file path or Base64-encoded file content.

    If you want to use self-signed certificates, press **`Enter`** to skip this step.

23. Enter `N` to skip specifying the `extended_incident_lifecycle` parameter. This is a service parameter. By default, the `extended_incident_lifecycle` parameter is disabled, do not change it.

24. Enter the user name of the account used to view OSMP metrics using the Grafana tool.

    The value must comply with the following rules:

    - The user name must be 1 to 30 characters long.
    - The user name must start with a letter.
    - The user name can contain the following characters:
        - Lowercase letters (a–z)
        - Numbers (0–9)
        - Underscore (_), hyphen (-), dot

25. Enter the password for the user name of the account used to view OSMP metrics using the Grafana tool.

The password must comply with the following rules:

- The user password cannot have fewer than 8 or more than 256 characters.
- The password must contain characters from at least three of the groups listed below:
  - Uppercase letters (A–Z)
  - Lowercase letters (a–z)
  - Numbers (0–9)
  - Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)

26. Check the specified parameters that are displayed in the numbered list.

    To edit the parameter, enter the parameter number, and then specify a new parameter value. Otherwise, press **Enter** to continue.

27. Press **Y** to save a new configuration file with the specified parameters or **N** to stop the Configuration wizard without saving.

The configuration file with the specified parameters is saved in the YAML format.

Other installation parameters are included in the configuration file, with default values. You can edit the configuration file manually before the deployment of Kaspersky EDR Expert.

If the terminal was closed or the session was interrupted while the Configuration wizard was running, the configuration file becomes corrupted. In this case, delete the corrupted configuration file and run the Configuration wizard again.

Installing Kaspersky EDR Expert

Kaspersky EDR Expert is deployed by using KDT. KDT automatically deploys the Kubernetes cluster within which the Kaspersky EDR Expert components and other infrastructure components are installed. The steps of the Kaspersky EDR Expert upgrade process do not depend on the selected deployment option.

If you need to install multiple Kubernetes clusters with Kaspersky EDR Expert instances, you can use the required number of contexts.

To install Kaspersky EDR Expert:

1. Unpack the downloaded distribution package with KDT on the administrator host.
2. Read the End User License Agreement (EULA) of KDT located in the distribution package with the Kaspersky EDR Expert components.

   When you start using KDT, you accept the terms of the EULA of KDT.

   You can read the EULA of KDT after the deployment of Kaspersky EDR Expert. The `license_kdt.txt` file is located in the `~/kaspersky_eula` directory of the user who runs the upgrade of Kaspersky EDR Expert.

3. During installation, KDT downloads missing packages from the OS repositories. Before installing Kaspersky EDR Expert, run the following command on the target hosts to make sure that the apt/yum cache is up-to-date.

   ```
   apt update
   ```

4. Restart target hosts.

5. On the administrator host, run the following commands to start deployment of Kaspersky EDR Expert by using KDT. Specify the path to the transport archive with the Kaspersky EDR Expert components and the path to the configuration file that you filled out earlier (installation parameter sets for the multi-node and single-node deployment differ).

   ```
   chmod +x kdt
   ```

   ```
   ./kdt apply -k <full_path_to_transport_archive> -i <full_path_to_configuration_file>
   ```

   You can install Kaspersky EDR Expert without prompting to read the terms of the EULA and the Privacy Policy of OSMP, if you use the `--accept-eula` flag. In this case, you must read the EULA and the Privacy Policy of OSMP before installing Kaspersky EDR Expert. The files are located in the distribution package with the Kaspersky EDR Expert components.

   If you want to read and accept the terms of the EULA and the Privacy Policy during the deployment, do not use the `--accept-eula` flag.

   If an error occurs during deployment of Kaspersky EDR Expert by using KDT, restart the deployment by specifying the path to the configuration file without the `-i` flag.

6. If you do not use the `--accept-eula` flag in the previous step, read the EULA and the Privacy Policy of OSMP. The text is displayed in the command line window. Press the space bar to view the next text segment. Then, when prompted, enter the following values:

   a. Enter `y` if you understand and accept the terms of the EULA.

      Enter `n` if you do not accept the terms of the EULA.

   b. Enter `y` if you understand and accept the terms of the Privacy Policy, and if you agree that your data will be handled and transmitted (including to third countries) as described in the Privacy Policy.

      Enter `n` if you do not accept the terms of the Privacy Policy.

      > To use Kaspersky EDR Expert, you must accept the terms of the EULA and the Privacy Policy.

   After you start the deployment, KDT checks whether the hardware, software, and network configuration of the Kubernetes cluster nodes meet the prerequisites for installing the solution. If all the strict pre-checks are successfully completed, KDT deploys the Kaspersky EDR Expert components within the Kubernetes cluster on the target hosts. Otherwise, the deployment will be interrupted. You can skip the pre-checks before the deployment, if needed (set the `ignore_precheck` installation parameter to `true`).

   Also KDT checks whether the required installation parameter are specified correctly. If the required parameters in the configuration file are missing or invalid, the deployment will be interrupted. The rules to be followed by the installation parameter values are specified in the configuration file templates (multinode.smp_param.yaml.template and singlenode.smp_param.yaml.template).

   > During the Kaspersky EDR Expert deployment, a new user is created on the primary Administration Server. To start configuring OSMP Console, this user is assigned the following roles: the EDR role of the Main administrator in the Root tenant and the Kaspersky Security Center role of the Main administrator.

7. View the installation logs of the Bootstrap component in the directory with the KDT utility and obtain diagnostic information about Kaspersky EDR Expert components, if needed.

8. Sign in to OSMP Console.

   The OSMP Console address is `https://<console_host>.<smp_domain>:443`.

   Addresses consist of the `console_host` and `smp_domain` parameter values specified in the configuration file.

Kaspersky EDR Expert is deployed on the target hosts. Install the KUMA services to get started with the solution.

Configuring internet access for the target hosts

If your organization's infrastructure uses the proxy server to access the internet, as well as you need to connect the target hosts to the internet, you must add the IP address of each target host to the `no_proxy` variable in the /etc/environment file before the Kaspersky EDR Expert deployment. This allows you to establish a direct connection of the target hosts to the internet and correctly deploy Kaspersky EDR Expert.

To configure internet access for the target hosts:

1. On the target host, open the /etc/environment file by using a text editor. For example, the following command opens the file by using the GNU nano text editor:

   ```
   sudo nano /etc/environment
   ```

2. In the /etc/environment file, add the IP address of the target host to the `no_proxy` variable separated by a comma without a space.

   For example, the `no_proxy` variable can be initially specified as follows:

   ```
   no_proxy=localhost,127.0.0.1
   ```

   You can add the IP address of the target host (192.168.0.1) to the `no_proxy` variable:

   ```
   no_proxy=localhost,127.0.0.1,192.168.0.1
   ```

   Alternatively, you can specify the subnet that includes the target hosts (in CIDR notation):

   ```
   no_proxy=localhost,127.0.0.1,192.168.0.0/24
   ```

3. Save the /etc/environment file.

4. Reboot the target host:

   ```
   reboot
   ```

After you add the IP addresses in the /etc/environment file to each target host and reboot them, you can continue preparing of the target hosts and further Kaspersky EDR Expert deployment.

Synchronizing time on machines

To configure time synchronization on machines:

1. Run the following command to install chrony:

   ```
   sudo apt install chrony
   ```

2. Configure the system time to synchronize with the NTP server:

   a. Make sure the virtual machine has internet access.

      If access is available, go to step b.

If internet access is not available, replace the current public sources (starting with `pool`) in the `/etc/chrony.conf` file with the name or IP address of your organization's internal NTP server.

b. Start the system time synchronization service by executing the following command:

```
sudo systemctl enable --now chrony
```

c. Wait a few seconds, and then run the following command:

```
sudo timedatectl | grep 'System clock synchronized'
```

If the system time is synchronized correctly, the output will contains the line `System clock synchronized: yes`.

Synchronization is configured.

Installing the KUMA services inside the Kubernetes cluster

Services are the main components of the KUMA SIEM-system, which helps the system to manage events. Services allow you to receive events from event sources and subsequently bring them to a common form that is convenient for finding correlation, as well as for storage and manual analysis.

Service types:

- Storages are used to save events.
- Collectors are used to receive events and convert them to the KUMA format.

  If you plan to use multiple tenants in your infrastructure, create a separate collector for each tenant.

- Correlators are used to analyze events and search for defined patterns.
- Agents are used to receive events on remote devices and forward them to the KUMA collectors.

You must install the KUMA services only after you deploy Kaspersky EDR Expert. During the Kaspersky EDR Expert deployment, the required infrastructure is prepared: the service directories are created on the prepared hosts, and the files that are required for the service installation are added to these directories. We recommend installing services in the following order: storage, collectors, correlators, and agents.

Limitations

When installing KUMA services inside the Kubernetes cluster, consider the following limitations:

- Only one instance of KUMA Core can be deployed per one installation.
- Passive collectors can be deployed only when HTTP or TCP connectors with TLS enabled are used.
- For passive HTTP and TCP connectors, the configured server address and port are replaced automatically with `0.0.0.0:7310`.

- A storage cluster must be deployed entirely inside Kubernetes or entirely outside it. Mixed deployments are not supported.
- If collectors or correlators deployed outside Kubernetes send events to storage services deployed inside Kubernetes, event delivery is performed through a single ingress URL. Load balancing between storage nodes is performed by Kubernetes at the TCP level.
- If traffic must be routed to different storage node groups, you need to deploy separate eventRouter services and route traffic through them.
- When you change settings of a collector deployed inside the Kubernetes cluster, KUMA does not verify the modified settings. Incorrect settings may prevent the collector from receiving events.
- Multiple storage services created from the same storage resource cannot be deployed in a single Kubernetes cluster using the same **Storage Node FQDN** value.

To install and configure the KUMA services inside the Kubernetes cluster:

1. Ensure that the administrator and target hosts for Kaspersky EDR Expert are prepared according to the selected deployment scheme by following one of the instructions below:
   - Multi-node deployment: Preparing the administrator and target hosts
   - Single-node deployment: Preparing the administrator and target hosts
2. In the OSMP Console, create a resource set for each KUMA service (storages, collectors, and correlators).
3. Create services for storages, collectors, and correlators.
4. **Deploy each service into the Kubernetes cluster**.
   1. In the main application window, go to the **Monitoring → Resources and services → Active services** section.
   2. Select the service you want to deploy and click the **Deploy** button.
   3. In the **Add service to Kubernetes** window, fill in the following fields:
      - **Storage Node FQDN**: Specify the name of the storage cluster node defined in the storage resource. This parameter is available only for a storage service and cannot be changed after the service is deployed.
      - **Storage Class**:Select the storage subsystem used to store the service state. The value of this parameter cannot be changed after deployment. Available values:
        - **longhorn**—this storage class provides network storage with replication support. By default, the service state is replicated across three network drives. This storage class is recommended for collector, correlator, metrics, and Core services because it allows Kubernetes to migrate the service pod to another worker node if the current node fails. It can also be used to provide high availability for a storage service deployed as a single instance.
        - **local-path**—this storage class uses local disk arrays of Kubernetes worker nodes mounted under /opt/lvp/hot directory and provides maximum performance. This storage class is recommended for a storage service because storage supports native clustering and does not rely on Kubernetes mechanisms for high availability. It can also be used for collector services that use HTTP or TCP connectors and for eventRouter services deployed in multiple instances created from a single KUMA resource. In single-node deployment, using **local-path** is recommended for all KUMA service types.

- **Cold Storage Class**: Select the storage subsystem used for long-term data storage. This parameter is available only for a storage service and cannot be changed after deployment. The **local-path-cold** storage class is similar to **local-path** but is intended for long-term storage on slower disk arrays mounted under /opt/lvp/cold directory.
- **Minimum CPU**: Specifiy the number of CPU cores (threads) reserved for the service. The value must be a positive integer. The default value is `0`.
- **Maximum CPU**: Specify the maximum number of CPU cores (threads) available to the service. The value must be a positive integer and cannot be less than the **Minimum CPU** value. The default value is `0`.
- **Minimum RAM**: Specifiy the amount of RAM in GB, reserved for the service. The value must be a positive integer. The default value is `0`.
- **Maximum RAM**: Specify the maximum amount of RAM in GB, available to the service. The value must be a positive integer and cannot be less than the **Minimum RAM** value. The default value is `0`.
- **Storage request**: Specify the amount of disk space in GB, allocated to the service. This parameter is available only when the **longhorn** storage class is used.
- **Cold Storage request**: Specify the amount of disk space in GB, allocated for long-term data storage. This parameter is available only for storage services that use the **longhorn** storage class.

4. Click the **Create service** button.

5. If necessary, verify that the collector and correlator are ready to receive events.

6. If necessary, install agents in the KUMA network infrastructure.

   The files required for the agent installation are located in the `/opt/kaspersky/kuma/utils` directory.

The KUMA services required for the function of Kaspersky EDR Expert are installed inside the Kubernetes cluster.

Installing KUMA services outside the Kubernetes cluster

Services are the main components of the KUMA component, which helps the system to manage events. Services allow you to receive events from event sources and subsequently bring them to a common form that is convenient for finding correlation, as well as for storage and manual analysis.

The KUMA services (collectors, correlators, and storages) can be installed entirely inside the cluster on worker nodes, entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the Kubernetes cluster.

Service types:

- Storages are used to save events.
- Collectors are used to receive events and convert them to the KUMA format.

  If you plan to use multiple tenants in your infrastructure, create a separate collector for each tenant.

- Correlators are used to analyze events and search for defined patterns.
- Agents are used to receive events on remote devices and forward them to the KUMA collectors.

You must install the KUMA services only after you deploy Kaspersky EDR Expert. During the Kaspersky EDR Expert deployment, the required infrastructure is prepared: the service directories are created on the prepared hosts, and the files that are required for the service installation are added to these directories. We recommend installing services in the following order: storage, collectors, correlators, and agents.

To install and configure the KUMA services outside the Kubernetes cluster:

1. In the main menu of OSMP Console, go to **Settings** → **KUMA**.
2. In KUMA section of OSMP Console, create a resource set for each KUMA service (storages, collectors, and correlators) that you want to install on the prepared hosts in the network infrastructure.
3. Create services for storages, collectors, and correlators.
4. Obtain the service identifiers to bind the created resource sets and the KUMA services:
   a. In the OSMP solution, go to the **Resources** → **Active services**.
   b. Select the required KUMA service, and then click the **Copy ID** button.
5. On the prepared hosts in the network infrastructure, run the corresponding commands to install the KUMA services. Use the service identifiers that were obtained earlier:
   - Installation command for the storage:

     ```
     sudo /opt/kaspersky/kuma/kuma storage --core https://<FQDN>:7210 --pair.fingerprint <fingerprint ID of the KUMA Core CA certificate> --id <service ID> --install
     ```

   - Installation command for the collector:

     ```
     sudo /opt/kaspersky/kuma/kuma collector --core https://<FQDN>:7210 --pair.fingerprint <fingerprint ID of the KUMA Core CA certificate> --id <service ID> --api.port <API port>
     ```

   - Installation command for the correlator:

     ```
     sudo /opt/kaspersky/kuma/kuma correlator --core https://<FQDN>:7210 --pair.fingerprint <fingerprint ID of the KUMA Core CA certificate> --id <service ID> --api.port <API port> --install
     ```

     where:

     - <FQDN> is the fully qualified domain name of the KUMA Core server.
     - <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

       The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

       You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.

- <service ID> is the identifier of a KUMA service copied from the web-interface.
- <API port> is the port used for communication with the installed component.

By default, the FQDN of KUMA Core is `<kuma_host>.<smp_domain>`.

The port that is used for connection to KUMA Core cannot be changed. The default port number is 7210.

Open ports that correspond to the installed collector and correlator on the server (TCP 7221 and other ports used for service installation as the `--api.port <port>` parameter values).

6. During the installation of the KUMA services, read the End User License Agreement (EULA) of KUMA. The text is displayed in the command line window. Press the space bar to view the next text segment. Then, when prompted, enter the following values:

   - Enter `y` if you understand and accept the terms of the EULA.
   - Enter `n` if you do not accept the terms of the EULA. To use the KUMA services, you must accept the terms of the EULA.

   You can read the EULA of KUMA after the installation of the KUMA services in one of the following ways:

   - On hosts, it is included in the `kuma_utils` group in the KUMA inventory file: open the LICENSE file located in the `/opt/kaspersky/kuma/utils` directory.
   - On hosts, it is included in other groups (`kuma_storage`, `kuma_collector`, or `kuma_correlator`) in the KUMA inventory file: open the LICENSE file located in the `/opt/kaspersky/kuma` directory.
   - Execute the following command:

     ```
     /opt/kaspersky/kuma/kuma license --show
     ```

   After you accept the EULA, the KUMA services are installed on the prepared machines in the network infrastructure.

7. If necessary, verify that the collector and correlator are ready to receive events.

8. If necessary, install agents in the KUMA network infrastructure.

   The files required for the agent installation are located in the `/opt/kaspersky/kuma/utils` directory.

The KUMA services required for the function of Kaspersky EDR Expert are installed.

Deployment of multiple Kubernetes clusters and Kaspersky EDR Expert instances

KDT allows you to deploy multiple Kubernetes clusters with Kaspersky EDR Expert instances and switch between them by using contexts. *Context* is a set of access parameters that define the Kubernetes cluster that the user can select to interact with. The context also includes data for connecting to the cluster by using KDT.

Prerequisites

Before creating contexts and installing Kubernetes clusters with Kaspersky EDR Expert instances, you must do the following:

1. Prepare the administrator and target hosts.

   For the installation of multiple clusters and Kaspersky EDR Expert instances, you need to prepare one administration host for all clusters and separate sets of target hosts for each of the clusters. Kubernetes components should not be installed on the target hosts.

2. Prepare the hosts for installation of the KUMA services.

   For installation of the KUMA services, you need to prepare separate sets of hosts for each Kaspersky EDR Expert instance.

3. Prepare the KUMA inventory file.

   For installation of the KUMA services, you need to prepare separate inventory files for each Kaspersky EDR Expert instance.

4. Prepare the configuration file.

   For installation of multiple clusters and Kaspersky EDR Expert instances, you need to prepare configuration files for each Kaspersky EDR Expert instance. In these configuration files, specify the corresponding administration and target hosts, and other parameters specific to a particular cluster and Kaspersky EDR Expert instance.

Process

To create a context with the Kubernetes cluster and Kaspersky EDR Expert instance:

1. On the administrator host where the KDT utility is located, run the following command and specify the context name:

   ```
   ./kdt ctx --create <context_name>
   ```

   The context with the specified name is created.

2. Install the Kubernetes cluster and Kaspersky EDR Expert.

The cluster with the Kaspersky EDR Expert instance is deployed in the context. The creation of the context is finished. When you obtain log files of Kaspersky EDR Expert components, the log files contain your current context name.

You can repeat this procedure to create the required number of contexts with installed clusters and Kaspersky EDR Expert instances.

You must deploy the Kubernetes cluster and the Kaspersky EDR Expert instance after you create the context to finish the context creation. If you do not perform the deployment in the context, and then create another context, the first context will be removed.

To view the list of created contexts and the active context name,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt ctx
```

To switch to the required context,

On the administrator host where the KDT utility is located, run the following command and specify the context name:

```
./kdt ctx <context_name>
```

After you select the context, KDT connects to the corresponding Kubernetes cluster. Now, you can work with this cluster and the Kaspersky EDR Expert instance. KDT commands are applied to the selected cluster.

When you remove the Kaspersky EDR Expert components installed in the Kubernetes cluster and the cluster itself by using KDT, the corresponding contexts are also removed. Other contexts and their clusters with Kaspersky EDR Expert instances are not removed.

Installing and upgrading Kaspersky EDR Expert in an air-gapped environment

Kaspersky EDR Expert can be installed or updated in an air-gapped environment. Installation and update in an air-gapped environment is performed by using the kdt-airgap-preparation utility, and consists of the following stages:

1. Preparing the administrator and target hosts, and the configuration file.
2. Obtaining information about packages installed on the target hosts located in the air-gapped environment

   This information is compared with the list of required packages and saves information about what is missing on target hosts to the YAML inventory file.
3. Downloading the required packages specified in the inventory file and their dependencies from public internet repositories or corporate mirror repositories in the open environment.

   The downloaded packages are saved into a local TAR package archive.
4. Installing or updating packages and their dependencies on the target hosts in the air-gapped environment from the local TAR archive.
5. Installation or upgrade of Kaspersky EDR Expert in the air-gapped environment.

Preparing the administrator and target hosts

Based on the selected deployment scheme, you must define the number of target hosts on which you will deploy the Kubernetes cluster and the Kaspersky EDR Expert components included in this cluster. Prepare the administrator host and target hosts for deployment of Kaspersky EDR Expert by using one of the following instructions, except steps with downloading and installation of packages:

- Multi-node deployment: Preparing the administrator and target hosts
- Single-node deployment: Preparing the administrator and target hosts

Prepare the configuration file in the YAML format. The configuration file contains the list of target hosts for deployment and a set of installation parameters of the Kaspersky EDR Expert components.

Use the configuration file that contains the installation parameters specific for the selected deployment scheme:

- Multi-node deployment: Specifying the installation parameters
- Single-node deployment: Specifying the installation parameters

When deploying Kaspersky EDR Expert in an air-gapped environment, set the `airgap_mode` installation parameter to `true`.

Obtaining information about packages installed on the target hosts located in the air-gapped environment.

To obtain information about the operating system and installed packages of target hosts:

1. On the administrator host, run the following command. Specify the path to the private part of the SSH key located on the administrator host and that is used for connection to target hosts, the path to the configuration file that you filled out earlier, and path to the inventory file to which information will be saved:

   ```
   kdt-airgap-preparation scan -k <full_path_to_ssh_key> -c
   <full_path_to_configuration_file> --airgap -i <full_path_to_inventory_file>
   ```

   The kdt-airgap-preparation utility compares the information with the list of required packages and saves information about what is missing on target hosts to the YAML inventory file. The YAML inventory file is saved to the specified directory, with the specified name.

If you need to check for additional packages on the target hosts, such as Docker, run the following command:

```
kdt-airgap-preparation scan -k <full_path_to_ssh_key> -c
<full_path_to_configuration_file> --airgap -i <full_path_to_inventory_file> --add-pkgs
<package_name>
```

Information about additional packages that are not installed on the target hosts is added to the YAML inventory file.

The created inventory file will be used to download missing packages for target hosts from public internet repositories or corporate mirror repositories in the open environment. If an error occurs, the kdt-airgap-prepare utility exits and sends a corresponding error message to the log file and to stdout.

Downloading the required packages in the open environment

To download the required packages specified in the inventory file:

1. Copy the YAML inventory file to a removable drive, and then move the file to the administrator host in the open environment.

2. On the administrator host, run the following command. Specify the path to the inventory file and path to the package archive to which the required missing packages should be saved:

   ```
   kdt-airgap-preparation pull -n <full_path_to_inventory_file> -a
   <full_path_to_package_archive>
   ```

   The kdt-airgap-preparation utility downloads the packages listed in the inventory file and their dependencies and saves packages to the TAR package archive. The package archive is saved to the specified directory, with the specified name.

3. Add the inventory file to the package archive.

The created package archive will be used to install the missing required packages on target hosts in the air-gapped environment. If an error occurs, the kdt-airgap-preparation utility terminates and outputs the corresponding error message to both the log file and stdout.

Installing or updating packages on the target hosts in the air-gapped environment

To install or update packages and their dependencies on the target hosts:

1. Copy the TAR package archive to a removable drive, and then move the archive to the administrator host in the air-gapped environment.

2. On the administrator host, run the following command. Specify the path to the TAR package archive and the path to the private part of the SSH key located on the administrator host and used for connection to target hosts:

   ```
   kdt-airgap-preparation install -a <full_path_to_package_archive> -k
   <full_path_to_ssh_key>
   ```

   The kdt-airgap-preparation utility installs or updates the required packages on the target hosts by using the inventory file and the package archive.

After you prepare target hosts, install or upgrade Kaspersky EDR Expert.

Pre-check of infrastructure readiness for deployment

After you start the deployment of Kaspersky EDR Expert, KDT checks whether the hardware, software, and network configuration of the Kubernetes cluster nodes meet the prerequisites for installing the solution. A pre-check is performed for each node of the cluster.

All checks are divided into two groups:

- Strict checks

  Checking the parameters that are critical for the operation of Kaspersky EDR Expert. If this check fails, the deployment is interrupted.

- Non-strict checks

  Checking the parameters that are not critical for the operation of Kaspersky EDR Expert. If this check fails, the deployment continues.

The following pre-checks are performed:

- Hardware:
  - Free space on disks is enough for deployment.
  - CPU configuration meets the requirements.
  - Free RAM space is enough for deployment.
  - CPU supports the AVX, SSE 4.2, and BMI instructions.
  - The amount of free disk space in the `/tmp` directory must be at least equal to the size of the transport archive (for administrator host, strict check).
- Software:
  - Operating system and its version meet the requirements.
  - Kernel version meets the requirements.
  - Systemctl is installed and available (strict check).
  - Update of the package manager cache is available (strict check).
  - Required packages of the correct version are installed on the node (strict check).
  - Prohibited packages (docker and podman) are not installed on the node (strict check).
  - Outdated k0s binaries are missing (strict check).
  - Outdated k0s configuration files are missing (strict check).
  - PostgreSQL or Postgres Pro DBMS server parameters meet the requirements (strict check).
- Network:
  - All cluster nodes are located in the same broadcast domain.
  - All cluster nodes have unique names (the `desc` parameter of the configuration file) (strict check).
  - user certificate file is valid for the specified domain and contains the private encrypted key (strict check).
  - The validity period for the custom intermediate certificate is 399 days or more (strict check).

- The validity period for the custom leaf certificate is 399 days or more (strict check).
- DNS name resolution on the node is available (strict check).
- Time synchronization on cluster nodes is configured (strict check).
- The local time on all nodes differs by no more than 5 seconds (strict check).
- Required ports are available.

If all the strict pre-checks are successfully completed, KDT deploys the Kaspersky EDR Expert components within the Kubernetes cluster on the target hosts. The results of all passed and failed checks are saved on each node in the file /tmp/k0s_report.txt. You can skip the pre-checks before the deployment, if needed (set the `ignore_precheck` installation parameter to `true`).

Pre-installation integrity check of Kaspersky EDR Expert components

After you receive the transport archive with the Kaspersky EDR Expert components, you can verify their authenticity and integrity. Each component (CNAB) in the transport archive includes a manifest file in XML format. The manifest contains the component checksums and is signed with a digital signature by using the GOST R 34.11-2012 256-bit algorithm. This digital signature ensures both the validity of the component file checksums and that the checksums in the manifest have not been changed.

You can verify that the components' checksums match the checksums specified in the manifests. This confirms that the components have not been modified and are obtained from a trusted source.

To check the integrity of the Kaspersky EDR Expert components:

1. Unpack the transport archive.
2. Run one of the following commands from the directory with extracted components and their manifests:

   - Verify a single component

     Specify the manifest name to verify the corresponding component. The `integrity_checker` utility verifies the digital signature of the specified manifest:

     ```
     ./integrity_checker --signature-purpose 1.3.6.1.4.1.23668.1800.1.1.15 --signature-type kds-with-filename
     <CNAB_manifest_file.xml>
     ```

   - Verify all components

     The `integrity_checker` utility verifies the digital signatures of all manifests:

     ```
     find . -type f -iname "*.xml" -print0 | xargs -0 -I {} echo --manifest {} | xargs ./integrity_checker --
     signature-purpose 1.3.6.1.4.1.23668.1800.1.1.15 --signature-type kds-with-filename
     ```

Example command output after a successful integrity check

The number of manifests that have successfully passed verification is shown in the `Manifests` line, in the `succeeded` column.

```
=============================================>
Summary( failed / skipped / succeeded ):
 Manifests: 0 / 0 / 38
 Files: 0 / 0 / 38
 Directories: 0 / 0 / 0
 Registries: 0 / 0 / 0
 Registry values: 0 / 0 / 0
=============================================>
SUCCEEDED
```

Example command output after a failed integrity check

In this example, a manifest was modified after signing or there is an issue with the signature. The number of skipped manifests or those that failed verification is shown in the `Manifests` line, in the `failed` column.

```
=============================================>
Summary( failed / skipped / succeeded ):
 Manifests: 2 / 0 / 36
 Files: 0 / 0 / 0
 Directories: 0 / 0 / 0
 Registries: 0 / 0 / 0
 Registry values: 0 / 0 / 0
=============================================>
FAILED
ERR Can't verify digital signature of file "/home/xdr_user/integrity_check.xml". Flags: None: 0x80000106
(Object is untrusted)
Manifest /home/xdr_user/integrity_check.xml failed.  Reason: Can't verify digital signature of file
"/home/xdr_user/integrity_check.xml". Flags: None: 0x80000106 (Object is untrusted)
```

The authenticity and integrity of Kaspersky EDR Expert components are verified.

Signing in to Kaspersky EDR Expert

To sign in to Kaspersky EDR Expert, you must know the web address of OSMP Console. In your browser, JavaScript must be enabled.

To sign in to OSMP Console:

1. In your browser, go to `https://<console_host>.<smp_domain>:443`.

   The OSMP Console address consists of the `console_host` and `smp_domain` parameter values specified in the configuration file.

   The sign-in page is displayed.

2. Do one of the following:

   - To sign in to OSMP Console by using a domain user account, enter the user name and password of the domain user.

     You can enter the user name of the domain user in one of the following formats:

     - `Username@dns.domain`
     - NTDOMAIN\`Username`

   - Enter the user name and password of the internal user.

3. Click the **Sign in** button.

4. Specify the one-time security code generated by the authenticator app on the mobile device.

   At the first sign-in, configure two-step authentication for your account. If two-factor authentication configuration is not available to you, contact a user who has the Modify object ACLs right in the **General features: User permissions** functional area and configured two-factor authentication to add your account to the two-factor authentication allowlist.

5. If forced password change is enabled for your account or your password has expired, the password change window will be displayed. Set a new password to sign-in to OSMP Console.

After sign-in, the dashboard is displayed, and it contains the language and theme that you used the last time you signed in.

Exceeded number of allowed login attempts

The OSMP distribution kit includes correlation rule *[OOTB] Multiple login attempts to OSMP console using the same account*. This rule is added to the correlator, which is installed during the OSMP deployment. The rule provides for creation of a correlation event after three unsuccessful attempts of a user logging in to the OSMP Console.

The generated correlation event is a basis for an alert about the exceeded number of allowed login attempts.

You can modify the allowed password entry attempts. Refer to the following article for details: Changing the number of allowed password entry attempts.

Domain authentication

Kaspersky EDR Expert enables you to use domain authentication over the Kerberos protocol. Refer to the following article for details: Configuring Kerberos domain authentication.

To sign out of OSMP Console,

in the upper pane, go to your account menu by clicking your account name, and then select **Sign out**.

OSMP Console is closed and the sign-in page is displayed.

Integration with Endpoint Agents

To integrate an Endpoint Agent, you need to get certificates required for establishing a *trusted connection* between OSMP and an Endpoint Agent.

To get a certificate for receiving telemetry from Endpoint Agents:

1. In the main menu, go to **Monitoring → Resources and services → Active services**.

2. In the list of services, right-click on the collector that you want to use for collecting telemetry sent by Endpoint Agents, and then select **Download certificate** from the context menu.

   Your browser downloads the server TLS certificate to the downloads folder.

To get a certificate for sending responses to Endpoint Agents:

1. In the main menu, go to **Settings** → **Tenants** → click on the tenant name → **Settings** tab → **Certificates**.
2. In the **Server certificate** section, click **Export**.

   Your browser downloads the server TLS certificate to the downloads folder.

To get Endpoint Agent TLS certificate:

1. In the main menu, go to **Settings** → **Tenants** → click on the tenant name → **Settings** tab → **Certificates**.
2. In the **Endpoint Agents** section, select the current TLS certificate, and then click **Export**.
3. Specify a password for a password-protected PFX archive containing the Endpoint Agent TLS certificate, and then click **Export**.

   Your browser downloads the PFX archive (crypto container) to the downloads folder.

   The obtained certificate is required for mutual TLS authentication when sending responses to Endpoint Agents and receiving telemetry from them.

After you have downloaded all required certificates, you can create a policy for integrating an Endpoint Agent. For detailed instructions on how to create a policy and add certificates, refer to an Endpoint Agent documentation:

- Kaspersky Endpoint Security for Windows
- Kaspersky Endpoint Security for Linux
- Kaspersky Endpoint Security for Mac

Sandbox preparation and installation

To prepare for installation and install Sandbox:

1. Prepare your IT infrastructure for the Sandbox installation.
2. Prepare a virtual machine.
3. Prepare an installation disk image.
4. Install Sandbox.

Preparing IT infrastructure for the Sandbox installation

To prepare your IT infrastructure for the Sandbox installation:

1. Deny access to the local network of the Sandbox server for the management network interface and the network interface used for internet access of processed objects.
2. Specify the ports for interaction with other components as follows:
   - Inbound direction (management interface):
     - TCP 22

       Connecting to the server over SSH
     - TCP 443

       Communication with OSMP
     - TCP 8443

       Access to the web interface of the application
   - Outbound direction (management interface):
     - TCP 80 or TCP 443

       Communication with Kaspersky update servers.
   - Outbound and corresponding inbound directions (interface for access of processed objects):

     Any port.

     Access to the internet for analyzing the network behavior of processed objects.

     > Deny access to the corporate LAN to protect the network from analyzed objects.

Preparing a virtual machine for installing Sandbox

To prepare the virtual machine for installing the Sandbox component:

1. Run the VMware ESXi hypervisor.
2. Open the virtual machine management console.
3. In the context menu of the virtual machine on which you want to install the Sandbox component, choose **Edit Settings**.

   Virtual machine properties window opens.
4. On the **Virtual Hardware** tab, expand the CPU settings group and select the **Expose hardware-assisted virtualization to guest OS** check box.

5. On the **VM Options** tab in the **Latency Sensitivity** drop-down list, select **High**.
6. Click **OK**.

The virtual machine is ready for installing the Sandbox component.

Preparing an installation disk image

Before installing Sandbox, you must prepare an iso image of the installation disk based on the Astra Linux operating system.

Minimum hardware requirements for a device that can be used to create the iso image:

- CPU: 4 cores, clock rate 2500 MHz or more.
- RAM: 8 GB
- Free disk space: 100 GB.

Software requirements:

- Operating system based on an up-to-date Linux kernel.
- Docker 20 or later.
- An ISO image of Astra Linux Special Edition 1.8.2.8 (hereinafter this image is referred to as astra-installation.iso).

Kaspersky EDR Expert does not support other versions of the Astra Linux operating system.

To mount an iso image of the Sandbox component based on the Astra Linux operating system:

1. Download the following files from the distribution kit:
   - tar.gz archive from the Sandbox distribution kit
   - the tool for creating an ISO image

2. Create an iso_builder.sh file with the following content:

```
#!/bin/bash

usage="Builds the KEDR install ISO.

Usage:

$(basename "$0") [-h] source_iso distribution iso_builder_image build target_iso_name

where:
 -h, --help - show this text and exit
 source_iso - absolute path to the source OS ISO file
 distribution - absolute path to the KEDR distribution archive
 iso_builder_image - absolute path to the iso_builder docker image
 build - absolute path to a temporary build directory
 target_iso_name - absolute path to the resulting ISO file
"

if [ "$#" -eq 0 ] || [ "$1" == "-h" ] || [ "$1" == "--help" ]
then
 echo "$usage"; exit 10;
fi

if [ "$#" -lt 5 ]
then
 echo "Error: not enough arguments. Please, refer the help text."; exit 11;
fi

docker load -i $3
docker run -v $1:$1 -v $2:$2 -v $4:/build kaspersky/kata/deployment/iso_builder:6.0 --source-iso-uri file://$1
--kata-distribution-uri file://$2 --target-iso-name $5
```

3. Execute the following command:

```
mkdir /var/kedr_builder
```

4. Put the files listed in step 1 and the astra-installation.iso image in the newly created /var/kedr_builder directory.

5. Execute the following command:

```
sudo ./iso_builder.sh \
 /var/kedr_builder/astra-installation.iso \
 /var/kedr_builder/kata-sb-distribution-<version>-x86_64_en-ru-zh.tar.gz \
 /var/kedr_builder/iso-builder-<version>-x86_64_en-ru-zh.tar \
 /var/kedr_builder buildSandboxAstra.iso
```

   where <version> is the Sandbox distribution version.

   The installation disk image buildSandboxAstra.iso is created in the /var/kedr_builder directory.

If you keep files in different directories, you can run the following command:

```
sudo ./iso_builder.sh <source_iso_host_path> <distribution_host_path> <iso_builder_image_host_path>
<build_host_path> <target_iso_name>
```

In the above command:

- source_iso_host_path is the path to the distribution kit of Astra Linux Special Edition 1.8.2.8.
- distribution_host_path is the path to the Sandbox distribution kit.
- iso_builder_image_host_path is the path to the ISO builder tool.

- build_host_path is the path where the mounted ISO image must be located, without specifying the name being assigned to the ISO image.
- target_iso_name is the name assigned to the iso image.

Installing Sandbox

To begin the installation of the Sandbox component:

1. Run the disk image containing the Sandbox component.

   The Setup Wizard starts.

2. Select **Continue** and press **Enter**.

Step 1. Viewing the End User License Agreement and Privacy Policy

To proceed with the installation, you must read and accept the terms and conditions of the End User License Agreement and the Privacy Policy of AO Kaspersky Lab (hereinafter also referred to as the "EULA" and the "Privacy Policy" respectively). Installation will not continue until you accept the terms of EULA and Privacy Policy.

On the Astra Linux operating system, you also need to accept the End User License Agreement of the Astra Linux operating system.

To accept the terms and conditions of EULA and Privacy Policy:

1. Select the language for reading the EULA and Privacy Policy texts in the list and press the **Enter** key.
2. On the Astra Linux operating system, you must first accept the End User License Agreement of the Astra Linux operating system. Read the EULA. If you accept its terms and conditions, select **I accept** and press **Enter**.
3. Read the EULA of Kaspersky. If you accept its terms and conditions, select **I accept** and press **Enter**.
4. Read the Privacy Policy. If you accept its terms and conditions, select **I accept** and press **Enter**.

The Setup Wizard proceeds to the next step.

Step 2. Selecting a disk for installing Sandbox

To select a disk for installing the component:

1. Select one of the suggested drives for installing the component and press **Enter**.
2. In the confirmation window, select **Yes** and press **Enter**.

The Setup Wizard proceeds to the next step.

Step 3. Configuring the minimum password length for the Sandbox administrator password

To set the minimum length of the administrator password for the Sandbox component:

1. In the **Minimal password length**, enter the length in characters.
   Passwords 12 or more characters long are recommended.
2. Select **OK** and press **Enter**.

The Setup Wizard proceeds to the next step.

Step 4. Creating the Sandbox administrator account

To create a Sandbox administrator account:

1. In the **New username** field, enter the name of the administrator account. The 'admin' account is used by default.
2. In the **New password** field, enter the password for the administrator account.
   The password must comply with the following rules:
   - The password must contain at least 8 characters.
   - The password must contain at least three types of characters:
     - Uppercase character (A-Z).
     - Lowercase character (a-z).
     - Number.
     - Special character.
   - The password must not be completely or substantially the same as the user name.
   - The password may not contain three or more identical characters in a row.
3. Enter the password again in the **Confirm password** field.
4. Select **OK** and press **Enter**.

The Setup Wizard proceeds to the next step.

Step 5. Configuring a management network interface

To ensure proper functioning of the Sandbox component, you must connect at least two network cards and configure the following network Interfaces:

- Management network interface. This interface is intended for providing SSH access to the Sandbox server; the Sandbox server also uses this interface to receive objects for scanning.
- Network interface used for Internet access of processed objects. Objects that are processed by Sandbox can use this interface to attempt activities on the Internet, and Sandbox can analyze their behavior. If you block Internet access, Sandbox cannot analyze the behavior of objects on the Internet, and will therefore only analyze the behavior of objects without internet access.

  > The network interface used for Internet access of processed objects must be isolated from the local network of your organization.

Select the network interface that you want to use as the management interface and configure it.

To select a management network interface and configure it:

1. In the list of network interfaces, select the network interface that you want to use as the management interface.
2. Press **Enter**.
3. In the **Address** field, enter the IP address that you want to assign to this network interface.
4. In the **Netmask** field, enter the network mask in which you want to use this network interface.
5. Select **OK** and press **Enter**.
6. Select **Continue** and press **Enter**.

The Setup Wizard proceeds to the next step.

Step 6. Assigning a hostname and adding DNS server addresses

Assign a server host name to be used by DNS servers and add DNS server addresses.

To assign a server host name and add DNS server addresses:

1. In the **DNS settings** window, select **Host name**.
2. Enter the full domain name of the server into the **Host name** field.

   Specify the server name in FQDN format (for example: host.domain.com or host.domain.subdomain.com).
3. Select **OK** and press **Enter**.
4. In the **DNS settings** window, select **DNS servers**.

5. Select **New** and press **Enter**.

   The DNS server address entry window opens.

6. In the **DNS server** text box, enter the IP address of the primary DNS server in IPv4 format.

7. Select **OK** and press **Enter**.

   The DNS server address entry window closes.

8. If you want to add the IP address of an additional DNS server, repeat steps 5 through 7 of these instructions for each server that you want to add.

9. Having added all DNS servers, select **Go back** and press **Enter**.

10. In the DNS servers window, select **Continue** and press **Enter**.

The Setup Wizard proceeds to the next step.

Step 7. Configuring a static network route

To configure a static network route:

1. In the **IPv4 Routes** window, select **New** and press **Enter**.

   The **IPv4 Static Route** window opens.

2. In the **Address/Mask** field, enter the IP address and mask of the subnet for which you want to configure the network route.

3. If you want to use the default network route, enter `0.0.0.0/0`.

4. In the **Gateway** field, enter the IP address of the gateway.

5. Select **OK** and press **Enter**.

6. If you want to add other network routes, repeat steps 1 through 5 of these instructions for each network route that you want to add.

7. If you are done adding network routes, click **Continue**.

The configuration may take some time. Then the installation is complete.

Integration with Sandbox

Integration with Sandbox involves two steps:

1. Creating a request to connect to the Sandbox server in the OSMP interface.

2. Accepting the request in the Sandbox web interface.

To create a connection request to a Sandbox server through the OSMP interface:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. In the **Settings** tab, go to the **Sandbox servers** section.

   Note the *OSMP certificate fingerprint*. You will need this fingerprint later to match with the one displayed in the Sandbox web interface.

4. Click **Add**.

   Add Sandbox server panel appears in the right part of the web interface window.

5. In the **IP** field, specify the IP address of the Sandbox server.

6. Click **Get certificate fingerprint**. Kaspersky EDR Expert displays the *Sandbox certificate fingerprint*. You will need this fingerprint later to match with the one displayed in the Sandbox web interface.

7. In the **Sandbox name** field, specify the Sandbox component name to be displayed in the OSMP interface.

8. Click **Save**.

OSMP sends a connection request to Sandbox. Now you need to accept the request.

To accept a connection request from OSMP:

1. In the Sandbox web interface, go to the **Authorization** section.

2. Compare the certificate fingerprints:

   - Sandbox certificate fingerprint displayed under Sandbox IP should match the Sandbox certificate fingerprint that you obtained earlier in the OSMP interface.

   - In the list of connection requests from OSMP, find the connection request from OSMP. The **Certificate fingerprint** column contains the certificate fingerprint of the OSMP server that has sent the connection request. This certificate fingerprint should match the OSMP certificate fingerprint you obtained earlier in the OSMP interface.

3. To accept the connection request, click **Accept**. Later you can revoke a previously accepted connection request by clicking the **Revoke** button.

4. Click **Apply**.

Integration with Sandbox is ready.

High-availability deployment of Kaspersky EDR Expert

This section covers Kaspersky EDR Expert deployment across four servers (see also the sizing calculations). While this setup does not guarantee full high-availability, it offers a reliable configuration that enables deployment with a minimal budget.

Following this scenario, you can prepare your infrastructure to deploy Open Single Management Platform and all required Kaspersky EDR Expert components in a high-availability configuration. You can also prepare a configuration file with the installation parameters and deploy the solution using the Kaspersky Deployment Toolkit utility (hereinafter referred to as KDT).

Before deploying the Open Single Management Platform and Kaspersky EDR Expert components, we recommend reading the Hardening Guide.

The deployment scenario proceeds in stages:

1. **Download the distribution package with the Kaspersky EDR Expert components**

   The distribution package includes:

   - Transport archive with the Kaspersky EDR Expert components, End User License Agreement for Kaspersky EDR Expert, and End User License Agreement for KDT.
   - Archive with the KDT utility, along with templates for the configuration file and the KUMA inventory file.

2. **Install a database management system (DBMS)**

   Manually install the DBMS on separate servers that are not part of the Kubernetes cluster.

   Use one of the supported high-availability database configurations: High-availability configuration of Kaspersky EDR Expert.

3. **Prepare the administrator and target hosts**

   Define the number of target hosts where the Kubernetes cluster and the Kaspersky EDR Expert components will be deployed. In the high-availability configuration of Kaspersky EDR Expert there must be at least four target hosts.

   Prepare the administrator host and target hosts for deployment.

   How-to: Multi-node deployment - preparing the administrator and target hosts

4. **Prepare the configuration file**

   Create a configuration file in YAML format. This file contains the list of target hosts for deployment and the installation parameters for Kaspersky EDR Expert components.

   How-to: Multi-node deployment - specifying the installation parameters

   You can either fill out the file manually or use the Configuration wizard to specify the installation parameters and generate the file automatically.

   How-to: Specifying the installation parameters using the Configuration wizard

5. **Deployment of Kaspersky EDR Expert**

   Deploy the solution using KDT. The tool automatically sets up the Kubernetes cluster and installs the Kaspersky EDR Expert components along with the required infrastructure.

   How-to instruction: Installing Kaspersky EDR Expert

6. **Install KUMA services within the Kubernetes cluster**

   Deploy the KUMA services (collectors, correlators, and storages).

   How-to: Installing KUMA services inside the Kubernetes cluster

7. **Add a secondary Administration Server**

A secondary Administration Server is required for further integration of Endpoint Agents.

It is recommended to use a secondary Administration Server, as this approach has clear hardware requirements for handling the load. This enables more accurate planning and configuration of the infrastructure, ensuring optimal performance and efficiency.

How-to: Adding a secondary Administration Server

8. **Install and integrate Endpoint Agents**

   Install Endpoint Agents in accordance with the relevant documentation:

   - Kaspersky Endpoint Security for Windows
   - Kaspersky Endpoint Security for Linux
   - Kaspersky Endpoint Security for Mac

   Configure integration with Endpoint Agents.

9. **Install and integrate Sandbox**

   Install and configure Sandbox, then deploy the required virtual machines within it. After that, configure integration with Sandbox.

   How-to instructions:

   - Installing the Sandbox component
   - Initial Sandbox setup
   - Making virtual machines ready for work
   - Integration with Sandbox

High-availability configuration of Kaspersky EDR Expert

High-availability configuration allows you to deploy the solution with a minimal budget. However, it depends on the availability of a single control-plane node. If a worker node fails, workload performance will be partially degraded. If the primary node fails, management operations will not be available, although services on the worker nodes will continue running.

This setup requires at least four Kubernetes cluster nodes:

- 1 primary (control-plane) node
- 3 worker nodes

The following high-availability database configurations are supported:

- Postgres Pro Enterprise BiHA cluster
  - Version: Postgres Pro Enterprise 16 or later
  - Cluster type: BiHA
  - Number of nodes: 3 to 15

- Replication type: Synchronous
- Connection string for accessing the DBMS includes the list of cluster nodes (specified by the `psql_dsn` parameter):

```
psql_dsn=postgres://<dbms_username>:<password>@<fqdn1>:<port>,<fqdn2>:<port>,<fqdn3>:<port>
```

- PostgreSQL cluster with virtual IP (Corosync/Pacemaker)
  - Cluster type: PostgreSQL cluster with virtual IP (Corosync/Pacemaker)
  - Number of nodes: 3 or more
  - Connection string for accessing the DBMS includes a virtual IP address of the DBMS cluster (specified by the `psql_dsn` parameter):

```
psql_dsn=postgres://postgres:pass!@<virtual ip>:<port>
```

The following high-availability configuration of KUMA services that will be installed inside the Kubernetes cluster is supported:

- KUMA storage
  - Number of worker nodes: 3 or more
  - KUMA storages are bound to these nodes and must not be migrated to other nodes.
  - KUMA storages use the disks of these nodes directly, without relying on Longhorn.
- KUMA Core
  - Number of worker nodes: 1

    High-availability is ensured by Kubernetes. In the event of a node failure, the downtime is about 6 minutes.
- KUMA collector

  Two high-availability configurations are possible:
  - Number of worker nodes: 2

    Minimal downtime in case of node failure.
  - Number of worker nodes: 1

    High-availability is ensured by Kubernetes. In the event of a node failure, the downtime is about 6 minutes.
- KUMA correlator
  - Number of worker nodes: 1

    High-availability is ensured by Kubernetes. In the event of a node failure, the downtime is about 6 minutes.
- KUMA metrics
  - Number of worker nodes: 1

    High-availability is ensured by Kubernetes. In the event of a node failure, the downtime is about 6 minutes.

Restoring a failed node in the Kubernetes cluster

If a Kubernetes cluster node experiences a power or network failure, but its disk data remains intact and its network name has not changed, the administrator should restore power and network connectivity. Once the node is operational again, it automatically rejoins the cluster within approximately 5–6 minutes.

If the node's disk data is corrupted or lost, or its hostname has changed as a result of failure, the node must be reconfigured and prepared again for operation as part of the Kubernetes cluster, and then re-added to the cluster.

To prepare and add a node to the Kubernetes cluster:

1. Prepare target hosts that will act as primary and worker nodes.
2. On the administrator host, export the current configuration file using the following command:

   ```
   ./kdt ec -e '<configuration_file_name_with_path>'
   ```

   The current version of the configuration file is saved to the specified directory, under the specified name.
3. In the `nodes` section of the exported configuration file, delete the failed node parameters and add the restored node parameters (`desc`, `type`, `host`, `kind`, `user`, and `key`). Save the updated configuration file.
4. Copy the public key to each new node (for example, to the `~/.ssh` directory) using the ssh-copy-id utility.
5. On the administrator host, run the following command to apply the modified configuration file to the Kubernetes cluster, specifying the full path to the configuration file:

   ```
   ./kdt apply -i '<full_path_to_configuration_file>'
   ```

   After execution, KDT validates the configuration file. It then checks whether the hardware, software, and network configuration of the Kubernetes cluster nodes meet the installation prerequisites. If all strict pre-checks are completed successfully, KDT outputs a success validation notification to stdout and KDT logs. Otherwise, logs with information about the failed validation are saved and the process of adding new hosts is interrupted. If needed, you can skip pre-checks before running the command by setting the `ignore_precheck` installation parameter to `true`.

The restored node is added to the Kubernetes cluster. KDT then outputs information about the restored node to stdout and KDT logs.

High-availability multi-site deployment of Kaspersky EDR Expert

A high-availability multi-site deployment of Kaspersky EDR Expert provides fault tolerance by distributing Kubernetes cluster nodes across multiple data centers. If a data center becomes unavailable, the workload is automatically transferred to cluster nodes in another data center, allowing Kaspersky EDR Expert to continue operating with minimal disruption.

The multi-site configuration requires a minimum of three data centers. Deploying Kaspersky EDR Expert across at least three data centers ensures that the Kubernetes quorum is maintained if one data center becomes unavailable. In each data center, you must deploy at least four cluster nodes: one primary node and three worker nodes. Each data center uses its own Kubernetes cluster gateway with a dedicated IP address. The target hosts and the Kubernetes cluster gateway must be located in the same subnet within the data center.

At least one Sandbox host is required in each data center. Traffic must be distributed across cluster nodes in different data centers using a customer-managed, highly available load balancer. You must also install the DBMS in a supported high-availability configuration.

For example, in the multi-site configuration with three data centers there must be at least 15 hosts:

- 12 target hosts included in the Kubernetes cluster:
  - One primary 3 primary nodes (at least 1 node per datacenter)
  - 9 worker nodes (at least 3 nodes per datacenter)
- 3 Sandbox hosts (at least 1 node per datacenter)

Additionally, the deployment requires a customer-managed, highly available load balancer and a DBMS deployed in a supported high-availability configuration.

Multi-site deployment limitations

- Inter-data center communication channels require a minimum of 10 Gb/s bandwidth and no more than 20 ms latency. However, the recommended specifications are at least 25 Gb/s bandwidth and no more than 5 ms latency.
- The distance between each data center should not exceed 800 kilometers. The distance between data centers is determined by the latency of components using synchronous replication, which has a maximum latency of 20 ms.
- Network connectivity must be established between nodes in different data centers over the ports used by Kaspersky EDR Expert.
- Within a single data center (zone), all nodes must be located in the same L2 segment (broadcast domain).
- The PostgreSQL database should be deployed in a high-availability configuration with synchronous replication, and the referee should be located in a different zone to ensure optimal performance and redundancy.
- An external load balancer must be provided by the customer.
- Manual failover of Endpoint Agents between data centers is not supported.
- Replication using Patroni is synchronous.
- Replication of telemetry data between data centers must be configured manually using ClickHouse tools.

Known issues during data center failures

- Files sent by Anti-Malware Engine for scanning to Sandbox in a data center may be lost if the data center goes down. Additionally, automatic scanning in the Sandbox may also experience delays.
- IRP tasks, including scan tasks, that were running in a data center at the time of outage may be lost. Detection results for these tasks will not be received.
- When data centers go down, the remaining data center's Sandbox may become overloaded due to queue buildup in external systems. As a result, task drops can occur as the Sandbox load increases.
- If files sent for scanning to a data center are not processed due to a data center outage, the scan results (detections) for those files will be lost, and the files could be marked as "clean" by default. The loss of files and detections can last up to 15 minutes if the Sandbox meets sizing requirements, and up to 1 hour otherwise.
- After restoring a data center or adding one to create a multi-site deployment, the solution may require 30–60 minutes to become fault-tolerant while the cluster data is synchronized. During this time, the solution operates normally but may become unavailable if one of the data centers goes offline. Synchronization may take longer if the data volumes are larger than the default size. Low bandwidth or high latency between data centers may also increase the synchronization time.

Stages

Following this scenario, you can prepare your infrastructure for the deployment of Open Single Management Platform and all the required components for Kaspersky EDR Expert in multiple data centers, prepare the configuration file containing the installation parameters, and deploy the solution by using the Kaspersky Deployment Toolkit utility (hereinafter referred to as KDT).

> Before deploying the Open Single Management Platform and Kaspersky EDR Expert components, we recommend reading the Hardening Guide.

The deployment scenario proceeds in stages:

1. **Downloading the distribution package with the Kaspersky EDR Expert components**

   The distribution package contains the following components:

   - Transport archive with the Kaspersky EDR Expert components and End User License Agreements for Kaspersky EDR Expert and KDT.

     The components are signed with RSA key and GOST R 34.11-2012 key. You can verify the authenticity and integrity of Kaspersky EDR Expert components.

   - Archive with the KDT utility, and templates of the configuration file and KUMA inventory file.

2 Installing a database management system (DBMS)

Manually install the DBMS on separated servers in one of the supported high-availability database configurations: High-availability configuration of Kaspersky EDR Expert.

The DBMS is provided and configured by the customer.

3 Configuring highly available load balancer

Configure a highly available load balancer to distribute incoming traffic between cluster nodes located in multiple data centers.

The load balancer is provided and configured by the customer.

Configuration file example

For example, you can use open-source HAProxy as the load balancer. Specify the Kubernetes cluster gateway IP address (the `ingress_ip` parameter if the configuration file) for each data center in the load balancer configuration.

```

4 Preparing the administrator and target hosts

Define the number of target hosts where the Kubernetes cluster and the Kaspersky EDR Expert components will be deployed in each data center, and then prepare the administrator host and target hosts for the deployment of Kaspersky EDR Expert.

If you are performing a multi-site deployment, you must also configure the DNS records so that the service FQDNs resolve to the IP address of the customer-managed load balancer.

How-to instruction: Multi-site deployment: Preparing the administrator and target hosts

5. **Preparing the KUMA hosts for installing KUMA services outside the Kubernetes cluster (optional)**

   KUMA services (collectors, correlators, and storages) can be installed entirely inside the Kubernetes cluster, entirely on separate hosts outside the cluster, or partially inside and partially outside the cluster.

   If you want to install KUMA services entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the cluster, prepare the KUMA target hosts for installing KUMA services.

   How-to instruction: Preparing KUMA hosts for installing KUMA service outside the Kubernetes cluster

6. **Preparing the KUMA inventory file for installing KUMA services outside the Kubernetes cluster (optional)**

   If you want to install KUMA services entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the cluster, prepare the KUMA inventory file in the YAML format. The KUMA inventory file contains parameters for installation of the KUMA services outside the Kubernetes cluster.

   How-to instruction: Preparing the KUMA inventory file for installing KUMA services outside the Kubernetes cluster

7. **Preparing the configuration file**

   Prepare the configuration file in the YAML format. The configuration file contains the list of target hosts for deployment and a set of installation parameters of the Kaspersky EDR Expert components.

   If you are performing a multi-site deployment, you must also specify parameters of the infrastructure regions and data centers.

   How-to instruction: Multi-site deployment: Specifying the installation parameters

8. **Deployment of Kaspersky EDR Expert**

   Deploy Kaspersky EDR Expert by using KDT. KDT automatically deploys the Kubernetes cluster within which the Kaspersky EDR Expert components and other infrastructure components are installed.

   How-to: Installing Kaspersky EDR Expert

9. **Installing the KUMA services**

   Install the KUMA services (collectors, correlators, and storages).

   KUMA services can be installed entirely inside the Kubernetes cluster, entirely on separate hosts outside the cluster, or partially inside and partially outside the Kubernetes cluster.

   How-to instruction: Installing KUMA services outside the Kubernetes cluster

   How-to instruction: Installing KUMA services inside the Kubernetes cluster

10. **Adding a secondary Administration Server**

    A secondary Administration Server is required for further integration of Endpoint Agents.

    How-to instructions: Adding a secondary Administration Server

11. **Installing and integrating Endpoint Agents**

Install Endpoint Agents according to Endpoint Agent documentation:

- Kaspersky Endpoint Security for Windows
- Kaspersky Endpoint Security for Linux
- Kaspersky Endpoint Security for Mac

Configure integration with Endpoint Agents.

12. **Installing and integrating Sandbox**

    Install Sandbox, configure it, and then install virtual machines in it.

    Configure integration with Sandbox.

Multi-site deployment: Preparing the administrator and target hosts

Preparing for a multi-site deployment includes configuring the administrator and target hosts. After preparing hosts and specifying the configuration file, you will be able to deploy Kaspersky EDR Expert on target hosts by using KDT.

Preparing the administrator host

You first need to prepare a device that will act as the administrator host from which KDT will launch. This host can be either included in the Kubernetes cluster that is created by KDT during the deployment or not. If the administrator host is not included in the cluster, it will be used only to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. If the administrator host is included in the cluster, it will also act as a target host that is used for operation of Kaspersky EDR Expert components.

To prepare the administrator host:

1. Make sure that the hardware and software on the administrator host meet the requirements.

   If the administrator host is not included in the Kubernetes cluster, use the KDT requirements.

   If the administrator host is included in the cluster, use the hardware requirements for the multi-node deployment and the software requirements for OSMP.

2. Allocate at least 15 GB of free space in the temporary files directory (by default, `/tmp`) for KDT. If you do not have enough free space in this directory, run the following command to specify the path to another directory:

   ```
   export TMPDIR=<new_directory>/tmp
   ```

3. Configure the container runtime. Use one of the following container runtimes:

   - KDT built-in container runtime (based on runc).

     Run the following command to install the built-in container runtime:

     ```
     sudo ./kdt init
     ```

     If the built-in container runtime does not suit your needs, you can use the Docker container runtime instead.

   - Docker container runtime.

     Install the package for Docker version 25 or later, and then perform the post-installation steps to configure the administration host for proper functioning with Docker.

     The disk partition for Docker data storage (by default, `/var/lib/docker`) must have at least 60 GB of available space.

     Do not install unofficial distributions of Docker packages from the operating system maintainer repositories.

4. For the administrator host that will be included in the cluster, perform additional preparatory steps:

   a. Since the device will act as the administrator and target host, make sure that it meets the requirements for multi-node deployment.

   b. Make sure that the cgroup v2 technology is supported on the administrator host.

Preparing the target hosts

The target hosts are physical or virtual machines that are used to deploy Kaspersky EDR Expert and included in the Kubernetes cluster. Kaspersky EDR Expert components work on these hosts.

> One of the target hosts can be used as the administrator host. In this case, you must prepare this host as the administrator host, as described in the previous procedure, and then prepare the target host.

For multi-site configuration with three data centers there must be at least 12 cluster nodes:

- One primary 3 primary nodes (at least 1 node per datacenter)

  The primary node is intended for managing the cluster, storing metadata, and distributing the workload.

- 9 worker nodes (at least 3 nodes per datacenter)

  The worker nodes are intended for performing the workload of the Kaspersky EDR Expert components.

The number of primary and worker nodes in the cluster may vary. For optimal workload distribution between nodes, it is recommended to use nodes with approximately the same performance.

KUMA services (collectors, correlators, and storages) can be installed entirely inside the cluster on worker nodes, entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the Kubernetes cluster.

To prepare the target hosts:

1. Make sure that the hardware and software on the target hosts meet the requirements for multi-node deployment, and the target hosts are located in the same broadcast domain.

   If KUMA services are installed inside the cluster, target hosts must meet the hardware, software, and installation requirements that are necessary for installing the KUMA services.

   > For proper functioning of Kaspersky EDR Expert, the Linux kernel version must be 5.15.0.107 or later on the target hosts with the Ubuntu family of operating systems.

   > Docker must not be installed on the target hosts, except the target host that will be used as the administrator host. KDT will install all necessary software and dependencies during the deployment.

2. Ensure that the filesystem mounted at `/var` has at least 700 GB of free space on each target host.

3. On each target host, install the sudo package, if this package is not already installed. For the Debian family of operating systems, install the UFW package on the target hosts.

4. On each target host, configure the /etc/environment file. If your organization's infrastructure uses a proxy server to access the internet, configure the internet access by using the proxy server on the target hosts.

5. On the primary nodes with the UFW configuration, allow IP forwarding. In the `/etc/default/ufw` file, set `DEFAULT_FORWARD_POLICY` to `ACCEPT`.

6. Provide access to the package repository that stores the following packages required for Kaspersky EDR Expert:

   - nfs-common
   - containerd
   - cron
   - cryptsetup
   - cryptsetup-bin
   - netcat-traditional
   - nfs-common
   - open-iscsi
   - python3-cffi-backend
   - python3-cryptography
   - python3-netaddr
   - python-apt-common

- systemd
- tar

KDT will try to install these packages during the deployment from the package repository. You can also install these packages manually.

7. Ensure that the following packages are installed:

   - On each target host: python3-apt
   - On primary nodes: curl

   These packages are not installed during the deployment from the package repository by using KDT. You must install these packages manually, if they are not already installed.

8. For the target hosts, disable ARP/MAC spoofing protection mechanisms at the hypervisor, virtual switch, or network infrastructure level.

   For VMware, enable **Forged Transmits** and **MAC Address Changes**. For Hyper-V, enable **MAC Address Spoofing**. For network equipment, disable **Dynamic ARP Inspection (DAI)** or configure the port as trusted.

   For an example, see the MetalLB troubleshooting guide on checking if ARP requests reach the node.

9. Reserve static IP addresses for the target hosts and Kubernetes cluster gateways.

   The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. The gateway IP address is an IPv4 address (for example, 10.80.23.182).

   In a multi-site configuration, each data center uses its own Kubernetes cluster gateway with a dedicated IP address. It is specified in the configuration file for each data center (the `ingress_ip` parameter in the `zones` section).

   The target hosts and the Kubernetes cluster gateway must be located in the same subnet within the data center.

   > The Kubernetes cluster gateway and target hosts require IPv4 addressing. If your environment requires IPv6 connectivity, configure the operating systems on the target hosts and the Kubernetes cluster gateway to route IPv6 traffic through an IPv6 gateway (NAT64) or an IPv6 tunnel. This configuration keeps the cluster running on IPv4 while providing interoperability with IPv6 networks.

10. On your DNS server, register the service FQDNs to connect to the Kaspersky EDR Expert services.

    By default, the Kaspersky EDR Expert services are available at the following addresses:

    - <console_host>.<smp_domain>
    - <ksc_host>.<smp_domain>
    - <kuma_host>.<smp_domain>
    - <api_host>.<smp_domain>
    - <monitoring_host>.<smp_domain>
    - <xdr_edr_ingress_host>.<smp_domain>

- <updater>.<smp_domain>

  Where <console_host>, <ksc_host>, <kuma_host>, <api_host>, <monitoring_host>, <xdr_edr_ingress_host>, and <updater> are service host names, <smp_domain> is a service domain name. These parameters are parts of the service FQDNs, which you can specify in the configuration file. If you do not specify custom values of service host names, the default values are used: `console_host—"console"`, `ksc_host—"admsrv"`, `kuma_host—"kuma"`, `api_host—"api"`, `monitoring_host—"monitoring"`, `xdr_edr_ingress_host—"agentserver"`, `updater—"updater"`.

The listed service FQDNs must be resolved to the IP address of the customer-managed load balancer.

For example:

- <load_balancer_host_ip>—admsrv.<smp_domain>
- <load_balancer_host_ip>—api.<smp_domain>
- <load_balancer_host_ip>—console.<smp_domain>
- <load_balancer_host_ip>—kuma.<smp_domain>
- <load_balancer_host_ip>—*.kuma.<smp_domain>
- <load_balancer_host_ip>—monitoring.<smp_domain>
- <load_balancer_host_ip>—agentserver.<smp_domain>
- <load_balancer_host_ip>—updater.<smp_domain>

11. On the target hosts, create the accounts that will be used for the Kaspersky EDR Expert deployment.

    These accounts are used for the SSH connection and must be able to elevate privileges (sudo) without entering a password. To do this, add the created user accounts to the `/etc/sudoers` file.

    View details

    To add the created user accounts to the `/etc/sudoers` file:

    1. Run the following commands:

       ```
       sudo useradd -m -s /bin/bash <user_name>
       sudo usermod -aG sudo <user_name>
       ```

    2. Open the `/etc/sudoers` file by using the following command:

       ```
       sudo visudo
       ```

    3. Add the following line to the end of the section `# Allow members of group sudo to execute any command`:

       ```
       <user_name> ALL=(ALL) NOPASSWD: ALL
       ```

       where `<user_name>` is the name of the created user.

    4. Save and close the `/etc/sudoers` file.

12. Configure the SSH connection between the administrator and target hosts:

    a. On the administrator host, generate SSH keys by using the ssh-keygen utility without a passphrase.

    b. Copy the public key to every target host and, if a load balancer is used, to the load balancer host (for example, to the `/home/<user_name>/.ssh` directory) by using the ssh-copy-id utility.

    If you use a target host as the administrator host, you must copy the public key to it, too.

13. For proper function of the Kaspersky EDR Expert components, provide network access between the target hosts and open the required ports on the firewall of the administrator and target hosts, if necessary.

14. Configure time synchronization over Network Time Protocol (NTP) on the administrator and target hosts.

15. If necessary, prepare user certificates for working with Kaspersky EDR Expert public services.

    You can use one intermediate certificate that is issued off the organization's root certificate or leaf certificates for each of the services. The prepared user certificates will be used instead of self-signed certificates.

Multi-site deployment: Specifying the installation parameters

The configuration file is a file in the YAML format and contains a set of installation parameters for the Kaspersky EDR Expert components.

Not all of the parameters listed below are included in the configuration file template. This template contains only those parameters that must be specified before Kaspersky EDR Expert deployment. Remaining parameters are set to default values, and they are not included in the template. You can manually add these parameters to the configuration file to override its values. Parameter values must follow the rules described below. During the Kaspersky EDR Expert deployment, KDT checks whether the required installation parameters are specified correctly. If the required parameters in the configuration file are missing or invalid, the deployment will be interrupted.

Sample of the configuration file for the multi-site deployment of Kaspersky EDR Expert

```

# Parameters for the Kaspersky EDR deployment
parameters:
  # Connection string for accessing the DBMS installed and configured on a separate
  server.
  # user_db—The user name of a privileged internal DBMS account. This account is granted
  permissions to create databases and other DBMS accounts.
  # password_db—The password of the privileged internal DBMS account.
  # fqdn_db:port_db—The FQDN and connection port of a separate server on which the DBMS
  is installed.
  # The 'psql_dsn' parameter value must comply with the URI format. If the connection URI
  includes symbols with special meaning in any of its parts, it must be encoded with
  percent-encoding.
  - name: psql_dsn
    source:
      value: "postgres://postgres:password@dbms.example.com:1234"
  # Path to the SSH private key for connection to the primary and workers nodes by KDT.
  The SSH private key is located on the administrator host.
  # The parameter value must be a Linux file path or Base64-encoded file content.
  - name: ssh_pk
    source:
      path: /root/.ssh/id_rsa
  # Password of the Kaspersky EDR user account that will be created during the
  installation.
  # Password must be 8 to 256 characters long.
  # It can contain lowercase or uppercase letters ('a' to 'z'), digits ('0' to '9'), and
  special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;).
  - name: admin_password
    source:
      value: "password"
  # Path to the KUMA inventory file that contains installation settings for KUMA service
  deployment. This file is located on the administrator host.
  # The parameter value must be a Linux file path or Base64-encoded file content.
  - name: inventory
    source:
      value: "/home/user/inventory.yml"
  # Path to the Kaspersky Endpoint Detection and Response license key. This file is
  located on the administrator host.
  # The parameter value must be a Linux file path or Base64-encoded file content.
  - name: license
    source:
      value: "/home/user/license.key"
  # Domain name. The parameter value must satisfy the naming requirements for domains up
  to the fourth level.
  # The service host name and domain name are parts of FQDNs of the Kaspersky EDR
  services.
  # Default values of service host names: nwc_host—"console", flow_host—"console",
  hydra_host—"console", login_host—"console", ksc_host—"admsrv", console_host—"console",
  api_host—"api", kuma_host—"kuma", monitoring_host—"monitoring".
  # Custom host names can be specified in the configuration file.
  # Example: console.smp.local is the FQDN of the service that provides access to the
  OSMP Console. This FQDN consists of the 'console_host' and 'smp_domain' parameter
  values.
  - name: smp_domain
    source:
      value: "smp.local"
```

```
# List of host names of the Kaspersky EDR services for which a self-signed or user
certificate must be generated.
# The parameter value must be a list of host names, separated by spaces. If custom host
names are not specified, the default host names are used.
- name: pki_host_list
  source:
    value: "admsrv api console kuma monitoring agentserver updater"
# The parameter that indicates whether to deploy the KUMA services for Kaspersky EDR or
for Kaspersky NGFW.
- name: autodeploy_plan
  source:
    value: "edr"
# User name for authentication on the SMTP server.
- name: grafana_admin_user
  source:
    value: xdr
# Password for authentication on the SMTP server.
- name: grafana_admin_password
  source:
    value: "password"
```

For correct function of KDT with the configuration file, add an empty line at the end of the file.

The `regions` section contains installation parameters for each logical infrastructure regions. A region represents a geographical area or deployment location and groups one or more data centers (zones).

Regions section

Parameter name	Required	Description
`description`	Yes	The name of the infrastructure region. The value must comply with the following rules: • The node name must be 1 to 63 characters long. • The node name can contain the following characters: • Uppercase ASCII letters (A–Z) • Lowercase ASCII letters (a–z) • Numbers (0–9) • Hyphen (-) All infrastructure regions must have unique names.

The `zones` section contains installation parameters for each data center. Each zone belongs to a specific region.

Zones section

Parameter name	Required	Description
`region`	Yes	The name of the infrastructure region that the zone belongs to. The value must comply with the following rules: • The node name must be 1 to 63 characters long. • The node name can contain the following characters: • Uppercase ASCII letters (A–Z) • Lowercase ASCII letters (a–z) • Numbers (0–9) • Hyphen (-) The value of the `region` parameter must match the identifier of a region defined in the `regions` section.

Parameter name	Required	Description
`ingress_ip`	Yes	The reserved static IPv4 address of the Kubernetes cluster gateway. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. Each data center must have its own unique cluster gateway IP address. The gateway must be included in the same subnet as the primary and worker nodes located in the same data center.

The `nodes` section of the configuration file contains installation parameters for each target host of the Kubernetes cluster. These parameters are listed in the table below.

Nodes section

Parameter name	Required	Description
`desc`	Yes	The node name. The value must comply with the following rules: • The node name must be 1 to 63 characters long. • The node name can contain the following characters: • Uppercase ASCII letters (A–Z) • Lowercase ASCII letters (a–z) • Numbers (0–9) • Hyphen (-) All cluster nodes must have unique names. This requirement is one of the prerequisites for the installation of Kaspersky EDR Expert and is verified by KDT.
`type`	Yes	The node type. Possible parameter values: • `primary` • `worker`
`host`	Yes	The IP address of the node. All nodes that belongs to a data center must be included in the same subnet as the Kubernetes cluster gateway of this data center. Nodes require IPv4 addressing. KDT automatically disables IPv6 on the cluster nodes.
`zone`	Yes	The name of the data center that the node belongs to. The value of the `zone` parameter must match the identifier of a data center defined in the `zones` section.
`kuma_role`	No	The KUMA service that you can specify for installation on the worker node. You can specify one, multiple, or no KUMA services. The `kuma_roles` parameter is considered when the KUMA service installing in the Kubernetes cluster by using the OSMP Console. If the node where you plan to install the KUMA service is overloaded, the cluster will select another, less busy node for the service installation. Set the `inventory` parameter to `/dev/null`. It is not allowed to place storages created from the same KUMA resource on the same worker node. This rule ensures the required level of fault tolerance. Possible parameter values: • `core` — KUMA Core • `metrics` — KUMA metrics • `collector` — Collector • `correlator` — Correlator • `storage` — Storage The parameter value is specified as a list of strings containing KUMA roles. For example: `kuma_roles: ["core","metrics","collector"]`

Parameter name	Required	Description
`user`	Yes	The user name of the account created on the target host and used for connection to the node by KDT. The value must comply with the following rules: • The user name must be 1 to 31 characters long. • The user name can contain the following characters: • Lowercase letters (a–z) • Numbers (0–9) • Underscore (_), hyphen (-)
`password`	No	The password for connecting to the node. Can be used instead of the SSH key specified by the `ssh_pk` parameter.

Other installation parameters are listed in the `parameters` section of the configuration file and are described in the table below.

Parameters section

Parameter name	Required	Description

`psql_dsn`	Yes	The connection string for accessing the DBMS that is installed and configured outside the Kubernetes cluster.
		Specify this parameter as follows:
		`psql_dsn=postgres://<dbms_username>:<password>@<fqdn>:<port>`
		where:
		• `dbms_username` —The user name of a privileged internal DBMS account. This account is granted permissions to create databases and other DBMS accounts. By using this privileged DBMS account, the databases and other DBMS accounts required for the Kaspersky EDR Expert components will be created during the deployment.
		• `password` —The password of the privileged internal DBMS account.
		• `fqdn:port` —The FQDN and connection port of the target host on which the DBMS is installed.
		To use a highly available cluster, specify this parameter as follows:
		`psql_dsn=postgres://<dbms_username>:<password>@<fqdn1>:<port>,<fqdn2>:<port>,<fqdn3>:<port>`
		To use Corosync/Pacemaker, specify this parameter with a virtual IP as follows:
		`psql_dsn=postgres://postgres:pass!@<virtual ip>:<port>`
		The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.
		Symbols that must be replaced in the `psql_dsn` parameter value:
		• Whitespace → `%20`
		• ! → `%21`
		• # → `%23`
		• % → `%25`
		• & → `%26`
		• / → `%2F`
		• : → `%3A`
		• = → `%3D`
		• ? → `%3F`
		• @ → `%40`
		• [→ `%5B`
		•] → `%5D`
		Refer to the PostgreSQL connection string article for details.

`nwc-language`	Yes	The language of the OSMP Console interface is specified by default. After installation, you can change the OSMP Console language. Possible parameter values: • `enUS` (default value) • `ruRu` The default value is used if you do not specify this parameter in the configuration file.

Parameter name	Required	Description
`ssh_pk`	Yes	The path to the private part of the SSH key located on the administrator host and used for connection to the primary worker node and nodes with the KUMA services (collectors, correlators, and storages) by using KDT. The parameter value must be a Linux file path or Base64-encoded file content.
`admin_password`	Yes	The `admin_password` parameter specifies the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The default user name of this account is "admin." The Main administrator role is assigned to this user account. The password must comply with the following rules: • The user password cannot have fewer than 10 or more than 256 characters. • The password must contain characters from at least three of the groups listed below: • Uppercase letters (A–Z) • Lowercase letters (a–z) • Numbers (0–9) • Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;) • The password must not contain any whitespaces, or the ".@" combination. When you specify the `admin_password` parameter value manually (not by the Deployment wizard), make sure that this value meets the YAML standard requirements for values in strings: • The parameter value containing special characters must be enclosed in single quotes. • Any single quote ' inside the parameter value must be doubled to escape this single quote. Example: the user account password `Any_pass%1234'5678"90` must be specified as the value `'Any_pass%1234''5678"90'` of the `admin_password` parameter.
`low_resources`	No	The parameter indicating that Kaspersky EDR Expert is installed on the target host with limited computing resources. Set the `low_resources` parameter to `false` for multi-node deployment. Possible parameter values: • `true` —Installation with limited computing resources (for single-node deployment) • `false` —Standard installation (default value)
`core_disk_request`	Yes	The parameter that specifies the amount of disk space for the operation of KUMA Core. If you do not specify the `core_disk_request` parameter and the `low_resources` parameter is set to `false` or is not specified, the default amount of disk space for the operation of KUMA Core is 100 GB. If you do not specify the `core_disk_request` parameter and the `low_resources` parameter is set to `true`, the default amount of disk space for the operation of KUMA Core is 4 GB. You can change the `core_disk_request` parameter later, after the application deployment.
`metrics_disk_request`	Yes	The parameter that specifies the amount of disk space for the operation of the Metrics service. If you do not specify the `metrics_disk_request` parameter and the `low_resources` parameter is set to `false` or is not specified, the default amount of disk space for the operation of the Metrics service is 80 GB. If you do not specify the `metrics_disk_request` parameter and the `low_resources` parameter is set to `true`, the default amount of disk space for the operation of the Metrics service is 4 GB. You can change the `metrics_disk_request` parameter later, after the application deployment.
`inventory`	Yes	The path to the KUMA inventory file located on the administrator host. The inventory file contains installation parameters for deployment of the KUMA services that are not included in the Kubernetes cluster. The parameter value must be a Linux file path or Base64-encoded file content. If all KUMA services will be installed inside the cluster, set the `inventory` parameter to `/dev/null`.

Parameter name	Required	Description
`host_inventory`	No	The path to the additional KUMA inventory file located on the administrator host. This file contains the installation parameters used to partially add or remove hosts with the KUMA services. The parameter value must be a Linux file path or Base64-encoded file content. If you perform an initial deployment of Kaspersky EDR Expert or run a custom action that requires configuration file, leave the default parameter value (`/dev/null`).
`license`	No	The path to the KUMA license key located on the administrator host. The parameter value must be a Linux file path or Base64-encoded file content. You can upload the license key or specify the activation code once you log in to OSMP after deployment is complete.

`nwc_host`
`flow_host`
`hydra_host`
`login_host`
`ksc_host`
`console_host`
`api_host`
`kuma_host`
`monitoring_host`
`xdr_edr_ingress_host`
	Yes	The host name that is used in the FQDNs of the public Kaspersky EDR Expert services. The service host name and domain name (the `smp_domain` parameter value) are parts of the service FQDN.
		If custom host names are not specified, the following default host names are used:
		• `nwc_host`—`"console"`
		• `flow_host`—`"console"`
		• `hydra_host`—`"console"`
		• `login_host`—`"console"`
		• `ksc_host`—`"admsrv"`
		• `console_host`—`"console"`
		• `api_host`—`"api"`
		• `kuma_host`—`"kuma"`
		• `monitoring_host`—`"monitoring"`
		• `xdr_edr_ingress_host`—`"agentserver"`

`smp_domain`	Yes	The domain name that is used in the FQDNs of the public Kaspersky EDR Expert services. The parameter value must satisfy the naming requirements for domains up to the fourth level. The service host name and domain name are parts of the service FQDN. For example, if the value of the `console_host` variable is `console`, and the value of the `smp_domain` variable is `smp.local`, then the full name of the service that provides access to the OSMP Console is `console.smp.local`.
`pki_host_list`	Yes	The list of host names of the public Kaspersky EDR Expert services for which a self-signed or user certificate is to be generated. The parameter value must be a list of host names, separated by spaces.
`intermediate_enabled`	No	The parameter that indicates whether to use the custom intermediate certificate instead of the self-signed certificates for the public Kaspersky EDR Expert services. Possible parameter values: • `true`—Use custom intermediate certificate. • `false`—Use self-signed certificates (default value).
`intermediate_bundle`	No	The path to the custom intermediate certificate used to work with public Kaspersky EDR Expert services. Specify this parameter if the `intermediate_enabled` parameter is set to `true`. The parameter value must be a Linux file path or Base64-encoded file content. The validity period for the custom intermediate certificate must be 399 days or more.

`admsrv_bundle`
`api_bundle`
`console_bundle`
`kuma_bundle`
`monitoring_bundle`
	No	The paths to the custom leaf certificates used to work with the corresponding public Kaspersky EDR Expert services: `<admsrv_host>.<smp_domain>`, `<api_host>.<smp_domain>`, `<kuma_host>.<smp_domain>`, `<monitoring_host>.<smp_domain>`, and `<console_host>.<smp_domain>`. The parameter values must be a Linux file path or Base64-encoded file content.
		If you want to specify the custom leaf certificates, set the `intermediate_enabled` parameter to `false` and do not specify the `intermediate_bundle` parameter and the `pki_host_list` parameter.

Parameter name	Required	Description
`ksc_state_size`	Yes	The amount of free disk space allocated to store the Administration Server data (updates, installation packages, and other internal service data). Measured in gigabytes, specified as "<amount>Gi". The required amount of free disk space depends on the number of managed devices and other parameters, and can be calculated. The default value is 30 GB. This value is used if you do not specify this parameter in the configuration file.
`prometheus_size`	Yes	The amount of free disk space allocated to store metrics. Measured in gigabytes, specified as "<amount>GB". The minimum recommended and default value is 5 GB. The default value is used if you do not specify this parameter in the configuration file.
`grafana_admin_user`	No	The user name of the account used to view OSMP metrics through the Grafana tool. The value must comply with the following rules: • The user name must be 1 to 30 characters long. • The user name can contain the following characters: • Lowercase letters (a–z) • Numbers (0–9) • Special characters (_ - .) • The user name must start with a letter. • The user name must not contain either whitespaces or the "@" symbol.
`grafana_admin_password`	No	The password of the account used to view OSMP metrics through the Grafana tool. The password must comply with the following rules: • The user password cannot have fewer than 8 or more than 256 characters. • The password must contain characters from the groups listed below: • Uppercase letters (A–Z) • Lowercase letters (a–z) • Numbers (0–9) • Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)
`loki_size`	Yes	The amount of free disk space allocated to store OSMP logs. Measured in gigabytes, specified as "<amount>Gi". The minimum recommended and default value is 40 GB. The default value is used if you do not specify this parameter in the configuration file.
`loki_retention_period`	Yes	The storage period of OSMP logs after which logs are automatically removed. The default value is 72 hours (set the parameter value in the configuration file as "<time in hours>h". For example, "72h"). The default value is used if you do not specify this parameter in the configuration file.
`file_storage_cp`	No	The amount of free disk space allocated to store data of the component for working with response actions. Measured in gigabytes, specified as "<amount>Gi". The minimum recommended value is 20 GB.
`psql_tls_off`	No	The parameter that indicates whether to encrypt the traffic between the Kaspersky EDR Expert components and the DBMS by using the TLS protocol. If the DBMS is installed outside the cluster, TLS encryption is disabled by default (the default value is `true`). Possible parameter values: • `true` —Do not encrypt the traffic (default value). • `false` —Encrypt the traffic.
`psql_trusted_cas`	No	The path to the PEM file that can contain the TLS certificate of the DBMS server or a root certificate from which the TLS server certificate can be issued. The parameter value must be a Linux file path or Base64-encoded file content. Specify the `psql_trusted_cas` parameter if the DBMS will be installed and configured on a separate server and traffic encryption is enabled (`psql_tls_off` is set to `false`).

Parameter name	Required	Description
`proxy_enabled`	No	The parameter that indicates whether to use the proxy server to connect the Kaspersky EDR Expert components to the internet. If the host on which Kaspersky EDR Expert is installed has internet access, you can also provide internet access for the operation of Kaspersky EDR Expert components (for example, Administration Server) and for specific integrations, both Kaspersky and third-party. To establish the proxy connection, you must also specify the proxy server parameters in the Administration Server properties. Possible parameter values: • `true` —Proxy server is used. • `false` —Proxy server is not used (default value).
`proxy_addresses`	No	The IP address of the proxy server. If the proxy server uses multiple IP addresses, specify these addresses separated by a space (for example, "`0.0.0.0 0.0.0.1 0.0.0.2`"). Specify this parameter if the `proxy_enabled` parameter is set to `true`.
`proxy_port`	No	The number of the port through which the proxy connection will be established. Specify this parameter if the `proxy_enabled` parameter is set to `true`.
`trace_level`	No	The verbosity level of Administration Server trace files. Traces are written during the Administration Server operation. The default value is 0, no traces are written. Possible parameter values: 0–5. The higher the parameter value, the more detailed the trace details.
`ansible_extra_flags`	No	The verbosity level of logs of the KUMA Core and KUMA services deployment that is performed by KDT. Possible parameter values: • `-v` • `-vv` • `-vvv` • `-vvvv` As the number of "v" letters in the flag increases, logs become more detailed. If this parameter is not specified in the configuration file, the standard component installation logs are saved.
`incident_attachments_max_count_limit`	No	The number of files that you can attach to the incident. The default value is `100`.
`incident_attachments_max_size_limit`	No	The total size of files attached to the incident. Measured in bytes. Specified without units of measurement. The default value is `26214400`.
`ignore_precheck`	No	The parameter indicating whether to check the hardware, software, and network configuration of the Kubernetes cluster nodes for compliance with the prerequisites for installing the solution before the deployment. Possible parameter values: • `true` —Skip the pre-checks. • `false` —Perform the pre-checks (default value).
`airgap_mode`	No	The parameter indicating whether to perform the APT package manager pre-check and update the package cache. This allows deploying Kaspersky EDR Expert in an air-gapped environment. Possible parameter values: • `true` —Skip the pre-check and the package cache update. • `false` —Perform the pre-check and update the package cache (default value).
`grafana_smtp_host`	No	SMTP server address for Grafana, used to send email notifications about Kubernetes cluster health events. Specify this parameter in the `<host>:<port>` format, for example, `localhost:25`.
`grafana_smtp_user`	No	User name for authentication on the SMTP server.
`grafana_smtp_password`	No	Password for authentication on the SMTP server.
`grafana_smtp_bundle`	No	File containing the X.509 certificate chain used for verifying TLS connection to the SMTP server.

Parameter name	Required	Description
`grafana_smtp_skip_verify`	No	The parameter that indicates whether to skip TLS certificate verification of the SMTP server. Possible parameter values: • `true` —Skip TLS certificate verification. • `false` —Perform TLS certificate verification (default value).
`grafana_smtp_from_address`	No	Email address of the sender, which will appear in the From field when sending email notifications.
`grafana_smtp_from_name`	No	Display name of the sender in email notifications.
`grafana_smtp_ehlo_identity`	No	Identifier used in the EHLO command when connecting to the SMTP server.
`grafana_starttls_policy`	No	Policy for using STARTTLS when connecting to the SMTP server. Possible parameter values: • `OpportunisticStartTLS` —Use STARTTLS if the SMTP server supports it; otherwise, connect to the SMPT server without encryption. • `MandatoryStartTLS` —Require STARTTLS; fail if the SMTP server does not support it. • `NoStartTLS` —Do not use STARTTLS; connect to the SMPT server without encryption. • `empty` —Use STARTTLS if the SMTP server supports it; otherwise, connect to the SMPT server without encryption (default value).
`grafana_smtp_enable_tracing`	No	The parameter that indicates whether to enable SMTP connection tracing for debugging email sending. Possible parameter values: • `true` —Enable SMTP connection tracing. • `false` —Disable SMTP connection tracing (default value).
`autodeploy_plan`	No	The parameter that indicates whether to deploy the KUMA services for Kaspersky EDR or for Kaspersky NGFW. Possible parameter values: • `edr` —Deploy the KUMA services for OSMP and for Kaspersky EDR inside the Kubernetes cluster (default value). • `ngfw` —Deploy the KUMA services for OSMP and for Kaspersky NGFW inside the Kubernetes cluster. Additionally, the predefined collector **[OOTB] Kaspersky NGFW** will be installed on the first host from the host list specified in the `kuma_collector` parameter of the KUMA inventory file. • `none` —Do not deploy the KUMA services for Kaspersky EDR or Kaspersky NGFW. Use this value for Kaspersky EDR Expert deployment without KUMA services for Kaspersky EDR and Kaspersky NGFW or for Kaspersky EDR Expert restoration from a backup. If you use the `edr` or `ngfw` values for Kaspersky EDR Expert restoration, this may lead to conflicts between the deployed services and the services stored in a backup.
`tokenhub_access_token`	No	The lifetime of an access token. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`1h10m`" or "`2h`". The minimum possible value is `5m` and the maximum is `2h`. The default value is `1h`. This value is used if you do not specify this parameter in the configuration file. You can change the `tokenhub_access_token` parameter later, after the application deployment.
`tokenhub_refresh_token`	No	The lifetime of a refresh token that is used for getting a new access token. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`24h`" or "`1240h30m`". The minimum possible value is `12h` and the maximum is `4320h`. The default value is `24h`. This value is used if you do not specify this parameter in the configuration file. You can change the `tokenhub_refresh_token` parameter later, after the application deployment.

Parameter name	Required	Description
`credentials_session_ttl`	No	The maximum single sign-on session idle time. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`24h`" or "`1h30m`". The minimum possible value is `5m` and the maximum is `96h`. The default value is `1h`. This value is used if you do not specify this parameter in the configuration file. You can change the `credentials_session_ttl` parameter later, after the application deployment.

Cross-datacenter multi-site deployment on standard Ubuntu Server 24.04 LTS virtual machines

This section contains instructions for cross-datacenter multi-site Kaspersky EDR Expert deployment on standard Ubuntu Server 24.04 LTS virtual machines.

Typical configuration of three primary nodes, nine worker nodes, and HAProxy
In this deployment, three datacenters are used, with one primary node and three worker nodes in each. In total, this deployment requires three primary nodes, nine worker nodes and one HAProxy node. The requirements for the nodes are:

- primary node: 4 vCPU, 8 GB of RAM, 500 GB of SSD*
- worker node: 10 vCPU, 20 GB of RAM, 1 TB of SSD*
- HAProxy node: 4 vCPU, 8 GB of RAM, 100 GB of SSD*

* Or any device with 8000 IOPS (input/output operations per second) in random access

> Hardware requirements must be calculated according to the sizing guide.

Configuring HAProxy, primary, and worker nodes
2.1 Configuring the HAProxy host

To implement a cross-datacenter solution, hosts must be distributed across different subnets, utilizing three Kubernetes cluster gateways from the respective subnets, along with a HAProxy host located in one of the subnets.

1. Install HAProxy:

```
sudo apt update
sudo apt install haproxy
```

2. Edit the HAProxy configuration file:

```
sudo nano /etc/haproxy/haproxy.cfg
```

Example configuration file:

```
global
 log /dev/log local0
 log /dev/log local1 notice
 chroot /var/lib/haproxy
 stats socket /run/haproxy/admin.sock mode 660 level admin
 stats timeout 30s
 user haproxy
 group haproxy
 daemon

defaults
 log global
 mode http
 option httplog
 option dontlognull
 timeout connect 5000
 timeout client 50000
 timeout server 50000
 errorfile 400 /etc/haproxy/errors/400.http
 errorfile 403 /etc/haproxy/errors/403.http
 errorfile 408 /etc/haproxy/errors/408.http
 errorfile 500 /etc/haproxy/errors/500.http
 errorfile 502 /etc/haproxy/errors/502.http
 errorfile 503 /etc/haproxy/errors/503.http
 errorfile 504 /etc/haproxy/errors/504.http

listen stats
 mode http
 bind *:8080

 server proxmox1 <first gateway IP>:13000 check inter 5s # ingress_ip number 1
 server proxmox2 <second gateway IP>:13000 check inter 5s # ingress_ip number 2
 server proxmox3 <third gateway IP>:13000 check inter 5s # ingress_ip number 3
```

3. Save (**Ctrl+S**), and then close the file (**Ctrl+X**).

4. Restart the HAProxy service:

```
sudo systemctl restart haproxy
```

2.2 Configuring primary and worker nodes

2.2.1 Configuring a user account for deploying Kaspersky EDR Expert

1. Open /etc/sudoers:

```
sudo visudo
```

2. Add the following line to the end of the file:

```
{user} ALL=(ALL) NOPASSWD: ALL
```

   Where `{user}` is the user account for deployment.

3. Save (**Ctrl+S**), and then close the file (**Ctrl+X**).

2.2.2 Checking free space in /var, /opt, and /tmp directories

1. On the primary node, run the following commands:

   ```
   df -h /var
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /opt
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /tmp
   ```

   At least 50 GB of free space must be available.

2. On worker1-worker3 nodes, run the following commands:

   ```
   df -h /var
   ```

   At least 200 GB of free space must be available.

   ```
   df -h /opt
   ```

   At least 700 GB of free space must be available.

   ```
   df -h /tmp
   ```

   At least 50 GB of free space must be available.

2.2.3 Ensuring there are no errors when synchronizing repositories

Execute the following command:

```
sudo apt update
```

The command should return no errors.

2.2.3 Installing python3-apt and curl

Execute the following command:

```
sudo apt install python3-apt curl -y
```

2.2.4 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

   The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

   The output must contain current date and time.

Configuring DBMS host
A DBMS host is a host with a DBMS instance installed.

Requirements to the target host on which the DBMS instance is installed:

- 10 vCPU
- 20 GB of RAM
- 1.6 TB of SSD or any device with 8000 IOPS (input/output operations per second) in random access

For supported PostgreSQL versions, refer to the Hardware and software requirements article.

3.1 Installing and configuring PostgreSQL

1. Install PostgreSQL:

```
sudo apt install -y postgresql-<version>
```

   Where <`version`> is PostgreSQL version.

   If the required PostgreSQL version is not available in the connected repository, you must add the `postgresql` repository. For instructions, refer to PostgreSQL website.

2. Create a separate PostgreSQL superuser:

```
sudo -u postgres createuser --superuser xdr
```

3. Set a password for the user:

```
sudo -u postgres psql -c "ALTER USER xdr WITH PASSWORD 'your_password';"
```

4. Create a database with the same name as the user:

```
sudo -u postgres psql -c "CREATE DATABASE xdr OWNER xdr;"
```

5. Allow PostgreSQL access from any IP address:

```
echo "host all all 0.0.0.0/0 scram-sha-256" | sudo tee -a /etc/postgresql/<version>/main/pg_hba.conf
```

Where <version> is PostgreSQL version.

6. Edit the following parameters in the PostgreSQL configuration file (/etc/postgresql/<version>/main/postgresql.conf), where <version> is PostgreSQL version. For example, for PostgreSQL 16: /etc/postgresql/16/main/postgresql.conf.

Commented (#) lines need to be uncommented.

```
listen_addresses = '*'
shared_buffers = 8192MB
max_stack_depth = 7MB
temp_buffers = 24MB
work_mem = 16MB
max_connections = 512
max_parallel_workers_per_gather = 0
maintenance_work_mem = 128MB
standard_conforming_strings = on
```

7. Restart PostgreSQL

```
sudo systemctl restart postgresql
```

3.2 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

The output must contain current date and time.

Configuring administrator host
Administrator host is the host from which the KDT utility is run. Files from the distribution kit including the archive with the KDT utility, must be located on the administrator host. This host may be part of the Kubernetes cluster created by the KDT utility during deploy, or it may remain outside the cluster. If the administrator host is not included in the cluster, it is used solely to deploy and manage the Kubernetes cluster and OSMP. If the administrator host is included in the cluster, in addition it also serves as a target host on which OSMP components are run.

4.1 Unpacking the KDT utility

Run the following command to create a directory and unpack the KDT utility:

```
mkdir ./kdt && tar -xvf bin.tar.gz -C ./kdt
```

4.2 Docker installation

Docker versions 25 and later are supported.

4.2.1 Installation on Ubuntu 24:

```
sudo apt update && sudo apt install docker.io
```

4.2.2 **OR** *Installation using official instructions:*

1. Install the required packages:

   ```
   sudo apt update && sudo apt install ca-certificates curl
   ```

2. Download Docker keyring:

   ```
   sudo curl -fsSL https://download.docker.com/linux/ubuntu/gpg -o /etc/apt/keyrings/docker.asc && sudo chmod 0755
   /etc/apt/keyrings/docker.asc
   ```

3. Add the Docker apt repository:

   ```
   sudo tee /etc/apt/sources.list.d/docker.sources <<EOF
   Types: deb
   URIs: https://download.docker.com/linux/ubuntu
   Suites: $(. /etc/os-release && echo "${UBUNTU_CODENAME:-$VERSION_CODENAME}")
   Components: stable
   Architectures: $(dpkg --print-architecture)
   Signed-By: /etc/apt/keyrings/docker.asc
   EOF
   ```

4. Update the repository cache and install Docker packages:

   ```
   sudo apt update && sudo apt install docker-ce docker-ce-cli containerd.io docker-buildx-plugin docker-compose-
   plugin
   ```

4.3 Docker configuration

1. Add the current user to the `docker` group:

```
sudo usermod -aG docker $USER
```

2. Activate user membership in the `docker` group in the current session:

```
newgrp docker
```

4.4 Configuring the system time to synchronize with the NTP server

1. Run the following commands:

```
sudo apt update
sudo apt install -y systemd-timesyncd
sudo timedatectl set-ntp true
sudo timedatectl set-timezone Europe/Moscow
sudo timedatectl set-local-rtc 0
timedatectl status
```

   The output will contain the line:

```
System clock synchronized: yes
```

2. To check synchronization, run:

```
date
```

   The output must contain current date and time.

4.5 Checking free space in the /tmp directory

Execute the following command:

```
df -h /tmp
```

At least 50 GB of free space must be available.

If you do not have enough free space in the /tmp directory, specify the path to another directory:

```
export TMPDIR=<new_directory>/tmp
```

Or allocate the required free space:

```
echo 'tmpfs /tmp tmpfs defaults,size=50G 0 0' | sudo tee -a /etc/fstab
```

After allocating the required space, reboot the host or remount the partition.

4.6 Configuring an SSH connection between administrator host and primary and worker nodes

1. Create SSH key:

```
ssh-keygen -t rsa -b 4096 -N ""
```

2. Copy the key to each target host one-by-one:

```
ssh-copy-id {user}@{primary_ip}
ssh-copy-id {user}@{worker_ip} # copy the key to each worker node in a subnet
```

Where `{user}` is the user account for Kaspersky EDR Expert deployment created during target host configuration.

4.7 DNS configuration

On your DNS server, register the FQDN of the services to connect to OSMP services (`<smp_domain>`).

To get started quickly, add a wildcard A record in your DNS server that points to the HAProxy IP address. HAProxy balances traffic between three Kubernetes cluster gateways (`<ingress_ip>`), which then route traffic to the appropriate services.

By default, OSMP services are available at the following addresses:

```
<haproxy_host_ip> - admsrv.<smp_domain>
<haproxy_host_ip> - api.<smp_domain>
<haproxy_host_ip> - console.<smp_domain>
<haproxy_host_ip> - kuma.<smp_domain>
<haproxy_host_ip> - *.kuma.<smp_domain>
<haproxy_host_ip> - monitoring.<smp_domain>
<haproxy_host_ip> - agentserver.<smp_domain>
<haproxy_host_ip> - updater.<smp_domain>
```

4.8 Creating a configuration to run the installation

Show legend

- `10.0.0.100`—IP address of the first primary node in the first subnet (`<primary1_ip>`)
- `10.10.20.18`—IP address of the second primary node in the second subnet (`<primary2_ip>`)
- `10.65.20.10`—IP address of the third primary node in the third subnet (`<primary3_ip>`)
- `10.0.0.101`—IP address of the first worker node in the first subnet (`<worker1_ip>`)
- `10.0.0.102`—IP address of the second worker node in the first subnet (`<worker2_ip>`)
- `10.0.0.103`—IP address of the third worker node in the first subnet (`<worker3_ip>`)
- `10.10.20.20`—IP address of the first worker node in the second subnet (`<worker4_ip>`)
- `10.10.20.21`—IP address of the second worker node in the second subnet (`<worker5_ip>`)
- `10.10.20.22`—IP address of the third worker node in the second subnet (`<worker6ip>`)

- `10.65.20.11`—IP address of the first worker node in the third subnet (`<worker7_ip>`)
- `10.65.20.12`—IP address of the second worker node in third first subnet (`<worker8_ip>`)
- `10.65.20.13`—IP address of the third worker node in the third subnet (`<worker9_ip>`)
- `10.0.0.150`—IP address of the DBMS host (`<DB_ip>`)
- `10.0.0.200`—IP address of the first Kubernetes cluster gateway
- `10.10.20.100`—IP address of the second Kubernetes cluster gateway
- `10.65.20.100`—IP address of the third Kubernetes cluster gateway
- `10.0.0.111`—IP address of the HAProxy host
- `user`—User account for deployment (`<user_name>`)
- `/home/user/.ssh/id_rsa`—Path to the SSH key created during SSH connection configuration on the administrator host (`<ssh_key_path>`)
- `xdr.mydomain.com`—Domain for ingress (`<smp_domain>`)

4.8.1 Specifying installation parameters using the configuration file

The template of the configuration file (multinode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility.

The `psql_dsn` parameter value must comply with the URI format. If the connection URI includes symbols with special meaning in any of its parts, it must be encoded with percent-encoding.

Symbols that must be replaced in the `psql_dsn` parameter value:

- Whitespace → `%20`
- ! → `%21`
- # → `%23`
- % → `%25`
- & → `%26`
- / → `%2F`
- : → `%3A`
- = → `%3D`
- ? → `%3F`
- @ → `%40`
- [→ `%5B`
-] → `%5D`

Refer to the PostgreSQL connection string article for details.

Installing Kaspersky EDR Expert

Run the following command:

```
./kdt/bin/kdt apply --accept-eula -k xdr-<program_version>.tar -i params.yaml
```

If the installation is successful, the following information will be displayed in the terminal:

```
INFO[0038] apply inventory ./conf.yaml
INFO[0039] preparing bootstrap_<ver>.tgz
INFO[0092] installing: bootstrap
INFO[0404] time: prepare 53.113895029s install 5m12.442326155s
INFO[0404] current installation is valid
INFO[0404] bundles will be published: 40
INFO[0536] bundles published 40
INFO[0536] bundles will be applied: 39
INFO[2450] apply done: 31m53.851140069s
INFO[2450] apply command completed successfully
INFO[2450] time: publish 2m11.679771805s install 31m53.930470045s
```

To check the installation, you need to go to the authorization page. To do this, enter the following in the search bar of the browser:

```
console.<smp_domain>
```

Where `<smp_domain>` is the FQDN from the step 4.7 of this procedure.

Kaspersky EDR Expert maintenance

This section describes updating, removing, and reinstalling Kaspersky EDR Expert components by using KDT. Also, the section provides instructions on how to stop the Kubernetes cluster nodes, update user certificates for public Kaspersky EDR Expert services, as well as obtain the current version of the configuration file, and perform other actions with Kaspersky EDR Expert components by using KDT.

Updating Kaspersky EDR Expert components

KDT allows you to update the Kaspersky EDR Expert components (including management web plug-ins) and the Bootstrap component. New versions of the Kaspersky EDR Expert components are included in the distribution package.

Installing components of an earlier version is not supported.

To update the Kaspersky EDR Expert components:

1. Download the distribution package with the new versions of the Kaspersky EDR Expert components.
2. If necessary, on the administrator host, export the current version of the configuration file.

   You need not export the configuration file if the installation parameters are not added or modified.
3. Update the Kaspersky EDR Expert components and Bootstrap.

   Specify the path to the transport archive with the Kaspersky EDR Expert components and the path to the configuration file. The configuration file path is optional if it is specified in the Bootstrap update command or no installation parameters are added or modified:

   - Run the following command for standard updating of the Kaspersky EDR Expert components:

     ```
     ./kdt apply -k <full_path_to_XDR_updates_archive> -i
     <full_path_to_configuration_file>
     ```

   - If the version of the installed Kaspersky EDR Expert component matches the component version in the distribution package, the update of this component is skipped. Run the following command to force an update of this component by using the `force` flag:

     ```
     ./kdt apply --force -k <full_path_to_XDR_updates_archive> -i
     <full_path_to_configuration_file>
     ```

4. Read the End User License Agreement (EULA) and the Privacy Policy of the Kaspersky EDR Expert component, if a new version of the EULA and the Privacy Policy appears. The text is displayed in the command line window. Press the space bar to view the next text segment. Then, when prompted, enter the following values:

   a. Enter `y` if you understand and accept the terms of the EULA.

      Enter `n` if you do not accept the terms of the EULA. To use the Kaspersky EDR Expert component, you must accept the terms of the EULA.

   b. Enter `y` if you understand and accept the terms of the Privacy Policy, and if you agree that your data will be handled and transmitted (including to third countries) as described in the Privacy Policy.

      Enter `n` if you do not accept the terms of the Privacy Policy.

   To update the Kaspersky EDR Expert component, you must accept the terms of the EULA and the Privacy Policy.

After you accept the EULA and the Privacy Policy, KDT updates the Kaspersky EDR Expert components.

You can read the EULA and the Privacy Policy of the Kaspersky EDR Expert component after the update. The files are located in the `~/kaspersky_eula` directory of the user that runs the installation of Kaspersky EDR Expert.

Checking the integrity of installed Kaspersky EDR Expert components

After you deploy Kaspersky EDR Expert, you can check the solution components for the authenticity and integrity. Each component (CNAB) in the transport archive includes a manifest file in XML format. The manifest contains the component checksums and is signed with a digital signature by using the GOST R 34.11-2012 256-bit algorithm. This digital signature ensures both the validity of the component file checksums and that the checksums in the manifest have not been changed.

You can verify that the components' checksums match the checksums specified in the manifests. This confirms that the components have not been modified and are obtained from a trusted source.

Checking the integrity of Kaspersky EDR Expert components installed inside the Kubernetes cluster

To check the integrity of the installed Kaspersky EDR Expert components:

1. Run the following command to extract Kaspersky EDR Expert components and their manifests from the deployed solution to the specified directory. Only components that are located in the transport archive are extracted from the solution:

```
./kdt extract --reference <path to transport archive> -d <path to extracted cnabs>
```

where:

- `<path to transport archive>` — the path to the transport archive
- `<path to extracted cnabs>` — the path to the directory where the solution components and their manifests will be extracted

2. Run the following command from the directory with extracted components and their manifests. The `integrity_checker` utility compares the checksums of the components extracted from the deployed solution with their checksums in the manifests extracted from the transport archive:

```
find . -type f -iname "*.xml" -print0 | xargs -0 -I {} echo --manifest {} | xargs ./integrity_checker --
signature-purpose 1.3.6.1.4.1.23668.1800.1.1.15 --signature-type kds-with-filename
```

Example command output after a successful integrity check

The number of manifests that have successfully passed verification is shown in the `Manifests` line, in the `succeeded` column.

```
=============================================>
Summary( failed / skipped / succeeded ):
 Manifests: 0 / 0 / 38
 Files: 0 / 0 / 38
 Directories: 0 / 0 / 0
 Registries: 0 / 0 / 0
 Registry values: 0 / 0 / 0
=============================================>
SUCCEEDED
```

Example command output after a failed integrity check

In this example, a manifest was modified after signing or there is an issue with the signature. The number of skipped manifests or those that failed verification is shown in the `Manifests` line, in the `failed` column.

```
=============================================>
Summary( failed / skipped / succeeded ):
 Manifests: 2 / 0 / 36
 Files: 0 / 0 / 0
 Directories: 0 / 0 / 0
 Registries: 0 / 0 / 0
 Registry values: 0 / 0 / 0
=============================================>
FAILED
ERR Can't verify digital signature of file "/home/xdr_user/integrity_check.xml". Flags: None: 0x80000106
(Object is untrusted)
Manifest /home/xdr_user/integrity_check.xml failed.  Reason: Can't verify digital signature of file
"/home/xdr_user/integrity_check.xml". Flags: None: 0x80000106 (Object is untrusted)
```

The integrity of Kaspersky EDR Expert components installed inside the Kubernetes cluster is verified. If KUMA services are also installed inside the cluster, their integrity is verified as well.

You can also check the integrity of KUMA services installed outside the Kubernetes cluster.

Changing the Kaspersky EDR Expert parameters without reinstalling

If the organization's infrastructure has changed, then Kaspersky EDR Expert may need to change the main parameter values quickly, without reinstalling the solution. Kaspersky EDR Expert supports changing the Kubernetes cluster IP address (the `ingress_ip` parameter) and FQDN of services (in particular, changing the service domain name, the `smp_domain` parameter) by using KDT.

To change the parameter values without reinstalling Kaspersky EDR Expert:

1. On the administrator host, export the current version of the configuration file.
2. In the exported configuration file, change the `smp_domain` or `ingress_ip` parameter values. You can change both parameters or either parameter separately.

   If you deploy Kaspersky EDR Expert across multiple data centers, change `ingress_ip` parameter values in the `zones` section of the configuration file.
3. Apply the parameter changes by using the command:

   ```
   ./kdt apply -i '<full_path_to_updated_configuration_file>'
   ```

   The values of the `smp_domain` and `ingress_ip` settings have been changed. and Kaspersky EDR Expert now uses the new parameter values.

When the value of the `smp_domain` parameter changes, the FQDN service names also change. Therefore, KDT reissues all certificates required for working with public Kaspersky EDR Expert services.

Adding and deleting primary and worker nodes of the Kubernetes cluster

If you need to scale the Kubernetes cluster to meet your current workload, increase its fault tolerance, or optimize computing resources, you can add or delete primary and worker nodes included in the cluster by using KDT.

You can add or delete primary and worker nodes only if Kaspersky EDR Expert is deployed on multiple nodes.

Adding new primary and worker nodes to the Kubernetes cluster

To add new primary and worker nodes:

1. Prepare target hosts that will act as primary and worker nodes.
2. On the administrator host, export the current configuration file using the following command:

```
./kdt ec -e '<configuration_file_name_with_path>'
```

The current version of the configuration file is saved to the specified directory with the specified name.

3. In the `nodes` section of the exported configuration file, add parameters of one or several new nodes (`desc`, `type`, `host`, `kind`, `user`, and `key`), and then save the configuration file.

4. Copy the public key to each new node (for example, to the `~/.ssh` directory) using the ssh-copy-id utility.

5. On the administrator host, run the following command to apply the modified configuration file to the Kubernetes cluster. In the command, specify the full path to this configuration file:

   ```
   ./kdt apply -i '< full_path_to_configuration_file >'
   ```

   After you start the command, KDT checks whether the configuration file is filled in correctly. Then, KDT checks whether the hardware, software, and network configuration of the Kubernetes cluster nodes meet the prerequisites for installing the solution. If all the strict pre-checks are successfully completed, KDT outputs the notification of successful validation to stdout and KDT logs. Otherwise, logs with information about the failed validation are saved and the process of adding new hosts is interrupted. You can skip the pre-checks before you run the command, if needed (set the `ignore_precheck` installation parameter to `true`).

New primary and worker nodes are added to the Kubernetes cluster. KDT outputs the information about added primary and worker nodes to stdout and KDT logs.

Deleting primary and worker nodes from the Kubernetes cluster

When deleting nodes, take into account that the minimum allowed number of primary nodes in the cluster is one and the number of workers is three. If fewer than one primary and three workers remain when deleting, the operation will be interrupted. You can view the number of primary and worker nodes in the configuration file that will be obtained after export.

To delete primary and worker nodes:

1. On the administrator host, export the current configuration file using the following command:

   ```
   ./kdt ec -e '<configuration_file_name_with_path>'
   ```

   The current version of the configuration file is saved to the specified directory with the specified name.

2. In the `nodes` section of the exported configuration file, delete parameters of one or several primary and worker nodes (`desc`, `type`, `host`, `kind`, `user`, and `key`), and then save the configuration file.

   Ensure that after deleting nodes, you will have at least one primary and three worker nodes left in the cluster. A minimum cluster configuration for the multi-node deployment includes four nodes (one primary node and three worker nodes). If this condition is not met, the deletion process is interrupted.

   You can also delete a node with `kind=admsrv`, if it is not the only remaining node with `kind=admsrv` in the cluster. If you attempt to delete this node from the cluster, it will be skipped during the deletion process.

3. On the administrator host, run the following command to apply the modified configuration file to the Kubernetes cluster. In the command, specify the full path to this configuration file:

   ```
   ./kdt apply -i '<full_path_to_configuration_file>'
   ```

   The specified nodes are deleted. KDT outputs the information about deleted primary and worker nodes to stdout and KDT logs.

Versioning the configuration file

When working with Kaspersky EDR Expert, you may need to change the parameters that were specified in the configuration file before the Kaspersky EDR Expert deployment. For example, when changing the disk space used to store the Administration Server data, the `ksc_state_size` parameter is modified. The current version of the configuration file with the modified `ksc_state_size` parameter is updated in the Kubernetes cluster.

If you try to use the previous version of the configuration file in a KDT custom action that requires the configuration file, a conflict occurs. To avoid conflicts, you have to use only the current version on the configuration file exported from the Kubernetes cluster.

To export the current version of the configuration file,

On the administrator host where the KDT utility is located, run the following custom action, and then specify the path to the configuration file and its name:

```
./kdt ec -e <configuration_file_name_with_path>
```

The current version of the configuration file is saved to the specified directory with the specified name.

You can use the exported configuration file, for example, when updating Kaspersky EDR Expert components or adding management plug-ins for Kaspersky applications.

> You do not need to export the configuration file if the installation parameters are not added or modified.

Uninstalling Kaspersky EDR Expert

KDT allows you to uninstall all Kaspersky EDR Expert components installed in the Kubernetes cluster, the cluster itself, the KUMA services installed outside the cluster, and other artifacts created during the deployment or operation of the solution.

To uninstall the Kaspersky EDR Expert components and related data:

1. On the administrator host, run the following command:

   ```
   ./kdt remove --all
   ```

   This command removes the following objects and artifacts:

   - All Kaspersky EDR Expert components installed in the Kubernetes cluster and the cluster itself.

- The Kaspersky EDR Expert user account that was created by KDT during the deployment.
- The database located on a separate server or inside the cluster, DBMS schemes, and DBMS accounts created by KDT during the deployment.
- The KUMA services installed outside the cluster on the hosts that were specified in the inventory file.
- The contents of the following directories on target hosts:
  - `/var/spool/ksc/logs`
  - `/var/spool/ksc/backup`
  - `/var/spool/ksc/`
  - `/var/lib/k0s`
  - `/run/k0s`
  - `/etc/k0s/`
  - `/etc/containerd/`
  - `/var/lib/containerd/`
  - `/run/containerd/`
- Logs obtained during the installation and operation of the Kaspersky EDR Expert components.
- Data related to the Kaspersky EDR Expert components on the administrator host.

If the administrator host does not have network access to a target host, uninstalling the components is interrupted. You can restore network access and restart the removal of Kaspersky EDR Expert. Alternatively, you can uninstall the Kaspersky EDR Expert components from the target hosts manually.

If you use multiple Kubernetes clusters managing by contexts, this command removes only the current Kubernetes context, the corresponding cluster, and the Kaspersky EDR Expert components installed in the cluster. Other contexts and their clusters with Kaspersky EDR Expert instances are not removed.

2. Close the ports used by Kaspersky EDR Expert that were opened during the deployment, if needed. These ports are not closed automatically.
3. Remove the operating system packages that were automatically installed during the deployment, if needed. These packages are not removed automatically.
4. Remove KDT and the contents of the `~/kaspersky_eula` and `~/.kdt` directories.

The Kaspersky EDR Expert components, database, and related data are removed, and the ports used by Kaspersky EDR Expert are closed.

Kaspersky applications installed on the managed devices are not removed by using the `./kdt remove` command. For information on how to remove Kaspersky applications, refer to their documentation.

After uninstalling Kaspersky EDR Expert, target hosts are not restarted automatically. You can restart these hosts manually if necessary.

Manual uninstalling of Kaspersky EDR Expert components

If the administrator host does not have network access to a target host, uninstalling the Kaspersky EDR Expert components by using KDT is interrupted. You can restore network access and restart the removal of the solution. Alternatively, you can uninstall the Kaspersky EDR Expert components from the target hosts manually.

To remove the Kaspersky EDR Expert components from the target hosts manually:

1. On the target host, run the following command to stop the k0s service:

   ```
   /usr/local/bin/k0s stop
   ```

2. Run the following command to reset cluster nodes to the initial state:

   ```
   /usr/local/bin/k0s reset
   ```

3. Remove the contents of the following directories:

   - Required directories:
     - `/etc/k0s/`
     - `/var/lib/k0s/`
     - `/usr/libexec/k0s/`
     - `/usr/local/bin/` (remove only the `k0s` file)
   - Optional directories:
     - `/var/lib/containerd/`
     - `/var/cache/k0s/`
     - `/var/cache/kubelet/`
     - `/var/cache/containerd/`

     You can remove the `/var/lib/containerd/` and `/var/cache/containerd/` directories if the containerd service is used only for the function of Kaspersky EDR Expert. Otherwise, your data contained in the `/var/lib/containerd/` and `/var/cache/containerd/` directories may be lost.

     The contents of the `/var/cache/k0s/`, `/var/cache/kubelet/`, and `/var/cache/containerd/` directories are automatically removed after you restart the target host. You do not have to clear these folders manually.

4. Restart all target hosts.

The Kaspersky EDR Expert components are deleted from the target hosts.

Reinstalling Kaspersky EDR Expert after a failed installation

If the installation of Kaspersky EDR Expert failed, you can restart the installation. Installation failure may occur during installation of Bootstrap or installation of Kaspersky EDR Expert components. The steps needed to reinstall Kaspersky EDR Expert depends on whether the Kubernetes cluster was deployed when the installation error occurred.

To determine the stage at which the installation failed,

Run the following command to view the list of all installed Kaspersky EDR Expert components:

```
./kdt state
```

If the Bootstrap installation error occurs, KDT displays a message that Bootstrap is not installed. In this case, you have to manually uninstall the directories created during the deployment.

If Bootstrap is installed successfully, it will have the `Success` status in the command output. This means that a Kaspersky EDR Expert components installation error occurred. In this case, you have to reinstall the components that were not installed correctly or reinstall the entire solution. In the command output, such components have the `Failed` status.

Reinstalling Kaspersky EDR Expert if Bootstrap is not installed

To restart the Kaspersky EDR Expert installation:

1. Go to the directory with the KDT utility, and view the installation logs of the Bootstrap component.

   If a failure occurred during the Bootstrap installation stage, this will be reflected in the log. In this case, Bootstrap has not been installed and the Kubernetes cluster has not been created.

   Run the `/.kdt/kdt-{date}.log | grep -iE "connect|auth|ident|password"` command to find log entries related to the most common installation issues:

   - Database connection settings
   - Administrator password format
   - Insufficient hardware resources
   - Problems with authorization when connecting to nodes

2. Manually uninstall the directories created during the deployment.

   a. On the administrator host, go to the `.kdt` directory, and then remove the `cluster.config` file.

   b. Remove the contents of the following directories:

   - Required directories:
     - `/etc/k0s/`
     - `/var/lib/k0s/`
     - `/usr/libexec/k0s/`
     - `/usr/local/bin/` (remove only the `k0s` file)
   - Optional directories:
     - `/var/lib/containerd/`
     - `/var/cache/k0s/`
     - `/var/cache/kubelet/`
     - `/var/cache/containerd/`

     You can remove the `/var/lib/containerd/` and `/var/cache/containerd/` directories if the containerd service is used only for the function of Kaspersky EDR Expert. Otherwise, data contained in the `/var/lib/containerd/` and `/var/cache/containerd/` directories may be lost.

     The contents of the `/var/cache/k0s/`, `/var/cache/kubelet/`, and `/var/cache/containerd/` directories are automatically removed after you restart the target host. You do not have to clear these folders manually.

   c. Restart all target hosts.

3. Restart the installation of Kaspersky EDR Expert.

Reinstalling Kaspersky EDR Expert if Bootstrap is installed

To reinstall incorrectly installed Kaspersky EDR Expert components,

1. View the full installation log of the incorrectly installed Kaspersky EDR Expert component by using the command:

   `./kdt state -l <component_name>`

   You can also output all diagnostic information about Kaspersky EDR Expert components by using the command:

   `./kdt logs get --to-archive`

2. Troubleshoot an installation error on your own or with the help of Kaspersky Technical Support.

3. Reinstall incorrectly installed Kaspersky EDR Expert components.

   - If you did not modify the configuration file, run the following command, and then specify the same transport archive that was used for the Kaspersky EDR Expert installation:

     ```
     ./kdt apply -k <full_path_to_transport_archive>
     ```

   - If you need to change the installation parameters, export the configuration file, modify it, and then run the following command with the transport archive and the updated configuration file:

     ```
     ./kdt apply -k <full_path_to_transport_archive> -i
     <full_path_to_configuration_file>
     ```

   KDT reinstalls only the incorrectly installed Kaspersky EDR Expert components.

4. Restart the installation of Kaspersky EDR Expert by using the command:

   ```
   ./kdt apply --force -k <full_path_to_XDR_updates_archive> -i
   <full_path_to_configuration_file>
   ```

If reinstalling the components did not fix an installation error, you can uninstall the entire solution.

To restart the Kaspersky EDR Expert installation:

1. Output all diagnostic information about Kaspersky EDR Expert components by using the following command:

   ```
   ./kdt logs get --to-archive
   ```

2. Troubleshoot an installation error on your own or with the help of Kaspersky Technical Support.

3. Uninstall Kaspersky EDR Expert. On the administrator host, run the following command:

   ```
   ./kdt remove --all
   ```

4. Restart the installation of Kaspersky EDR Expert by using the command:

   ```
   ./kdt apply --force -k <full_path_to_XDR_updates_archive> -i
   <full_path_to_configuration_file>
   ```

Reinstalling Kaspersky EDR Expert components

During the installation of Kaspersky EDR Expert, on the administrator host, KDT displays an installation log that shows whether the Kaspersky EDR Expert components are installed correctly.

After installing Kaspersky EDR Expert, you can run the following command to view the list of all installed components:

```
./kdt state
```

The installed components list is displayed. Correctly installed components have the `Success` status. If the component installation failed, this component has the `Failed` status.

To view the full installation log of the incorrectly installed Kaspersky EDR Expert component, run the command:

```
./kdt state -l <component_name>
```

You can also output all diagnostic information about Kaspersky EDR Expert components by using the following command:

```
./kdt logs get --to-archive
```

You can use the obtained logs to troubleshoot problems on your own or with the help of Kaspersky Technical Support.

To reinstall incorrectly installed Kaspersky EDR Expert components,

- If you did not modify the configuration file, run the following command, and then specify the same transport archive that was used for the Kaspersky EDR Expert installation:

  ```
  ./kdt apply -k <full_path_to_transport_archive>
  ```

- If you need to change the installation parameters, export the configuration file, modify it, and then run the following command with the transport archive and the updated configuration file:

  ```
  ./kdt apply -k <full_path_to_transport_archive> -i <full_path_to_configuration_file>
  ```

  KDT reinstalls only the incorrectly installed Kaspersky EDR Expert components.

Stopping the Kubernetes cluster nodes

You may need to stop the entire Kubernetes cluster or temporarily detach one of the nodes of the cluster for maintenance.

In a virtual environment, do not power off virtual machines that are hosting active Kubernetes cluster nodes.

If you do not have superuser privileges, you either have to get them or elevate your privileges by prefixing every command below with `sudo`, for example: `sudo k0s status`, `sudo k0s stop`.

We recommend that you refer to the official documentation of your operating system for details on the commands to be executed.

Stopping a multi-node Kubernetes cluster

To stop a multi-node Kubernetes cluster (multi-node deployment scheme):

1. Log in to a worker node and initiate graceful shut down:

   a. Stop the node by running the command:

   ```
   k0s stop
   ```

   b. Check if the node is stopped by running the command:

   ```
   k0s status
   ```

c. Shut down the node by running the command:

```
shutdown -now
```

For security reasons, we do not recommend that you use the `--force` keys.

2. Repeat this process for all worker nodes.

3. Log in to the primary node and initiate graceful shut down as described at steps a-c.

If the number of active nodes in the Kubernetes cluster becomes less than three, a partial loss of functionality may occur until the initial number of nodes is restored.
When shutting down the primary node, an ability to manage the cluster (including via the kdt utility) will be lost until the primary node is restarted.

Stopping a single-node Kubernetes cluster

To stop a single-node Kubernetes cluster (single-node deployment scheme):

Log in to the primary node and initiate graceful shut down as described at steps a-c.

Starting a Kubernetes cluster

To start a Kubernetes cluster:

1. After the operating system is loaded, run the command:

```
k0s start
```

2. Check if the node is started by running the command:

```
k0s status
```

3. For a multi-node deployment scheme, repeat this process for all nodes.

Using certificates for public Kaspersky EDR Expert services

For working with public Kaspersky EDR Expert services, you can use self-signed or user certificates. By default, Kaspersky EDR Expert uses self-signed certificates.

Certificates are required for the following Kaspersky EDR Expert public services:

- `<console_host>.<smp_domain>`—Access to the OSMP Console interface.
- `<ksc_host>.<smp_domain>`—Interaction with Administration Server.
- `<api_host>.<smp_domain>`—Access to the Kaspersky EDR Expert API.

- `<monitoring_host>.<smp_domain>`—Access to OSMP metrics.
- `<kuma_host>.<smp_domain>`—Access to the SIEM component.

FQDNs of public Kaspersky EDR Expert services consist of the host names and domain name specified in the configuration file. The list of addresses of public Kaspersky EDR Expert services, for which self-signed or user certificates are defined during the deployment, is specified in the `pki_host_list` installation parameter.

A user certificate must be specified as a file in the PEM format, and that contains the complete certificate chain (or only one certificate) and an unencrypted private key.

You can specify the intermediate certificate from your organization's private key infrastructure (PKI). user certificates for public Kaspersky EDR Expert services are issued from this custom intermediate certificate. Alternatively, you can specify leaf certificates for each of the public services. If leaf certificates are specified only for a part of the public services, then self-signed certificates are issued for the other public services.

For the `<console_host>.<smp_domain>`, `<kuma_host>.<smp_domain>`, `<monitoring_host>.<smp_domain>`, and `<api_host>.<smp_domain>` public services, you can specify user certificates only before the deployment in the configuration file. Specify the `intermediate_bundle` and `intermediate_enabled` installation parameters to use the custom intermediate certificate. The validity period for the custom intermediate certificate must be 399 days or more.

If you want to use the custom leaf certificates to work with the public Kaspersky EDR Expert services, specify the corresponding `console_bundle`, `admsrv_bundle`, `kuma_bundle`, `monitoring_bundle`, and `api_bundle` installation parameters. Set the `intermediate_enabled` parameter to `false`, and do not specify the `intermediate_bundle` parameter and the `pki_host_list` parameter. The validity period for the custom leaf certificate must be 399 days or more.

For the `<ksc_host>.<smp_domain>` service, you can replace the issued Administration Server self-signed certificate with a user certificate by using the klsetsrvcert utility.

> Automatic rotation of certificates is not supported. Take into account the validity term of the certificate, and then update the certificate when it expires.

To update user certificates:

1. On the administrator host, export the current configuration file.
2. In the exported configuration file, specify the path to a new custom intermediate certificate in the `intermediate_bundle` installation parameter. If you use the leaf user certificates for each of the public services, specify the `console_bundle`, `admsrv_bundle`, `kuma_bundle`, `monitoring_bundle`, and `api_bundle` installation parameters.
3. Run the following command and specify the full path to the modified configuration file:

   ```
   ./kdt apply -i <full_path_to_configuration_file>
   ```

   user certificates are updated.

Calculation and changing of disk space for storing Administration Server data

Administration Server data includes the following objects:

- Information about assets (devices).
- Information about events logged on the Administration Server for the selected client device.
- Information about the domain in which the assets are included.
- Data of the Application Control component.
- Updates. The shared folder additionally requires at least 4 GB to store updates.
- Installation packages If some installation packages are stored on the Administration Server, the shared folder will require an additional amount of free disk space equal to the total size of all of the available installation packages to be installed.
- Remote installation tasks. If remote installation tasks are present on the Administration Server, an additional amount of free disk space equal to the total size of all installation packages to be installed will be required.

Calculation of the minimum disk space for storing Administration Server data

The minimum disk space required for storing the Administration Server data can be estimated approximately by using the formula:

```
(724 * C + 0.15 * E + 0.17 * A + U), KB
```

where:

- C is the number of assets (devices).
- E is the number of events to store.
- A is the total number of domain objects:
  - Device accounts
  - User accounts
  - Accounts of security groups
  - Organizational units
- U is the size of updates (at least 4 GB).

If domain polling is disabled, A is considered to equal zero.

The formula calculates the disk space required for storing typical data from managed devices and the typical size of updates. The formula does not include the amount of disk space occupied by data that is independent of the number of managed devices for the Application Control component, installation packages, and remote installation tasks.

Changing of the disk space for storing the Administration Server data

The amount of free disk space allocated to store the Administration Server data is specified in the configuration file before the deployment of Kaspersky EDR Expert (the `ksc_state_size` parameter). Take into account the minimum disk space calculated by using the formula.

To check the disk space used to store the Administration Server data after the deployment of Kaspersky EDR Expert,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke ksc --action getPvSize
```

The amount of the required free disk space in gigabytes is displayed.

To change the disk space used to store the Administration Server data after the deployment of Kaspersky EDR Expert,

On the administrator host where the KDT utility is located, run the following command and specify the required free disk space in gigabytes (for example, "50Gi"):

```
./kdt invoke ksc --action setPvSize --param ksc_state_size='<new_disk_space_amount>Gi'
```

The amount of free disk space allocated to store the Administration Server data is changed.

Viewing and changing disk space for KUMA Core and the Metrics service

You can view the current amount of disk space allocated for the operation of KUMA Core and the Metrics service. If required, you can change the allocated disk space.

Viewing the currently allocated disk space

The commands for viewing the disk space do not affect the operation of the running services.

To view the disk space allocated for KUMA Core:

On the administrator host, run the following command:

```
./kdt invoke kuma --action getCorePvcSize
```

To view the disk space allocated for the Metrics service:

On the administrator host, run the following command:

```
./kdt invoke kuma --action getMetricsPvcSize
```

Changing the currently allocated disk space

The commands change the `core_disk_request` and the `metrics_disk_request` parameters. When you run a command, the corresponding service is stopped, the disk space is changed, and the service is restarted. The application updates the `core_disk_request` and `metrics_disk_request` parameters only if the commands are successfully completed.

You can only enlarge the current disk space. If you try to set a disk space value smaller than the current one, a command returns an error. In this case, the services do not stop.

If an error occurs after the services have already been stopped, the application tries to restart the services and keep the previous disk space value.

To change the disk space allocated for KUMA Core:

On the administrator host, run the following command:

```
./kdt invoke kuma --action setCorePvcSize --param core_disk_request=<value>
```

where `<value>` is new disk space size, for example `50Gi`.

To change the disk space allocated for the Metrics service:

On the administrator host, run the following command:

```
./kdt invoke kuma --action setMetricsPvcSize --param metrics_disk_request=<value>
```

where `<value>` is new disk space size, for example `50Gi`.

Viewing and changing the object storage size

Object storage is a component for storing temporary playbook data, alert and incident files, and supporting the S3 API for external integrations. If an object storage volume is filling up, you can check the current allocated size for it. You can change the storage size using the KDT utility. This prevents storage overflow and the associated service disruption.

To check the object storage size:

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke objectstorage --action getDataPvSize
```

The current allocated size of the object storage PV in gigabytes is displayed in the command output (for example, 10Gi).

To increase the object storage size:

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke objectstorage --action setDataPvSize --param volumeDataSize=<new_size>
```

Where `<new_size>` is the required object storage size in gigabytes (for example, 11Gi). The value must be greater than the current size.

The object storage is resized. The new object storage size becomes available without restarting the service.

Increasing the observability storage size

Observability component is a component that provides centralized visibility into events, threats, and assets. KDT allows you to increase the storage size for the observability component (VictoriaMetrics).

To increase the storage size for the observability component manually,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke observability --action increaseVMPvSize --param prometheus_size=<new_size>
```

Where `<new_size>` is the required storage size in gigabytes (for example, 11Gi). The value must be greater than the current size.

The storage size for the observability component is resized to the specified value.

Rotation of Kubernetes cluster certificates

KDT allows you to rotate the Kubernetes cluster certificates that provide access to the Kubernetes cluster and to the infrastructure components of Kaspersky EDR Expert. Kubernetes cluster certificates are located on the target hosts inside the Kubernetes cluster.

To rotate Kubernetes cluster certificates manually,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke foreach --action RotateK0sConfig
```

New Kubernetes cluster certificates are generated. The default rotation period is 10 years.

When updating Bootstrap, Kubernetes cluster certificates are updated automatically.

Rotation of Registry access credentials

KDT allows you to rotate Registry access credentials in accordance with your organization's information security requirements.

To rotate Registry access credentials manually,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke bootstrap --action RotateRegistryCreds
```

Registry access credentials are updated.

When updating Bootstrap, Registry access credentials are updated automatically.

Rotation of DBMS credentials and certificates

KDT allows you to rotate the DBMS credentials and certificates used to connect to the DBMS. You can rotate the DBMS secrets in accordance with your organization's information security requirements.

To rotate the DBMS credentials and certificates manually,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke foreach --action rotatedbcreds
```

DBMS credentials and certificates are updated.

Adding hosts for installing the additional KUMA services

If you need to expand the storage, or add new collectors and correlators for the increased flow of events, you can add additional hosts for installation of the KUMA services.

You must specify the parameters of the additional hosts in the expand.inventory.yml file. This file is located in the distribution package with the transport archive, KDT, the configuration file, and other files. In the expand.inventory.yml file, you can specify several additional hosts for collectors, correlators, and storages at once. Ensure that hardware, software, and installation requirements for the selected hosts are met.

To prepare the required infrastructure on the hosts specified in the expand.inventory.yml file, you need to create the service directories to which the files that are required for the service installation are added. To prepare the infrastructure, run the following command and specify the expand.inventory.yml file:

```
./kdt invoke kuma --action addHosts --param host_inventory='<path_to_inventory_file>'
```

On the hosts specified in the expand.inventory.yml file, the service directories to which the files that are required for the service installation are added.

Sample of the additional KUMA inventory file for installation of the KUMA services (the expand.inventory.yml file)

```
all:
  vars:
    ansible_connection: local
    ansible_user: nonroot
kuma:
  vars:
    ansible_connection: ssh
    ansible_user: root
  children:
    kuma_utils:
    kuma_collector:
      hosts:
        kuma1.example.com:
         ansible_host: 0.0.0.0
        kuma2.example.com:
         ansible_host: 0.0.0.0
    kuma_correlator:
      hosts:
        kuma3.example.com:
         ansible_host: 0.0.0.0
        kuma4.example.com:
         ansible_host: 0.0.0.0
    kuma_storage:
      hosts:
        kuma5.example.com:
         ansible_host: 0.0.0.0
        kuma6.example.com:
         ansible_host: 0.0.0.0
```

Adding an additional storage, collector, or correlator

You can add an additional storage cluster, collector, or correlator to your existing infrastructure. If you want to add several services, it is recommended to install them in the following order: storages, collectors, and correlators.

To add an additional storage cluster, collector, or correlator:

1. In the main menu of OSMP Console, go to **Settings** → **KUMA**.
2. In KUMA section of OSMP Console, create a resource set for each KUMA service (storages, collectors, and correlators) that you want to install on the prepared hosts.

3. Create services for storages, collectors, and correlators.

4. Obtain the service identifiers to bind the created resource sets and the KUMA services:

   a. In the OSMP solution, go to the **Resources** → **Active services**.

   b. Select the required KUMA service, and then click the **Copy ID** button.

5. Install the KUMA services on each prepared host listed in the kuma_storage, kuma_collector, and kuma_correlator sections of the expand.inventory.yml inventory file. On each machine, in the installation command, specify the service ID corresponding to the host. Run the corresponding commands to install the KUMA services:

   - Installation command for the storage:

     ```
     sudo /opt/kaspersky/kuma/kuma storage --core https://<FQDN>:7210 --pair.fingerprint <fingerprint ID of the
     KUMA Core CA certificate> --id <service ID> --install
     ```

   - Installation command for the collector:

     ```
     sudo /opt/kaspersky/kuma/kuma collector --core https://<FQDN>:7210 --pair.fingerprint <fingerprint ID of
     the KUMA Core CA certificate> --id <service ID> --api.port <API port>
     ```

   - Installation command for the correlator:

     ```
     sudo /opt/kaspersky/kuma/kuma correlator --core https://<FQDN>:7210 --pair.fingerprint <fingerprint ID of
     the KUMA Core CA certificate> --id <service ID> --api.port <API port> --install
     ```

     Collector and correlator installation commands are automatically generated on the **Scan** tab in the setup wizard. The port used for communication is automatically added to the command. Use the generated commands to install the collector and correlator on the hosts. This will allow you to make sure that the ports for communication with the services specified in the command are available.

   where:

   - <FQDN> is the fully qualified domain name of the KUMA Core server. The FQDN of the KUMA Core is <kuma_host>.<smp_domain>. The port used for connecting to the KUMA Core cannot be changed. By default, port 7210 is used.

   - <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

     The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

     You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

     To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.

- <service ID> is the identifier of a KUMA service copied from the web-interface.
- <API port> is the port used for communication with the installed component.

The additional KUMA services are installed.

Adding hosts to an existing storage

You can expand an existing storage (storage cluster) by adding hosts as new storage cluster nodes.

To add hosts to an existing storage:

1. In the main menu of OSMP Console, go to **Settings** → **KUMA**.
2. Add new nodes to the storage cluster. To do this, edit the settings of the existing storage cluster:
   a. In the **Resources** → **Storages** section, select an existing storage and open the storage for editing.
   b. In the **ClickHouse cluster nodes** section, click **Add nodes**, and then specify roles in the fields for the new node. Specify the corresponding host domain names from the kuma_storage section of the expand.inventory.yml file, and then specify the roles for the new nodes.
   c. Save your changes.

   You do not need to create a separate storage because you are adding servers to an existing storage cluster.
3. Create storage services for each added storage cluster node in the KUMA section of OSMP Console, and then bind the services to the storage cluster.
4. Obtain the storage service identifiers for each prepared host to install the KUMA services:
   a. In the KUMA section of OSMP Console, go to **Resources** → **Active services**.
   b. Select the required KUMA service, and then click the **Copy ID** button.
5. Install the storage service on each prepared host listed in the kuma_storage section of the expand.inventory.yml inventory file. On each machine, in the installation command, specify the service ID corresponding to the host. Run the following command to install the storage service:

   ```
   sudo /opt/kaspersky/kuma/kuma storage --core https://<FQDN>:7210 --pair.fingerprint <fingerprint ID of the KUMA Core CA certificate> --id <service ID> --install
   ```

   where:

   - <FQDN> is the fully qualified domain name of the KUMA Core server. The FQDN of the KUMA Core is <kuma_host>.<smp_domain>. The port used for connecting to the KUMA Core cannot be changed. By default, port 7210 is used.
   - <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

     The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.

- <service ID> is the KUMA service ID copied from the web interface.

The additional hosts are added to the storage cluster.

Specify the added hosts in the distributed.inventory.yml inventory file so that it has up-to-date information in case of a KUMA components update.

Replacing a host that uses KUMA storage

To replace a host that uses KUMA storage with another one:

1. Fill in the expand.inventory.yml file, specifying the parameters of the host you want to replace.
2. Run the following command, specifying the expand.inventory.yml file to remove the host:

   ```
   ./kdt invoke kuma --action removeHosts --param
   host_inventory='<path_to_inventory_file>'
   ```

3. Fill in the expand.inventory.yml file, specifying the parameters of the new host that you want to replace the previous host, and then run the following command:

   ```
   ./kdt invoke kuma --action addHosts --param host_inventory='<path_to_inventory_file>'
   ```

4. Follow steps 2–6 of the instruction for adding new hosts for KUMA services to add a new host with the KUMA storage.

The host with the KUMA storage is replaced with another one.

If your storage configuration includes a shard containing two replicas, and you replaced the second replica host with a new one by using the steps described above, then you may receive an error when installing a new replica. In this case, the new replica will not work.

To fix an error when adding a new replica of a shard:

1. On another host with a replica of the same shard that owns the incorrectly added replica, launch the ClickHouse client by using the command:

   ```
   /opt/kaspersky/kuma/clickhouse/bin/client.sh
   ```

   If this host is unavailable, run the client on any other host with a replica included in the same storage cluster.

2. Run the command to remove the data about the host you wanted to replace.

   - If the host with a replica of the same shard that owns the incorrectly added replica is available, run the following command:

     ```
     SYSTEM DROP REPLICA '<replica number of read-only node>' FROM TABLE
     kuma.events_local_v2
     ```

   - If you are using another storage cluster host with a replica, run the following command:

     ```
     SYSTEM DROP REPLICA '<replica number of read-only node>' FROM ZKPATH
     '/clickhouse/tables/kuma/<shard number of read-only node>/kuma/events_local_v2
     ```

3. Run the following command to restore the operation of the added host with a replica:

   ```
   SYSTEM RESTORE REPLICA kuma.events_local_v2
   ```

Operability of the added host with a replica is restored.

Working with Kaspersky EDR Expert deployed on virtual machines

If you have deployed Kaspersky EDR Expert on virtual machines, we do not recommend taking snapshots or migrating these virtual machines by using a hypervisor while the solution is running. In this case, Kaspersky EDR Expert will not function properly. To ensure proper functioning of Kaspersky EDR Expert, stop all virtual machines within the Kubernetes cluster before creating snapshots or performing the migration.

Demonstration deployment of Kaspersky EDR Expert

If you want to get acquainted with Kaspersky EDR Expert, you can perform a demonstration deployment of the solution.

Use the demonstration deployment of Kaspersky EDR Expert (in which the DBMS is installed into the Kubernetes cluster) only to get acquainted the solution. We do not recommend using this approach to solve standard work tasks. For standard usage, perform a multi-node or single-node deployment.

In the demonstration deployment, all Kaspersky EDR Expert components are installed on a single node or on multiple nodes of the Kubernetes cluster.

In the scenario below, the demonstration deployment on a single node is described. Single-node deployment requires less resources and is therefore more often used for demonstration deployment. In the demonstration deployment on a single node, the Kubernetes cluster, Kaspersky EDR Expert components, and the DBMS are installed on one target host. Also you need the administrator host to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert, as well as the target host for installing the KUMA services.

In the single-node configuration, you need at least three hosts:

- 1 administrator host
- 1 target host for installing the Kubernetes cluster, the Kaspersky EDR Expert components, and the DBMS
- 1 KUMA target host for installing the KUMA services

The main difference between a demonstration deployment and a standard one is the DBMS location. In a standard deployment (multi-node or single-node), the DBMS is installed on a host located outside the cluster. In a demonstration deployment, the DBMS is installed on the target host inside the cluster.

Before deploying the Open Single Management Platform and Kaspersky EDR Expert components, we recommend reading the Hardening Guide.

Following this scenario, you can prepare the infrastructure for the demonstration deployment, prepare the configuration file, and deploy the solution by using the Kaspersky Deployment Toolkit utility (hereinafter referred to as KDT).

The demonstration deployment scenario proceeds in stages:

1. **Downloading the distribution package with the Kaspersky EDR Expert components**

   The distribution package contains the following components:

   - Transport archive with the Kaspersky EDR Expert components and End User License Agreements for Kaspersky EDR Expert and KDT.

     The components are signed with RSA key and GOST R 34.11-2012 key.

   - Archive with the KDT utility, and templates of the configuration file and KUMA inventory file.

2. **Preparing the administrator and target hosts**

   Prepare the selected administrator host and target hosts for a demonstration deployment of Kaspersky EDR Expert.

   How-to instruction: Preparing the administrator and target hosts

3. **Preparing the KUMA hosts**

   Prepare the KUMA target hosts for the installation of the KUMA services (collectors, correlators, and storages).

   How-to instruction: Preparing the hosts for installation of the KUMA services

4. **Preparing the KUMA inventory file for installation of the KUMA services**

   Prepare the KUMA inventory file in the YAML format. The KUMA inventory file contains parameters for installation of the KUMA services.

   How-to instruction: Preparing the KUMA inventory file

5. **Preparing the configuration file**

   Prepare the configuration file in the YAML format. The configuration file contains the target host parameters and a set of installation parameters of the Kaspersky EDR Expert components.

   How-to instructions: Specifying the installation parameters

6. **Deployment of Kaspersky EDR Expert**

   Deploy Kaspersky EDR Expert by using KDT. KDT automatically deploys the Kubernetes cluster within which the Kaspersky EDR Expert components and other infrastructure components are installed.

   How-to: Installing Kaspersky EDR Expert

7 Installing the KUMA services

Install the KUMA services (collectors, correlators, and storages) on the prepared KUMA target hosts that are located outside the Kubernetes cluster.

How-to instruction: Installing KUMA services

8 Configuring integration with Kaspersky Anti Targeted Attack Platform

Install Central Node to receive telemetry from Kaspersky Anti Targeted Attack Platform, and then configure integration between Kaspersky EDR Expert and KATA/KEDR to manage threat response actions on assets connected to Kaspersky Endpoint Detection and Response servers.

If necessary, you can install multiple Central Node components to use them independently of each other or to combine them for centralized management in the distributed solution mode. To combine multiple Central Node components, you have to organize the servers with the components into a hierarchy.

When configuring the Central Node servers, you have to specify the minimum possible value in the **Storage** field, to avoid duplication of data between Kaspersky EDR Expert and KEDR databases.

Preparing the administrator and target hosts

Preparing for a demonstration deployment includes configuring the administrator and target hosts. In the demonstration deployment on a single node, the Kubernetes cluster, Kaspersky EDR Expert components, and the DBMS are installed on one target host. After preparing the target host and specifying the configuration file, you will be able to deploy Kaspersky EDR Expert on the target host by using KDT.

Use the demonstration deployment of Kaspersky EDR Expert (in which the DBMS is installed into the Kubernetes cluster) only to get acquainted the solution. We do not recommend using this approach to solve standard work tasks.

Preparing the administrator host

You first need to prepare a device that will act as the administrator host from which KDT will launch. This host can be either included in the Kubernetes cluster that is created by KDT during the deployment or not. If the administrator host is not included in the cluster, it will be used only to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert. If the administrator host is included in the cluster, it will also act as a target host that is used for operation of Kaspersky EDR Expert components. In this case, only one host will be used for deployment and operation of the solution.

To prepare the administrator host:

1. Make sure that the hardware and software on the administrator host meet the requirements for KDT.
2. Allocate at least 10 GB of free space in the temporary files directory (by default, `/tmp`) for KDT. If you do not have enough free space in this directory, run the following command to specify the path to another directory:

   ```
   export TMPDIR=<new_directory>/tmp
   ```

3. Configure the container runtime. Use one of the following container runtimes:

   - KDT built-in container runtime (based on runc).

     To install the runtime, run the following command:

     ```
     sudo ./kdt init
     ```

     If the built-in container runtime is not suitable for your environment, you can use the Docker container runtime instead.

   - Docker container runtime.

     Install the package for Docker version 25 or later. Do not install unofficial distributions of Docker packages from the operating system maintainer repositories.

     If Docker keyring cannot be downloaded automatically, download it manually:

     a. Open the https://download.docker.com/linux/ubuntu/gpg link in your browser to save the key as docker.asc.

     b. Run the following command:

     ```
     sudo mv docker.asc /etc/apt/keyrings/docker.asc
     ```

     The disk partition for Docker data storage (by default, `/var/lib/docker`) must have at least 60 GB of available space.

     Perform the post-installation steps to configure the administration host for proper functioning with Docker:

     ```
     sudo groupadd docker
     sudo usermod -aG docker $USER
     newgrp docker
     sudo systemctl enable docker.service
     sudo systemctl enable containerd.service
     sudo systemctl status docker.service
     ```

4. For the administrator host that will be included in the cluster, perform additional preparatory steps:

   a. Since the device will act as the administrator and target host, make sure that it meets the requirements for the single-node deployment.

   b. Make sure that the cgroup v2 technology is supported on the administrator host.

Preparing the target hosts

The target host is a physical or virtual machine that is used to deploy Kaspersky EDR Expert and included in the Kubernetes cluster. The target host manages the Kubernetes cluster, stores metadata, as well as the Kaspersky EDR Expert components work on this host. A minimum cluster configuration for the demonstration deployment includes one target host, which acts as the primary and worker nodes. On this primary worker node, the Kubernetes cluster, the DBMS, and Kaspersky EDR Expert components are installed.

The KUMA services (collectors, correlators, and storages) can be installed entirely inside the cluster on the primary worker node, entirely on separate hosts outside the Kubernetes cluster, or partially inside and partially outside the Kubernetes cluster.

If you want to run the Kaspersky EDR Expert deployment from the target host, you must prepare this host as the administrator host, as described in the previous procedure, and then perform the preparing for the target host.

To prepare the target host:

1. Make sure that the hardware and software on the target host meet the requirements for the single-node deployment (because the demonstration and single-node deployment have a similar deployment scheme).

   If KUMA services are installed inside the cluster, the target host must meet the hardware, software, and installation requirements for installing the KUMA services.

   For proper functioning of Kaspersky EDR Expert, the Linux kernel version must be 5.15.0.107 or later on the target host with the Ubuntu family operating systems.

   For proper functioning of Kubernetes cluster and its components, swap must be disabled on all cluster nodes. If swap is enabled on a node, KDT will automatically disable it during the deployment.

   Do not install Docker on the target host unless the target host will be used as the administrator host. KDT will install all necessary software and dependencies during the deployment.

2. Ensure that the filesystem mounted at `/var` has at least 360 GB of free space on the target host.

   We recommend placing the `/opt/lvp/hot` directory on a dedicated high-performance disk subsystem and the `/opt/lvp/cold` directory on a separate high-capacity disk subsystem.

3. Install the sudo package, if this package is not already installed. For Debian family operating systems, install the UFW package.

4. Configure the /etc/environment file. If your organization's infrastructure uses a proxy server to access the internet, you also need to connect the target host to the internet.

5. If the primary worker node has the UFW configuration, allow IP forwarding. In the `/etc/default/ufw` file, set `DEFAULT_FORWARD_POLICY` to `ACCEPT`.

6. Provide access to the package repository that stores the following packages required for Kaspersky EDR Expert:

   - nfs-common
   - containerd
   - cron
   - cryptsetup
   - cryptsetup-bin

- netcat-traditional
- nfs-common
- open-iscsi
- python3-cffi-backend
- python3-cryptography
- python3-netaddr
- python-apt-common
- systemd
- tar

KDT will try to install these packages during the deployment from the package repository. You can also install these packages manually.

7. Ensure that the following packages are installed on the primary worker node:

   - python3-apt
   - curl

   These packages are not installed during the deployment from the package repository by using KDT. You must install these packages manually, if they are not already installed.

8. Reserve static IP addresses for the target hosts and the Kubernetes cluster gateway.

   The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster.

   Since you install the DBMS inside the Kubernetes cluster, the gateway IP address is an IP range (for example, 192.168.0.1—192.168.0.2). The first IP address of the range is the address of the Kaspersky EDR Expert services (excluding the DBMS IP address), The second IP address in the range is the IP address of the DBMS.

   Make sure that the target host and the Kubernetes cluster gateway are located in the same broadcast domain.

9. On your DNS server, register the service FQDNs to connect to the Kaspersky EDR Expert services.

   By default, the Kaspersky EDR Expert services are available at the following addresses:

   - <console_host>.<smp_domain>—Access to the OSMP Console interface.
   - <ksc_host>.<smp_domain>—Interaction with Administration Server.
   - <kuma_host>.<smp_domain>—Access to the SIEM component.
   - <api_host>.<smp_domain>—Access to the Kaspersky EDR Expert API.
   - <monitoring_host>.<smp_domain>—Access to OSMP metrics.

- <xdr_edr_ingress_host>.<smp_domain>—Interaction with Agent server.

  Where <console_host>, <ksc_host>, <kuma_host>, <api_host>, <monitoring_host>, and <xdr_edr_ingress_host> are service host names, <smp_domain> is a service domain name. These parameters are parts of the service FQDNs, which you can specify in the configuration file. If you do not specify custom values of service host names, the default values are used: `console_host`—`"console"`, `ksc_host`—`"admsrv"`, `kuma_host`—`"kuma"`, `api_host`—`"api"`, `monitoring_host`—`"monitoring"`, `"xdr_edr_ingress_host"`—`"agentserver"`.

The listed service FQDNs must be resolved to the IP address of the Kubernetes cluster. For example, if the Kubernetes cluster address is 10.80.23.182, service FQDNs are resolved to the IP address as follows:

- <console_host>.<smp_domain>—10.80.23.182
- <ksc_host>.<smp_domain>—10.80.23.182
- <kuma_host>.<smp_domain>—10.80.23.182
- <api_host>.<smp_domain>—10.80.23.182
- <xdr_edr_ingress_host>.<smp_domain>—10.80.23.182

10. Create the user accounts that will be used for the Kaspersky EDR Expert deployment.

    These accounts are used for the SSH connection and must be able to elevate privileges (sudo) without entering a password. To do this, add the created user accounts to the `/etc/sudoers` file.

    View details

    To add the created user accounts to the `/etc/sudoers` file:

    1. Run the following commands:

       ```
       sudo useradd -m -s /bin/bash <user_name>
       sudo usermod -aG sudo <user_name>
       ```

    2. Open the `/etc/sudoers` file by using the following command:

       ```
       sudo visudo
       ```

    3. Add the following line to the end of the section `# Allow members of group sudo to execute any command`:

       ```
       <user_name> ALL=(ALL) NOPASSWD: ALL
       ```

       where `<user_name>` is the name of the created user.

    4. Save and close the `/etc/sudoers` file.

11. Configure the SSH connection between the administrator and target hosts:

    a. On the administrator host, generate SSH keys by using the ssh-keygen utility without a passphrase.

    b. Copy the public key to the target host (for example, to the `/home/<user_name>/.ssh` directory) by using the ssh-copy-id utility.

       If you use a target host as the administrator host, you must copy the public key to it, too.

12. For proper function of the Kaspersky EDR Expert components, open the required ports on the firewall of the administrator and target hosts, if necessary.

13. Configure time synchronization over Network Time Protocol (NTP) on the administrator and target hosts.

14. If necessary, prepare user certificates for working with Kaspersky EDR Expert public services.

    You can use one intermediate certificate that is issued off the organization's root certificate or leaf certificates for each of the services. The prepared user certificates will be used instead of self-signed certificates.

Specifying the installation parameters

The configuration file used to deploy Kaspersky EDR Expert on a single node contains the installation parameters that are required both for the multi-node and single-node deployment. Also, this configuration file contains parameters specific only for the single-node deployment (`openbao_ha_mode`, `openbao_standalone`, and `default_class_replica_count`). The template of the configuration file (singlenode.smp_param.yaml.template) is located in the distribution package in the archive with the KDT utility. This configuration file can be used for a demonstration installation.

Use the demonstration deployment of Kaspersky EDR Expert (in which the DBMS is installed into the Kubernetes cluster) only to get acquainted the solution. We do not recommend using this approach for regular production purposes. For standard usage, perform a multi-node or single-node deployment.

Not all of the parameters listed below are included in the configuration file template. This template contains only those parameters that must be specified before Kaspersky EDR Expert deployment. The remaining parameters are set to default values, and they are not included in the template. You can manually add these parameters to the configuration file to override its values. Parameter values must follow the rules described below. During the Kaspersky EDR Expert deployment, KDT checks whether the required installation parameters are specified correctly. If the required parameters in the configuration file are missing or invalid, the deployment will be interrupted.

For correct function of KDT with the configuration file, add an empty line at the end of the file.

The `nodes` section of the configuration file contains the target host parameters that are listed in the table below.

Nodes section

Parameter name	Required	Description
`desc`	Yes	The node name. The value must comply with the following rules: • The node name must be 1 to 63 characters long. • The node name can contain the following characters: • Uppercase ASCII letters (A–Z) • Lowercase ASCII letters (a–z) • Numbers (0–9) • Hyphen (-) All cluster nodes must have unique names. This requirement is one of the prerequisites for the installation of Kaspersky EDR Expert and is verified by KDT.

Parameter name	Required	Description
`type`	Yes	The node type. For the target host, set the `type` parameter to `primary-worker` to enable the **demonstration deployment on a single node**. In this case, the target host will act as the primary and worker nodes.
`host`	Yes	The IP address of the node. The primary worker node must be included in the same subnet as the Kubernetes cluster gateway. The node requires IPv4 addressing. KDT automatically disables IPv6 on the cluster nodes.
`kind`	No	The node kind that specifies the Kaspersky EDR Expert component that will be installed on this node. For the **single-node demonstration deployment**, leave this parameter empty, because all components will be installed on a single node.
`user`	Yes	The user name of the account created on the target host and used for connection to the node by KDT. The value must comply with the following rules: • The user name must be 1 to 31 characters long. • The user name can contain the following characters: • Lowercase letters (a–z) • Numbers (0–9) • Underscore (_), hyphen (-)
`password`	No	The password for connecting to the node. Can be used instead of the SSH key specified by the `ssh_pk` parameter.

Other installation parameters are listed in the `parameters` section of the configuration file and are described in the table below.

Parameters section

Parameter name	Required	Description
`nwc-language`	Yes	The language of the OSMP Console interface is specified by default. After installation, you can change the OSMP Console language. Possible parameter values: • `enUS` (default value) • `ruRu` The default value is used if you do not specify this parameter in the configuration file.
`ingress_ip`	Yes	The reserved static IPv4 address of the Kubernetes cluster gateway. The Kubernetes cluster gateway is intended for connecting to the Kaspersky EDR Expert components installed inside the Kubernetes cluster. The gateway must be included in the same subnet as the primary worker node. The Kubernetes cluster gateway requires IPv4 addressing. KDT automatically disables IPv6 on the cluster nodes. The value of this parameter cannot be the IP address of the same host on which the deployment is being performed. For the **demonstration deployment**, when you install the DBMS inside the cluster, the DBMS IP address matches the cluster gateway IP address.
`ssh_pk`	Yes	The path to the private part of the SSH key located on the administrator host and used for connection to the primary worker node and nodes with the KUMA services (collectors, correlators, and storages) by using KDT. The parameter value must be a Linux file path or Base64-encoded file content.

Parameter name	Required	Description
admin_password	Yes	The admin_password parameter specifies the password of the Kaspersky EDR Expert user account that will be created by KDT during the installation. The default user name of this account is "admin." The Main administrator role is assigned to this user account. The password must comply with the following rules: • The user password cannot have fewer than 10 or more than 256 characters. • The password must contain characters from at least three of the groups listed below: • Uppercase letters (A–Z) • Lowercase letters (a–z) • Numbers (0–9) • Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;) • The password must not contain any whitespaces, or the ".@" combination. When you specify the admin_password parameter value manually (not by the Deployment wizard), make sure that this value meets the YAML standard requirements for values in strings: • The parameter value containing special characters must be enclosed in single quotes. • Any single quote ' inside the parameter value must be doubled to escape this single quote. Example: the user account password Any_pass%1234'5678"90 must be specified as the value 'Any_pass%1234''5678"90' of the admin_password parameter.
low_resources	Yes	The parameter that indicates that Kaspersky EDR Expert is installed on the target host with limited computing resources. For the **demonstration deployment on a single node**, set the low_resources parameter to true so that Kaspersky EDR Expert components will require less memory and CPU resources. Also, if you enable this parameter, 4 GB of free disk space will be allocated to install KUMA Core on the target host.
openbao_ha_mode	Yes	The parameter that indicates whether to run the secret storage in the High Availability (HA) mode. For the **demonstration deployment on a single node**, set the openbao_ha_mode parameter to false.
openbao_standalone	Yes	The parameter that indicates whether to run the secret storage in the standalone mode. For the **demonstration deployment on a single node**, set the openbao_standalone parameter value to true.
default_class_replica_count	Yes	The number of disk volumes that are used to store the service data of Kaspersky EDR Expert components and KDT. The default value is 3. For the **demonstration deployment on a single node**, set the default_class_replica_count parameter value to 1.
core_disk_request	Yes	The parameter that specifies the amount of disk space for the operation of KUMA Core. If you do not specify the core_disk_request parameter and the low_resources parameter is set to false or is not specified, the default amount of disk space for the operation of KUMA Core is 100 GB. If you do not specify the core_disk_request parameter and the low_resources parameter is set to true, the default amount of disk space for the operation of KUMA Core is 4 GB. You can change the core_disk_request parameter later, after the application deployment.
inventory	Yes	The path to the KUMA inventory file located on the administrator host. The inventory file contains installation parameters for deployment of the KUMA services that are not included in the Kubernetes cluster. The parameter value must be a Linux file path or Base64-encoded file content. If all KUMA services will be installed inside the cluster, set the inventory parameter to /dev/null.
host_inventory	No	The path to the additional KUMA inventory file located on the administrator host. This file contains the installation parameters used to partially add or remove hosts with the KUMA services. The parameter value must be a Linux file path or Base64-encoded file content. If you perform an initial deployment of Kaspersky EDR Expert or run a custom action that requires configuration file, leave the default parameter value (/dev/null).

Parameter name	Required	Description
`license`	No	The path to the KUMA license key located on the administrator host. The parameter value must be a Linux file path or Base64-encoded file content. You can upload the license key or specify the activation code once you log in to OSMP after deployment is complete.

`nwc_host`
`flow_host`
`hydra_host`
`login_host`
`ksc_host`
`console_host`
`api_host`
`kuma_host`
`monitoring_host`
	Yes	The host name that is used in the FQDNs of the public Kaspersky EDR Expert services. The service host name and domain name (the `smp_domain` parameter value) are parts of the service FQDN.
		Default values of the parameters:
		• `nwc_host—"console"`
		• `flow_host—"console"`
		• `hydra_host—"console"`
		• `login_host—"console"`
		• `ksc_host—"admsrv"`
		• `console_host—"console"`
		• `api_host—"api"`
		• `kuma_host—"kuma"`
		• `monitoring_host—"monitoring"`

`smp_domain`	Yes	The domain name that is used in the FQDNs of the public Kaspersky EDR Expert services. The parameter value must satisfy the naming requirements for domains up to the fourth level. The service host name and domain name are parts of the service FQDN. For example, if the value of the `console_host` variable is `console`, and the value of the `smp_domain` variable is `smp.local`, then the full name of the service that provides access to the OSMP Console is `console.smp.local`.
`pki_host_list`	No	The list of host names of the public Kaspersky EDR Expert services for which a self-signed or custom certificate is to be generated. The parameter value must be a list of host names, separated by spaces.
`intermediate_enabled`	No	The parameter that indicates whether to use the custom intermediate certificate instead of the self-signed certificates for the public Kaspersky EDR Expert services. Possible parameter values: • `true`—Use custom intermediate certificate. • `false`—Use self-signed certificates (default value).
`intermediate_bundle`	No	The path to the custom intermediate certificate used to work with public Kaspersky EDR Expert services. Specify this parameter if the `intermediate_enabled` parameter is set to `true`. The parameter value must be a Linux file path or Base64-encoded file content. The validity period for the custom intermediate certificate must be 399 days or more.

`admsrv_bundle`
`api_bundle`
`console_bundle`
`kuma_bundle`
`monitoring_bundle`
	No	The paths to the custom leaf certificates used to work with the corresponding public Kaspersky EDR Expert services: `<ksc_host>.<smp_domain>`, `<api_host>.<smp_domain>`, `<console_host>.<smp_domain>`, `<kuma_host>.<smp_domain>`, and `<monitoring_host>.<smp_domain>`. The parameter values must be a Linux file path or Base64-encoded file content.
		If you want to specify the custom leaf certificates, set the `intermediate_enabled` parameter to `false` and do not specify the `intermediate_bundle` parameter.

`ksc_state_size`	Yes	The amount of free disk space allocated to store the Administration Server data (updates, installation packages, and other internal service data). Measured in gigabytes, specified as "<amount>Gi". The required amount of free disk space depends on the number of managed devices and other parameters, and can be calculated. The default value is 30 GB. This value is used if you do not specify this parameter in the configuration file.
`prometheus_size`	Yes	The amount of free disk space allocated to store metrics. Measured in gigabytes, specified as "<amount>GB". The minimum recommended and default value is 5 GB. The default value is used if you do not specify this parameter in the configuration file.

Parameter name	Required	Description
`grafana_admin_user`	No	The user name of the account used to view OSMP metrics through the Grafana tool. The value must comply with the following rules: • The user name must be 1 to 30 characters long. • The user name can contain the following characters: • Lowercase letters (a–z) • Numbers (0–9) • Special characters (_ - .) • The user name must start with a letter. • The user name must not contain either whitespaces or the "@" symbol.
`grafana_admin_password`	No	The password of the account used to view OSMP metrics through the Grafana tool. The password must comply with the following rules: • The user password cannot have fewer than 8 or more than 256 characters. • The password must contain characters from the groups listed below: • Uppercase letters (A–Z) • Lowercase letters (a–z) • Numbers (0–9) • Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)
`loki_size`	Yes	The amount of free disk space allocated to store OSMP logs. Measured in gigabytes, specified as "<amount>Gi". The minimum recommended and default value is 40 GB. The default value is used if you do not specify this parameter in the configuration file.
`loki_retention_period`	Yes	The storage period of OSMP logs after which logs are automatically removed. The default value is 72 hours (set the parameter value in the configuration file as "<time in hours>h". For example, "72h"). The default value is used if you do not specify this parameter in the configuration file.
`file_storage_cp`	No	The amount of free disk space allocated to store data of the component for working with response actions. Measured in gigabytes, specified as "<amount>Gi". The minimum recommended value is 20 GB.
`psql_tls_off`	No	The parameter that indicates whether to encrypt the traffic between the Kaspersky EDR Expert components and the DBMS by using the TLS protocol. If the DBMS is installed outside the cluster, TLS encryption is disabled by default. For the **demonstration deployment**, if the DBMS is installed inside the cluster, TLS encryption must be disabled (`psql_tls_off` is set to `true`). Possible parameter values: • `true` —Do not encrypt the traffic (default value). • `false` —Encrypt the traffic.
`proxy_enabled`	No	The parameter that indicates whether to use the proxy server to connect the Kaspersky EDR Expert components to the internet. If the host on which Kaspersky EDR Expert is installed has internet access, you can also provide internet access for the operation of Kaspersky EDR Expert components (for example, Administration Server) and for specific integrations, both Kaspersky and third-party. To establish the proxy connection, you must also specify the proxy server parameters in the Administration Server properties. Possible parameter values: • `true` —Proxy server is used. • `false` —Proxy server is not used (default value).
`proxy_addresses`	No	The IP address of the proxy server. If the proxy server uses multiple IP addresses, specify these addresses separated by a space (for example, "`0.0.0.0 0.0.0.1 0.0.0.2`"). Specify this parameter if the `proxy_enabled` parameter is set to `true`.
`proxy_port`	No	The number of the port through which the proxy connection will be established. Specify this parameter if the `proxy_enabled` parameter is set to `true`.

Parameter name	Required	Description
`trace_level`	No	The verbosity level of Administration Server trace files. Traces are written during the Administration Server operation. The default value is 0, no traces are written. Possible parameter values: 0–5. The higher the parameter value, the more detailed the trace details.
`ansible_extra_flags`	No	The verbosity level of logs of the KUMA Core and KUMA services deployment that is performed by KDT. Possible parameter values: • `-v` • `-vv` • `-vvv` • `-vvvv` As the number of "v" letters in the flag increases, logs become more detailed. If this parameter is not specified in the configuration file, the standard component installation logs are saved.
`incident_attachments_max_count_limit`	No	The number of files that you can attach to the incident. The default value is `100`.
`incident_attachments_max_size_limit`	No	The total size of files attached to the incident. Measured in bytes. Specified without units of measurement. The default value is `26214400`.
`ignore_precheck`	No	The parameter indicating whether to check the hardware, software, and network configuration of the Kubernetes cluster nodes for compliance with the prerequisites for installing the solution before the deployment. Possible parameter values: • `true` —Skip the pre-checks. • `false` —Perform the pre-checks (default value).
`airgap_mode`	No	The parameter indicating whether to perform the APT package manager pre-check and update the package cache. This allows deploying Kaspersky EDR Expert in an air-gapped environment. Possible parameter values: • `true` —Skip the pre-check and the package cache update. • `false` —Perform the pre-check and update the package cache (default value).
`grafana_smtp_host`	No	SMTP server address for Grafana, used to send email notifications about Kubernetes cluster health events. Specify this parameter in the `<host>:<port>` format, for example, `localhost:25`.
`grafana_smtp_user`	No	User name for authentication on the SMTP server.
`grafana_smtp_password`	No	Password for authentication on the SMTP server.
`grafana_smtp_bundle`	No	File containing the X.509 certificate chain used for verifying TLS connection to the SMTP server.
`grafana_smtp_skip_verify`	No	The parameter that indicates whether to skip TLS certificate verification of the SMTP server. Possible parameter values: • `true` —Skip TLS certificate verification. • `false` —Perform TLS certificate verification (default value).
`grafana_smtp_from_address`	No	Email address of the sender, which will appear in the From field when sending email notifications.
`grafana_smtp_from_name`	No	Display name of the sender in email notifications.
`grafana_smtp_ehlo_identity`	No	Identifier used in the EHLO command when connecting to the SMTP server.

Parameter name	Required	Description
`grafana_starttls_policy`	No	Policy for using STARTTLS when connecting to the SMTP server. Possible parameter values: • `OpportunisticStartTLS` —Use STARTTLS if the SMTP server supports it; otherwise, connect to the SMPT server without encryption. • `MandatoryStartTLS` —Require STARTTLS; fail if the SMTP server does not support it. • `NoStartTLS` —Do not use STARTTLS; connect to the SMPT server without encryption. • `empty` —Use STARTTLS if the SMTP server supports it; otherwise, connect to the SMPT server without encryption (default value).
`grafana_smtp_enable_tracing`	No	The parameter that indicates whether to enable SMTP connection tracing for debugging email sending. Possible parameter values: • `true` —Enable SMTP connection tracing. • `false` —Disable SMTP connection tracing (default value).
`tokenhub_access_token`	No	The lifetime of an access token. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`1h10m`" or "`2h`". The minimum possible value is `5m` and the maximum is `2h`. The default value is `1h`. This value is used if you do not specify this parameter in the configuration file. You can change the `tokenhub_access_token` parameter later, after the application deployment.
`tokenhub_refresh_token`	No	The lifetime of a refresh token that is used for getting a new access token. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`24h`" or "`1240h30m`". The minimum possible value is `12h` and the maximum is `4320h`. The default value is `24h`. This value is used if you do not specify this parameter in the configuration file. You can change the `tokenhub_refresh_token` parameter later, after the application deployment.
`credentials_session_ttl`	No	The maximum single sign-on session idle time. Set the parameter value in the configuration file as "`<time in hours>h<time in minutes>m<time in seconds>s`". For example, "`24h`" or "`1h30m`". The minimum possible value is `5m` and the maximum is `96h`. The default value is `1h`. This value is used if you do not specify this parameter in the configuration file. You can change the `credentials_session_ttl` parameter later, after the application deployment.

Sample of the configuration file for the demonstration deployment on a single node

Quick start guide

The following scenarios are step-by-step walkthroughs from the initial setup of Kaspersky EDR Expert to incident investigation and threat hunting.

Initial setup of Kaspersky EDR Expert

Following this scenario, you can perform the required preliminary Kaspersky EDR Expert configurations and integrations.

Prerequisites

Before you start, make sure that:

- You have a license key for Kaspersky EDR Expert and the compatible EPP applications.
- Your infrastructure meets the hardware and software requirements.

Stages

The main initial setup scenario proceeds in stages:

1. **Activation**

   Activate the Kaspersky EDR Expert solution under your license.

2. **Multi-tenant configuration**

   If necessary, you can use the multitenancy features:

   1. Plan and create the required hierarchy of tenants.
   2. Create the matching hierarchy of Administration Servers in Open Single Management Platform.
   3. Bind tenants to the corresponding Administration Servers.
   4. Create user accounts for all Kaspersky EDR Expert users, and then assign roles.

3. **Adding assets**

   The devices in your infrastructure that must be protected are represented as assets in Kaspersky EDR Expert. Open Single Management Platform allows you to discover the devices in your network and manage their protection. You will also be able to add assets manually or import them from other sources during stage 8.

   User accounts are also represented as assets in Kaspersky EDR Expert. Make sure to configure the integration with Active Directory during stage 9, to enable the display of affected user accounts in the related events, alerts, and incidents.

4. **Adding users and assigning roles**

   Assign roles to the user accounts, to define their access rights to various Kaspersky EDR Expert features depending on their tasks.

5. **Connecting to an SMTP server**

   Configure the connection to an SMTP server for email notifications about events occurring in Kaspersky EDR Expert.

6. **Configuring event sources, storage, and correlation**

   Specify where events are received from and how they should be stored and processed:

   1. Set up integration of Kaspersky Unified Monitoring and Analysis Platform and Kaspersky Security Center.

   2. **Import assets from Kaspersky Security Center**.

      All assets that are protected by this program are registered in Kaspersky Security Center. Information about assets protected by Kaspersky Security Center can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

      KUMA imports the following device information received from Kaspersky Security Center Network Agents:

      - Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
      - Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

      To import information about the Kaspersky Security Center assets:

      1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
      2. Click **Import**, and then select one of the following actions:
         - To import information about the basic attributes of assets, click **Import KSC assets**.

           This opens the **Import KSC assets** window.
         - To import information about other attributes of assets, click **Import KSC assets attributes**.

           This opens the **Import KSC assets attributes** window.
      3. In the drop-down list, select the tenant for which you want to perform the import.

         In this case, the program downloads information about all assets of all Kaspersky Security Center servers that have been configured to connect to the selected tenant.

         If you want to import information about all assets of all Kaspersky Security Center servers for all tenants, select **All**.
      4. Click the **Import** button.

      The asset information will be imported.

      Also, in a tenant properties window, you can schedule regular import of asset information or run import manually.

3. Add assets manually or import them from other sources (optional).
4. Configure the event sources to specify where you want to receive the events from.
5. Create storage for events.
6. Create collectors to receive, process (normalize), and transfer events.
7. Create correlators for the initial analysis of normalized events and their further processing.

   During the correlator creation, you can create correlation rules to define the rules of processing and responding to the events.You can also import the previously saved correlation rules or use the ready-made set of correlation rules provided with the Kaspersky EDR Expert solution. After the correlator is created, you can link correlation rules to the correlator, if needed.

   > It is recommended to configure exclusions at this stage to avoid false positives and irrelevant data.

7 Configuring integrations

Configure the integration of Kaspersky EDR Expert with Active Directory and with other Kaspersky solutions to extend its possibilities and to enrich data available for incident investigation.

1. Integration with Active Directory (strongly recommended).
2. Integration with Kaspersky CyberTrace (optional integration; license is required).
3. Integration with Kaspersky TIP (optional integration; license is required) or Kaspersky Open TIP.
4. Integration with Kaspersky Managed Detection and Response (optional integration; license is required).

8 Configuring updates

Create the Download updates to the Administration Server repository task.

9 Verify correctness of configuration

Use the EICAR test file on one of the assets. If the initial setup was performed correctly and the necessary correlation rules were configured, this event will trigger creation of an alert in the alerts list.

After the initial setup is complete, events from the protected assets will be received and processed by Kaspersky EDR Expert, and an alert will be created when a correlation rule is triggered.

Verifying correctness of the Kaspersky EDR Expert configuration

You can use the EICAR test virus on one of the assets, to ensure that Kaspersky EDR Expert is deployed and configured correctly. If the initial setup was performed correctly and the necessary correlation rules were configured, the correlation event will trigger the creation of an alert in the alerts list.

To verify correctness of the Kaspersky EDR Expert configuration:

1. Create a new correlator in KUMA section of OSMP Console.

   When creating the correlator, do not specify parameters in the **Correlation** section.

2. Import correlation rules from the SOC Content package to obtain the predefined correlation rules used to detect the EICAR test virus.

3. Specify the correlation rule for the created correlator.

   You can use one of the following methods to specify the correlation rule:

   - Link the predefined correlation rule to the created correlator:

     a. Go to **Resources**, click **Correlation rules**, and then select the tenant to which the correlation rule will be applied.

     b. In the list of the predefined correlation rules, select the **R077_02_KSC.Malware detected** rule to detect events from Kaspersky Security Center.

     c. Click **Link to correlator**, and then select the created correlator to link the selected correlation rule to the correlator.

   - Create the correlation rule with the predefined filters manually:

     a. Open the created correlator settings, go to the **Correlation section**, and then click **Add**.

     b. In the **Create correlation rule** window, on the **General** tab, set the following parameters, as well as other rule parameters:

        - **Kind**: simple.

        - **Propagated fields**: DestinationAddress, DestinationHostName, DestinationAccountID, DestinationAssetID, DestinationNtDomain, DestinationProcessName, DestinationUserName, DestinationUserID, SourceAccountID, SourceUserName.

     c. Go to **Selectors** → **Settings**, and then specify the expression to filter the required events:

        - In builder mode, add the **f: KSC events**, **f: KSC virus found**, and **f: Base events** filters with the AND operator.

        - Alternatively, you can specify this expression in the source code mode as follows:

          ```
          filter='b308fc22-fa79-4324-8fc6-291d94ef2999'
          AND filter='a1bf2e45-75f4-45c1-920d-55f5e1b8843f'
          AND filter='1ffa756c-e8d9-466a-a44b-ed8007ca80ca'
          ```

     d. In the **Actions** section of the correlation rule settings, select only the **Output** check box (the **Loop to correlator** and **No alert** check boxes must be cleared). In this case, when the EICAR test virus is detected, a correlation event will be created and an alert will be created in the alert list of Kaspersky EDR Expert.

     e. Click **Create new** to save the correlation rule settings linked to the correlator.

4. Create, and then configure, a collector in KUMA section of OSMP Console for receiving information about Administration Server events from an MS SQL database.

   Alternatively, you can use the predefined [OOTB] KSC SQL collector.

5. In the **Routing** section of the collector settings, set **Type** to **correlator**, and then specify the created correlator in the **URL** field, to forward the processed events to it.

6. Install Network Agent and the endpoint protection application (for example, Kaspersky Endpoint Security) on an asset of your organization network. Ensure that the asset is connected to Administration Server.

7. Place the EICAR test file on the asset, and then detect the test virus by using the endpoint protection application.

After that, Administration Server will be notified about the event on the asset. This event will be forwarded to the KUMA component, transformed to the correlation event, and then this event will trigger creation of an alert in the alerts list in Kaspersky EDR Expert. If the alert has been created, it means that Kaspersky EDR Expert is working correctly.

Using the threat monitoring, detection and hunting capabilities

After you have installed and configured Kaspersky EDR Expert, you can use Kaspersky EDR Expert features for monitoring the security of your infrastructure, investigating security incidents, automating workflows and proactive searching for threats:

- **Using dashboard and customizing widgets**

  The **Analysis and response** tab of the dashboard can contain widgets that display information about detected and registered alerts and incidents, and response actions to them. You can use and customize the preconfigured layouts of widgets for your dashboard or create new layouts and widgets.

  Open Single Management Platform also provides various security monitoring and reporting tools.

- **Using reports**

  You can configure the generation of reports in Kaspersky Unified Monitoring and Analysis Platform to receive the required summary data according to the specified schedule.

- **Using threat hunting**

  You can use threat hunting tools to analyze events to search for threats and vulnerabilities that have not been detected automatically. Threat hunting can be used both for alert and incident investigation and for proactive search for threats.

- **Using playbooks**

  You can use playbooks to automate response to alerts and incidents according to the specified algorithm. There are a number of predefined playbooks that you can launch in various operation modes. You can create custom playbooks.

Example of incident investigation with Kaspersky EDR Expert

This scenario represents a sample workflow of an incident investigation.

Incident investigation proceeds in stages:

1. **Assigning an alert to a user**

   You can assign an alert to yourself or to another user.

2. **Checking if the triggered correlation rule matches the data of the alert events**

   View the information about the alert and make sure that the alert event data matches the triggered correlation rule. If the alert is a false positive, edit the correlation rule.

3. **Analyzing alert information**

   Analyze the information about the alert to determine what data is required for further analysis of the alert.

4. **Manual enrichment**

   Launch the available solutions for additional enrichment of an event (for example, Kaspersky TIP).

5. **False positive check**

   Make sure that the activity that triggered the correlation rule is abnormal for the organization IT infrastructure.

6. **Incident creation**

   If steps from 3 to 5 reveal that the alert requires investigation, you can create an incident or link the alert to an existing incident.

   You can also merge incidents.

7. **Incident management**

   You can manage incidents by changing incident statuses and priorities, and by assigning them to other analyst.

   You can also manage incident SLAs, types, and workflows. In addition, you can track the effort spent on incident-related work.

8. **Investigation**

   This step includes viewing information about the assets, user accounts, and alerts related to the incident. You can use the investigation graph and threat hunting tools to get additional information.

9. **Searching for related assets**

   You can view the alerts that occurred on the assets related to the incident.

10. **Searching for related events**

    You can expand your investigation scope by searching for events of related alerts.

11. **Viewing the history of the incident**

    You can view the incident's change log and response history.

12. **Commenting**

    You can leave comments with the information necessary for the investigation of the incident.

13. **Response**

    You can perform response actions manually.

14. **Responding by using playbooks**

    You can respond to an incident by launching playbooks manually.

15 Closing the incident

After taking measures to clean up the traces of the attacker's presence from the organization's IT infrastructure, you can close the incident.

Upgrading Kaspersky EDR Expert from version 8.2 to version 8.3

To upgrade Kaspersky EDR Expert solution, follow the steps listed below.

1. **Reinstall Sandbox**

   Since upgrades are not available for the Sandbox component, you need to install the new version of Sandbox and integrate it with Kaspersky EDR Expert.

   When installing on VMware ESXi, configure VMware ESXi according to the Calculations for Sandbox guidelines.

   After installation, specify the maximum number of virtual machines that can run simultaneously. The default number is 48.

2. **Upgrade Kaspersky EDR Expert components**

   You can upgrade Kaspersky EDR Expert from version 8.2 to 8.3 by using KDT. KDT updates the Kubernetes cluster and the Kaspersky EDR Expert components. When upgrading, you do not need to fill in the configuration file, because the installation parameters specified during deployment are used. The steps of the Kaspersky EDR Expert upgrade process do not depend on the selected deployment option.

   To update the Kaspersky EDR Expert components:

   1. Download and unpack the distribution package with Kaspersky EDR Expert version 8.3.

   2. Read the End User License Agreement (EULA) of KDT located in the distribution package with the Kaspersky EDR Expert components.

      When you start using KDT, you accept the terms of the EULA of KDT.

      You can read the EULA of KDT after upgrading Kaspersky EDR Expert. The `license_kdt.txt` file is located in the `~/kaspersky_eula` directory of the user who runs the upgrade of Kaspersky EDR Expert.

   3. Run the following command to upgrade Kaspersky EDR Expert and the Bootstrap component:

      ```
      ./kdt apply -k <full_path_to_XDR_updates_archive>
      ```

      To start upgrading Kaspersky EDR Expert, accept the terms of the EULA and the Privacy Policy.

      You can install Kaspersky EDR Expert without prompting to read the terms of the EULA and the Privacy Policy of OSMP, if you use the `--accept-eula` flag. In this case, you must read the EULA and the Privacy Policy of OSMP before upgrading Kaspersky EDR Expert. The files are located in the distribution package with the Kaspersky EDR Expert components. By using the `--accept-eula` flag, you confirm that you have fully read, understand, and accept the terms of the EULA and the Privacy Policy.

      If you want to read and accept the terms of the EULA and the Privacy Policy during the upgrade, do not use the `--accept-eula` flag.

   4. If you do not use the `--accept-eula` flag in the previous step, read the EULA and the Privacy Policy of OSMP. The text is displayed in the command line window. Press the space bar to view the next text segment. Then, when prompted, enter the following values:

      - Enter `y` if you understand and accept the terms of the EULA.

        Enter `n` if you do not accept the terms of the EULA.

- Enter `y` if you understand and accept the terms of the Privacy Policy, and if you agree that your data will be handled and transmitted (including to third countries) as described in the Privacy Policy.

  Enter `n` if you do not accept the terms of the Privacy Policy.

If you do not accept the terms of the EULA and the Privacy Policy, Kaspersky EDR Expert will not be upgraded.

5. Download the `chrome_full.tar.gz` package, place the package in the `/root/xdr/kdt/bin/` directory, and then run the following command:

   ```
   ./kdt invoke kuma --action=enableReporting --if reporting_archive=chrome_full.tar.gz
   ```

   This command ensures the correct generation of reports in PDF and HTML formats.

6. Import the [OOTB] Kaspersky OSMP collector (named **[OOTB] Kaspersky OSMP audit** in previous versions) to ensure you receive the audit events from the OSMP components. Depending on the storage configuration, follow the appropriate steps:

   - Default storage in Kaspersky EDR Expert 8.2 → default storage in Kaspersky EDR Expert 8.3.

     If the default storage **[OOTB] OSMP Storage** was configured in the **[OOTB] Kaspersky OSMP** collector in OSMP 2.2 and will be used after the upgrade to OSMP 2.3, go the **Active services** section and restart the [OOTB] Kaspersky OSMP collector service. No additional actions required.

   - Default storage in Kaspersky EDR Expert 8.2 → custom storage in Kaspersky EDR Expert 8.3.

     If the default storage **[OOTB] OSMP Storage** was configured in the **[OOTB] Kaspersky OSMP** collector in Kaspersky EDR Expert 8.2 and you decide to switch to a custom storage after the upgrade to Kaspersky EDR Expert 8.3:

   a. Ensure that the **osmp_technical_events** space is created in the custom storage.

   b. Ensure that the same tags as in the default storage **[OOTB] OSMP Storage** are configured in the custom storage.

   c. Go the **Active services** section and restart the [OOTB] Kaspersky OSMP collector service.

      Custom storage in Kaspersky EDR Expert 8.2 → custom storage in Kaspersky EDR Expert 8.3.

   - If you configured a custom storage to be used for **[OOTB] Kaspersky OSMP** collector in OSMP 2.2 and this storage is used after the upgrade to OSMP 2.3:

   a. Ensure that the **osmp_technical_events** space is created in the custom storage.

   b. Ensure that the same tags as in the default storage **[OOTB] OSMP Storage** are configured in the custom storage.

   c. Go the **Active services** section and restart the [OOTB] Kaspersky OSMP collector service.

7. Edit the collector resource file:

a. Copy the collector resource ID. Go to the **Active services** section and click the name of **[OOTB] Kaspersky OSMP** collector in the list of services, and then copy the collector resource ID in one of the following ways:

- In the collector settings pane, copy the collector resource ID value from the URL in your browser.
- Copy the collector resource ID from the terminal:
  - Run the following command on one of the primary nodes of the Kubernetes cluster:

```
k0s kubectl get collector -n kuma -o custom-
columns=SERVICE_NAME:.metadata.name,RESOURCE_ID:.spec.clusterId
```

  - Copy the collector resource ID from the displayed table:

```
SERVICE_NAME RESOURCE_ID
<collector service ID> <collector resource ID>
```

Do not use the **Copy ID** button in the collector context menu, as it copies the collector service ID. You must use the collector resource ID instead.

a. Use the copied collector resource ID to run the following command to open the collector resource file in the editor:

```
k0s kubectl edit service/collector-cluster-<collector resource ID> -n kuma
```

The collector resource file is open in the editor.

b. In the 'labels' section, add `kuma.kaspersky.com/sd: osmp-logs` record and save the collector resource file.

KDT performs the update and displays its progress in the console. Wait until the update is complete. Kaspersky EDR Expert is upgraded from version 8.2 to 8.3.

3 Install the Kaspersky Endpoint Security web plug-in

The required web plug-ins are provided with the distribution kit.

Kaspersky Endpoint Security for Windows and Kaspersky Endpoint Security for Linux web plug-ins are already included in the Kaspersky EDR Expert package, therefore no additional installation is required.

To install Kaspersky Endpoint Security for Mac web plug-in, use the KDT utility.

4 Upgrade EPP applications

Upgrade EPP applications to the latest compatible versions. For information on how to upgrade the application, refer to the Kaspersky Endpoint Security documentation:

- Upgrading Kaspersky Endpoint Security for Windows
- Upgrading Kaspersky Endpoint Security for Linux
- Upgrading Kaspersky Endpoint Security for Mac

You may also need information about migration from a [KES+KEA] configuration to a [KES+built-in agent] configuration.

Migration to Kaspersky EDR Expert

This section describes the migration of data to Kaspersky EDR Expert 8.3 from Kaspersky Security Center Windows and KATA 7.1.

About migration from Kaspersky Security Center Windows

Following this scenario, you can transfer the administration group structure, included managed devices and other group objects (policies, tasks, global tasks, tags, and device selections) from Kaspersky Security Center Windows under management of Kaspersky EDR Expert.

Limitations:

- Migration is only possible from Kaspersky Security Center 15.1 Windows to Kaspersky XDR Expert starting from version 8.0.
- You can perform this scenario only by using Kaspersky Security Center Web Console.

Stages

The migration scenario proceeds in stages:

1. **Choose a migration method**

   You migrate to Kaspersky EDR Expert through the Migration wizard. The Migration wizard steps depend on whether or not Administration Servers of Kaspersky Security Center Windows and Kaspersky EDR Expert are arranged into a hierarchy:

   - Migration by using a hierarchy of Administration Servers

     Choose this option if Administration Server of Kaspersky Security Center Windows acts as secondary to Administration Server of Kaspersky EDR Expert. You manage the migration process and switch between Servers within OSMP Console. If you prefer this option, you can arrange Administration Servers into a hierarchy to simplify the migration procedure. To do this, create the hierarchy before starting the migration.

     If you connect secondary Administration Servers to Kaspersky EDR Expert, disable background integration for Web Consoles that manage them.

     To disable background integration:

     1. Log in to Administration Server Web Console.
     2. In the main menu, go to **Settings** → **Integration**.
     3. In the **Background connection** section, disable the **Background connection for integration Enabled** toggle switch.

- Migration by using an export file (ZIP archive)

  Choose this option if Administration Servers of Kaspersky Security Center Windows and Kaspersky EDR Expert are not arranged into a hierarchy. You manage the migration process with two Consoles—an instance for Kaspersky Security Center Windows and OSMP Console. In this case, you will use the export file that you created and downloaded during the export from Kaspersky Security Center Windows and import this file to Kaspersky EDR Expert.

2. **Export data from Kaspersky Security Center Windows**

   Open Kaspersky Security Center Windows, and then run the Migration wizard.

3. **Import data to Kaspersky EDR Expert**

   Continue the Migration wizard to import the exported data to Kaspersky EDR Expert.

   If the Servers are arranged into a hierarchy, the import starts automatically after a successful export within the same wizard. If the Servers are not arranged into a hierarchy, you continue the Migration wizard after switching to Kaspersky EDR Expert.

4. **Perform additional actions to transfer objects and settings from Kaspersky Security Center Windows to Kaspersky EDR Expert manually (optional step)**

   You might also want to transfer the objects and settings that cannot be transferred through the Migration wizard. For example, you could additionally do the following:

   - Configure global tasks of Administration Server
   - Configure Network Agent policy settings
   - Create installation packages of applications
   - Create virtual Servers
   - Assign and configure distribution points
   - Configure device moving rules.
   - Configure rules for auto-tagging devices
   - Create application categories

5. **Move the imported managed devices under management of Kaspersky EDR Expert**

   To complete the migration, move the imported managed devices under management of Kaspersky EDR Expert. You can do it by one of the following methods:

   - Through Kaspersky Security Center group task

     Use the Change Administration Server task to change the Administration Server to a different one for specific client devices.

   - Through the klmover utility

     Use the klmover utility and specify the connection settings for the new Administration Server.

   - Through installation or re-installation of Network Agent on the managed devices

     Create a new Network Agent installation package and specify the connection settings for the new Administration Server in the installation package properties. Use the installation package to install Network Agent on the imported managed devices through a remote installation task.

     You can also create and use a stand-alone installation package to install Network Agent locally.

6. **Update Network Agent to the latest version**

   We recommend that you upgrade the Network Agent to the same version as OSMP Console.

7. **Make sure the managed devices are visible on the new Administration Server**

   On Kaspersky EDR Expert Administration Server, open the managed devices list (**Asset management** → **Assets (Devices)**), and check the values in the **Visible**, **Network Agent is installed**, and **Last connected to Administration Server** columns.

Other methods of data migration

Besides the Migration wizard, you can also transfer specific tasks and policies:

- Export the task from Kaspersky Security Center Windows, and then import the tasks to Kaspersky EDR Expert.
- Export the policies from Kaspersky Security Center Windows, and then import the policies to Kaspersky EDR Expert. The related policy profiles are exported and imported together with the selected policies.

Exporting group objects from Kaspersky Security Center Windows

Migration administration group structure, included managed devices and other group objects from Kaspersky Security Center Windows to Kaspersky EDR Expert requires that you first select data for exporting and create an export file. The export file contains information about all group objects that you want to migrate. The export file will be used for subsequent import to Kaspersky EDR Expert.

You can export the following objects:

- Tasks and policies of managed applications
- Global tasks
- Custom device selections
- Administration group structure and included devices
- Tags that have been assigned to migrating devices

Before you start exporting, read general information about migration to Kaspersky EDR Expert. Choose the migration method—by using or not using the hierarchy of Administration Servers of Kaspersky Security Center Windows and Kaspersky EDR Expert.

To export managed devices and related group objects through the Migration wizard:

1. Depending on whether or not the Administration Servers of Kaspersky Security Center Windows and Kaspersky EDR Expert are arranged into a hierarchy, do one of the following:

   - If the Servers are arranged into a hierarchy, open OSMP Console, and then switch to the Server of Kaspersky Security Center Windows.

   - If the Servers are not arranged into a hierarchy, open Kaspersky Security Center Web Console connected to Kaspersky Security Center Windows.

2. In the main menu, go to **Operations** → **Migration**.

3. Select **Migrate to Kaspersky Security Center Linux or Open Single Management Platform** to start the wizard and follow its steps.

4. Select the administration group or subgroup to export. Please make sure that the selected administration group or subgroup contains no more than 10,000 devices.

5. Select the managed applications whose tasks and policies will be exported. Select only applications that are supported by Kaspersky EDR Expert. The objects of unsupported applications will still be exported, but they will not be operable.

6. Use the links on the left to select the global tasks, device selections, and reports to export. The **Group objects** link allows you to exclude custom roles, internal users and security groups, and custom application categories from the export.

The export file (ZIP archive) is created. Depending on whether or not you perform migration with Administration Server hierarchy support, the export file is saved as follows:

- If the Servers are arranged into a hierarchy, the export file is saved to the temporary folder on OSMP Console Server.

- If the Servers are not arranged into a hierarchy, the export file is downloaded to your device.

For migration with Administration Server hierarchy support, the import starts automatically after a successful export. For migration without Administration Server hierarchy support, you can import the saved export file to Kaspersky EDR Expert manually.

Importing the export file to Kaspersky EDR Expert

To transfer information about managed devices, objects, and their settings that you exported from Kaspersky Security Center Windows, you must import it to Kaspersky EDR Expert.

To import managed devices and related group objects through the Migration wizard:

1. Depending on whether or not the Administration Servers of Kaspersky Security Center Windows and Kaspersky EDR Expert are arranged into a hierarchy, do one of the following:

   - If the Servers are arranged into a hierarchy, proceed to the next step of the Migration wizard after the export is completed. The import starts automatically after a successful export within this wizard (see step 2 of this instruction).

   - If the Servers are not arranged into a hierarchy:

     a. Open OSMP Console.

     b. In the main menu, go to **Operations** → **Migration**.

     c. Select the export file (ZIP archive) that you created and downloaded during the export from Kaspersky Security Center Windows. The upload of the export file starts.

2. After the export file is uploaded successfully, you can continue importing. If the Servers are not arranged into a hierarchy, you can specify another export file by clicking the **Change** link, and then selecting the required file.

3. The entire hierarchy of administration groups of Kaspersky EDR Expert is displayed.

   Select the check box next to the target administration group to which the objects of the exported administration group (managed devices, policies, tasks, and other group objects) must be restored.

4. The import of group objects starts. You cannot minimize the Migration wizard and perform any concurrent operations during the import. Wait until the refresh icons (🔄) next to all items in the list of objects are replaced with green check marks (✓) and the import finishes.

5. When the import completes, the exported structure of administration groups, including device details, appears under the target administration group that you selected. If the name of the object that you restore is identical to the name of an existing object, the restored object has an incremental suffix added.

> If in a migrated task the details of the account under which the task is run are specified, you have to open the task and enter the password again after the import is completed.

If the import has completed with an error, you can do one of the following:

- For migration with Administration Server hierarchy support, you can start to import the export file again. In this case, you have to select the administration group as described at step 3.

- For migration without Administration Server hierarchy support, you can start the Migration wizard to select another export file, and then import it again.

You can check whether the group objects included in the export scope have been successfully imported to Kaspersky EDR Expert. To do this, go to the **Asset management** section and ensure whether the imported objects appear in the corresponding subsections.

Note that the imported managed devices are displayed in the **Managed devices** subsection, but they are not visible in the network, and Network Agent is not installed or running on these (*No* in the **Visible**, **Network Agent is installed**, and **Last connected to Administration Server** columns).

To complete the migration, you need to switch the managed devices to be under management of Kaspersky EDR Expert as described at stage 5 in Migration to Kaspersky EDR Expert.

Switching managed devices to be under management of Kaspersky EDR Expert

After a successful import of information about managed devices, objects, and their settings to Kaspersky EDR Expert, you need to switch the managed devices to be under management of Kaspersky EDR Expert to complete the migration.

You can move the managed devices to be under Kaspersky EDR Expert by one of the following methods:

- Using the klmover utility.
- Using the *Change Administration Server* task.
- Installing Network Agent on the managed devices through a remote installation task.

To switch managed devices to be under management of Kaspersky EDR Expert by installing Network Agent:

1. Remove Network Agent on the imported managed devices that will be switched under management of Kaspersky EDR Expert.
2. Switch to Administration Server of Kaspersky Security Center Windows.
3. Go to **Software management** → **Installation packages**, and then open the properties of an existing installation package of Network Agent.

   If the installation package of Network Agent is absent in the package list, download a new one.

   You can also create and use a stand-alone installation package to install Network Agent locally.
4. On the **Settings** tab, select the **Connection** section. Specify the connection settings of Administration Server of Kaspersky EDR Expert.
5. Create a remote installation task for imported managed devices, and then specify the reconfigured Network Agent installation package.

   You can install Network Agent through Administration Server of Kaspersky Security Center Windows or through a Windows-based device that acts as a distribution point. If you use Administration Server, enable the **Using operating system resources through Administration Server** option. If you use a distribution point, enable the **Using operating system resources through distribution points** option.
6. Run the remote installation task.

After the remote installation task finishes successfully, go to Administration Server of Kaspersky EDR Expert and ensure that managed devices are visible in the network, and that Network Agent is installed and running on them (the *Yes* value in the **Visible**, **Network Agent is installed**, and **Network Agent is running** columns).

About migration from KEDR 7.1

Direct data migration from Kaspersky EDR Expert 7.1 to 8.3 is not supported because version 8.3 offers only minor functional differences compared with version 8.1.

To transfer data from Kaspersky EDR Expert 8.1 to Kaspersky EDR Expert 8.3, follow these steps:

1. Install Kaspersky EDR Expert 8.1.

2. Perform the data migration from Kaspersky EDR Expert 7.1 to Kaspersky EDR Expert 8.1 as described in the Kaspersky EDR Expert 8.1 Help.

   To transfer data, you must use the cnab gateway-migration package that you can find in the transport archive. You must install and run cnab gateway-migration as the same user that was used to install Kaspersky EDR Expert.

3. Upgrade Kaspersky EDR Expert from version 8.1 to version 8.3.

Setting up and working with the SIEM component

This section provides information about installing and configuring the KUMA SIEM system.

KUMA services

Services are the main components of KUMA that help the system to manage events: services allow you to receive events from event sources and subsequently bring them to a common form that is convenient for finding correlation, as well as for storage and manual analysis. Each service consists of two parts that work together:

- One part of the service is created inside the KUMA Console based on set of resources for services.
- The other part of the service is installed in the network infrastructure where KUMA is deployed, as one of KUMA components. The server part of a service can consist of multiple instances: for example, services of the same storage can be installed on multiple devices at once.

  > On the server side, KUMA services are located in the `/opt/kaspersky/kuma` directory.

  When you install KUMA in high availability mode, only the KUMA Core is installed in the cluster. Collectors, correlators, and storages are hosted on hosts outside of the Kubernetes cluster.

Parts of services are connected to each other via the service ID.

Service types:

- Collectors are used to receive events and convert them to the KUMA format.
- Correlators are used to analyze events and search for defined patterns.
- Storages are used to save events.

In the KUMA Console, services are displayed in the **Resources** → **Active services** section in table format. The table of services can be updated by clicking the **Refresh** button and sorted by columns by clicking on the active headers.

The maximum table size is not limited. If you want to select all services, scroll to the end of the table and select the **Select all** check box, which selects all available services in the table.

Table columns:

- **Status**—service status:
  - Green means that the service is running.
  - Red means that the service is not running.

- The yellow status means that the service is running, but there are errors or alerts from VictoriaMetrics. You can view the error message by hovering the mouse pointer over the status.

- Purple is the status that is applied to running services whose configuration file in the database has changed, but that have no other errors. If a service has an incorrect configuration file and has errors, for example, from VictoriaMetrics, status of the service is yellow.

- Gray—if a deleted tenant had a running service that continues to work, that service is displayed with a gray status on the **Active services** page. Services with the gray status are kept to let you copy the ID and remove services on your servers. Only the Main administrator can delete services with the gray status. When a tenant is deleted, the services of that tenant are assigned to the Main tenant.

- **Type**—type of service: **collector**, **correlator**, or **storage**.
- **Name**—name of the service. Clicking on the name of the service opens its settings.
- **Version**—service version.
- **Tenant**—the name of the tenant that owns the service.
- **FQDN**—fully qualified domain name of the service server.
- **IP address**—IP address of the server where the service is installed.
- **API port**—Remote Procedure Call port number.
- **Uptime**—the time showing how long the service has been running.
- **Created**—the date and time when the service was created.

The table can be sorted in ascending and descending order, as well as by the **Status** parameter. To sort active services, right-click the context menu and select one or more statuses.

You can click the buttons in the upper part of the **Services** window to perform the following group actions:

- Add service

  You can create new services based on existing service resource sets. We do not recommend creating services outside the main tenant without first carefully planning the inter-tenant interactions of various services and users.

- Refresh

  You can refresh the list of active services.

- Update configuration
- Restart

To perform an action with an individual service, right-click the service to display its context menu. The following actions are available:

- Reset certificate
- Delete

- Download log

  If you want to receive detailed information, enable the Debug mode in the service settings.

- Copy service ID

  You need this ID to install, restart, stop, or delete the service.

- Go to Events
- Go to active lists
- Go to context tables
- Go to partitions

To change a service, select a service under **Resources** → **Active services**. This opens a window with a resource set based on which the service was created. You can edit the settings of the resource set and save your changes. To apply the saved changes, restart the service.

If, when changing the settings of a collector resource set, you change or delete conversions in a normalizer connected to it, the edits will not be saved, and the normalizer itself may be corrupted. If you need to modify conversions in a normalizer that is already part of a service, the changes must be made directly to the normalizer under **Resources** → **Normalizers** in the web interface.

Services tools

This section describes the tools for working with services available in the **Resources and services** → **Active services** section of OSMP.

Getting service identifier

The service identifier is used to bind parts of the service residing within OSMP and installed in the network infrastructure into a single complex. An identifier is assigned to a service when it is created in OSMP, and is then used when installing the service to the server.

To get the identifier of a service:

1. Log in to OSMP and open **Resources and services** → **Active services**.
2. Select the check box next to the service whose ID you want to obtain, and click **Copy ID**.

   The identifier of the service will be copied to the clipboard. For instance, this ID can be used to install the service on a server.

Stopping, starting, checking status of the service

While managing OSMP, you may need to perform the following operations.

- Temporarily stop the service. For example, when restoring the Core from backup, or to edit service settings related to the operating system.
- Start the service.
- Check the status of the service.

The table below lists commands that may be useful when managing OSMP.

Commands for stopping, starting, and checking the status of a service

Service	Stop service	Start service	Check the status of the service
Core	`sudo systemctl stop kuma-core.service`	`sudo systemctl start kuma-core.service`	`sudo systemctl status kuma-core.service`
Services with an ID: • collector • correlator • storage	`sudo systemctl stop kuma-<collector/correlator/storage>-<service ID>.service`	`sudo systemctl start kuma-<collector/correlator/storage>-<service ID>.service`	`sudo systemctl status kuma-<collector/correlator/storage><service ID>.service`
Services without an ID: • kuma-grafana.service • kuma-mongodb.service • kuma-victoria-metrics.service • kuma-vmalert.service	`sudo systemctl stop kuma-<grafana/victoria-metrics/vmalert>.service`	`sudo systemctl start kuma-<grafana/victoria-metrics/vmalert>.service`	`sudo systemctl status kuma-<grafana/victoria-metrics/vmalert>.service`

Restarting the service

To restart the service:

1. Log in to OSMP and open **Resources and services** → **Active services**.
2. Select the check box next to the service and select the necessary option:
   - **Update configuration**—perform a hot update of a running service configuration. For example, you can change the field mapping settings or the destination point settings this way.
   - **Restart**—stop a service and start it again. This option is used to modify the port number or connector type.
   - **Reset certificate**—remove certificates that the service uses for internal communication. This option may not be used to renew the Core certificate. To renew KUMA Core certificates, they must be reissued.

Deleting the service

Before deleting the service get its ID. The ID will be required to remove the service for the server.

To remove a service in OSMP:

1. Log in to OSMP and open **Resources and services** → **Active services**.
2. Select the check box next to the service you want to delete, and click **Delete**.

   The confirmation window opens.
3. Click the **OK** button.

The service has been deleted from OSMP.

To remove a service from the server, run the following command:

```
sudo /opt/kaspersky/kuma/kuma <collector/correlator/storage> --id <service ID> --uninstall
```

The service has been deleted from the server.

Viewing the table of active queries

A Main administrator can view the queries of other users and OSMP resources that are currently being executed.

To view the table of active queries:

1. In the main application window, go to the **Monitoring** → **Resources and services** → **Active services** section.
2. Select the check boxes next to the relevant storages.
3. In the toolbar or in the menu (⋮), click **Active queries**.

   This opens the window with the **ClickHouse active queries** table. When selecting multiple storages, the table displays active queries from each selected storage.

The resource table contains the following columns:

- **Started** is the date and time when the query was initiated.
- **Created by** is the initiator of the query. For user queries, the user name is displayed. For queries of the **Resource** type, the resource name is displayed.
- **Query** is the text of the SQL query executed in ClickHouse.

- **Type** is the type of the query. The following query types are available:
  - **In background** indicates that the query was initiated by the user in the background using the **Run in background** button.
  - **Resource** indicates an internal SQL query initiated by a OSMP resource, for example, during data processing or analysis.
  - **User** indicates an SQL query initiated by the user using the **Run query** button and executed normally.
- **Storage** is the name of the ClickHouse storage in whose context the query is being executed.

Click the ⚙ button to configure the displayed columns of the queries table. If necessary, you can force the update of the data by clicking ↻.

If you want to sort the queries by a specific column, click its title and select one of the available options in the drop-down list: **Ascending** or **Descending**.

If necessary, you can cancel queries.

To cancel a query:

1. Open the **ClickHouse active queries** table.
2. Select the check box next to a query and click **Cancel query**.

   A confirmation window opens. You can also specify the reason for canceling the query in the **Specify a reason** field.
3. Click **OK**.

The query is canceled and removed from the table. An audit event is automatically generated.

Partitions window

If the storage service was created and installed, you can view its partitions in the **Partitions** table.

*To open **Partitions** table:*

1. Log in to OSMP and open **Resources and services** → **Active services**.
2. Select the check box next to the relevant storage and click **Go to partitions**.

The **Partitions** table opens.

The table has the following columns:

- **Tenant**—the name of the tenant that owns the stored data.
- **Created**—partition creation date.
- **Space**—the name of the space.
- **Size**—the size of the space.

- **Events**—the number of stored events.
- **Transfer to cold storage**—the date when data will be migrated from the ClickHouse clusters to cold storage disks.
- **Expires**—the date when the partition expires. After this date, the partition and the events it contains are no longer available.

You can delete partitions.

To delete a partition:

1. Open the **Partitions** table (see above).
2. Select the check box to the left from the required partition.
3. Select **Delete**.

   A confirmation window opens.
4. Click the **OK** button.

The partition has been deleted. Audit event partitions cannot be deleted.

Searching for related events

You can search for events processed by the Correlator or the Collector services.

To search for events related to the Correlator or the Collector service:

1. Log in to the KUMA web interface and open **Resources** → **Active services**.
2. Select the check box next to the required correlator or collector and click **Go to Events**.

   A new browser tab opens with the KUMA **Events** section open.
3. To find events, click the **Run query** button.

   A table with events selected by the search expression `ServiceID = <ID of the selected service>` will be displayed.

Service resource sets

Service resource sets are a resource type, an OSMP component, a set of settings based on which the OSMP services are created and operate. Resource sets for services are collections of resources.

Any resources added to a resource set must be owned by the same tenant that owns the created resource set. An exception is the shared tenant, whose owned resources can be used in the sets of resources of other tenants.

Resource sets for services are displayed in the **Resources and services** → **<Resource set type for the service>** section of OSMP. Available types:

- Collectors.
- Correlators.
- Storages
- Agents.

When you select the required type, a table opens with the available sets of resources for services of this type. The resource table contains the following columns:

- **Name**—the name of a resource set. Can be used for searching and sorting.
- **Updated**—the date and time of the last update of the resource set. Can be used for sorting.
- **Created by**—the name of the user who created the resource set.
- **Description**—the description of the resource set.

Creating a storage

A storage consists of two parts: one part is created inside OSMP, and the other part is installed on network infrastructure servers intended for storing events. The server part of an OSMP storage consists of ClickHouse nodes collected into a cluster. ClickHouse clusters can be supplemented with cold storage disks.

For each ClickHouse cluster, a separate storage must be installed.

Prior to storage creation, carefully plan the cluster structure and deploy the necessary network infrastructure. When choosing a ClickHouse cluster configuration, consider the specific event storage requirements of your organization.

We recommend using the ext4 file system.

A storage is created in several steps:

1. **Creating a set of resources for a storage in OSMP**
2. **Creating a storage service in OSMP**
3. **Installing storage nodes in the network infrastructure**

When creating storage cluster nodes, verify the network connectivity of the system and open the ports used by the components.

If the storage settings are changed, the service must be restarted.

ClickHouse cluster structure

A ClickHouse *cluster* is a logical group of devices that possess all accumulated normalized KUMA events. It consists of one or more logical *shards*.

A *shard* is a logical group of devices that possess a specific **portion** of all normalized events accumulated in the cluster. It consists of one or more *replicas*. Increasing the number of shards lets you do the following:

- Accumulate more events by increasing the total number of servers and disk space.
- Absorb a larger **stream** of events by distributing the load associated with an influx of new events.
- Reduce the time taken to search for events by distributing search zones among multiple devices.

A *replica* is a device that is a member of a logical shard and possesses a single copy of that shard's data. If multiple replicas exist, it means multiple copies exist (the data is replicated). Increasing the number of replicas lets you do the following:

- Increase fault tolerance.
- Distribute the total load related to data searches among multiple machines (although it's best to increase the number of shards for this purpose).

A *keeper* is a device that participates in **coordination** of data replication at the **whole** cluster level. At least one device per cluster must have this role. The recommended number of the devices with this role is 3. The number of devices involved in coordinating replication must be an **odd** number. The *keeper* and *replica* roles can be combined in one machine.

ClickHouse cluster node settings

Prior to storage creation, carefully plan the cluster structure and deploy the necessary network infrastructure. When choosing a ClickHouse cluster configuration, consider the specific event storage requirements of your organization.

When creating ClickHouse cluster nodes, verify the network connectivity of the system and open the ports used by the components.

For each node of the ClickHouse cluster, you need to specify the following settings:

- Fully qualified domain name (FQDN)—a unique address to access the node. Specify the entire FQDN, for example, `kuma-storage.example.com`.
- Shard, replica, and keeper IDs—the combination of these settings determines the position of the node in the ClickHouse cluster structure and the node role.

Node roles

The roles of the nodes depend on the specified settings:

- shard, replica, keeper—the node participates in the accumulation and search of normalized KUMA events and helps coordinate data replication at the cluster-wide level.
- shard, replica—the node participates in the accumulation and search of normalized KUMA events.
- keeper—the node **does not** accumulate normalized events, but helps coordinate data replication at the cluster-wide level. Dedicated keepers must be specified at the beginning of the list in the **Resources** → **Storages** → <Storage> → **Basic settings** → **ClickHouse cluster nodes** section.

ID requirements:

- If multiple shards are created in the same cluster, the shard IDs must be unique within this cluster.
- If multiple replicas are created in the same shard, the replica IDs must be unique within this shard.
- The keeper IDs must be unique within the cluster.

Example of ClickHouse cluster node IDs:

- shard 1, replica 1, keeper 1;
- shard 1, replica 2;
- shard 2, replica 1;
- shard 2, replica 2, keeper 3;
- shard 2, replica 3;
- keeper 2.

Cold storage of events

In OSMP, you can configure the migration of legacy data from a ClickHouse cluster to the cold storage. Cold storage can be implemented using the local disks mounted in the operating system, a Hadoop Distributed File System (HDFS), or an S3 cloud storage (Simple Storage Service).

Starting with OSMP version 2.1, data stored on HDFS disks will be gradually migrated to S3 cloud storage. Support for the HDFS file system will be discontinued in a future release of the solution.

Cold storage is enabled when at least one cold storage disk is specified. If multiple storages are used, a cold storage disk or a HDFS or S3 disk must be mounted at the path specified in the storage configuration on each node with data. If a cold storage disk is not configured and the server runs out of disk space in hot storage, the storage service is stopped. If both hot storage and cold storage are configured, and space runs out on the cold storage disk, the OSMP storage service is stopped. We recommend avoiding such situations by adding custom event storage conditions in hot storage.

Cold storage disks can be added or removed. If you have added multiple cold storage disks, data is written to them in a round-robin manner. If data to be written to disk would take up more space than is available on that disk, this data and all subsequent data is written round-robin to the next cold storage disks. If you added only two cold storage disks, the data is written to the drive that has free space left.

After changing the cold storage settings, the storage service must be restarted. If the service does not start, the reason is indicated in the storage log.
Restarting the service is also necessary if the path to the S3 storage is specified incorrectly. Note that the created *storage.xml* file is not automatically deleted. You need to manually clear the `/opt/kaspersky/kuma/clickhouse/cfg/config.d/` folder and configure cold storage again.

If the cold storage disk specified in the storage settings has become unavailable (for example, out of order), this may lead to errors in the operation of the storage service. In this case, recreate a disk with the same path (for local disks) or the same address (for HDFS and S3 disks) and then remove it from the storage settings.

Rules for moving the data to the cold storage disks

You can configure the storage conditions for events in hot storage of the ClickHouse cluster by setting a limit based on retention time or on maximum storage size. When cold storage is used, every 15 minutes and after each Core restart, OSMP checks if the specified storage conditions are satisfied:

1. OSMP gets the partitions for the storage being checked and groups the partitions by cold storage disks and spaces.

2. For each space, OSMP checks whether the specified storage condition is satisfied.

3. If the condition is satisfied (for example, if the space contains that exceed their retention time, or if the size of the storage has reached or exceeded limit specified in the condition), OSMP transfers all partitions with the oldest date to cold storage disks or deletes these partitions if no cold storage disk is configured or if it is configured incorrectly. This action is repeated while the configured storage condition remains satisfied in the space; for example, if after deleting partitions for a date, the storage size still exceeds the maximum size specified in the condition.

   OSMP generates an audit event when data transfer starts and ends, or when data is deleted.

4. If retention time is configured in OSMP, whenever partitions are transferred to cold storage disks, it is checked whether the configured conditions are satisfied on the disk. If events are found on the disk that have been stored for longer than the **Event retention time**, which is counted from the moment the events were received in OSMP, the solution deletes these events or all partitions for the oldest date.

   OSMP generates an audit event when data is deleted.

If the disks of the ClickHouse cluster are 97% full, the largest partitions are either automatically transferred to cold storage disks, or deleted if there are no cold storage disks.

During data transfer, the storage service remains operational, and its status stays green in the **Resources → Active services** section of the OSMP web interface. When you hover over the status icon, a message is displayed about the data transfer. When a cold storage disk is removed, the storage service has the yellow status.

Special considerations for storing and accessing events

- When using HDFS disks for cold storage, protect your data in one of the following ways:
  - Configure a separate physical interface in the VLAN, where only HDFS disks and the ClickHouse cluster are located.
  - Configure network segmentation and traffic filtering rules that exclude direct access to the HDFS disk or interception of traffic to the disk from ClickHouse.
- Events located in the ClickHouse cluster and on the cold storage disks are equally available in the OSMP web interface. For example, when you search for events or view events related to alerts.
- You can disable the storage of events or audit events on cold storage disks. To do so, specify the following in storage settings:
  - If you do not want to store events on cold storage disks, do one of the following:
    - If in the **Retention policy options** field, you have selected a gigabyte or percentage based storage condition, in the **Events storage time** field, specify `0`.
    - If in the **Retention policy options** field, you have selected a storage condition in days, in the **Event storage time** field, specify the same number of days as in the **Retention policy options**.
  - If you do not want to store audit events on cold storage disks, in the **Audit cold retention period** field, specify `0` (days).

Special considerations for using HDFS disks

- Before connecting HDFS disks, create directories for each node of the ClickHouse cluster on them in the following format: `<HDFS disk host>/<shard ID>/<replica ID>`. For example, if a cluster consists of two nodes containing two replicas of the same shard, the following directories must be created:

  - hdfs://hdfs-example-1:9000/clickhouse/1/1/

  - hdfs://hdfs-example-1:9000/clickhouse/1/2/

  Events from the ClickHouse cluster nodes are migrated to the directories with names containing the IDs of their shard and replica. If you change these node settings without creating a corresponding directory on the HDFS disk, events may be lost during migration.

- HDFS disks added to storage operate in the JBOD mode. This means that if one of the disks fails, access to the storage will be lost. When using HDFS, take high availability into account and configure RAID, as well as storage of data from different replicas on different devices.

- The speed of event recording to HDFS is usually lower than the speed of event recording to local disks. The speed of accessing events in HDFS, as a rule, is significantly lower than the speed of accessing events on local disks. When using local disks and HDFS disks at the same time, the data is written to them in turn.

- HDFS is used only as distributed file data storage of ClickHouse. Compression mechanisms of ClickHouse, not HDFS, are used to compress data.

- The ClickHouse server must have write access to the corresponding HDFS storage.

Removing cold storage disks

Before physically disconnecting cold storage disks, remove these disks from the storage settings.

To remove a disk from the storage settings:

- In OSMP, under **Resources and services** → **Storages**, select the relevant storage.

  This opens the storage.

- In the window, in the **Disks for cold storage** section, in the required disk's group of settings, click **Delete disk**.

  Data from removed disk is automatically migrated to other cold storage disks or, if there are no such disks, to the ClickHouse cluster. During data migration, the storage status icon is highlighted in yellow. Audit events are generated when data transfer starts and ends.

- After event migration is complete, the disk is automatically removed from the storage settings. It can now be safely disconnected.

Removed disks can still contain events. If you want to delete them, you can manually delete the data partitions using the DROP PARTITION command.

If the cold storage disk specified in the storage settings has become unavailable (for example, out of order), this may lead to errors in the operation of the storage service. In this case, create a disk with the same path (for local disks) or the same address (for HDFS disks) and then delete it from the storage settings.

Detaching, archiving, and attaching partitions

If you want to optimize disk space and speed up queries in OSMP, you can detach data partitions in ClickHouse, archive partitions, or move partitions to a drive. If necessary, you can later reattach the partitions you need and perform data processing.

Detaching partitions

To detach partitions:

1. Determine the shard on all replicas of which you want to detach the partition.

2. Get the partition ID using the following command:

   ```
   sudo /opt/kaspersky/kuma/clickhouse/bin/client.sh -d kuma --multiline --query "SELECT partition, name FROM system.parts;" |grep 20231130
   ```

   In this example, the command returns the partition ID for November 30, 2023.

3. One each replica of the shard, detach the partition using the following command and specifying the partition ID:

   ```
   sudo /opt/kaspersky/kuma/clickhouse/bin/client.sh -d kuma --multiline --query "ALTER TABLE events_local_v2 DETACH PARTITION ID '<partition ID>'"
   ```

As a result, the partition is detached on all replicas of the shard. Now you can move the data directory to a drive or archive the partition.

Archiving partitions

To archive detached partitions:

1. Find the detached partition in disk subsystem of the server:

   ```
   sudo find /opt/kaspersky/kuma/clickhouse/data/ -name <ID of the detached partition>\*
   ```

2. Change to the 'detached' directory that contains the detached partition, and while in the 'detached' directory, perform the archival:

```
sudo cd <path to the 'detached' directory containing the detached partition>
sudo zip -9 -r detached.zip *
```

For example:

```
sudo cd /opt/kaspersky/kuma/clickhouse/data/store/d5b/d5bdd8d8-e1eb-4968-95bd-d8d8e1eb3968/detached/
sudo zip -9 -r detached.zip *
```

The partition is archived.

Attaching partitions

To attach archived partitions to OSMP:

1. Increase the **Retention period** value.

   OSMP deletes data based on the date specified in the Timestamp field, which records the time when the event is received, and based on the **Retention period** value that you set for the storage.

   Before restoring archived data, make sure that the **Retention period** value overlaps the date in the Timestamp field. If this is not the case, the archived data will be deleted within 1 hour.

2. Place the archive partition in the 'detached' section of your storage and extract the archive:

   ```
   sudo unzip detached.zip -d <path to the 'detached' directory>
   ```

   For example:

   ```
   sudo unzip detached.zip -d /opt/kaspersky/kuma/clickhouse/data/store/d5b/d5bdd8d8-e1eb-4968-95bd-d8d8e1eb3968/detached/
   ```

3. Run the command to attach the partition:

   ```
   sudo /opt/kaspersky/kuma/clickhouse/bin/client.sh -d kuma --multiline --query "ALTER TABLE events_local_v2 ATTACH PARTITION ID '<partition ID>'"
   ```

   ```
   Repeat the steps of extracting the archive and attaching the partition on each replica of the shard.
   ```

As a result, the archived partition is attached and its events are again available for search.

Creating a set of resources for a storage

In the OSMP web interface, a storage service is created based on the resource set for the storage.

To create a set of resources for a storage in the OSMP web interface:

1. In OSMP, in the **Resources** → **Storages** section, click **Create new**.

   This opens the **Create storage** window.

2. On the **Basic settings** tab, in the **Storage name** field, enter a unique name for the service you are creating. The name must contain 1 to 128 Unicode characters.

3. In the **Tenant** drop-down list, select the tenant that will own the storage.

4. In the **Tags** drop-down list, select the tags for the resource set that you are creating.

   The list includes all available tags created in the tenant of the resource and in the Shared tenant. You can find a tag in the list by typing its name in the field. If the tag you entered does not exist, you can press **Enter** or click **Add** to create it.

5. You can optionally add up to 256 Unicode characters describing the service in the **Description** field.

6. In the **Retention policy options** field, select an event storage condition in the ClickHouse cluster for the storage, which, when satisfied, will cause events to be transferred to cold storage disks or deleted if cold storage is not configured or is configured incorrectly. The condition is applied to the default space and to events from deleted spaces.

   By default, ClickHouse moves events to cold storage disks or deletes them if more than 97% of the storage is full. OSMP also applies an additional **365 days** storage condition when creating a storage. You can configure custom storage conditions for more stable performance of the storage.

   To set the storage condition, do one of the following:

   - If you want to limit the storage period for events, select **Days** from the drop-down list, and in the field, specify the maximum event storage period (in days) in the ClickHouse hot storage cluster.

     After the specified period, events are automatically transferred to cold storage disks or deleted from the ClickHouse cluster, starting with the partitions with the oldest date. The minimum value is 1. The default value is 365.

     For [OOTB] Storage, the default event storage period is two days. If you want to use this storage, you can change the event storage condition for it, if necessary.

   - If you want to limit the maximum storage size, select **GB** from the drop-down list, and in the field, specify the maximum storage size in gigabytes.

     When the storage reaches the specified size, events are automatically transferred to cold storage disks or deleted from the ClickHouse cluster, starting with the partitions with the oldest date. The minimum and default value is 1.

   - If you want to limit the storage size to a percentage of disk space that is available to the storage, select **Percent** from the drop-down list and specify the maximum storage size as a percentage of the available disk space.

     > You can get information about available disk space from ClickHouse by sending the `'SELECT hostname(), name, total_space FROM system.disks'` query.

     When the storage reaches the specified percentage of disk space available to it, events are automatically transferred to cold storage disks or deleted from the ClickHouse cluster, starting with the partitions with the oldest date. Possible values: 1 to 95. The default value is 80. If you want to use percentages for all storage spaces, the sum total of percentages in the conditions of all spaces may not exceed 95, but we recommend specifying a limit of at most 90% for the entire storage or for individual spaces.

     We do not recommend specifying a value less than 5% as this increases the likelihood of data loss in the storage.

     > If the storage is organized as a cluster, the amount of occupied disk space is determined for each of the several servers separately. Stored data may be unevenly distributed among disks on the servers. OSMP pushes events to cold storage disks or deletes events when the maximum storage size is reached *on any individual server in the cluster*.

The algorithm for determining the size of occupied storage space

The size of occupied storage space is determined as follows:

1. Information about the state of KUMA disks and partitions is obtained from all available replicas.

2. If occupied space exceeds the configured values, KUMA takes action depending on the type of data storage: hot or cold.

   For hot storage, the following actions are performed for each available node and space:

   a. The total size of the partitions of this space on the replica is calculated.

   b. The maximum space size on the replica is calculated:

   - If an absolute value in GB is set for the storage size, the maximum space size on the replica is calculated as follows:

     `<maximum space size> = <configured threshold> / <number of replicas in the cluster>`

     For example, consider a cluster with three shards, each of which contains two replicas; a threshold of 6 GB is set, and the maximum size of data on a replica is 1 GB.

   - If a relative value is set for the storage size as a percentage, the maximum space on the replica is calculated as follows:

     `<maximum space size> = <space size on the replica> / <size of the replica disk> * 100%`

     > The size of the replica disk does not include the space reserved for `ext4`.

   If the specified threshold is exceeded, partitions on the host are deleted or moved to cold storage. Partitions are deleted on all shards.

   For cold storage, partitions are deleted for each available space in accordance with the event retention period (TTL) configured in KUMA.

7. If you want to use an additional storage condition, click **Add policy options** and specify an additional storage condition as described in step 6.

   The maximum number of conditions is two, and you can combine only conditions the following types:

   - Days and storage size in GB
   - Days and storage size as a percentage

   If you want to remove a storage condition, click the X icon next to this condition.

8. In the **Audit retention period** field, specify the period, in days, to store audit events. The minimum value and default value is `365`.

9. If cold storage is required, specify the event storage term:

   - **Event retention time** specifies the total OSMP event storage duration in days, counting from the moment when the event is received. When the specified period expires, events are automatically deleted from the cold storage disk. The default value is 0.

The event retention time is calculated as the sum of the event retention time in the ClickHouse hot storage cluster until the condition specified in the **Retention policy options** setting is triggered, and the event retention time on the cold storage disk. After one of storage conditions is triggered, the data partition for the earliest date is moved to the cold storage disk, and there it remains until the event retention time in OSMP expires.

Depending on the specified storage condition, the resulting retention time is as follows:

- If you specified a storage condition in days, the **Event retention time** must be strictly greater than the number of days specified in the storage condition. You can calculate the cold retention period for events as the **Events storage time** minus the number of days specified in the **Retention policy options** setting.

  If you do not want to store events on the cold storage disk, you can specify the same number of days in the **Event retention time** field as in the storage condition.

- If you specified the storage condition in terms of disk size (absolute or percentage), the minimum value of the **Event retention time** is 1. The cold storage duration for events is calculated as **Event retention time** minus the number of days from the receipt of the event to triggering of the condition and the disk partition filling up, but until the condition is triggered, calculating an exact duration is impossible. In this case, we recommend specifying a relatively large value for **Event retention time** to avoid events being deleted.

  If you do not want to store events on the cold storage disk, you can set **Event retention time** to 0.

- **Audit cold retention period**—the number of days to store audit events. The minimum value is 0.

The **Events storage time** and **Audit cold retention period** settings become available only after at least one cold storage disk has been added.

10. If you want to change ClickHouse settings, in the **ClickHouse configuration override** field, paste the lines with settings from the ClickHouse configuration XML file /opt/kaspersky/kuma/clickhouse/cfg/config.xml. Specifying the root elements <yandex>, </yandex> is not required. Settings passed in this field are used instead of the default settings.

    Example:

    <merge_tree>

    <parts_to_delay_insert>600</parts_to_delay_insert>

    <parts_to_throw_insert>1100</parts_to_throw_insert>

    </merge_tree>

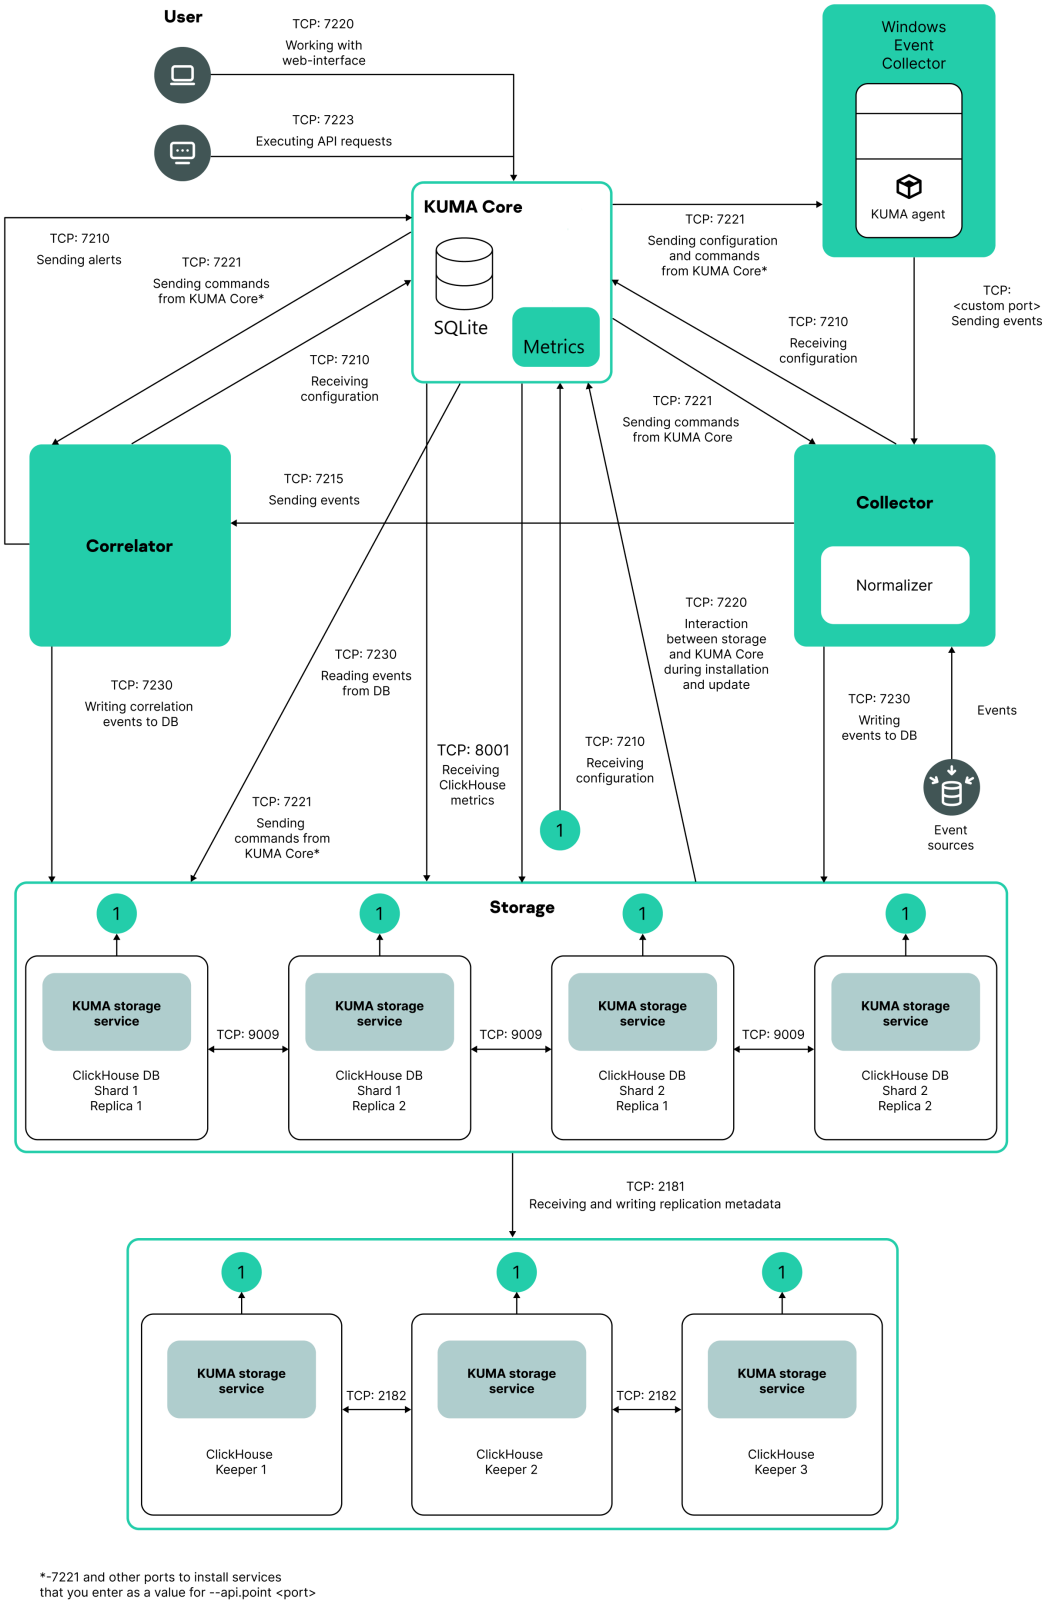
    If you want to speed up the graph and threat hunting, you can change the ClickHouse compression algorithm. The ZSTD algorithm is used by default. You can replace the default setting with LZ4. To do this, in the **ClickHouse configuration override** field, specify the compression algorithm as follows:

    ```
    <compression>
     <case>
     <method>lz4</method>
     </case>
    <compression>
    ```

    The solution begins to apply the LZ4 algorithm after the storage service is restarted. All events stored in the storage before you changed the algorithm will stay compressed using the ZSTD algorithm.

11. Use the **Debug** toggle switch to specify whether resource logging must be enabled. If you want to only log errors for all KUMA components, disable debugging. If you want to get detailed information in the logs, enable debugging.

12. If necessary, in the **ClickHouse cluster nodes** section, add ClickHouse cluster nodes to the storage.



There can be multiple nodes. You can add nodes by clicking the **Add node** button or remove nodes by clicking the X icon of the relevant node.

Available settings:

- In the **FQDN** field, enter the fully qualified domain name of the node that you want to add. For example, `kuma-storage-cluster1-server1.example.com`.

- In the **Shard ID**, **Replica ID**, and **Keeper ID** fields, specify the role of the node in the ClickHouse cluster. The shard and keeper IDs must be unique within the cluster, the replica ID must be unique within the shard. The following example shows how to populate the **ClickHouse cluster nodes** section for a storage with dedicated keepers in a distributed installation. You can adapt this example according to your needs.

Distributed installation diagram

Distributed Installation diagram

Example:

ClickHouse cluster nodes

FQDN: kuma-storage-cluster1-server1.example.com

Shard ID: 0

Replica ID: 0
Keeper ID: 1
FQDN: kuma-storage-cluster1server2.example.com
Shard ID: 0
Replica ID: 0
Keeper ID: 2
FQDN: kuma-storage-cluster1server3.example.com
Shard ID: 0
Replica ID: 0
Keeper ID: 3
FQDN: kuma-storage-cluster1server4.example.com
Shard ID: 1
Replica ID: 1
Keeper ID: 0

13. If necessary, in the **Spaces** section, add spaces to the storage to distribute the stored events.

    There can be multiple spaces. You can add spaces by clicking the **Add space** button or remove spaces by clicking the X icon of the relevant space.

    Available settings:

    - In the **Name** field, specify a name for the space containing 1 to 128 Unicode characters.

    - In the **Retention policy options** field, select an event storage condition in the ClickHouse cluster for the space, which, when satisfied, will cause events to be transferred to cold storage disks or deleted if cold storage is not configured or is configured incorrectly. OSMP applies the **365 days** storage condition when a space is added.

      To set the storage condition for a space, do one of the following:

      - If you want to limit the storage period for events, select **Days** from the drop-down list, and in the field, specify the maximum event storage period (in days) in the ClickHouse hot storage cluster.

        After the specified period, events are automatically transferred to cold storage disks or deleted from the ClickHouse cluster, starting with the partitions with the oldest date. The minimum value is 1. The default value is 365.

      - If you want to limit the maximum storage space size, select **GB** from the drop-down list, and in the field, specify the maximum space size in gigabytes.

        When the space reaches the specified size, events are automatically transferred to cold storage disks or deleted from the ClickHouse cluster, starting with the partitions with the oldest date. The minimum value and default value is 1.

      - If you want to limit the space size to a percentage of disk space that is available to the storage, select **Percent** from the drop-down list, and in the field, specify the maximum space size as a percentage of the size of the disk available to the storage. In this case, the condition can also be triggered when the disk space available to the storage is decreased.

When the space reaches the specified percentage of disk space available to the storage, events are automatically transferred to cold storage disks or deleted from the ClickHouse cluster, starting with the partitions with the oldest date. Possible values: 1 to 95. The default value is 80. If you want to use percentages for all storage spaces, the sum total of percentages in the conditions of all spaces may not exceed 95, but we recommend specifying a limit of at most 90% for the entire storage or for individual spaces.

We do not recommend specifying small percentage values because this increases the probability of data loss in the storage.

When using size as the storage condition, you must ensure that the total size of all spaces specified in the storage conditions does not exceed the physical size of the storage, otherwise an error will be displayed when starting the service.

In storage conditions with a size limitation, use the same units of measure for all spaces of a storage (only gigabytes or only percentage values). Otherwise, if the condition is specified as a percentage for one space, and in gigabytes for another space, the storage may overflow due to mismatch of values, leading to data loss.

- If you want to make a space inactive if it is outdated and no longer relevant, select the **Read only** check box.

  This prevents events from going into that space. To make the space active again, clear the **Read only** check box. This check box is cleared by default.

- If necessary, in the **Event retention time** field, specify the total KUMA event storage duration in days, counting from the moment when the event is received. When the specified period expires, events are automatically deleted from the cold storage disk. The default value is 0.

  The event retention time is calculated as the sum of the event retention time in the ClickHouse hot storage cluster until the condition specified in the **Retention policy options** setting is triggered, and the event retention time on the cold storage disk. After one of storage conditions is triggered, the data partition for the earliest date is moved to the cold storage disk, and there it remains until the event retention time in OSMP expires.

  Depending on the specified storage condition, the resulting retention time is as follows:

  - If you specified a storage condition in days, the **Event retention time** must be strictly greater than the number of days specified in the storage condition. The cold storage duration for events is calculated as the **Event storage time** minus the number of days specified in the **Retention policy options** setting.

    If you do not want to store events from this space on the cold storage disk, you can specify the same number of days in the **Event retention time** field as in the storage condition.

  - If you specified the storage condition in terms of disk size (absolute or percentage), the minimum value of the **Event retention time** is 1. The cold storage duration for events is calculated as **Event retention time** minus the number of days from the receipt of the event to triggering of the condition and the disk partition filling up, but until the condition is triggered, calculating an exact duration is impossible. In this case, we recommend specifying a relatively large value for **Event retention time** to avoid events being deleted.

    If you do not want to store events from this space on the cold storage disk, you can set **Event retention time** to 0.

  The **Event retention time** setting becomes available only after adding at least one cold storage disk.

- In the **Filter settings** section, you can specify conditions to identify events that will be put into this space. To create a new filter, in the **Filter** drop-down list, select an existing filter or **Create new**.

  Creating a filter in resources

All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

To create a filter:

1. In the **Filter** drop-down list, select **Create new**.
2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.
3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.
4. Under **Conditions**, specify the conditions that the events must meet:
   a. Click the **Add condition** button.
   b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.
   c. In the **Operator** drop-down list, select an operator.

      Filter operators

      - **=** means the left operand equals the right operand.
      - **<** means the left operand is less than the right operand.
      - **<=** means the left operand is less than or equal to the right operand.
      - **>** means the left operand is greater than the right operand.
      - **>=** means the left operand is greater than or equal to the right operand.
      - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
      - **contains** means the left operand contains values of the right operand.
      - **startsWith** means the left operand starts with one of the values of the right operand.
      - **endsWith** means the left operand ends with one of the values of the right operand.
      - **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
      - **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

        The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.

- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.

- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.

- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.

- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.

- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.

- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.

- **inContextTable** checks for the presence of the entry in the specified context table.

- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

After the service is created, you can view and delete spaces in the storage resource settings.

> There is no need to create a separate space for audit events. Events of this type (Type=4) are automatically placed in a separate Audit space with a storage term of at least 365 days. This space cannot be edited or deleted from the OSMP web interface.

14. If necessary, in the **Disks for cold storage** section, add to the storage the disks where you want to transfer events from the ClickHouse cluster for long-term storage.

There can be multiple disks. You can add disks by clicking the **Add disk** button and remove them by clicking the **Remove disk** button.

Available settings:

- In the **Type** drop-down list, select the type of the domain name of the disk being connected:
  - **Local**—for the disks mounted in the operating system as directories.
  - **HDFS**—for the disks of the Hadoop Distributed File System.
  - **S3**—for S3 cloud storage disks used in KUMA.

    Starting with version 4.2, data stored on HDFS drives will be gradually migrated to S3 storage disks. Support for the HDFS file system will be discontinued in a future release of the solution.

- In the **Name** field, specify the disk name. The name must contain 1 to 128 Unicode characters.

  You cannot change the name of an S3 drive without changing the path to the drive.

- If you select the **Local** domain name type for the disk, in the **Path** field, enter one of the following values.
  - If the storage service is deployed locally, enter the absolute path to the directory at which the local drive is mounted. The path must begin and end with a "/" character.

    The directory of the mounted local disk must be owned by the KUMA user.

  - If the storage service is deployed on a Kubernetes cluster, enter the path: `/opt/cold/`. The `/opt/lvp/cold/` directory of the Kubernetes cluster node on which the storage service will be deployed is mounted to the `/opt/cold` directory.

- If you select **HDFS** domain name type for the disk, specify the path to HDFS in the **Host** field (for example, `hdfs://hdfs1:9000/clickhouse/`).

- If you selected **S3** as the domain name type for the disk, specify the following parameters:
  - In the **Host** field, enter the address of the S3 storage (for example, `https://www.company.com/clickhouse/storagefolder/`).

    Rules for specifying the address of the S3 storage

    When specifying an S3 storage address, the following requirements must be satisfied:

    - The address must be specified in the URL format, for example:
      `https://<web address/IP address of the server>/<path to disk>/`
    - The address must end with a "/" character.
    - The maximum length is 2048 characters.
    - Non-Latin letters are not allowed.

You cannot change the address of an S3 storage disk without changing the name of the disk.

- In the **Secret** field, specify the secret for access to the S3 storage. You can select a secret from the drop-down list or create a secret by clicking **Create new**.

15. In the **Configure backup and restore** section, manage the following settings:

    a. In the **Storage backup** field, specify the path at which you want to save the backup file. For example, /mnt/data.

    Path requirements:

    - The path must exist and be the same on all nodes of the storage cluster.
    - The user must have read, write, and execute permissions in the specified directory.
    - The specified directory must belong to the second or deeper nesting level. You cannot use a directory at the first nesting level, for example, /backup.
    - The directory name may not contain a period.
    - **The path may not contain the following prefixes**.

      Prefixes that cannot be used when specifying paths to files:

      - `/*`
      - `/bin`
      - `/boot`
      - `/dev`
      - `/etc`
      - `/home`
      - `/lib`
      - `/lib64`
      - `/proc`
      - `/root`
      - `/run`
      - `/sys`
      - `/tmp`
      - `/usr/*`
      - `/usr/bin/`

- `/usr/local/*`
- `/usr/local/sbin/`
- `/usr/local/bin/`
- `/usr/sbin/`
- `/usr/lib/`
- `/usr/lib64/`
- `/var/*`
- `/var/lib/`
- `/var/run/`
- `/opt/kaspersky/kuma/`

These prefixes are used by the system as regular expressions for checking the path. The * character in prefixes matches any sequence of characters and must not be manually specified in the path itself if it is not part of a valid path.

Files are available at the following paths:

- `/opt/kaspersky/kuma/clickhouse/logs/`
- `/opt/kaspersky/kuma/metrics/log/`

Two directories are automatically created at the specified path: **backup** and **restore**.

If no path is specified, the scheduled backup, manual backup, restoration from backup, and import functions are not available.

b. If you want to configure scheduled backup, enable the **Scheduled backup** toggle switch.

c. In the **Back up after several days** field, specify an integer number of days after the creation of a partition after which you want a backup copy to be created. For example, if the value is **1**, backup is performed for the partition created the day before yesterday.

d. In the **Replicas** drop-down list, select one replica that you want to back up. Selecting multiple replicas of the same shard causes data duplication.

e. Under **Partitions**, click **Add partition** and manage the following settings:

a. In the **Tenant** drop-down list, select the tenant that contains the partition that you want to back up.

b. In the **Spaces** drop-down list, select one or more storage spaces that belong to the partition that you want to back up. If no value is specified, the whole partition is backed up.

You can manage settings for multiple partitions. If necessary, click **Add partition** and manage the settings of the new partition in the displayed fields. For example, if you want to back up the **Audit** space and you have 10 tenants, you must configure the backup separately for each tenant.

16. Go to the **Advanced settings** tab and fill in the following fields:

- In the **Buffer size** field, enter the buffer size in bytes at which events must be sent to the database. The default value is 128 MB. No maximum value is configured. If the virtual machine has less free RAM than the specified **Buffer size**, OSMP sets the limit to 128 MB.

  If the expected traffic to the storage service is greater than 1 Gbps, we recommend changing the **Buffer size** setting in bytes to the expected value and setting the **Buffer flush interval** to 2.

  The value of the **Buffer size** setting can be determined empirically. If the **Insert QPS** metric of the storage is greater than 1 and you see that a queue of requests is growing, follow the recommendations for calculating and adjusting the **Buffer size** setting in the Insert QPS section of the Viewing OSMP metrics article.

- In the **Maximum buffer size** field, specify the maximum buffer size in bytes. The default value is 256 MB.

  By default, events are written to the database once per second. If the EPS rises and events are registered more often than once per second, the buffer size is automatically increased. The buffer is increased up to three times the **Buffer size** value, but cannot exceed the **Maximum buffer size** value. When the load goes back to normal, the buffer size stays the same; there is no automatic reduction of buffer size.

  If the **Maximum buffer size** is less than or equal to the **Buffer size**, the buffer size does not change.

  Restarting the storage service resets the increased buffer size to the value in the **Buffer size** field.

- In the **Buffer flush interval** field, enter the time in seconds for OSMP to wait for the buffer to fill up. If the buffer is not full, but the specified time has passed, OSMP sends events to the database. The default value is 1 second.

- In the **Required memory size** field, specify the minimum amount of free RAM in bytes. The default value is 128 MB.

  If the node on which the storage is installed has less free RAM than this setting, database insert request returns an error, and the events are recorded later. Limiting the memory size allows avoiding the situation when the memory fills up if, for any reason, the recording of events in the database is blocked and data begins to accumulate in memory.

- In the **Disk buffer size limit** field, enter a value in bytes. The disk buffer is used to temporarily store events that could not be sent for further processing or storage. If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer. The default value is 10 GB.

- Use the **Disk buffer** toggle switch to enable or disable the disk buffer. By default, the disk buffer is enabled.

- Use the **Write to local database table** toggle switch to enable or disable writing to the local database table. Writing is disabled by default.

  If enabled, data is written only on the host on which the storage is located. We recommend using this functionality only if you have configured balancing on the collector and/or correlator at step **6. Routing**, in the **Advanced settings** section, the **URL selection policy** field is set to **Round robin**.

  If you disable writing, the data is distributed across the shards of the cluster.

- If necessary, use the **Debug** toggle switch to enable logging of service operations.

- You can use the **Create dump periodically** toggle switch at the request of Technical Support to generate resource utilization reports (CPU or RAM) as dumps.

- In the **Dump settings** field, you can specify the settings to be used when creating dumps. For instructions on filling out this field, please contact Technical Support.

The set of resources for the storage is created and is displayed under **Resources** → **Storages**. Now you can create a storage service.

Creating a storage service in OSMP

When a set of resources is created for a storage, you can proceed to create a storage service in KUMA.

To create a storage service in the OSMP:

1. In the KUMA Console, under **Resources** → **Active services**, click **Add service**.
2. In the opened **Choose a service** window, select the set of resources that you just created for the storage and click **Create service**.

The storage service is created in OSMP and is displayed in the **Resources** → **Active services** section. Now storage services must be installed to each node of the ClickHouse cluster by using the service ID.

Installing a storage in the OSMP network infrastructure

To create a storage:

1. Log in to the server where you want to install the service.
2. Create the /opt/kaspersky/kuma/ folder.
3. Copy the "kuma" file to the /opt/kaspersky/kuma/ folder. The file is located in the installer in the /kuma-ansible-installer/roles/kuma/files/ folder.

   Make sure the kuma file has sufficient rights to run.

4. Execute the following command:

   ```
   sudo /opt/kaspersky/kuma/kuma storage --core https://<FQDN>:<port> --pair.fingerprint <fingerprint ID of the KUMA Core CA certificate> --id <service ID> --install
   ```

   where:

   - <FQDN> is full qualified domain name of KUMA Core server.
   - <port> is the port that the KUMA Core uses for internal communications (port 7210 is used by default).
   - <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

     The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

     You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.

- <service ID> is the identifier of a KUMA service copied from the web-interface.

Example:

```
sudo /opt/kaspersky/kuma/kuma storage --core https://kuma.example.com:7210 --pair.fingerprint XXXX --id XXXXX --install
```

When deploying several KUMA services on the same host, during the installation process you must specify unique ports for each component using the `--api.port <port>` parameter. The following setting values are used by default: `--api.port 7221`.

5. Repeat steps 1 and 2 for each storage node.

The storage is installed.

Backing up, restoring, and importing partitions

Users with the General Administrator role have access to the following OSMP actions:

- Scheduling partition backup.
- Manually backing up partitions.
- Restoring partitions from backup.
- Importing partitions from an external OSMP instance.

You can configure and use cold storage of events and partition backup at the same time.

You can view the status of partition backup, restoration, and import in an audit event. Also, after starting a manual backup of partitions, restoration of partitions from backup, or import of partitions from an external instance of OSMP, a corresponding task is created in the **Task manager** section.

Scheduling partition backup

Users with the Main administrator role can configure scheduled backup of partitions.

To schedule backup:

1. In the main menu, go to the **Monitoring** → **Resources and services** → **Active services** section and open an active storage to manage its settings.

2. In the **Edit storage** window that is opened, on the **Basic settings** tab, in the **Setting up backup and restoration** section, manage the following settings:

   a. In the **Storage backup** field, specify the path at which you want to save the backup file. For example, /mnt/data. If no path is specified, performing the backup is impossible.

   b. Enable the **Scheduled backup** toggle switch.

   c. In the **Backup after days** field, specify how many days after a partition is created you want a backup copy of it to be created. For example, if the value is **1**, backup is performed for the partition created the day before yesterday.

   d. In the **Replicas** drop-down list, select one replica that you want to back up. Selecting multiple replicas of the same shard causes data duplication.

   If multiple shards are used in the cluster, the **Replicas** list contains only those replicas whose IDs are specified in all shards.

3. Under **Backup partitions**, click **Add partition** and manage the following settings:

   a. In the **Tenant** drop-down list, select the tenant that contains the partition that you want to back up.

   b. In the **Spaces** drop-down list, select one or more storage spaces that belong to the partition that you want to back up. If no value is specified, the whole partition is backed up.

   You can manage settings for multiple partitions. If necessary, click **Add partition** and manage the settings of the new partition in the displayed fields. For example, if you want to back up the **Audit** space and you have 10 tenants, you must configure the backup separately for each tenant.

4. Click **Save**.

After saving the settings, the **backup** and **restore** directories are automatically created at the specified path. Subdirectories with tenant ID and space ID are automatically created in the **backup** directory. For example, if you specify /mnt/data as the backup path, the full path to the backup file is /mnt/data/backup/<tenant ID>/<storage space ID>/<partition creation date>.zip. If you need to look up the ID of a tenant or space, you can go to the **Events** section, open the event card and view the information that you need.

To restore from backup, you need to move the backup file to the **restore** directory.

Scheduled partition backup is configured. If a backup fails, a corresponding audit event is generated, the storage service gets the yellow status in the **Active services** section, and an error message is displayed when you hover over the yellow status indicator. The next time a scheduled backup is started, an attempt is made to back up the old data first.

Manually backing up partitions

Users with the Main administrator role can manually back up partitions.

To manually create a backup copy of a partition:

1. In the main menu, go to the **Monitoring** → **Resources and services** → **Active services** section and open an active storage to manage its settings.

2. This opens the **Edit storage** window; in that window, on the **Basic settings** tab, in the **Backup settings** section, in the **Storage backup** field, specify the path for the backup file. For example, /mnt/data. Make sure that the 'kuma' user has access rights to the specified directory.

   Path requirements:

   - The path must exist and be the same on all nodes of the storage cluster.
   - The user must have read, write, and execute permissions in the specified directory.
   - The specified directory must belong to the second or deeper nesting level. You cannot use a directory at the first nesting level, for example, /backup.
   - The directory name may not contain a period.
   - **The path may not contain the following prefixes**.

     Prefixes that cannot be used when specifying paths to files:

     - `/*`
     - `/bin`
     - `/boot`
     - `/dev`
     - `/etc`
     - `/home`
     - `/lib`
     - `/lib64`
     - `/proc`
     - `/root`
     - `/run`
     - `/sys`
     - `/tmp`
     - `/usr/*`
     - `/usr/bin/`
     - `/usr/local/*`

- `/usr/local/sbin/`
- `/usr/local/bin/`
- `/usr/sbin/`
- `/usr/lib/`
- `/usr/lib64/`
- `/var/*`
- `/var/lib/`
- `/var/run/`
- `/opt/kaspersky/kuma/`

These prefixes are used by the system as regular expressions for checking the path. The * character in prefixes matches any sequence of characters and must not be manually specified in the path itself if it is not part of a valid path.

Files are available at the following paths:

- `/opt/kaspersky/kuma/clickhouse/logs/`
- `/opt/kaspersky/kuma/metrics/log/`

3. In the main menu, go to the **Monitoring** → **Resources and services** → **Active services** section and select the check box next to the storage service with the green status.

4. In the toolbar or in the menu (⋮), select **Backup** and click **Back up**.

   The **Back up** option is available if one storage service is selected and it has the green status.

   This option is not available under the following conditions:

   - If at the previous step, you selected the check box next to more than one service.
   - If the storage service has the red status.
   - If no check boxes are selected.
   - If you have selected a check box next to a service of another type.

5. In the **Partition backup** window that is opened, manage the following settings:

   a. In the **Tenant** drop-down list, select the tenant that contains the partition that you want to back up.

   b. In the **Spaces** drop-down list, select one or more storage spaces that belong to the partition that you want to back up. If no value is specified, the whole partition is backed up.

c. In the **Replicas** drop-down list, select one replica or all replicas that you want to back up. Selecting multiple replicas of the same shard causes data duplication.

d. In the **Range of dates** field, use the calendar to specify the date range for the partitions to be included in the backup.

6. Click **OK**.

7. In the **Backup will be performed** confirmation window, click **OK**.

   After confirming the settings in the **Task manager** section, a partition backup task and an audit event are created.

Manual backup is completed.

After saving the settings, the **backup** and **restore** directories are automatically created at the specified path. Subdirectories with tenant ID and space ID are automatically created in the **backup** directory. For example, if you specify /mnt/data as the backup path, the full path to the backup file is /mnt/data/backup/<tenant ID>/<storage space ID>/<partition creation date>.zip. If you need to look up the ID of a tenant or space, you can go to the **Events** section, open the event card and view the information that you need.

To restore from backup, you need to move the backup file to the **restore** directory.

If the file name for manual backup is the same as the name of the scheduled backup file, an error is returned stating that the backup file cannot be saved. You must rename the file or delete the file and perform the manual backup again.

You can find out about the backup error in the **Active services** section by looking at the yellow status of the storage service and the error message, in the **Task manager** section, or the audit event.

Importing partitions from an external OSMP instance

Users with the General Administrator role can import partitions from an external instance OSMP.

To import partitions from an external instance OSMP:

1. Grant the 'kuma' user access rights to the backup directory that you specified when managing the backup settings, as well as access rights to the backup file itself using the following commands:

   ```
   sudo chown kuma <full path to the backup directory>
   sudo chown kuma *.zip
   ```

2. Place the file from which you want to import partitions into the **restore** directory. Partitions will be imported from this directory.

3. In the main menu, go to the **Monitoring** → **Resources and services** → **Active services** section, and select the check box next to the storage service with the green status.

4. In the toolbar or the menu (⋮), select **Backup** → **Import**.

5. In the **Import from an external instance OSMP** window that is displayed, manage the following settings:

   a. In the **Tenant** drop-down list, select the tenant for which partitions will be imported.

   b. In the **Replicas** drop-down list, select one replica to which the partitions will be imported.

   c. In the **Fields for exclusions** drop-down list, specify the fields that you want to remove during import by selecting or clearing the check boxes.

   By default, the check boxes are selected for the following fields:

   - AggregationRuleName
   - CorrelationRuleName
   - SourceAccountID
   - DestinationAccountID
   - SourceAssetID
   - DestinationAssetID
   - DeviceAssetID
   - KUMA extended event schema fields:
     - Extended event schema fields
     - KSC asset fields
     - KLCorrelationRulePriority = "KL_CorrelationRulePriority"
     - KLSourceAssetDisplayName = "KL_SourceAssetDisplayName"
     - KLDestinationAssetDisplayName = "KL_DestinationAssetDisplayName"
     - KLDeviceAssetDisplayName = "KL_DeviceAssetDisplayName"
     - KLSourceAccountDisplayName = "KL_SourceAccountDisplayName"
     - KLDestinationAccountDisplayName = "KL_DestinationAccountDisplayName"
     - KLDllHijackingResult = "KL_AI_DLLHijackingCheckResult"

       When you select the **KUMA extended event schema fields** category for removal, the whole group of fields is removed. You cannot remove individual fields.

   By default, the following fields are removed and therefore not available for selection in the web interface:

   - ServiceID
   - ServiceName
   - CorrelationRuleID
   - AggregationRuleID

6. Click **OK**.

7. In the **Import will be performed** confirmation window, click **OK**.

   After confirming the settings in the **Task manager** section, a partition import task and an audit event are created.

Importing partitions from an external instance OSMP.

Restoring partitions from backup

Only users with the Main administrator role can restore partitions from backup.

To restore a partition from backup:

1. Grant the 'kuma' user access rights to the backup directory that you specified when managing the backup settings, as well as access rights to the backup file itself using the following commands:

   ```
   sudo chown kuma <full path to the backup directory>
   sudo chown kuma *.zip
   ```

2. Move the backup file from the **backup** directory to the **restore** directory.

3. In the main menu, go to the **Monitoring** → **Resources and services** → **Active services** section and select the check box next to the storage service with the green status.

4. In the toolbar or the menu (⋮), select **Backup** → **Restore**.

5. In the **Restore from the current KUMA installation** window that opens, in the **Replicas** drop-down list, select one replica in which you want to perform restoration from backup.

6. Click **OK**.

7. In the **Restoration will be performed** confirmation window, click **OK**.

   After confirming the settings in the **Task manager** section, a partition restoration task and an audit event are created.

The restoration of partitions from backup is completed.

Creating a collector

A collector consists of two parts: one part is created inside OSMP, and the other part is installed on a server in the network infrastructure intended for receiving events.

Actions in the KUMA Console

A collector is created in OSMP by using the Installation Wizard. This Wizard combines the necessary resources into a set of resources for the collector. Upon completion of the Wizard, the service itself is automatically created based on this set of resources.

To create a collector in OSMP,

Start the Collector Installation Wizard:

- In OSMP, in the main menu, in the **Resources and services** section, click **Add event source**.
- In OSMP, in the main menu, in the **Resources and services** → **Collectors** section, click **Add collector**.

As a result of completing the steps of the Wizard, a collector service is created in OSMP.

A resource set for a collector includes the following resources:

- Connector
- Normalizer (at least one)
- Filters (if required)
- Aggregation rules (if required)
- enrichment rules (if required);
- Destinations (normally two are defined for sending events to the correlator and storage)

These resources can be prepared in advance, or you can create them while the Installation Wizard is running.

Actions on the OSMP Collector Server

When installing the collector on the server that you intend to use for receiving events, run the command displayed at the last step of the Installation Wizard. When installing, you must specify the ID automatically assigned to the service in OSMP, as well as the port used for communication.

Testing the installation

After creating a collector, you are advised to make sure that it is working correctly.

Starting the Collector Installation Wizard

A collector consists of two parts: one part is created inside OSMP, and the other part is installed on the network infrastructure server intended for receiving events. The Installation Wizard creates the first part of the collector.

To start the Collector Installation Wizard:

- In OSMP, in the main menu, in the **Resources and services** section, click **Add event source**.
- In OSMP, in the main menu, in the **Resources and services** → **Collectors** section, click **Add collector**.

Follow the steps of the wizard.

Aside from the first and last steps of the Wizard, the steps of the Wizard can be performed in any order. You can switch between steps by using the **Next** and **Previous** buttons, as well as by clicking the names of the steps in the left side of the window.

After the Wizard completes, a resource set for a collector is created in OSMP under **Resources and services** → **Collectors**, and a collector service is added under **Resources and services** → **Active services**.

Step 1. Connect event sources

This is a required step of the Installation Wizard. At this step, you specify the main settings of the collector: its name and the tenant that will own it.

To specify the basic settings of the collector:

1. In the **Collector name** field, enter a unique name for the service you are creating. The name must contain 1 to 128 Unicode characters.

   When certain types of collectors are created, agents named "agent: <Collector name>, auto created" are also automatically created together with the collectors. If this type of agent was previously created and has not been deleted, it will be impossible to create a collector named <Collector name>. If this is the case, you will have to either specify a different name for the collector or delete the previously created agent.

2. In the **Tenant** drop-down list, select the tenant that you want to own the collector. The tenant selection determines what resources will be available when the collector is created.

   If you return to this window from another subsequent step of the Installation Wizard and select another tenant, you will have to manually edit all the resources that you have added to the service. Only resources from the selected tenant and shared tenant can be added to the service.

3. If required, specify the number of processes that the service can run concurrently in the **Workers** field. By default, the number of worker processes is the same as the number of vCPUs on the server where the service is installed.

4. If necessary, use the **Debug** drop-down list to enable logging of service operations.

   Error messages of the collector service are logged even when debug mode is disabled. The log can be viewed on the computer where the collector is installed, in the /opt/kaspersky/kuma/collector/<collector ID>/log/collector directory.

5. You can optionally add up to 256 Unicode characters describing the service in the **Description** field.

The main settings of the collector are specified. Proceed to the next step of the Installation Wizard.

Step 2. Transport

This is a required step of the Installation Wizard. On the **Transport** tab of the Installation Wizard, select or create a connector and in its settings, specify the source of events for the collector service.

To add an existing connector to a resource set,

select the name of the required connector from the **Connector** drop-down list.

The **Transport** tab of the Installation Wizard displays the settings of the selected connector. You can open the selected connector for editing in a new browser tab using the button.

For the **[OOTB] Kaspersky EDR** predefined collector to work correctly, the **TLS mode** setting in the properties of the connector that you specified must be set to **Enabled**.

To create a new connector:

1. Select **Create new** from the **Connector** drop-down list.
2. In the **Type** drop-down list, select the connector type and specify its settings on the **Basic settings** and **Advanced settings** tabs. The available settings depend on the selected type of connector:
   - tcp
   - udp
   - netflow
   - sflow
   - nats-jetstream
   - kafka
   - http
   - sql
   - file
   - ftp
   - nfs
   - wmi
   - wec
   - snmp

   When using the **tcp** or **udp** connector type at the normalization stage, IP addresses of the assets from which the events were received will be written in the DeviceAddress event field if it is empty.

   When using a **wmi** or **wec** connector, agents will be automatically created for receiving Windows events.

   It is recommended to use the default encoding (UTF-8), and to apply other settings only if bit characters are received in the fields of events.

Making OSMP collectors to listen on ports up to 1,000 requires running the service of the relevant collector with root privileges. To do this, after installing the collector, add the line `AmbientCapabilities = CAP_NET_BIND_SERVICE` to its systemd configuration file in the [Service] section.
The systemd file is located in the /usr/lib/systemd/system/kuma-collector-<`collector ID`>.service directory.

The connector is added to the resource set of the collector. The created connector is only available in this resource set and is not displayed in the web interface **Resources and services** → **Connectors** section.

Proceed to the next step of the Installation Wizard.

Step 3. Event parsing

This is a required step of the Installation Wizard. On the **Event parsing** tab of the Installation Wizard, select or create a normalizer whose settings will define the rules for converting raw events into normalized events. You can add multiple event parsing rules to the normalizer to implement complex event processing logic. You can test the normalizer using test events.

When creating a new normalizer in the Installation Wizard, by default it is saved in the set of resources for the collector and cannot be used in other collectors. The **Save normalizer** check box lets you create the normalizer as a separate resource, in which case the normalizer can be selected in other collectors of the tenant.

If, when changing the settings of a collector resource set, you change or delete conversions in a normalizer connected to it, the edits will not be saved, and the normalizer itself may be corrupted. If you need to modify conversions in a normalizer that is already part of a service, the changes must be made directly to the normalizer under **Resources** → **Normalizers** in the web interface.

Adding a normalizer

To add an existing normalizer to a resource set:

1. Click the **Add event parsing** button.

   This opens the **Basic event parsing** window with the normalizer settings and the **Normalization scheme** tab active.

2. In the **Normalizer** drop-down list, select the required normalizer. The drop-down list includes normalizers belonging to the tenant of the collector and the Shared tenant.

   The **Basic event parsing** window displays the settings of the selected normalizer.

   If you want to edit the normalizer settings, in the **Normalizer** drop-down list, click the pencil icon next to the name of the relevant normalizer. This opens the **Edit normalizer** window with a dark circle. Clicking the dark circle opens the **Basic event parsing** window where you can edit the normalizer settings.

   If you want to edit advanced parsing settings, move the cursor over the dark circle to make a plus icon appear; click the plus icon to open the **Advanced event parsing** window. For details about configuring advanced event parsing, refer to the instruction below.

3. Click **OK**.

The normalizer is displayed as a dark circle on the **Basic event parsing** tab of the Installation Wizard. Clicking on the circle will open the normalizer options for viewing.

To create a new normalizer in the collector:

1. At the Event parsing step, on the **Parsing schemes** tab, click the **Add event parsing**.

   This opens the **Basic event parsing** window with the normalizer settings and the **Normalization scheme** tab active.

2. If you want to save the normalizer as a separate resource, select the **Save normalizer** check box; this makes the saved normalizer available for use in other collectors of the tenant. This check box is cleared by default.

3. In the **Name** field, enter a unique name for the normalizer. The name must contain 1 to 128 Unicode characters.

4. In the **Parsing method** drop-down list, select the type of events to receive. Depending on your choice, you can use the preconfigured rules for matching event fields or set your own rules. When you select some of the parsing methods, additional settings fields may need to be filled.

   Available parsing method: json.

   This parsing method is used to process JSON data where each object, including its nested objects, occupies a single line in a file.

   When processing files with hierarchically arranged data, you can access the fields of nested objects by specifying the names of the parameters dividing them by a period. For example, the `username` parameter from the string `"user": {"username": "system: node: example-01"}` can be accessed by using the `user.username` query.

   Files are processed line by line. Multi-line objects with nested structures may be normalized incorrectly.

   In complex normalization schemes where additional normalizers are used, all nested objects are processed at the first normalization level, except for cases when the extra normalization conditions are not specified and, therefore, the event being processed is passed to the additional normalizer in its entirety.

   Newline characters can be `\n` and `\r\n`. Strings must be UTF-8 encoded.

   If you want to send the raw event for advanced normalization, at each nesting level in the **Advanced event parsing** window, select **Yes** in the **Keep raw event** drop-down list.

5. In the **Keep raw event** drop-down list, specify whether to store the original raw event in the newly created normalized event. Available values:

   - **Don't save**—do not save the raw event. This is the default setting.
   - **Only errors**—save the raw event in the `Raw` field of the normalized event if errors occurred when parsing it. This value is convenient to use when debugging a service. In this case, every time an event has a non-empty `Raw` field, you know there was a problem.

     > If fields containing the names `*Address` or `*Date*` do not comply with normalization rules, these fields are ignored. No normalization error occurs in this case, and the values of the fields are not displayed in the `Raw` field of the normalized event even if the **Keep raw event** → **Only errors** option was selected.

   - **Always**—always save the raw event in the `Raw` field of the normalized event.

6. In the **Keep extra fields** drop-down list, choose whether you want to store the raw event fields in the normalized event if no mapping rules have been configured for them (see below). The data is stored in the `Extra` event field. Normalized events can be searched and filtered based on the data stored in the `Extra` field.

   Filtering based on data from the Extra event field

Conditions for filters based on data from the **Extra** event field:

- Condition—**If**.
- Left operand—**event field**.
- In this event field, you can specify one of the following values:
  - **Extra** field.
  - Value from the Extra field in the following format:

    `Extra.<field name>`

    For example, `Extra.app`.

    A value of this type is specified manually.
  - Value from the array written to the **Extra** field in the following format:

    `Extra.<field name>.<array element>`

    For example, `Extra.array.0`.

    The values in the array are numbered starting from 0.

    A value of this type is specified manually.

    To work with a value from the Extra field at depth 3 and below, use backquotes ``. For example, `Extra.lev1.lev2.lev3`.
- Operator – =.
- Right operand—**constant**.
- Value—the value by which you need to filter events.

By default, fields are not saved.

7. Copy an example of the data you want to process to the **Event examples** field. This is an optional but recommended step.
8. In the **Mapping** table, configure the mapping of raw event fields to fields of the event in KUMA format:
   a. In the **Source** column, provide the name of the raw event field that you want to convert into the KUMA event field.

      For details about the field format, refer to the "Normalized event data model" article. For a description of the mapping, refer to the "Mapping fields of predefined normalizers" article.

      Clicking the button next to the field names in the **Source** column opens the **Conversion** window, in which you can click the **Add conversion** button to create rules for modifying the original data before they are written to the KUMA event fields.

      Available conversions

      Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

      Available conversions:

      - **lower**—is used to make all characters of the value lowercase
      - **upper**—is used to make all characters of the value uppercase

- **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.

- **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.

- **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:

  - **Replace chars**—in this field you can specify the character sequence that should be replaced.

  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.

- **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.

- **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.

- **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.

- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.

  - **Expression**—in this field you can specify the regular expression which results that should be replaced.

  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.

- Converting encoded strings to text:

  - **decodeHexString**—used to convert a HEX string to text.

  - **decodeBase64String**—used to convert a Base64 string to text.

  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.

- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.
- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.
- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

In the **Conversion** window, you can swap the added rules by dragging them by the ⣿ icon; you can also delete them using the ✕ icon.

b. In the **KUMA field** column, select the required KUMA event field from the drop-down list. You can search for fields by entering their names in the field.

Recommendations concerning the KUMA field column

We recommend that you configure the mapping for the following KUMA fields. Otherwise, you will not be able to view observables in alert details and incident details.

The recommended KUMA fields depend on the observable types:

- For observables of the MD5 hash and SHA256 types:
  - FileHash
- For observables of the URL type:
  - RequestUrl
- For observables of the IP address type:
  - DeviceCustomIPv6Address1
  - DeviceCustomIPv6Address2
  - DeviceCustomIPv6Address3
  - DeviceCustomIPv6Address4
  - DestinationTranslatedAddress
  - DeviceTranslatedAddress
  - DestinationAddress
  - DeviceAddress
  - SourceTranslatedAddress
  - SourceAddress

- For observables of the Domain name type:
  - DestinationDnsDomain
  - DeviceDnsDomain
  - DeviceNtDomain
  - DestinationNtDomain
  - SourceDnsDomain
  - SourceNtDomain
- For observables of the UserName type:
  - DestinationUserName
  - SourceUserName
- For observables of the HostName type:
  - DestinationHostName
  - DeviceHostName
  - SourceHostName

c. If the name of the KUMA event field selected at the previous step begins with `DeviceCustom*` or `Flex*`, you can add a unique custom label in the **Label** field.

New table rows can be added by using the **Add row** button. Rows can be deleted individually using the ✕ button or all at once using the **Clear all** button.

If you want KUMA to enrich events with asset information, and the asset information to be available in the alert card when a correlation rule is triggered, in the **Mapping** table, configure a mapping of host address and host name fields depending on the purpose of the asset. For example, the mapping can apply to SourceAddress and SourceHostName, or DestinationAddress and DestinationHostName fields. As a result of enrichment, the event card includes a SourceAssetID or DestinationAssetID field, and a link to the asset card. Also, as a result of enrichment, asset information is available in the alert card.

If you have loaded data into the **Event examples** field, the table will have an **Examples** column containing examples of values carried over from the raw event field to the KUMA event field.

If the size of the KUMA event field is less than the length of the value placed in it, the value is truncated to the size of the event field.

9. Click the **OK** button.

The normalizer is displayed as a dark circle on the **Event parsing** tab of the Installation Wizard. If you want to open the normalizer settings for viewing, click the dark circle. When you hover the mouse over the circle, a plus sign is displayed. Click it to add event parsing rules (refer to the instruction below).

Enriching normalized events with additional data

You can add additional data to newly created normalized events by creating enrichment rules in the normalizer. These enrichment rules are stored in the normalizer where they were created. There can be more than one enrichment rule.

To add enrichment rules to the normalizer:

1. Select the main or additional normalization rule to open a window, and in that window, click the **Enrichment** tab.
2. Click the **Add enrichment** button.

   The enrichment rule parameter block appears. You can delete the group of settings by clicking the ✕ button.
3. Select the enrichment type from the **Source kind** drop-down list. Depending on the selected type, there may be advanced settings that will also need to be completed.

   Available Enrichment rule source types:

   - **constant**

     This type of enrichment is used when a constant needs to be added to an event field. Settings of this type of enrichment:

     - In the **Constant** field, specify the value that should be added to the event field. The value may not be longer than 255 Unicode characters. If you leave this field blank, the existing event field value will be cleared.
     - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

     If you are using the event enrichment functions for extended schema fields of `String`, `Number`, or `Float` type with a constant, the constant is added to the field.

     If you are using the event enrichment functions for extended schema fields of `Array of strings`, `Array of numbers`, or `Array of floats` type with a constant, the constant is added to the elements of the array.

   - **dictionary**

     This type of enrichment is used if you need to add a value from the dictionary of the **Dictionary** type.

     When this type is selected in the **Dictionary name** drop-down list, you must select the dictionary that will provide the values. In the **Key fields** settings block, you have to click the **Add field** button and select the event fields whose values will be used for dictionary entry selection.

     If you are using event enrichment with the "Dictionary" type selected as the "Source kind" setting, and an array field is specified in the "Key enrichment fields" setting, when an array is passed as the dictionary key, the array is serialized into a string in accordance with the rules of serializing a single value in the TSV format.

     Example: The "Key enrichment fields" setting uses the SA.StringArrayOne extended schema field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b" and "c". The following value is passed to the dictionary as the key: ['a','b','c'].

     If the "Key enrichment fields" setting uses an extended schema array field and a regular event schema field, the field values are separated by the "|" character when the dictionary is queried.

Example: The "Key enrichment fields" setting uses two fields: the SA.StringArrayOne extended schema field and the Code field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b", and "c"; the Code string field contains the character sequence "myCode". The following value is passed to the dictionary as the key: ['a','b','c']|myCode.

- **table**

  This type of enrichment is used if you need to add a value from the dictionary of the **Table** type.

  When this enrichment type is selected in the **Dictionary name** drop-down list, select the dictionary for providing the values. In the **Key fields** group of settings, click the **Add field** button to select the event fields whose values are used for dictionary entry selection.

  In the **Mapping** table, configure the dictionary fields to provide data and the event fields to receive data:

  - In the **Dictionary field** column, select the dictionary field. The available fields depend on the selected dictionary resource.
  - In the **KUMA field** column, select the event field to which the value is written. For some of the selected fields (`*custom*` and `*flex*`), in the **Label** column, you can specify a name for the data written to them.

  New table rows can be added by clicking the **Add new element** button. Columns can be deleted by clicking the ✕ button.

- **event**

  This type of enrichment is used when you need to write a value from another event field to the current event field. Settings of this type of enrichment:

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.
  - In the **Source field** drop-down list, select the event field whose value will be written to the target field.
  - Clicking the 🔧 button opens the **Conversion** window in which you can, using the **Add conversion** button, create rules for modifying the original data before writing them to the KUMA event fields.

    Available conversions

    Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

    Available conversions:

    - **lower**—is used to make all characters of the value lowercase
    - **upper**—is used to make all characters of the value uppercase
    - **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
    - **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.

- **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
  - **Replace chars**—in this field you can specify the character sequence that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.
- **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.
- **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.
- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.
  - **Expression**—in this field you can specify the regular expression which results that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- Converting encoded strings to text:
  - **decodeHexString**—used to convert a HEX string to text.
  - **decodeBase64String**—used to convert a Base64 string to text.
  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.
- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.
- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.
- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

When using enrichment of events that have the **Event** selected as the **Source kind** setting and the fields of the extended event schema are used as arguments, the following special considerations apply:

- If the source field is an `Array of strings` field and the target field is a `String` field, the values are written to the target field in the TSV format.

  Example: The SA.StringArray extended event schema field contains values: "string1", "string2", "string3". An event enrichment operation is performed. The result of the operation is written to the DeviceCustomString1 event schema field. As a result of the operation, the DeviceCustomString1 field contains ["string1", "string2", "string3"].

- If the source field is an `Array of strings` field and the target field is an `Array of strings` field, the values of the source field are appended to the values of the target field and are placed in the target field, with commas (",") used as the separator character.

  Example: The SA.StringArrayOne extended event schema field contains values: "string1", "string2", "string3". An event enrichment operation is performed. The result of the operation is written to the SA.StringArrayTwo event schema field. As a result of the operation, the SA.StringArrayTwo field contains "string1", "string2", "string3".

- **template**

  This type of enrichment is used when you need to write a value obtained by processing Go templates into the event field. Settings of this type of enrichment:

  - In the **Template** field, enter the Go template.

    Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field from which the value must be passed to the script.

    Example: `Attack on {{.DestinationAddress}} from {{.SourceAddress}}`.

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

  To convert the data in an array field in a template into the TSV format, you must use the toString function.

  If you are using enrichment of events that have the **Template** type selected as the **Source kind** setting, in which the target field has the `String` type, and the source field is an extended event schema field containing an array of strings, you can use one of the following examples for the template.

  Example:

  {{.SA.StringArrayOne}}

  Example:

{{- range $index, $element := . SA.StringArrayOne -}}

{{- if $index}}, {{end}}"{{$element}}"{{- end -}}

4. In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

   This setting is not available for the enrichment source of the **Table** type.

5. If you want to enable details in the normalizer log, set the **Debug** toggle switch to enabled. Details are disabled by default.

6. Click the **OK** button.

Event enrichment rules with the additional data are added to the normalizer, to the selected parsing rule.

Configuring parsing linked to IP addresses

You can direct events from multiple IP addresses, from sources of different types, to the same collector, and the collector will apply the corresponding configured normalizers.

You can use this method for collectors with a connector of the UDP, TCP, or HTTP type. If a UDP, TCP, or HTTP connector is specified in the collector at the **Transport** step, then at the **Event parsing** step, you can specify multiple IP addresses on the **Parsing settings** tab and choose the normalizer that you want to use for events coming from the specified addresses. The following types of normalizers are available: json, cef, regexp, syslog, csv, kv, xml.

In a collector with configured normalizers linked to IP addresses, if you change the connector type to any type other than UDP, TCP, HTTP, the **Parsing settings** tab disappears and only the first of the previously specified normalizers is specified at the **Parsing** step. The tab disappears from the web interface immediately, but the changes are applied after the resource is saved. If you want to restore the previous settings, exit the collector installation wizard without saving.

For normalizers of the Syslog and regexp types, you can use a normalizer chain by specifying extra normalization conditions depending on the value of the DeviceProcessName field. The difference from extra normalization is that you can specify shared normalizers.

To configure parsing with linking to IP addresses:

1. At the **Event parsing** step, go to the **Parsing settings** tab.

2. In the **IP address(-es)** field, specify one or more IP addresses from which events will be received. You can specify multiple IP addresses separated by commas. Available format: IPv4. The length of the address list is unlimited; however, we recommend specifying a reasonable number of addresses to keep the load on the collector balanced. This field is mandatory if you want to apply multiple normalizers in one collector.

   Limitation: for each IP+normalizer combination, the IP address must be unique. OSMP checks the uniqueness of addresses. If you specify the same IP address for different normalizers, the **The field must be unique** message is displayed.

   If you want to send all events to the same normalizer without specifying IP addresses, we recommend creating a separate collector. We also recommend creating a separate collector with one normalizer if you want to apply the same normalizer to events from a large number of IP addresses; this helps improve the performance.

3. In the **Normalizer** field, create a normalizer or select an existing normalizer from the drop-down list. The arrow next to the drop-down list takes you to the **Parsing schemes** tab.

   Normalization is triggered if you have a connector type configured: UDP, TCP, HTTP; the event source header must be specified in the HTTP case.

Taking into account the available connectors, the following normalizer types are available for automatic source recognition: json, cef, regexp, syslog, csv, kv, xml.

4. If you selected the Syslog or regexp normalizer type, you can **Additional condition**. Conditional normalization is available if **Field mapping** for DeviceProcessName is configured in the main normalizer. Under **Condition**, specify the process name in the DeviceProcessName field and create a normalizer or select an existing normalizer from the drop-down list. You can specify multiple combinations of DeviceProcessName + normalizer, normalization is performed until the first match is achieved.

Parsing with linking to IP addresses is configured.

Creating a structure of event normalization rules

To implement a complex event processing logic, you can add multiple event parsing rules to the normalizer. Events are transmitted between the parsing rules depending on the specified conditions. The sequence of creating parsing rules is important. The event is processed sequentially, and its path is shown using arrows.

To create an additional parsing rule:

1. Create a normalizer (refer to the instruction above).

   The created normalizer is displayed in the window as a dark circle.

2. Hover the mouse over the circle and click the plus sign button that appears.

3. In the **Additional event parsing** window that opens, specify the parameters of the additional event parsing rule:

   - **Extra normalization conditions** tab:

     If you want to send a raw event for extra normalization, select **Yes** in the **Keep raw event** drop-down list. The default value is **No**. We recommend passing a raw event to normalizers of json and xml types. If you want to send a raw event for extra normalization to the second, third, etc nesting levels, at each nesting level, select **Yes** in the **Keep raw event** drop-down list.

     To send only the events with a specific field to the additional normalizer, specify this field in the **Field to pass into normalizer** field.

     On this tab, you can also define other conditions. When these conditions are met, the event is sent for additional parsing.

   - **Normalization scheme** tab:

     On this tab, you can configure event processing rules, similar to the main normalizer settings (refer to the instruction above). The **Keep raw event** setting is not available. The **Event examples** field displays the values specified when the initial normalizer was created.

   - **Enrichment** tab:

     On this tab, you can configure event enrichment rules (refer to the instruction above).

4. Click **OK**.

The additional parsing rule is added to the normalizer. It is displayed as a dark block with the conditions under which this rule is triggered. You can change the settings of the additional parsing rule by clicking it. If you hover the mouse over the additional parsing rule, a plus button appears. You can click this button to create a new additional parsing rule. To delete a normalizer, use the button with the trash icon.

The upper right corner of the window contains a search window where you can search parsing rules by name.

Proceed to the next step of the Installation Wizard.

Step 4. Filtering events

This is an optional step of the Installation Wizard. The **Event filtering** tab of the Installation Wizard allows you to select or create a filter whose settings specify the conditions for selecting events. You can add multiple filters to the collector. You can swap the filters by dragging them by the ⣿ icon as well as delete them. Filters are combined by the AND operator.

To add an existing filter to a collector resource set,

Click the **Add filter** button and select the required filter from the **Filter** drop-down menu.

To add a new filter to the collector resource set:

1. Click the **Add filter** button and select **Create new** from the **Filter** drop-down menu.
2. If you want to keep the filter as a separate resource, select the **Save filter** check box. This can be useful if you decide to reuse the same filter across different services. This check box is cleared by default.
3. If you selected the **Save filter** check box, enter a name for the created filter in the **Name** field. The name must contain 1 to 128 Unicode characters.
4. In the **Conditions** section, specify the conditions that must be met by the filtered events:
   - The **Add condition** button is clicked to add filtering conditions. You can select two values (two operands, left and right) and assign the operation you want to perform with the selected values. The result of the operation is either True or False.
     - In the **operator** drop-down list, select the function to be performed by the filter.

       In this drop-down list, you can select the **do not match case** check box if the operator should ignore the case of values. This check box is ignored if the **InSubnet**, **InActiveList**, **InCategory**, **InActiveDirectoryGroup** operators are selected. This check box is cleared by default.

       Filter operators

       - **=** means the left operand equals the right operand.
       - **<** means the left operand is less than the right operand.
       - **<=** means the left operand is less than or equal to the right operand.
       - **>** means the left operand is greater than the right operand.
       - **>=** means the left operand is greater than or equal to the right operand.
       - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
       - **contains** means the left operand contains values of the right operand.
       - **startsWith** means the left operand starts with one of the values of the right operand.
       - **endsWith** means the left operand ends with one of the values of the right operand.

- **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.

- **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

  The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

  If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.

- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.

- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.

- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.

- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.

- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.

- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.

- **inContextTable** checks for the presence of the entry in the specified context table.

- **intersect**—presence in the left operand of the list items specified in the right operand.

- In the **Left operand** and **Right operand** drop-down lists, select where the data to be filtered will come from. As a result of the selection, Advanced settings will appear. Use them to determine the exact value that will be passed to the filter. For example, when choosing **active list** you will need to specify the name of the active list, the entry key, and the entry key field.

- You can use the **If** drop-down list to choose whether you need to create a negative filter condition.

Conditions can be deleted by clicking the ✕ button.

- The **Add group** button is used to add groups of conditions. The **AND** can be switched between **And**, **OR**, **NOT**.

  A condition group can be deleted by clicking the ✕ button.

- By clicking **Add filter**, you can add existing filters selected in the **Select filter** drop-down list to the conditions. You can click ↗ to navigate to a nested filter.

  A nested filter can be deleted by clicking the ✕ button.

The filter has been added.

Proceed to the next step of the Installation Wizard.

Step 5. Event aggregation

This is an optional step of the Installation Wizard. The **Event aggregation** tab of the Installation Wizard allows you to select or create an aggregation rule whose settings specify the conditions for aggregating events of the same type. You can add multiple aggregation rules to the collector.

To add an existing aggregation rule to a set of collector resources,

click **Add aggregation rule** and select **Aggregation rule** in the drop-down list.

To add a new aggregation rule to a set of collector resources:

1. Click the **Add aggregation rule** button and select **Create new** from the **Aggregation rule** drop-down menu.
2. Enter the name of the newly created aggregation rule in the **Name** field. The name must contain 1 to 128 Unicode characters.
3. In the **Threshold** field, specify how many events must be accumulated before the aggregation rule triggers and the events are aggregated. The default value is `100`.
4. In the **Triggered rule lifetime** field, specify how long (in seconds) the collector must accumulate events to be aggregated. When this time expires, the aggregation rule is triggered and a new aggregation event is created. The default value is `60`.
5. In the **Identical fields** section, click the **Add field** button to select the fields that will be used to identify the same types of events. Selected events can be deleted by clicking the buttons with a cross icon.
6. In the **Unique fields** section, you can click **Add field** to select the fields that will disqualify events from aggregation even if the events contain fields listed in the **Identical fields** section. Selected events can be deleted by clicking the buttons with a cross icon.
7. In the **Sum fields** section, you can click the **Add field** button to select the fields whose values will be summed during the aggregation process. Selected events can be deleted by clicking the buttons with a cross icon.
8. In the **Filter** section, you can specify the conditions to define events that will be processed by this resource. You can select an existing filter from the drop-down list or create a new filter.

   Creating a filter in resources

   All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

   To create a filter:

   1. In the **Filter** drop-down list, select **Create new**.
   2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.
   3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.

4. Under **Conditions**, specify the conditions that the events must meet:

   a. Click the **Add condition** button.

   b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.

   c. In the **Operator** drop-down list, select an operator.

   Filter operators

   - **=** means the left operand equals the right operand.
   - **<** means the left operand is less than the right operand.
   - **<=** means the left operand is less than or equal to the right operand.
   - **>** means the left operand is greater than the right operand.
   - **>=** means the left operand is greater than or equal to the right operand.
   - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
   - **contains** means the left operand contains values of the right operand.
   - **startsWith** means the left operand starts with one of the values of the right operand.
   - **endsWith** means the left operand ends with one of the values of the right operand.
   - **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
   - **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

     The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

     If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
   - **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

     If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.
   - The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
   - **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
   - **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.

- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.

- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.

- **inContextTable** checks for the presence of the entry in the specified context table.

- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Aggregation rule added. You can delete it by clicking the button.

Proceed to the next step of the Installation Wizard.

Step 6. Event enrichment

This is an optional step of the Installation Wizard. On the **Event enrichment** tab of the Installation Wizard, you can specify which data from which sources should be added to events processed by the collector. Events can be enriched with data obtained using enrichment rules or LDAP.

Rule-based enrichment

There can be more than one enrichment rule. You can add them by clicking the **Add enrichment** button and can remove them by clicking the button. You can use existing enrichment rules or create rules directly in the Installation Wizard.

To add an existing enrichment rule to a set of resources:

1. Click **Add enrichment**.

   This opens the enrichment rules settings block.

2. In the **Enrichment rule** drop-down list, select the relevant resource.

The enrichment rule is added to the resource set for the collector.

To create a new enrichment rule in a set of resources:

1. Click **Add enrichment**.

   This opens the enrichment rules settings block.

2. In the **Enrichment rule** drop-down list, select **Create new**.

3. In the **Source kind** drop-down list, select the source of data for enrichment and define its corresponding settings:

   - **constant**

     This type of enrichment is used when a constant needs to be added to an event field. Settings of this type of enrichment:

     - In the **Constant** field, specify the value that should be added to the event field. The value may not be longer than 255 Unicode characters. If you leave this field blank, the existing event field value will be cleared.

     - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

     If you are using the event enrichment functions for extended schema fields of `String`, `Number`, or `Float` type with a constant, the constant is added to the field.

     If you are using the event enrichment functions for extended schema fields of `Array of strings`, `Array of numbers`, or `Array of floats` type with a constant, the constant is added to the elements of the array.

   - **dictionary**

     This type of enrichment is used if you need to add a value from the dictionary of the **Dictionary** type.

     When this type is selected in the **Dictionary name** drop-down list, you must select the dictionary that will provide the values. In the **Key fields** settings block, you have to click the **Add field** button and select the event fields whose values will be used for dictionary entry selection.

     If you are using event enrichment with the "Dictionary" type selected as the "Source kind" setting, and an array field is specified in the "Key enrichment fields" setting, when an array is passed as the dictionary key, the array is serialized into a string in accordance with the rules of serializing a single value in the TSV format.

     Example: The "Key enrichment fields" setting uses the SA.StringArrayOne extended schema field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b" and "c". The following value is passed to the dictionary as the key: ['a','b','c'].

     If the "Key enrichment fields" setting uses an extended schema array field and a regular event schema field, the field values are separated by the "|" character when the dictionary is queried.

     Example: The "Key enrichment fields" setting uses two fields: the SA.StringArrayOne extended schema field and the Code field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b", and "c"; the Code string field contains the character sequence "myCode". The following value is passed to the dictionary as the key: ['a','b','c']|myCode.

- **event**

  This type of enrichment is used when you need to write a value from another event field to the current event field. Settings of this type of enrichment:

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.
  - In the **Source field** drop-down list, select the event field whose value will be written to the target field.
  - Under **Conversion**, you can create rules for modifying the original data before it is written to the KUMA event fields. The conversion type can be selected from the drop-down list. You can use the **Add conversion** and **Delete** buttons to add or delete a conversion, respectively. The order of conversions is important.

    Available conversions

    Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

    Available conversions:

    - **lower**—is used to make all characters of the value lowercase
    - **upper**—is used to make all characters of the value uppercase
    - **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
    - **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.
    - **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
      - **Replace chars**—in this field you can specify the character sequence that should be replaced.
      - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
    - **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.
    - **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.
    - **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.
    - **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.
      - **Expression**—in this field you can specify the regular expression which results that should be replaced.
      - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.

- Converting encoded strings to text:

  - **decodeHexString**—used to convert a HEX string to text.

  - **decodeBase64String**—used to convert a Base64 string to text.

  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.

- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.

- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.

- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

- **template**

  This type of enrichment is used when you need to write a value obtained by processing Go templates into the event field. Settings of this type of enrichment:

  - In the **Template** field, enter the Go template.

    Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field from which the value must be passed to the script.

    Example: `Attack on {{.DestinationAddress}} from {{.SourceAddress}}`.

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

  To convert the data in an array field in a template into the TSV format, you must use the toString function.

  If you are using enrichment of events that have the **Template** type selected as the **Source kind** setting, in which the target field has the `String` type, and the source field is an extended event schema field containing an array of strings, you can use one of the following examples for the template.

  Example:

{{.SA.StringArrayOne}}

Example:

{{- range $index, $element := . SA.StringArrayOne -}}

{{- if $index}}, {{end}}"{{$element}}"{{- end -}}

- **dns**

  This type of enrichment is used to send requests to a private network DNS server to convert IP addresses into domain names or vice versa. IP addresses are converted to DNS names only for private addresses: 10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16, 100.64.0.0/10, fd00::/8.

  The settings of this type of enrichment are described in the table below.

  Parameters of enrichment type "dns"

Setting	Description
URL	URL of the DNS server to which you want to send requests. You can use the **Add URL** button to specify multiple URLs. If the **URL** setting is not specified, KUMA takes the list of DNS servers from the localhost's `/etc/resolv.conf` file. In this case, you need to enable the **Recursive queries** option. Otherwise, the enrichment will not occur.
Requests per second	Maximum number of queries sent to the DNS server per second. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Workers	Number of handlers that the service can run simultaneously to process response rules in parallel. Specify a positive integer number from 0 to 999. If 0 is specified, the number of logical CPU cores is used. The default value is `1`.
Maximum number of events in enrichment queue	The maximum number of events to hold in the resubmission queue. The default value is `1,000,000`.
Timeout	The time to wait for a response from the DNS server (in seconds). The default value is `5`.
DNS mode override	Resolution method used: • **Forward DNS only** resolves a domain name to an IP address. • **Reverse DNS only** resolves an IP address to a domain name. • **Forward and reverse DNS** resolves a domain name to an IP address or an IP address to a domain name.
Cache TTL	The lifetime (in seconds) of values stored in the cache. The default value is `60` seconds.
Cache disabled	You can enable or disable caching using this setting. Caching is enabled by default.
Cache refresh disabled	If cache update is enabled, then upon expiry of the cache's TTL the collector sends repeated requests to the DNS server to update the data stored in the cache. This setting is available only when cache is enabled. By default, cache update is enabled.
Recursive queries	Allows a collector to send recursive queries to authoritative DNS servers for the purposes of enrichment. The default value is **Disabled**.

- **cybertrace**

  This type of enrichment is used to add information from CyberTrace data streams to event fields.

Available settings:

- **URL** (required)—in this field, you can specify the URL of a CyberTrace server to which you want to send requests.
- **Number of connections**—maximum number of connections to the CyberTrace server that can be simultaneously established by KUMA. By default, this value is equal to the number of vCPUs of the KUMA Core server.
- **RPS**—maximum number of requests sent to the server per second. The default value is `1000`.
- **Timeout**—amount of time to wait for a response from the CyberTrace server, in seconds. The default value is `30`.
- **Mapping** (required)—this settings block contains the mapping table for mapping KUMA event fields to CyberTrace indicator types. The **KUMA field** column displays the names of KUMA event fields, and the **CyberTrace indicator** column displays the types of CyberTrace indicators.

  Available types of CyberTrace indicators:

  - **ip**
  - **url**
  - **hash**

  In the mapping table, you must provide at least one string. You can click the **Add row** button to add a string, and can click the ✕ button to remove a string.

- **timezone**

  This type of enrichment is used in collectors and correlators to assign a specific timezone to an event. Timezone information may be useful when searching for events that occurred at unusual times, such as nighttime.

  When this type of enrichment is selected, the required timezone must be selected from the **Timezone** drop-down list.

  > Make sure that the required time zone is set on the server hosting the enrichment-utilizing service. For example, you can do this by using the `timedatectl list-timezones` command, which shows all time zones that are set on the server. For more details on setting time zones, please refer to your operating system documentation.

  When an event is enriched, the time offset of the selected timezone relative to Coordinated Universal Time (UTC) is written to the DeviceTimeZone event field in the `+-hh:mm` format. For example, if you select the **Asia/Yekaterinburg** timezone, the value `+05:00` will be written to the DeviceTimeZone field. If the enriched event already has a value in the DeviceTimeZone field, it will be overwritten.

  By default, if the timezone is not specified in the event being processed and enrichment rules by timezone are not configured, the event is assigned the timezone of the server hosting the service (collector or correlator) that processes the event. If the server time is changed, the service must be restarted.

  Permissible time formats when enriching the DeviceTimeZone field

  When processing incoming raw events in the collector, the following time formats can be automatically converted to the +-hh:mm format:

Time format in a processed event	Example
+-hh:mm	-07:00
+-hhmm	-0700
+-hh	-07

If the date format in the `DeviceTimeZone` field differs from the formats listed above, the collector server timezone is written to the field when an event is enriched with timezone information. You can create custom normalization rules for non-standard time formats.

- **geographic data**

  This type of enrichment is used to add IP address geographic data to event fields. Learn more about linking IP addresses to geographic data.

  When this type is selected, under **Mapping geographic data to event fields**, you must specify from which event field the IP address will be read, select the required attributes of geographic data, and define the event fields in which geographic data will be written:

  1. In the **Event field with IP address** drop-down list, select the event field from which the IP address is read. Geographic data uploaded to KUMA is matched against this IP address.

     You can use the **Add event field with IP address** button to specify multiple event fields with IP addresses that require geographic data enrichment. You can delete event fields added in this way by clicking the **Delete event field with IP address** button.

     > When the `SourceAddress`, `DestinationAddress`, and `DeviceAddress` event fields are selected, the **Apply default mapping** button becomes available. You can click this button to add preconfigured mapping pairs of geographic data attributes and event fields.

  2. For each event field you need to read the IP address from, select the type of geographic data and the event field to which the geographic data should be written.

     You can use the **Add geodata attribute** button to add field pairs for **Geodata attribute** – **Event field to write to**. You can also configure different types of geographic data for one IP address to be written to different event fields. To delete a field pair, click ✕.

     - In the **Geodata attribute** field, select which geographic data corresponding to the read IP address should be written to the event. Available geographic data attributes: **Country**, **Region**, **City**, **Longitude**, **Latitude**.
     - In the **Event field to write to**, select the event field which the selected geographic data attribute must be written to.

     You can write identical geographic data attributes to different event fields. If you configure multiple geographic data attributes to be written to the same event field, the event will be enriched with the last mapping in the sequence.

4. Use the **Debug** drop-down list to indicate whether or not to enable logging of service operations. Logging is disabled by default.

5. In the **Filter** section, you can specify conditions to identify events that will be processed by the enrichment rule resource. You can select an existing filter from the drop-down list or create a new filter.

   Creating a filter in resources

All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

To create a filter:

1. In the **Filter** drop-down list, select **Create new**.
2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.
3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.
4. Under **Conditions**, specify the conditions that the events must meet:
   a. Click the **Add condition** button.
   b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.
   c. In the **Operator** drop-down list, select an operator.

      Filter operators

      - **=** means the left operand equals the right operand.
      - **<** means the left operand is less than the right operand.
      - **<=** means the left operand is less than or equal to the right operand.
      - **>** means the left operand is greater than the right operand.
      - **>=** means the left operand is greater than or equal to the right operand.
      - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
      - **contains** means the left operand contains values of the right operand.
      - **startsWith** means the left operand starts with one of the values of the right operand.
      - **endsWith** means the left operand ends with one of the values of the right operand.
      - **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
      - **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

        The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

        If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.

- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.

- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.

- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.

- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.

- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.

- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.

- **inContextTable** checks for the presence of the entry in the specified context table.

- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

The new enrichment rule was added to the resource set for the collector.

LDAP enrichment

To enable enrichment using LDAP:

1. Click **Add enrichment with LDAP data**.

   This opens the group of settings for LDAP enrichment.

2. In the **LDAP accounts mapping** settings block, click the **New domain** button to specify the domain of the user accounts. You can specify multiple domains.

3. In the **LDAP mapping** table, define the rules for mapping KUMA fields to LDAP attributes:

   - In the **KUMA field** column, specify the KUMA event field whose data you want to compare with the LDAP attribute.
   - In the **LDAP attribute** column, specify the attribute that must be compared with the KUMA event field. The drop-down list contains standard attributes and can be augmented with **custom attributes**.

     Before configuring event enrichment using custom attributes, make sure that custom attributes are configured in AD.

     To enrich events with accounts using custom attributes:

     1. Add **Custom AD Account Attributes** in the LDAP connection settings.

        Standard **imported attributes from AD** cannot be added as custom attributes. For example, if you add the standard `accountExpires` attribute as a custom attribute, KUMA returns an error when saving the connection settings.

        The following account attributes can be requested from Active Directory:

        - `accountExpires`
        - `badPasswordTime`
        - `cn`
        - `co`
        - `company`
        - `department`
        - `description`
        - `displayName`
        - `distinguishedName`
        - `division`
        - `employeeID`
        - `givenName`
        - `l`
        - `lastLogon`
        - `lastLogonTimestamp`
        - `Mail`
        - `mailNickname`
        - `managedObjects`

- `manager`
- `memberOf` (this attribute can be used for search during correlation)
- `mobile`
- `name`
- `objectCategory`
- `objectGUID` (this attribute always requested from Active Directory even if a user doesn't specify it)
- `objectSID`
- `physicalDeliveryOfficeName`
- `pwdLastSet`
- `sAMAccountName`
- `sAMAccountType`
- `sn`
- `streetAddress`
- `telephoneNumber`
- `title`
- `userAccountControl`
- `UserPrincipalName`
- `whenChanged`
- `whenCreated`

After you add custom attributes in the LDAP connection settings, the **LDAP attribute** to receive drop-down list in the collector automatically includes the new attributes. Custom attributes are identified by a question mark next to the attribute name. If you added the same attribute for multiple domains, the attribute is listed only once in the drop-down list. You can view the domains by moving your cursor over the question mark. Domain names are displayed as links. If you click a link, the domain is automatically added to **LDAP accounts mapping** if it was not previously added.

If you deleted a custom attribute in the LDAP connection settings, manually delete the row containing the attribute from the mapping table in the collector. Account attribute information in KUMA is updated each time you import accounts.

2. Import accounts.
3. In the collector, in the **LDAP mapping** table, define the rules for mapping KUMA fields to LDAP attributes.
4. Restart the collector.

   After the collector is restarted, KUMA begins enriching events with accounts.

- In the **KUMA event field to write to** column, specify in which field of the KUMA event the ID of the user account imported from LDAP should be placed if the mapping was successful.

You can click the **Add row** button to add a string to the table, and can click the ✕ button to remove a string. You can use the **Apply default mapping** button to fill the mapping table with standard values.

Event enrichment rules for data received from LDAP were added to the group of resources for the collector.

If you add an enrichment to an existing collector using LDAP or change the enrichment settings, you must stop and restart the service.

Proceed to the next step of the Installation Wizard.

Step 7. Routing

This is an optional step of the Installation Wizard. On the **Routing** tab of the Installation Wizard, you can select or create destinations with settings indicating the forwarding destination of events processed by the collector. Typically, events from the collector are routed to two points: to the correlator to analyze and search for threats; and to the storage, both for storage and so that processed events can be viewed later. Events can be sent to other locations as needed. There can be more than one destination point.

To add an existing destination to a collector resource set:

1. In the **Add destination** drop-down list, select the type of destination resource you want to add:

   - Select **Storage** if you want to configure forwarding of processed events to the storage.
   - Select **Correlator** if you want to configure forwarding of processed events to a correlator.
   - Select **Other** if you want to send events to other locations.

     This type of resource includes correlator and storage services that were created in previous versions of the program.

   The **Add destination** window opens where you can specify parameters for events forwarding.

2. In the **Destination** drop-down list, select the necessary destination.

   The window name changes to **Edit destination**, and it displays the settings of the selected resource. To open the settings of a destination for editing in a new browser tab, click ↗.

3. Click **Save**.

The selected destination is displayed on the Installation Wizard tab. A destination resource can be removed from the resource set by selecting it and clicking **Delete** in the opened window.

To add a new destination resource to a collector resource set:

1. In the **Add destination** drop-down list, select the type of destination resource you want to add:

   - Select **Storage** if you want to configure forwarding of processed events to the storage.
   - Select **Correlator** if you want to configure forwarding of processed events to a correlator.
   - Select **Other** if you want to send events to other locations.

     This type of resource includes correlator and storage services that were created in previous versions of the program.

   The **Add destination** window opens where you can specify parameters for events forwarding.

2. Specify the settings on the **Basic settings** tab:

   - In the **Destination** drop-down list, select **Create new**.
   - In the **Name** field, enter a unique name for the destination resource. The name must contain 1 to 128 Unicode characters.
   - Use the **Disabled** toggle button to specify whether events will be sent to this destination. By default, sending events is enabled.
   - Select the **Type** for the destination resource:
     - Select **storage** if you want to configure forwarding of processed events to the storage.
     - Select **correlator** if you want to configure forwarding of processed events to a correlator.
     - Select **nats-jetstream**, **tcp**, **http**, **kafka**, or **file** if you want to configure sending events to other locations.
   - Specify the **URL** to which events should be sent in the hostname:<API port> format.

     You can specify multiple destination addresses using the **URL** button for all types except **nats-jetstream**, **file**, and **diode**.
   - For the **nats-jetstream** and **kafka** types, use the **Topic** field to specify which topic the data should be written to. The topic must contain Unicode characters. The Kafka topic is limited to 255 characters.

3. If necessary, specify the settings on the **Advanced settings** tab. The available settings vary based on the selected destination resource type:

   - **Compression** is a drop-down list where you can enable Snappy compression. By default, compression is **disabled**.
   - **Proxy** is a drop-down list for proxy server selection.
   - The **Buffer size** field is used to set buffer size (in bytes) for the destination. The default value is 1 MB, and the maximum value is 64 MB.
   - **Timeout** field is used to set the timeout (in seconds) for another service or component response. The default value is `30`.

- **Disk buffer size limit** field is used to specify the size of the disk buffer in bytes. The default size is 10 GB.
- **Cluster ID** is the ID of the NATS cluster.
- **TLS mode** is a drop-down list where you can specify the conditions for using TLS encryption:
  - **Disabled** (default)—do not use TLS encryption.
  - **Enabled**—encryption is enabled, but without verification.
  - **With verification**—use encryption with verification that the certificate was signed with the KUMA root certificate. The root certificate and key of KUMA are created automatically during program installation and are stored on the KUMA Core server in the folder /opt/kaspersky/kuma/core/certificates/.

  When using TLS, it is impossible to specify an IP address as a URL.
- **URL selection policy** is a drop-down list in which you can select a method for determining which URL to send events to if several URLs have been specified:
  - **Any**. Events are sent to one of the available URLs as long as this URL receives events. If the connection is broken (for example, the receiving node is disconnected) a different URL will be selected as the events destination.
  - **Prefer first**. Events are sent to the first URL in the list of added addresses. If it becomes unavailable, events are sent to the next available node in sequence. When the first URL becomes available again, events start to be sent to it again.
  - **Balanced** means that packages with events are evenly distributed among the available URLs from the list. Because packets are sent either on a destination buffer overflow or on the flush timer, this URL selection policy does not guarantee an equal distribution of events to destinations.
- **Delimiter** is used to specify the character delimiting the events. By default, `\n` is used.
- **Path**—the file path if the **file** destination type is selected.
- **Buffer flush interval**—this field is used to set the time interval (in seconds) at which the data is sent to the destination. The default value is `100`.
- **Workers**—this field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
- You can set health checks using the **Health check path** and **Health check timeout** fields. You can also disable health checks by selecting the **Health Check Disabled** check box.
- **Debug**—a toggle switch that lets you specify whether resource logging must be enabled. By default, this toggle switch is in the **Disabled** position.
- The **Disk buffer disabled** drop-down list is used to enable or disable the use of a disk buffer. By default, the disk buffer is disabled.

  The disk buffer is used if the collector cannot send normalized events to the destination. The amount of allocated disk space is limited by the value of the **Disk buffer size limit** setting.

  If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer.

- In the **Filter** section, you can specify the conditions to define events that will be processed by this resource. You can select an existing filter from the drop-down list or create a new filter.

  Creating a filter in resources

  All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

  To create a filter:

  1. In the **Filter** drop-down list, select **Create new**.
  2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.
  3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.
  4. Under **Conditions**, specify the conditions that the events must meet:
     a. Click the **Add condition** button.
     b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.
     c. In the **Operator** drop-down list, select an operator.

        Filter operators

        - **=** means the left operand equals the right operand.
        - **<** means the left operand is less than the right operand.
        - **<=** means the left operand is less than or equal to the right operand.
        - **>** means the left operand is greater than the right operand.
        - **>=** means the left operand is greater than or equal to the right operand.
        - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
        - **contains** means the left operand contains values of the right operand.
        - **startsWith** means the left operand starts with one of the values of the right operand.
        - **endsWith** means the left operand ends with one of the values of the right operand.
        - **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
        - **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.

- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.

- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.

- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.

- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.

- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.

- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.

- **inContextTable** checks for the presence of the entry in the specified context table.

- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

4. Click **Save**.

The created destination is displayed on the Installation Wizard tab. A destination resource can be removed from the resource set by selecting it and clicking **Delete** in the opened window.

Proceed to the next step of the Installation Wizard.

Step 8. Setup validation

This is the required, final step of the Installation Wizard. At this step, OSMP creates a service resource set, and the Services are created automatically based on this set:

- The set of resources for the collector is displayed under **Resources and services** → **Collectors**. It can be used to create new collector services. When this set of resources changes, all services that operate based on this set of resources will start using the new parameters after the services restart. To do so, you can click the **Save and restart services** and **Save and update service configurations** buttons.

  A resource set can be modified, copied, moved from one folder to another, deleted, imported, and exported, like other resources.

- Services are displayed in **Resources and services** → **Active services**. The services created using the Installation Wizard perform functions inside OSMP. To communicate with external parts of the network infrastructure, you need to install similar external services on the servers and assets intended for them. For example, an external collector service should be installed on a server intended as an events recipient, external storage services should be installed on servers that have a deployed ClickHouse service, and external agent services should be installed on the Windows assets that must both receive and forward Windows events.

To finish the Installation Wizard:

1. Click **Create and save service**.

   The **Setup validation** tab of the Installation Wizard displays a table of services created based on the set of resources selected in the Installation Wizard. The lower part of the window shows examples of commands that you must use to install external equivalents of these services on their intended servers and assets.

   For example:

   ```
   /opt/kaspersky/kuma/kuma collector --core <FQDN>:<port> --pair.fingerprint <fingerprint ID of the KUMA Core CA certificate> --id <service ID> --api.port <API port> --install
   ```

   where:

   - <FQDN> is full qualified domain name of KUMA Core server.
   - <port> is the port used for communication with the KUMA Core.
   - <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

     The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

     You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

     To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.

   - <service ID> is the identifier of a KUMA service copied from the web-interface.
   - <API port> is the port used for communication with the installed component.

The "kuma" file can be found inside the installer in the /kuma-ansible-installer/roles/kuma/files/ directory.

The port for communication with the KUMA Core, the fingerprint ID of the KUMA Core CA certificate, the service ID, and the port for communication with the service are added to the command automatically. You must also ensure the network connectivity of OSMP and open the ports used by its components, if necessary.

2. Close the Wizard by clicking **Save collector**.

The collector service is created in OSMP. Now you will install a similar service on the server intended for receiving events.

If a wmi or wec connector was selected for collectors, you must also install the automatically created OSMP agents.

Installing a collector in a KUMA network infrastructure

A collector consists of two parts: one part is created inside the KUMA Console, and the other part is installed on the network infrastructure server intended for receiving events. The second part of the collector is installed in the network infrastructure.

To install a collector:

1. Log in to the server where you want to install the service.
2. Create the /opt/kaspersky/kuma/ folder.
3. Copy the "kuma" file to the /opt/kaspersky/kuma/ folder. The file is located in the installer in the /kuma-ansible-installer/roles/kuma/files/ folder.

   Make sure the kuma file has sufficient rights to run. If the file is not executable, make it executable:

   ```
   sudo chmod +x /opt/kaspersky/kuma/kuma
   ```
4. Place the LICENSE file from the /kuma-ansible-installer/roles/kuma/files/ directory in the /opt/kaspersky/kuma/ directory and accept the terms and conditions of the End User License Agreement by running the following command:

   ```
   sudo /opt/kaspersky/kuma/kuma license
   ```
5. Create the 'kuma' user:

   ```
   sudo useradd --system kuma && usermod -s /usr/bin/false kuma
   ```
6. Make the 'kuma' user the owner of the /opt/kaspersky/kuma directory and all files inside the directory:

   ```
   sudo chown -R kuma:kuma /opt/kaspersky/kuma/
   ```

7. Execute the following command:

```
sudo /opt/kaspersky/kuma/kuma collector --core <FQDN>:<port> --pair.fingerprint <fingerprint ID of the KUMA
Core CA certificate> --id <service ID> --api.port <API port>
```

where:

- <FQDN> is full qualified domain name of KUMA Core server.
- <port> is the port used for communication with the KUMA Core.
- <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

  The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

  You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

  To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.
- <service ID> is the identifier of a KUMA service copied from the web-interface.
- <API port> is the port used for communication with the installed component.

Example:

```
sudo /opt/kaspersky/kuma/kuma collector --core https://kuma.example.com:7210 --pair.fingerprint XXXX --id XXXX
--api.port YYYY
```

If errors are detected as a result of the command execution, make sure that the settings are correct. For example, the availability of the required access level, network availability between the collector service and the Core, and the uniqueness of the selected API port. After fixing errors, continue installing the collector.

If no errors were found, and the collector status in the KUMA Console is changed to *green*, stop the command execution and proceed to the next step.

The command can be copied at the last step of the installer wizard. It automatically specifies the address and port of the KUMA Core server, the identifier of the collector to be installed, and the port that the collector uses for communication.

When deploying multiple KUMA services on the same host, during the installation process you must specify unique ports for each component using the `--api.port <port>` parameter. The following setting values are used by default: `--api.port 7221`.

Before installation, ensure the network connectivity of KUMA components.

8. Run the command again by adding the `--install` key:

```
sudo /opt/kaspersky/kuma/kuma collector --core <FQDN>:<port> --pair.fingerprint <fingerprint ID of the KUMA
Core CA certificate> --id <service ID> --api.port <API port> --install
```

where:

- <FQDN> is the fully qualified domain name of the KUMA Core server.
- <port> is the port used for communication with the KUMA Core (port 7210 is used by default).
- <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

  The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

  You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

  To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.
- <service ID> is the identifier of a KUMA service copied from the web-interface.
- <API port> is the port used for communication with the installed component.

Example:

```
sudo /opt/kaspersky/kuma/kuma collector --core https://kuma.example.com:7210 --pair.fingerprint XXXX --id XXXX
--api.port YYYY --install
```

9. Add KUMA collector port to firewall exclusions.

> For the program to run correctly, ensure that the KUMA components are able to interact with other components and programs over the network via the protocols and ports specified during the installation of the KUMA components.

The collector is installed. You can use it to receive data from an event source and send it for processing.

Validating collector installation

To verify that the collector is ready to receive events:

1. In the KUMA Console, go to the **Resources** → **Active services** section.
2. Make sure that the collector you installed has the green status.

   If the status of the collector is not green, view the log of this service on the machine where it is installed, in the /opt/kaspersky/kuma/collector/<collector ID>/log/collector directory. Errors are logged regardless of whether debug mode is enabled or disabled.

If the collector is installed correctly and you are sure that data is coming from the event source, the table should display events when you search for events associated with the collector.

*To check for normalization errors using the **Events** section of the KUMA Console:*

1. Make sure that the Collector service is running.
2. Make sure that the event source is providing events to the KUMA.
3. Make sure that you selected **Only errors** in the **Keep raw event** drop-down list of the **Normalizer** resource in the **Resources** section of the KUMA Console.
4. In the **Events** section of KUMA, search for events with the following parameters:

   - `ServiceID = <ID of the collector to be checked>`
   - `Raw != ""`

   If any events are found with this search, it means that there are normalization errors and they should be investigated.

To check for normalization errors using the Grafana™ Dashboard:

1. Make sure that the Collector service is running.
2. Make sure that the event source is providing events to the KUMA.
3. Open the Metrics section and follow the KUMA Collectors link.
4. See if the Errors section of the Normalization widget displays any errors.

   If there are any errors, it means that there are normalization errors and they should be investigated.

For WEC and WMI collectors, you must ensure that unique ports are used to connect to their agents. This port is specified in the **Transport** section of Collector Installation Wizard.

Ensuring uninterrupted collector operation

An uninterrupted event stream from the event source to KUMA is important for protecting the network infrastructure. Continuity can be ensured though automatic forwarding of the event stream to a larger number of collectors:

- On the KUMA side, two or more identical collectors must be installed.
- On the event source side, you must configure control of event streams between collectors using third-party server load management tools, such as rsyslog or nginx.

With this configuration of the collectors in place, no incoming events will be lost if the collector server is unavailable for any reason.

Please keep in mind that when the event stream switches between collectors, each collector will aggregate events separately.

If the KUMA collector fails to start, and its log includes the "panic: runtime error: slice bounds out of range [8:0]" error:

1. Stop the collector.

   ```
   sudo systemctl stop kuma-collector-<collector ID>
   ```

2. Delete the DNS enrichment cache files.

   ```
   sudo rm -rf /opt/kaspersky/kuma/collector/<collector ID>/cache/enrichment/DNS-*
   ```

3. Delete the event cache files (disk buffer). Run the command only if you can afford to jettison the events in the disk buffers of the collector.

   ```
   sudo rm -rf /opt/kaspersky/kuma/collector/<collector ID>/buffers/*
   ```

4. Start the collector service.

   ```
   sudo systemctl start kuma-collector-<collector ID>
   ```

Event stream control using rsyslog

To enable rsyslog event stream control on the event source server:

1. Create two or more identical collectors that you want to use to ensure uninterrupted reception of events.
2. Install rsyslog on the event source server (refer to the rsyslog documentation).
3. Add rules for forwarding the event stream between collectors to the configuration file /etc/rsyslog.conf:

   ```
   *. * @@ <main collector server FQDN>: <port for incoming events>
   $ActionExecOnlyWhenPreviousIsSuspended on
   *. * @@ <backup collector server FQDN>: <port for incoming events>
   $ActionExecOnlyWhenPreviousIsSuspended off
   ```

   Example configuration file

Example configuration file specifying one primary and two backup collectors. The collectors are configured to receive events on TCP port 5140.

```
*.* @@kuma-collector-01.example.com:5140
$ActionExecOnlyWhenPreviousIsSuspended on
& @@kuma-collector-02.example.com:5140
& @@kuma-collector-03.example.com:5140
$ActionExecOnlyWhenPreviousIsSuspended off
```

4. Restart rsyslog by running the following command:

   `systemctl restart rsyslog`.

Event stream control is now enabled on the event source server.

Event stream control using nginx

To control event stream using nginx, you need to create and configure an ngnix server to receive events from the event source and then forward these to collectors.

To enable nginx event stream control on the event source server:

1. Create two or more identical collectors that you want to use to ensure uninterrupted reception of events.

2. Install nginx on the server intended for event stream control.

   - Installation command in Oracle Linux 8.6:

     `$sudo dnf install nginx`

   - Installation command in Ubuntu 20.4:

     `$sudo apt-get install nginx`

     When installing from sources, you must compile with the parameter `-with-stream` option:
     `$ sudo ./configure -with-stream -without-http_rewrite_module -without-http_gzip_module`

3. On the nginx server, add the stream module to the nginx.conf configuration file that contains the rules for forwarding the stream of events between collectors.

   Example stream module

   Example module in which event stream is distributed between the collectors kuma-collector-01.example.com and kuma-collector-02.example.com, which receive events via TCP on port 5140 and via UDP on port 5141. Balancing uses the nginx.example.com ngnix server.

```
stream {
 upstream syslog_tcp {
server kuma-collector-1.example.com:5140;
server kuma-collector-2.example.com:5140;
}
upstream syslog_udp {
server kuma-collector-1.example.com:5141;
server kuma-collector-2.example.com:5141;
}
 server {
listen nginx.example.com:5140;
proxy_pass syslog_tcp;
}
server {
listen nginx.example.com:5141 udp;
proxy_pass syslog_udp;
proxy_responses 0;
}
}
 worker_rlimit_nofile 1000000;
events {
worker_connections 20000;
}
# worker_rlimit_nofile is the limit on the number of open files (RLIMIT_NOFILE) for workers. This is used to raise the limit without restarting the main process.
# worker_connections is the maximum number of connections that a worker can open simultaneously.
```

4. Restart nginx by running the following command:

   `systemctl restart nginx`

5. On the event source server, forward events to the ngnix server.

Event stream control is now enabled on the event source server.

Nginx Plus may be required to fine-tune balancing, but certain balancing methods, such as Round Robin and Least Connections, are available in the base version of ngnix.

For more details on configuring nginx, please refer to the nginx documentation.

Predefined collectors

The predefined collectors listed in the table below are included in the OSMP distribution kit.

If you need to adapt a predefined OOTB resource to your organization's infrastructure, use the duplication operation. You can also export and import resources. A manually created copy of a predefined resource is not guaranteed to work.

Predefined collectors

Name	Description
[OOTB] CEF	Collects CEF events received over the TCP protocol.
[OOTB] Kaspersky EDR	Collects events from Kaspersky Endpoint Detection and Response in JSON format.

Name	Description
[OOTB] KSC	Collects events from Kaspersky Security Center over the Syslog TCP protocol.
[OOTB] KSC SQL	Collects events from Kaspersky Security Center using an MS SQL database query.
[OOTB] Syslog	Collects events via the Syslog protocol.
[OOTB] Syslog-CEF	Collects CEF events that arrive over the UDP protocol and have a Syslog header.

Creating a correlator

A correlator consists of two parts: one part is created inside OSMP, and the other part is installed on the network infrastructure server intended for processing events.

Actions in OSMP

A correlator is created in OSMP by using the Installation Wizard. This Wizard combines the necessary resources into a set of resources for the correlator. Upon completion of the Wizard, the service itself is automatically created based on this set of resources.

To create a correlator in OSMP,

Start the Correlator Installation Wizard:

- In OSMP, in the main menu, under **Resources and services**, click **Add correlator**.
- In OSMP, in the main menu, under **Resources and services** → **Correlators**, click **Add correlator**.

As a result of completing the steps of the Wizard, a correlator service is created in OSMP.

A resource set for a correlator includes the following resources:

- Correlation rules
- enrichment rules (if required);
- Response rules (if required)
- Destinations (normally one for sending events to a storage)

These resources can be prepared in advance, or you can create them while the Installation Wizard is running.

Actions on the OSMP correlator server

If you are installing the correlator on a server that you intend to use for event processing, you need to run the command displayed at the last step of the Installation Wizard on the server. When installing, you must specify the ID automatically assigned to the service in OSMP, as well as the port used for communication.

Testing the installation

After creating a correlator, it is recommended to make sure that it is working correctly.

Starting the Correlator Installation Wizard

To start the Correlator Installation Wizard:

- In OSMP, in the main menu, under **Resources and services**, click **Add correlator**.
- In OSMP, in the main menu, under **Resources and services** → **Correlators**, click **Add correlator**.

Follow the steps of the wizard.

Aside from the first and last steps of the Wizard, the steps of the Wizard can be performed in any order. You can switch between steps by using the **Next** and **Previous** buttons, as well as by clicking the names of the steps in the left side of the window.

After the Wizard completes, a resource set for the correlator is created in OSMP under **Resources and services** → **Correlators**, and a correlator service is added under **Resources and services** → **Active services**.

Step 1. General correlator settings

This is a required step of the Installation Wizard. At this step, you specify the main settings of the correlator: the correlator name and the tenant that will own it.

To define the main settings of the correlator:

- In the **Name** field, enter a unique name for the service you are creating. The name must contain 1 to 128 Unicode characters.
- In the **Tenant** drop-down list, select the tenant that must own the correlator. The tenant selection determines what resources will be available when the collector is created.

  > If you return to this window from another subsequent step of the Installation Wizard and select another tenant, you will have to manually edit all the resources that you have added to the service. Only resources from the selected tenant and shared tenant can be added to the service.

- If required, specify the number of processes that the service can run concurrently in the **Workers** field. By default, the number of worker processes is the same as the number of vCPUs on the server where the service is installed.
- If necessary, use the **Debug** drop-down list to enable logging of service operations.
- You can optionally add up to 256 Unicode characters describing the service in the **Description** field.

The main settings of the correlator are defined. You can proceed to the next step of the Installation Wizard.

Step 2. Global variables

If tracking values in event fields, active lists, or dictionaries is not enough to cover some specific security scenarios, you can use global and local variables. You can use them to take various actions on the values received by the correlators by implementing complex logic for threat detection. Variables can be assigned a specific function and then queried from correlation rules as if they were ordinary event fields, with the triggered function result received in response.

To add a global variable in the correlator,

Click the **Add variable** button and specify the following parameters:

- In the **Variable** window, enter the name of the variable.

  Variable naming requirements

  - Must be unique within the correlator.
  - Must contain 1 to 128 Unicode characters.
  - Must not begin with the character $.
  - Must be written in camelCase or CamelCase.

- In the **Value** window, enter the variable function.

  Description of variable functions.

The global variable is added. It can be queried from correlation rules by adding the $ character in front of the variable name. There can be multiple variables. Added variables can be edited or deleted by using the ✕ icon.

Proceed to the next step of the Installation Wizard.

Step 3. Correlation

This is an optional but recommended step of the Installation Wizard. On the **Correlation** tab of the Installation Wizard, select or create correlation rules. These resources define the sequences of events that indicate security-related incidents. When these sequences are detected, the correlator creates a correlation event and an alert.

If you have added global variables to the correlator, all added correlation rules can query them.

Correlation rules that are added to the resource set for the correlator are displayed in the table with the following columns:

- **Correlation rules**—name of the correlation rule resource.
- **Type**—type of correlation rule: **standard**, **simple**, **operational**. The table can be filtered based on the values of this column by clicking the column header and selecting the relevant values.
- **Actions**—list of actions that will be performed by the correlator when the correlation rule is triggered. These actions are indicated in the correlation rule settings. The table can be filtered based on the values of this column by clicking the column header and selecting the relevant values.

Available values:

- **Output**—correlation events created by this correlation rule are transmitted to other correlator resources: enrichment, response rule, and then to other OSMP services.
- **Edit active list**—the correlation rule changes the active lists.
- **Loop to correlator**—the correlation event is sent to the same correlation rule for reprocessing.
- **Categorization**—the correlation rule changes asset categories.
- **Event enrichment**—the correlation rule is configured to enrich correlation events.
- **Do not create alert**—when a correlation event is created as a result of a correlation rule triggering, no alert is created for that. If you do not want to create an alert when a correlation rule is triggered, but you still want to send a correlation event to the storage, select the **Output** and **No alert** check boxes. If you select only the **No alert** check box, a correlation event is not saved in the storage.
- **Shared resource**—the correlation rule or the resources used in the correlation rule are located in a shared tenant.

You can use the **Search** field to search for a correlation rule. Added correlation rules can be removed from the resource set by selecting the relevant rules and clicking **Delete**.

Selecting a correlation rule opens a window with its settings, which can be edited and then saved by clicking **Save**. If you click **Delete** in this window, the correlation rule is unlinked from the resource set.

Click the **Move up** and **Move down** buttons to change the position of the selected correlation rules in the table. It affects their execution sequence when events are processed. Using the **Move operational to top** button, you can move correlation rules of the **operational** type to the beginning of the correlation rules list.

To link the existing correlation rules to the resource set for the correlator:

1. Click **Link**.

   The resource selection window opens.

2. Select the relevant correlation rules and click **OK**.

   The correlation rules will be linked to the resource set for the correlator and will be displayed in the rules table.

To create a new correlation rule in a resource set for a correlator:

1. Click **Add**.

   The correlation rule creation window opens.

2. Specify the correlation rule settings and click **Save**.

   The correlation rule will be created and linked to the resource set for the correlator. It is displayed in the correlation rules table and in the list of resources under **Resources** → **Correlation rules**.

Proceed to the next step of the Installation Wizard.

Step 4. Enrichment

This is an optional step of the Installation Wizard. In the **Enrichment** tab of the Installation Wizard, you can select or create enrichment rules and indicate which data from which sources you want to add to correlation events that the correlator creates. There can be more than one enrichment rule. You can add them by clicking the **Add** button and can remove them by clicking the ✕ button.

To add an existing enrichment rule to a set of resources:

1. Click **Add**.

   This opens the enrichment rule settings block.

2. In the **Enrichment rule** drop-down list, select the relevant resource.

The enrichment rule is added to the resource set for the correlator.

To create a new enrichment rule in a resource set:

1. Click **Add**.

   This opens the enrichment rule settings block.

2. In the **Enrichment rule** drop-down list, select **Create new**.

3. In the **Source kind** drop-down list, select the source of data for enrichment and define its corresponding settings:

   - **constant**

     This type of enrichment is used when a constant needs to be added to an event field. Settings of this type of enrichment:

     - In the **Constant** field, specify the value that should be added to the event field. The value may not be longer than 255 Unicode characters. If you leave this field blank, the existing event field value will be cleared.

     - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

     If you are using the event enrichment functions for extended schema fields of `String`, `Number`, or `Float` type with a constant, the constant is added to the field.

     If you are using the event enrichment functions for extended schema fields of `Array of strings`, `Array of numbers`, or `Array of floats` type with a constant, the constant is added to the elements of the array.

   - **dictionary**

     This type of enrichment is used if you need to add a value from the dictionary of the **Dictionary** type.

     When this type is selected in the **Dictionary name** drop-down list, you must select the dictionary that will provide the values. In the **Key fields** settings block, you have to click the **Add field** button and select the event fields whose values will be used for dictionary entry selection.

If you are using event enrichment with the "Dictionary" type selected as the "Source kind" setting, and an array field is specified in the "Key enrichment fields" setting, when an array is passed as the dictionary key, the array is serialized into a string in accordance with the rules of serializing a single value in the TSV format.

Example: The "Key enrichment fields" setting uses the SA.StringArrayOne extended schema field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b" and "c". The following value is passed to the dictionary as the key: ['a','b','c'].

If the "Key enrichment fields" setting uses an extended schema array field and a regular event schema field, the field values are separated by the "|" character when the dictionary is queried.

Example: The "Key enrichment fields" setting uses two fields: the SA.StringArrayOne extended schema field and the Code field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b", and "c"; the Code string field contains the character sequence "myCode". The following value is passed to the dictionary as the key: ['a','b','c']|myCode.

- **event**

  This type of enrichment is used when you need to write a value from another event field to the current event field. Settings of this type of enrichment:

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.
  - In the **Source field** drop-down list, select the event field whose value will be written to the target field.
  - Under **Conversion**, you can create rules for modifying the original data before it is written to the KUMA event fields. The conversion type can be selected from the drop-down list. You can use the **Add conversion** and **Delete** buttons to add or delete a conversion, respectively. The order of conversions is important.

    Available conversions

    Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

    Available conversions:

    - **lower**—is used to make all characters of the value lowercase
    - **upper**—is used to make all characters of the value uppercase
    - **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
    - **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.
    - **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
      - **Replace chars**—in this field you can specify the character sequence that should be replaced.
      - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.

- **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.

- **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.

- **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.

- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.

  - **Expression**—in this field you can specify the regular expression which results that should be replaced.

  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.

- Converting encoded strings to text:

  - **decodeHexString**—used to convert a HEX string to text.

  - **decodeBase64String**—used to convert a Base64 string to text.

  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.

- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.

- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.

- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

- **template**

This type of enrichment is used when you need to write a value obtained by processing Go templates into the event field. Settings of this type of enrichment:

- In the **Template** field, enter the Go template.

  Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field from which the value must be passed to the script.

  Example: `Attack on {{.DestinationAddress}} from {{.SourceAddress}}`.

- In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

To convert the data in an array field in a template into the TSV format, you must use the toString function.

If you are using enrichment of events that have the **Template** type selected as the **Source kind** setting, in which the target field has the `String` type, and the source field is an extended event schema field containing an array of strings, you can use one of the following examples for the template.

Example:

{{.SA.StringArrayOne}}

Example:

{{- range $index, $element := . SA.StringArrayOne -}}

{{- if $index}}, {{end}}"{{$element}}"{{- end -}}

- **dns**

  This type of enrichment is used to send requests to a private network DNS server to convert IP addresses into domain names or vice versa. IP addresses are converted to DNS names only for private addresses: 10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16, 100.64.0.0/10, fd00::/8.

  The settings of this type of enrichment are described in the table below.

Parameters of enrichment type "dns"

Setting	Description
URL	URL of the DNS server to which you want to send requests. You can use the **Add URL** button to specify multiple URLs. If the **URL** setting is not specified, KUMA takes the list of DNS servers from the localhost's `/etc/resolv.conf` file. In this case, you need to enable the **Recursive queries** option. Otherwise, the enrichment will not occur.
Requests per second	Maximum number of queries sent to the DNS server per second. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Workers	Number of handlers that the service can run simultaneously to process response rules in parallel. Specify a positive integer number from 0 to 999. If 0 is specified, the number of logical CPU cores is used. The default value is `1`.
Maximum number of events in enrichment queue	The maximum number of events to hold in the resubmission queue. The default value is `1,000,000`.
Timeout	The time to wait for a response from the DNS server (in seconds). The default value is `5`.
DNS mode override	Resolution method used: • **Forward DNS only** resolves a domain name to an IP address. • **Reverse DNS only** resolves an IP address to a domain name. • **Forward and reverse DNS** resolves a domain name to an IP address or an IP address to a domain name.

Setting	Description
Cache TTL	The lifetime (in seconds) of values stored in the cache. The default value is `60` seconds.
Cache disabled	You can enable or disable caching using this setting. Caching is enabled by default.
Cache refresh disabled	If cache update is enabled, then upon expiry of the cache's TTL the collector sends repeated requests to the DNS server to update the data stored in the cache. This setting is available only when cache is enabled. By default, cache update is enabled.
Recursive queries	Allows a collector to send recursive queries to authoritative DNS servers for the purposes of enrichment. The default value is **Disabled**.

- **cybertrace**

  This type of enrichment is used to add information from CyberTrace data streams to event fields.

  Available settings:

  - **URL** (required)—in this field, you can specify the URL of a CyberTrace server to which you want to send requests.
  - **Number of connections**—maximum number of connections to the CyberTrace server that can be simultaneously established by KUMA. By default, this value is equal to the number of vCPUs of the KUMA Core server.
  - **RPS**—maximum number of requests sent to the server per second. The default value is `1000`.
  - **Timeout**—amount of time to wait for a response from the CyberTrace server, in seconds. The default value is `30`.
  - **Mapping** (required)—this settings block contains the mapping table for mapping KUMA event fields to CyberTrace indicator types. The **KUMA field** column displays the names of KUMA event fields, and the **CyberTrace indicator** column displays the types of CyberTrace indicators.

    Available types of CyberTrace indicators:

    - **ip**
    - **url**
    - **hash**

    In the mapping table, you must provide at least one string. You can click the **Add row** button to add a string, and can click the ✕ button to remove a string.

- **timezone**

  This type of enrichment is used in collectors and correlators to assign a specific timezone to an event. Timezone information may be useful when searching for events that occurred at unusual times, such as nighttime.

  When this type of enrichment is selected, the required timezone must be selected from the **Timezone** drop-down list.

  Make sure that the required time zone is set on the server hosting the enrichment-utilizing service. For example, you can do this by using the `timedatectl list-timezones` command, which shows all time zones that are set on the server. For more details on setting time zones, please refer to your operating system documentation.

When an event is enriched, the time offset of the selected timezone relative to Coordinated Universal Time (UTC) is written to the DeviceTimeZone event field in the `+-hh:mm` format. For example, if you select the **Asia/Yekaterinburg** timezone, the value `+05:00` will be written to the DeviceTimeZone field. If the enriched event already has a value in the DeviceTimeZone field, it will be overwritten.

By default, if the timezone is not specified in the event being processed and enrichment rules by timezone are not configured, the event is assigned the timezone of the server hosting the service (collector or correlator) that processes the event. If the server time is changed, the service must be restarted.

Permissible time formats when enriching the DeviceTimeZone field

When processing incoming raw events in the collector, the following time formats can be automatically converted to the +-hh:mm format:

Time format in a processed event	Example
+-hh:mm	-07:00
+-hhmm	-0700
+-hh	-07

If the date format in the `DeviceTimeZone` field differs from the formats listed above, the collector server timezone is written to the field when an event is enriched with timezone information. You can create custom normalization rules for non-standard time formats.

4. Use the **Debug** drop-down list to indicate whether or not to enable logging of service operations. Logging is disabled by default.

5. In the **Filter** section, you can specify conditions to identify events that will be processed using the enrichment rule. You can select an existing filter from the drop-down list or create a new filter.

   Creating a filter in resources

   All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

   To create a filter:

   1. In the **Filter** drop-down list, select **Create new**.

   2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.

   3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.

   4. Under **Conditions**, specify the conditions that the events must meet:

      a. Click the **Add condition** button.

      b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.

c. In the **Operator** drop-down list, select an operator.

Filter operators

- **=** means the left operand equals the right operand.
- **<** means the left operand is less than the right operand.
- **<=** means the left operand is less than or equal to the right operand.
- **>** means the left operand is greater than the right operand.
- **>=** means the left operand is greater than or equal to the right operand.
- **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
- **contains** means the left operand contains values of the right operand.
- **startsWith** means the left operand starts with one of the values of the right operand.
- **endsWith** means the left operand ends with one of the values of the right operand.
- **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
- **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

  The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

  If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.
- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.

- **inContextTable** checks for the presence of the entry in the specified context table.
- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

The new enrichment rule was added to the resource set for the correlator.

Proceed to the next step of the Installation Wizard.

Step 5. Response

This is an optional step of the Installation Wizard. On the **Response** tab of the Installation Wizard, you can select or create response rules and indicate which actions must be performed when the correlation rules are triggered. There can be multiple response rules. You can add them by clicking the **Add** button and can remove them by clicking the button.

To add an existing response rule to a resource set:

1. Click **Add**.

   The response rule settings window opens.

2. In the **Response rule** drop-down list, select the relevant resource.

The response rule is added to the resource set for the correlator.

To create a new response rule in a resource set:

1. Click **Add**.

   The response rule settings window opens.

2. In the **Response rule** drop-down list, select **Create new**.

3. In the **Type** drop-down list, select the type of response rule and define its corresponding settings:

   - **KSC response**—response rules for automatically launching the tasks on Kaspersky Security Center assets. For example, you can configure automatic startup of a virus scan or database update.

     Tasks are automatically started when OSMP is integrated with Kaspersky Security Center. Tasks are run only on assets that were imported from Kaspersky Security Center.

Response settings

- **Kaspersky Security Center task** (required)—name of the Open Single Management Platform task that you want to start. Tasks must be created beforehand, and their names must begin with "`KUMA `". For example, "`KUMA antivirus check`".

  Types of Open Single Management Platform tasks that can be started using KUMA:

  - Update
  - Virus scan

- **Event field** (required)—defines the event field of the asset for which the Open Single Management Platform task must be started. Possible values:

  - SourceAssetID
  - DestinationAssetID
  - DeviceAssetID

To send requests to Open Single Management Platform, you must make sure that the Open Single Management Platform is reachable over UDP.

- **Run script**—response rules for automatically running a script. For example, you can create a script containing commands to be executed on the OSMP server when selected events are detected.

  The script file is stored on the server where the correlator service using the response resource is installed: /opt/kaspersky/kuma/correlator/<Correlator ID>/scripts.

  The `kuma` user of this server requires the permissions to run the script.

  Response settings

  - **Timeout**—the number of seconds the system will wait before running the script.
  - **Script name** (required)—the name of the script file.

    If the script Response resource is linked to the Correlator service, but the is no script file in the /opt/kaspersky/kuma/correlator/<Correlator ID>/scripts directory, the service will not start.

  - **Script arguments**—parameters or event field values that must be passed to the script.

    If the script includes actions taken on files, you should specify the absolute path to these files.

    Parameters can be written with quotation marks (").

    Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field which value must be passed to the script.

    Example: `-n "\"usr\": {{.SourceUserName}}"`

- **KEDR response**—response rules for automatically creating prevention rules, starting network isolation, or starting the application on Kaspersky Endpoint Detection and Response and Kaspersky Security Center assets.

  Automatic response actions are carried out when OSMP is integrated with Kaspersky Endpoint Detection and Response.

Response settings

- **Event field** (required)—event field containing the asset for which the response actions are needed. Possible values:
  - SourceAssetID
  - DestinationAssetID
  - DeviceAssetID
- **Task type**—response action to be performed when data matching the filter is received. The following types of response actions are available:
  - Enable network isolation.

    When selecting this type of response, you need to define values for the following settings:

    - **Isolation timeout**—the number of hours during which the network isolation of an asset will be active. You can indicate from 1 to 9,999 hours.

      If necessary, you can **add an exclusion for network isolation**.

      To add an exclusion for network isolation:

      a. Click the **Add exclusion** button.

      b. Select the direction of network traffic that must not be blocked:

      - Inbound.
      - Outbound.
      - Inbound/Outbound.

      c. In the **Asset IP** field, enter the IP address of the asset whose network traffic must not be blocked.

      d. If you selected **Inbound** or **Outbound**, specify the connection ports in the **Remote ports** and **Local ports** fields.

      e. If you want to add more than one exclusion, click **Add exclusion** and repeat the steps to fill in the **Traffic direction**, **Asset IP**, **Remote ports** and **Local ports** fields.

      f. If you want to delete an exclusion, click the **Delete** button under the relevant exclusion.

      When adding exclusions to a network isolation rule, Kaspersky Endpoint Detection and Response may incorrectly display the port values in the rule details. This does not affect application performance. For more details on viewing a network isolation rule, please refer to the *Kaspersky Anti Targeted Attack Platform Help Guide*.
  - Disable network isolation.
  - Add prevention rule.

When selecting this type of response, you need to define values for the following settings:

- **Event fields to extract hash from**—event fields from which KUMA extracts SHA256 or MD5 hashes of the files that must be prevented from starting.

  The selected event fields and the values selected in the **Event field** must be added to the inherited fields of the correlation rule.

- **File hash #1**—SHA256 or MD5 hash of the file to be blocked.

At least one of the above fields must be completed.

- Delete prevention rule.
- Start application

  When selecting this type of response, you need to define values for the following settings:

  - **File path**—path to the file of the process that you want to start.
  - **Command line parameters**—parameters with which you want to start the file.
  - **Working directory**—directory in which the file is located at the time of startup.

  When a response rule is triggered for users with the Main administrator role, the **Run program** task will be displayed in the **Task manager** section of the program web interface. **Scheduled task** is displayed for this task in the **Created** column of the task table. You can view task completion results.

  All of the listed operations can be performed on assets that have Kaspersky Endpoint Agent for Windows. On assets that have Kaspersky Endpoint Agent for Linux, the program can only be started.

  At the software level, the capability to create prevention rules and network isolation rules for assets with Kaspersky Endpoint Agent for Linux is unlimited. KUMA and Kaspersky Endpoint Detection and Response do not provide any notifications about unsuccessful application of these rules.

- **Response via KICS for Networks**—response rules for automatically starting tasks on KICS for Networks assets. For example, you can change the asset status in KICS for Networks.

  Tasks are automatically started when OSMP is integrated with KICS for Networks.

  Response settings

  - **Event field** (required)—event field containing the asset for which the response actions are needed. Possible values:
    - SourceAssetID
    - DestinationAssetID
    - DeviceAssetID

- **KICS for Networks task**—response action to be performed when data matching the filter is received. The following types of response actions are available:

  - **Change asset status to Authorized**.

  - **Change asset status to Unauthorized**.

  When a response rule is triggered, KUMA will send KICS for Networks an API request to change the status of the specified device to **Authorized** or **Unauthorized**.

- **Response via Active Directory**—response rules for changing the permissions of Active Directory users. For example, block a user.

  Tasks are started if integration with Active Directory is configured.

  Response settings

  - **Account ID source**—event field, source of the Active Directory account ID value. Possible values:

    - SourceAccountID

    - DestinationAccountID

  - **AD command**—command that is applied to the account when the response rule is triggered. Possible values:

    - Add account to group

    - Remove account from group

    - Reset account password

    - Block account

- In the **Workers** field, specify the number of processes that the service can run simultaneously.

  By default, the number of workers is the same as the number of virtual processors on the server where the service is installed.

  This field is optional.

1. In the **Filter** section, you can specify conditions to identify events that will be processed using the response rule. You can select an existing filter from the drop-down list or create a new filter.

   Creating a filter in resources

   All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

   To create a filter:

   1. In the **Filter** drop-down list, select **Create new**.

   2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.

3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.

4. Under **Conditions**, specify the conditions that the events must meet:

   a. Click the **Add condition** button.

   b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.

   c. In the **Operator** drop-down list, select an operator.

   Filter operators

   - **=** means the left operand equals the right operand.
   - **<** means the left operand is less than the right operand.
   - **<=** means the left operand is less than or equal to the right operand.
   - **>** means the left operand is greater than the right operand.
   - **>=** means the left operand is greater than or equal to the right operand.
   - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
   - **contains** means the left operand contains values of the right operand.
   - **startsWith** means the left operand starts with one of the values of the right operand.
   - **endsWith** means the left operand ends with one of the values of the right operand.
   - **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
   - **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

     The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

     If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
   - **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

     If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.
   - The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
   - **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.

- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.
- **inContextTable** checks for the presence of the entry in the specified context table.
- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.
6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

The new response rule was added to the resource set for the correlator.

Proceed to the next step of the Installation Wizard.

Step 6. Routing

This is an optional step of the Installation Wizard. On the **Routing** tab of the Installation Wizard, you can select or create destinations with settings indicating the forwarding destination of events created by the correlator. Events from a correlator are usually redirected to storage so that they can be saved and later viewed if necessary. Events can be sent to other locations as needed. There can be more than one destination point.

To add an existing destination to a resource set for a correlator:

1. In the **Add destination** drop-down list, select the type of destination resource you want to add:
   - Select **Storage** if you want to configure forwarding of processed events to the storage.
   - Select **Correlator** if you want to configure forwarding of processed events to a correlator.
   - Select **Other** if you want to send events to other locations.

   This type of resource includes correlator and storage services that were created in previous versions of the program.

The **Add destination** window opens where you can specify parameters for events forwarding.

2. In the **Destination** drop-down list, select the necessary destination.

   The window name changes to **Edit destination**, and it displays the settings of the selected resource. The resource can be opened for editing in a new browser tab using the button.

3. Click **Save**.

The selected destination is displayed on the Installation Wizard tab. A destination resource can be removed from the resource set by selecting it and clicking **Delete** in the opened window.

To add a new destination to a resource set for a correlator:

1. In the **Add destination** drop-down list, select the type of destination resource you want to add:

   - Select **Storage** if you want to configure forwarding of processed events to the storage.
   - Select **Correlator** if you want to configure forwarding of processed events to a correlator.
   - Select **Other** if you want to send events to other locations.

     This type of resource includes correlator and storage services that were created in previous versions of the program.

   The **Add destination** window opens where you can specify parameters for events forwarding.

2. Specify the settings on the **Basic settings** tab:

   - In the **Destination** drop-down list, select **Create new**.
   - In the **Name** field, enter a unique name for the destination resource. The name must contain 1 to 128 Unicode characters.
   - Use the **Disabled** toggle button to specify whether events will be sent to this destination. By default, sending events is enabled.
   - Select the **Type** for the destination resource:
     - Select **storage** if you want to configure forwarding of processed events to the storage.
     - Select **correlator** if you want to configure forwarding of processed events to a correlator.
     - Select **nats-jetstream**, **tcp**, **http**, **kafka**, or **file** if you want to configure sending events to other locations.
   - Specify the **URL** to which events should be sent in the hostname:<API port> format.

     You can specify multiple destination addresses by clicking the **URL** button for all types except **nats-jetstream** and **file**.
   - For the **nats-jetstream** and **kafka** types, use the **Topic** field to specify which topic the data should be written to. The topic must contain Unicode characters. The Kafka topic is limited to 255 characters.

3. If necessary, specify the settings on the **Advanced settings** tab. The available settings vary based on the selected destination resource type:

   - **Compression** is a drop-down list where you can enable Snappy compression. By default, compression is **disabled**.
   - **Proxy** is a drop-down list for proxy server selection.
   - The **Buffer size** field is used to set buffer size (in bytes) for the destination. The default value is 1 MB, and the maximum value is 64 MB.
   - **Timeout** field is used to set the timeout (in seconds) for another service or component response. The default value is `30`.
   - **Disk buffer size limit** field is used to specify the size of the disk buffer in bytes. The default size is 10 GB.
   - **Cluster ID** is the ID of the NATS cluster.
   - **TLS mode** is a drop-down list where you can specify the conditions for using TLS encryption:
     - **Disabled** (default)—do not use TLS encryption.
     - **Enabled**—encryption is enabled, but without verification.
     - **With verification**—use encryption with verification that the certificate was signed with the KUMA root certificate. The root certificate and key of KUMA are created automatically during program installation and are stored on the KUMA Core server in the folder /opt/kaspersky/kuma/core/certificates/.

     When using TLS, it is impossible to specify an IP address as a URL.
   - **URL selection policy** is a drop-down list in which you can select a method for determining which URL to send events to if several URLs have been specified:
     - **Any**. Events are sent to one of the available URLs as long as this URL receives events. If the connection is broken (for example, the receiving node is disconnected) a different URL will be selected as the events destination.
     - **Prefer first**. Events are sent to the first URL in the list of added addresses. If it becomes unavailable, events are sent to the next available node in sequence. When the first URL becomes available again, events start to be sent to it again.
     - **Balanced** means that packages with events are evenly distributed among the available URLs from the list. Because packets are sent either on a destination buffer overflow or on the flush timer, this URL selection policy does not guarantee an equal distribution of events to destinations.
   - **Delimiter** is used to specify the character delimiting the events. By default, `\n` is used.
   - **Path**—the file path if the **file** destination type is selected.
   - **Buffer flush interval**—this field is used to set the time interval (in seconds) at which the data is sent to the destination. The default value is `100`.
   - **Workers**—this field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.

- You can set health checks using the **Health check path** and **Health check timeout** fields. You can also disable health checks by selecting the **Health Check Disabled** check box.

- **Debug**—a toggle switch that lets you specify whether resource logging must be enabled. By default, this toggle switch is in the **Disabled** position.

- The **Disk buffer disabled** drop-down list is used to enable or disable the use of a disk buffer. By default, the disk buffer is disabled.

- In the **Filter** section, you can specify the conditions to define events that will be processed by this resource. You can select an existing filter from the drop-down list or create a new filter.

  Creating a filter in resources

  All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

  To create a filter:

  1. In the **Filter** drop-down list, select **Create new**.

  2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.

  3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.

  4. Under **Conditions**, specify the conditions that the events must meet:

     a. Click the **Add condition** button.

     b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.

     c. In the **Operator** drop-down list, select an operator.

        Filter operators

        - **=** means the left operand equals the right operand.
        - **<** means the left operand is less than the right operand.
        - **<=** means the left operand is less than or equal to the right operand.
        - **>** means the left operand is greater than the right operand.
        - **>=** means the left operand is greater than or equal to the right operand.
        - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
        - **contains** means the left operand contains values of the right operand.
        - **startsWith** means the left operand starts with one of the values of the right operand.

- **endsWith** means the left operand ends with one of the values of the right operand.
- **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
- **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

  The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

  If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.
- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.
- **inContextTable** checks for the presence of the entry in the specified context table.
- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.
6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

4. Click **Save**.

The created destination is displayed on the Installation Wizard tab. A destination resource can be removed from the resource set by selecting it and clicking **Delete** in the opened window.

Proceed to the next step of the Installation Wizard.

Step 7. Setup validation

This is the required, final step of the Installation Wizard. At this step, OSMP creates a service resource set, and the Services are created automatically based on this set:

- The set of resources for the correlator is displayed under **Resources** → **Correlators**. It can be used to create new correlator services. When this set of resources changes, all services that operate based on this set of resources will start using the new parameters after the services restart. To do so, you can click the **Save and restart services** and **Save and update service configurations** buttons.

  A resource set can be modified, copied, moved from one folder to another, deleted, imported, and exported, like other resources.

- Services are displayed in **Resources** → **Active services**. The services created using the Installation Wizard perform functions inside OSMP. To communicate with external parts of the network infrastructure, you need to install similar external services on the servers and assets intended for them. For example, an external correlator service should be installed on a server intended to process events, external storage services should be installed on servers with a deployed ClickHouse service, and external agent services should be installed on Windows assets that must both receive and forward Windows events.

To finish the Installation Wizard:

1. Click **Create and save service**.

   The **Setup validation** tab of the Installation Wizard displays a table of services created based on the set of resources selected in the Installation Wizard. The lower part of the window shows examples of commands that you must use to install external equivalents of these services on their intended servers and assets.

   For example:

   ```
   /opt/kaspersky/kuma/kuma correlator --core <FQDN>:<port> --pair.fingerprint <fingerprint ID of the KUMA Core CA certificate> --id <service ID> --api.port <API port> --install
   ```

   where:

   - <FQDN> is full qualified domain name of KUMA Core server.
   - <port> is the port used for communication with the KUMA Core.
   - <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

     The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

     You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.

- <service ID> is the identifier of a KUMA service copied from the web-interface.
- <API port> is the port used for communication with the installed component.

> The "kuma" file can be found inside the installer in the /kuma-ansible-installer/roles/kuma/files/ directory.

The port for communication with the KUMA Core, the service ID, the fingerprint ID of the KUMA Core CA certificate, and the port for communication with the service are added to the command automatically. You must also ensure the network connectivity of OSMP and open the ports used by its components, if necessary.

2. Close the Wizard by clicking **Save**.

The correlator service is created in OSMP. Now the equivalent service must be installed on the server intended for processing events.

Installing a correlator in OSMP network infrastructure

A correlator consists of two parts: one part is created inside OSMP, and the other part is installed on the network infrastructure server intended for processing events. The second part of the correlator is installed in the network infrastructure.

To install a correlator:

1. Log in to the server where you want to install the service.
2. Create the /opt/kaspersky/kuma/ folder.
3. Copy the "kuma" file to the /opt/kaspersky/kuma/ folder. The file is located in the installer in the /kuma-ansible-installer/roles/kuma/files/ folder.

> Make sure the kuma file has sufficient rights to run.

4. Execute the following command:

```
sudo /opt/kaspersky/kuma/kuma correlator --core https://<FQDN>:<port> --pair.fingerprint <fingerprint ID of the KUMA Core CA certificate> --id <service ID> --api.port <API port> --install
```

where:

- <FQDN> is full qualified domain name of KUMA Core server.
- <port> is the port that the KUMA Core uses for internal communications (port 7210 is used by default).
- <fingerprint ID of the KUMA Core CA certificate> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

The `--pair.fingerprint` argument is optional. When creating a service, OSMP automatically adds this option to the installation command and specifies the fingerprint ID.

You can install a service without specifying the `--pair.fingerprint` option. In this case, OSMP uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If the value is `insecure`, the fingerprint does not need to be renewed after reissuing the CA certificate.

To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. When reissuing a CA certificate, you need to copy the new certificate fingerprint from the web interface and restart the service with the updated fingerprint ID.

- <service ID> is the identifier of a KUMA service copied from the web-interface.
- <API port> is the port used for communication with the installed component.

Example:

```
sudo /opt/kaspersky/kuma/kuma correlator --core https://kuma.example.com:7210 --pair.fingerprint XXXX --id XXXX
--api.port YYYY --install
```

You can copy the correlator installation command at the last step of the Installation Wizard. It automatically specifies the address and port of the KUMA Core server, the identifier of the correlator to be installed, and the port that the correlator uses for communication. Before installation, ensure the network connectivity of KUMA components.

When deploying several KUMA services on the same host, during the installation process you must specify unique ports for each component using the `--api.port <port>` parameter. The following setting values are used by default: `--api.port 7221`.

The correlator is installed. You can use it to analyze events for threats.

Validating correlator installation

To verify that the correlator is ready to receive events:

1. In OSMP, go to the **Resources and services** → **Active services** section.
2. Make sure that the correlator you installed has the green status.

If the events that are fed into the correlator contain events that meet the correlation rule filter conditions, the events tab will show events with the `DeviceVendor=Kaspersky` and `DeviceProduct=KUMA` parameters. The name of the triggered correlation rule will be displayed as the name of these correlation events.

If no correlation events are found

You can create a simpler version of your correlation rule to find possible errors. Use a **simple** correlation rule and a single **Output** action. It is recommended to create a filter to find events that are regularly received by OSMP.

When updating, adding, or removing a correlation rule, you must update configuration of the correlator.

When you finish testing your correlation rules, you must remove all testing and temporary correlation rules from OSMP and update configuration of the correlator.

Creating a correlator-ng correlator

The correlator-ng correlator is an OSMP component for correlating and processing events from various sources. It allows filtering, combining, and analyzing events using correlation rules, selectors, and expressions.

The current version of Kaspersky EDR Expert includes a beta version of correlator-ng, which is intended for test-driving. Methods, algorithms, syntax of conditions, and other functions and characteristics may change before the release of the fully functional version of the correlator API.

In the current version, the correlator can only be managed using the YAML configuration. After initially getting a configuration from the KUMA Core, you make further changes to the settings in files; you cannot use the OSMP web interface to manage this correlator.

Correlator-ng is not a drop-in replacement for the standard model of the correlator.

The main differences are:

- New syntax for rules and selectors, compatible with SQL-like expressions and functions.
- Support for join selectors: events from different selectors are compared in parallel in the order in which they are received.
- The `anyMatch` attribute can be used to trigger a correlation rule if at least one selector has reached its threshold value.
- Extended set of functions for working with data types, arrays, strings, timestamps, and CyberTrace fields.
- Stricter typing of expressions and automatic casting of field and variable values to the required type for correct handling of operations.
- The regular expression syntax has been changed: correlator-ng uses PCRE-like syntax, whereas the standard correlator model uses RE2.

Limitations of correlator-ng

The current implementation of correlator-ng has a number of limitations:

- The correlator cannot automatically classify assets based on incoming events and does not support actions that are usually performed when a response rule is triggered.
- The correlator cannot automatically enrich events with additional data from external sources, such as DNS queries, scripts for calculations and checks, or the CyberTrace system.
- Destinations of the **storage**, **correlator**, and **internal** types are supported only if they do not have a disk buffer.
- The `S.KL_EventRoute` field is not added to the correlation event.
- The correlator cannot enrich a correlation event with the following additional fields: `SourceAssetKSCInstanceID`, `SourceAssetKSCHostID`, `DestinationAssetKSCInstanceID`, `DestinationAssetKSCHostID`, `DeviceAssetKSCInstanceID`, `DeviceAssetKSCHostIDKSC`, `S.KL_SourceAccountDisplayName`, `S.KL_DestinationAccountDisplayName`.
- Templates are partially supported: some templates may not be processed, and functions of the `to_string` type may not work in some cases.
- A limited number of metrics is available.
- The `debug` parameter does not change the logging level.
- Bucket content can only be exported in JSON format. Importing and searching the contents of buckets is not available.
- The collection and analysis of correlator statistics for performance optimization is not supported.
- Regular expressions do not support constructs such as `(?=...)` and `(?<=...)`.
- Links to active lists, context tables, dictionaries, and asset categories must use unique IDs instead of names.

Configuring the correlator correlator-ng

The current version of Kaspersky EDR Expert includes a beta version of correlator-ng, which is intended for test-driving. Methods, algorithms, syntax of conditions, and other functions and characteristics may change before the release of the fully functional version of the correlator API.

Correlator-ng is deployed as a separate KUMA service. Its settings are defined by YAML configuration files and command line options of the process. After starting, the service establishes a connection with the KUMA Core, receives the configuration of rules and buckets, and proceeds to processing events.

Correlator-ng can be managed using a set of YAML files. Each file is described below.

File	Description
config.yaml	Contains basic information about the service, including the name, description, and general settings of the correlator.
correlation-rules.yaml	Contains the configuration of correlation rules, including the types of rules: standard, simple, operational, and periodical.
selector-includes.yaml	Contains nested filters that are linked to correlation rules for reusability.
active-lists.yaml	Contains the configuration of active lists.
context-tables.yaml	Contains the configuration of context tables.
dictionaries.yaml	Contains static dictionaries for use in selectors and correlation rules.
global-variables.yaml	Contains global variables available in correlation rules and selectors.
destinations.yaml	Contains event destinations (`storage`, `correlator`, `internal`) with IDs and sending settings.

The files are loaded at correlator startup in the following order: first config.yaml, then files with rules and selectors, then files with active lists, context tables, dictionaries, and global variables. The destination file is loaded last to ensure that events are routed correctly.

Systemd-unit and starting the correlator

The systemd unit file is used to start the correlator as a system service; this file defines the settings for starting, stopping and restarting correlator-ng.

Example configuration file:

```
[Unit]
Description=KUMA Correlator NG
StartLimitIntervalSec=1
After=network.target

[Service]
Type=simple
Restart=always
RestartPreventExitStatus=99
TimeoutSec=0
RestartSec=5

Environment="RUST_BACKTRACE=full"

User=kuma
Group=kuma

ExecStart=/opt/kuma correlator --id <correlator_service_ID> --core https://<FQDN_of_KUMA_Core>:7210 --wd
/opt/correlator-ng --api.port <API port of the correlator>
LimitFSIZE=infinity
LimitCPU=infinity
LimitAS=infinity
LimitNOFILE=500000
LimitNPROC=64000
LimitMEMLOCK=infinity
TasksMax=infinity
TasksAccounting=false

[Install]
WantedBy=multi-user.target
```

Correlator-ng logging

The `--logger.filter` option sets the logging level of correlator-ng. In this option, you can specify the same logging levels as in the standard `RUST_LOG` variable: `trace`, `debug`, `info`, `warn`, `error`.

Example:

```
--logger.filter debug
```

You can additionally use the `RUST_BACKTRACE` environment variable. Setting it to `full` enables the output of extended error information.

Supported data types in correlator-ng

The current version of Kaspersky EDR Expert includes a beta version of correlator-ng, which is intended for test-driving. Methods, algorithms, syntax of conditions, and other functions and characteristics may change before the release of the fully functional version of the correlator API.

Correlator-ng has a stricter data model compared to the standard version of the correlator. This affects correlation rules, selectors, and event processing functions. Each field of an event, variable, or selector now has a defined type. Automatic type casting is used only for compatible types; in other cases, the `to_string`, `to_integer`, and `to_float` conversion functions must be used.

The following data types are supported:

Supported data types

Data type	Description
String	String
VecString	Array of strings
I64	64-bit integer
VecI64	Array of 64-bit integers
F64	Float
VecF64	Array of floats
Timestamp	UNIX Timestamp (in milliseconds)
VecTimestamp	Array of UNIX Timestamps (in milliseconds)
Uuid	Unique ID in the UUIDv4 format
VecUuid	Array of UUIDv4 values
Ip	IPv4 or IPv6 address
VecIp	Array of IP addresses
IpNet	Subnet with a CIDR prefix, for example, `192.168.1.0/24`.
VecIpNet	Array of subnets
Bool	Boolean value (`true` or `false`)
VecBool	Array of boolean values.

Stronger typing improves the efficiency of the correlator and reduces errors when compiling correlation rules. However, all operations with arrays, strings and timestamps must now take into account the data type, otherwise runtime errors can occur.

Correlation rule selectors and expressions

The current version of Kaspersky EDR Expert includes a beta version of correlator-ng, which is intended for test-driving. Methods, algorithms, syntax of conditions, and other functions and characteristics may change before the release of the fully functional version of the correlator API.

In correlator-ng, selectors can do all that variables can, and can use functions for working with strings, arrays, and numbers (for example, `substring`, `tr`, `to_lower`). It is not necessary to create a separate variable to use functions; the selectors themselves can use these functions.

Selectors are described using the SQL syntax applicable to `WHERE` clauses.

Selectors and variables are configured using expressions for filtering and merging events. They support the same operations as variables, with the ability to construct sophisticated conditions. The following expression types are available.

When writing expressions for comparing values that involve constants, the constant must go on the right. This lets the correlator apply various optimizations. If the constant is in the left part, no optimization is done.

Constants

Constants

Constant	Type
`1`	I64 (integer)
`3.14`	F64 (float)
`'myString'`	String

References to values

References to values

Reference	Description
`DeviceVendor`	Value of `DeviceVendor` event field
`S.MyCustomField`	Value of `S.MyCustomField` composite field
`$myVariable`	Value of `myVariable` variable

Logical and group operators

Logical and group operators

Expression	Description
`<expression> AND <expression>`	Logical AND operator
`<expression> OR <expression>`	Logical OR operator
`NOT <expression>`	Negation of the result of an expression

Expression	Description
`IS [NOT] NULL`	Checking for the absence of a value (in correlator-ng, an unset value is `NULL`)
`()`	Grouping expressions

Comparison operators

Comparison operators

Expression	Description
`<expression> = <expression>`	Checks for equality of values
`<expression> > <expression>`	Compares values using the `>` operator
`<expression> >= <expression>`	Compares values using the `>=` operator
`<expression> < <expression>`	Compares values using the `<` operator
`<expression> <= <expression>`	Compares values using the `<=` operator
`Type BETWEEN 1 AND 3`	Checks if the value of the `Type` field is between 1 and 3 inclusive

Arithmetic operators

Arithmetic operators

Expression	Description
`<expression> + <expression>`	Addition
`<expression> - <expression>`	Subtraction
`<expression> * <expression>`	Multiplication
`<expression> / <expression>`	Division
`<expression> % <expression>`	Modulo division

Features

Features

Function	Description
`eq_fold (<left operand expression>, <right operand expression>)`	Calls the `eq_fold` function.

For details about the available functions, see the Data processing functions in correlator-ng section.

Attributes of the 'standard' correlation rule

The current version of Kaspersky EDR Expert includes a beta version of correlator-ng, which is intended for test-driving. Methods, algorithms, syntax of conditions, and other functions and characteristics may change before the release of the fully functional version of the correlator API.

The **standard** correlation rule in correlator-ng supports additional attributes that allow modifying the conditions of a Full Match and specify the matching of events between selectors. These attributes extend the standard operation model of the correlation rule bucket and are applied at the stage when events are analyzed that have already been placed in the bucket.

The current implementation of correlator-ng supports two attributes:

- `anyMatch`
- `joinSelector`

Both attributes are applicable only to correlation rules of the **standard** type and are used directly in the configuration of the rule itself.

The anyMatch attribute

In the standard model of the correlator, the correlation rule is considered fulfilled when the bucket reaches the Full Match state, that is, when all selectors have accumulated the number of events equal to their threshold values.

If `anyMatch: true` is specified in the configuration of the correlation rule, the bucket reaches the Full Match state when any of the selectors of the rule (except for selectors of the **recovery** type) reaches its threshold value. Thus, the rule is triggered by the first fulfilled condition, without waiting for other selectors to accumulate events. Each selector continues to independently accumulate events in accordance with its configuration, however, correlation finishes immediately after one of the selectors reaches its threshold.

The correlation event generated by such a rule additionally contains the `$KL_selectorName` local variable. The value of this variable is equal to the tag of the selector whose threshold triggered the rule. This allows identifying the source of the triggering and applying various further processing steps to the result.

> A rule with the `anyMatch` attribute does not support a trigger of the **On timeout** type.

The JoinSelector attribute

In the standard model of the correlator, the correlation rule is considered fulfilled when the bucket reaches the Full Match state, that is, when all selectors have accumulated the number of events equal to their threshold values.

If `anyMatch: true` is specified in the configuration of the correlation rule, the bucket reaches the Full Match state when any of the selectors of the rule (except for selectors of the **recovery** type) reaches its threshold value. Thus, the rule is triggered by the first fulfilled condition, without waiting for other selectors to accumulate events. Each selector continues to independently accumulate events in accordance with its configuration, however, correlation finishes immediately after one of the selectors reaches its threshold.

The correlation event generated by such a rule additionally contains the `$KL_selectorName` local variable. The value of this variable is equal to the tag of the selector whose threshold triggered the rule. This allows identifying the source of the triggering and applying various further processing steps to the result.

> A rule with the `anyMatch` attribute does not support a trigger of the **On timeout** type.

The JoinSelector attribute

The `joinSelector` attribute allows additionally checking the relatedness of events accumulated by different selectors within the same bucket before it reaches the Full Match state.

The value of the attribute is an SQL-like expression, `joinSelector: < expression >`

The expression specifies the condition for comparing the events of different selectors. It must be a binary operation or function that accepts as its operands only constants and expressions of the form `with_selector('<selector_tag>', <expression>)`.

The `with_selector` function indicates that the expression is evaluated against the events of a particular selector.

When parsing the configuration, the correlator automatically determines the minimum threshold value of the selector among the selectors participating in the expression. The comparison is performed only for the number of events that is equal to this minimum value.

For example:

The selector threshold (number of events) for selector A is 5, and for selector B, it is 9. In the expression `with_selector('A', DeviceHostName) = with_selector('B', DeviceHostName)`, only the first five events of each selector are compared.

Events are compared in parallel in the order of their arrival: the first event of selector A is compared with the first event of selector B; the second with the second, and so on.

The `joinSelector` attribute can also use functions. For example: `joinSelector: contains_fold(with_selector('A', $var_A), with_selector('B', DeviceCustomString1))`

This example uses the `contains_fold` function, which checks for the presence of the value of the `$var_A` correlator variable, calculated for selector A, in the `DeviceCustomString1` field of events of selector B, case-insensitive.

The following functions are not supported in expressions of the `joinSelector` attribute:

- `has_ti_detect`
- `has_ti_detect_with_category`
- `has_ti_detect_with_indicator`
- `has_ti_detect_with_category_and_indicator`

Data functions in correlator-ng

> The current version of Kaspersky EDR Expert includes a beta version of correlator-ng, which is intended for test-driving. Methods, algorithms, syntax of conditions, and other functions and characteristics may change before the release of the fully functional version of the correlator API.

Functions in correlator-ng are used in selectors and variables for working with event data, type casting, and filtering.

General syntax:

- Required arguments are enclosed in `< >`, optional arguments are enclosed in `[ ]`.
- Three dots `...` stand for an indefinite number of arguments.

- The return type is denoted by `-> <data type>`. The letter `T` indicates that the type depends on the type of the arguments.
- The type of the arguments can be concrete (for example, `String`, `I64`) or `T`, which stands for any available data type.

Type casting functions

These functions cast a value to a certain type.

Type casting functions

Function	Description
`to_string(< expression >)`	Casts the value to string.
`to_integer(< expression >)`	Casts the value to integer (I64).
`to_float(< expression >)`	Casts the value to float (F64).
`to_uuid(< expression >)`	Casts the value to UUIDv4.
`to_ip(< expression >)`	Casts the value to IPv4 or IPv6 address.
`to_ip_net(< expression >)`	Casts the value to an IPNet subnet.
`to_bool(< expression >)`	Casts the value to boolean.
`to_timestamp(< expression >, '[ timezone ]')`	Casts the value to a timestamp with an optional timezone.

Functions for comparing values

Functions for comparing values

Function	Description
`eq_fold(< left_operand >, < right_operand >) -> Bool`	Checks if the left-side value is the same as the right-side value, ignoring case.
`eq_any(< left_operand >, < right_operand 1>, [...]) -> Bool`	Checks if one of the right-side values is the same as the left-side value.
`eq_any_fold(< left_operand >, < right_operand >, [...]) -> Bool`	Compares the left-side value with multiple right-side values, ignoring case.
`contains(< left_operand >, < right_operand >) -> Bool`	Checks if the left-side value contains the right-side value.
`contains_fold(< left_operand >, < right_operand >) -> Bool`	Checks if the left-side value contains the right-side value, ignoring case.
`contains_any(< left_operand >, < right_operand 1>, [...]) -> Bool`	Checks if the left-side value contains any of the right-side values.
`contains_any_fold(< left_operand >, < right_operand >, [...]) -> Bool`	Checks if the left-side value contains any of the right-side values, ignoring case.
`starts_with(< left_operand >, < right_operand >) -> Bool`	Checks if the right-side value is a prefix of the left-side value.
`starts_with_fold(< left_operand >, < right_operand >) -> Bool`	Checks the prefix, case-insensitive.
`starts_with_any(< left_operand >, < right_operand 1>, [...]) -> Bool`	Checks if one of the right-side values is a prefix of the left-side value.
`starts_with_any_fold(< left_operand >, < right_operand 1>, [...]) -> Bool`	Checks the prefix for one of the right-side values, case-insensitive.
`ends_with(< left_operand >, < right_operand >) -> Bool`	Checks if the right-side value is a suffix of the left-side value.
`ends_with_fold(< left_operand >, < right_operand >) -> Bool`	Checks the suffix, case-insensitive.

Function	Description
`ends_with_any(< left_operand >, < right_operand 1>, [...]) -> Bool`	Checks if one of the right-side values is a suffix of the left-side value.
`ends_with_any_fold(< left_operand >, < right_operand 1>, [...]) -> Bool`	Checks the suffix, case-insensitive.
`match(< left_operand >, < right_operand >) -> Bool`	Checks if the left-side value matches the regular expression on the right side.
`match_any(< left_operand >, '< right_operand 1>', '[ right_operand 2]', [...]) -> Bool`	Checks if the left-side value matches one of the regular expressions on the right side.

Functions for working with active lists, dictionaries, and context tables

Functions for working with active lists, dictionaries, and context tables

Function	Description
`in_active_list('< active_list_ID >', < key_element 1>, [...]) -> Bool`	Checks for the presence of a value in the active list by key.
`in_context_table('< context_table_ID >', '< key_field_name 1>', < key_field_value 1>, '[ key_field_name 2]', [ key_field_value 2], [...]) -> Bool`	Checks for the presence of a value in the context table by key.
`in_dictionary('< dictionary_ID >', < key_element 1>, [ key_element 2], ...) -> Bool`	Checks for the presence of a value in the dictionary by key.
`dict('< dictionary_ID >', < key 1>, [...]) -> String`	Returns a value from a dictionary by key.
`table_dict('< dictionary_ID >', < column_name >, < key 1>, [...]) -> String`	Returns a value from a table dictionary.
`active_list('< active_list_ID >', < field_name >, < key 1>, [...]) -> String`	Returns a value from an active list.
`context_table('< context_table_ID >', '< field_name >', '< key_field >', < value >) -> T`	Returns the value of a field from the context table.
`context_table_list_item('< context_table_ID >', '< field_name >', < index >, ...) -> T`	Returns an array element from a context table.
`match_active_list(...)`	Returns a value from an active list if the key matches a regular expression.
`match_context_table(...)`	Returns a value from a context table if a regular expression is matched.
`match_dictionary(...)`	Returns a value from a dictionary if a regular expression is matched.

Subnet functions

Subnet functions

Function	Description
`in_subnet(< left_operand >, < subnet >) -> Bool`	Checks if an IP address belongs to a subnet.
`in_subnet_any(< left_operand >, < subnet 1>, [...]) -> Bool`	Checks if an IP address belongs to one of the subnets.
`in_subnet_active_list(...)`	Checks if an IP address belongs to a subnet from an active list.
`in_subnet_context_table(...)`	Checks if an IP address belongs to a subnet from a context table.
`in_subnet_dictionary(...)`	Checks if an IP address belongs to a subnet from a dictionary.

String functions

String functions

Function	Description
`to_lower(< operand >) -> String`	Converts the string to lower case.
`to_upper(< operand >) -> String`	Converts the string to upper case.
`substring(< string >, < beginning_of_substring >, [ end_of_substring ]) -> String`	Returns a substring.
`index_of(< find_what >, < find_where >) -> I64`	Returns the position of the first occurrence.
`last_index_of(< find_what >, < find_where >) -> I64`	Returns the position of the last occurrence.
`tr(< operand >) -> String`	Trims whitespace at the beginning and end of a string.
`replace(< string >, < substring >, < replacement >) -> String`	Replaces a substring.
`regexp_replace(< string >, '< regular_expression >', '< replacement >') -> String`	Replaces a substring using a regular expression.
`regexp_capture(< string >, '< regular_expression >') -> String`	Gets a substring matching a regular expression.
`str_join('< separator >', < string 1>, [...]) -> String`	Joins multiple strings.

Array functions

Array functions

Function	Description
`append(< left operand >, < right operand >, '[ separator ]') -> T`	Adds a value to the end of an array or string.
`prepend(< left operand >, < right operand >, '[ separator ]') -> T`	Adds a value to the beginning of an array or string.
`len(< operand >) -> I64`	Returns the length of a string or array.
`item(< array >, < index >) -> T`	Returns an element of an array by index.
`distinct_items(< array >) -> T`	Removes duplicate elements from an array.
`sort_items(< array >, '< sorting_order >') -> T`	Sorts an array.

Timestamp functions

Timestamp functions

Function	Description
`now() -> Timestamp`	Returns the current timestamp.
`year(<timestamp>) -> I64`	Returns the year.
`month(<timestamp>) -> I64`	Returns the month number.
`month_str(<timestamp>) -> String`	Returns the month in string form.
`weekday(<timestamp>) -> I64`	Returns the number of the day of the week.
`weekday_str(<timestamp>) -> String`	Returns the day of the week in string form.
`day(<timestamp>) -> I64`	Returns the day of the month.
`hour(<timestamp>) -> I64`	Returns the hour.
`minute(<timestamp>) -> I64`	Returns the minute.
`second(<timestamp>) -> I64`	Returns the second.

Function	Description
`millisecond(<timestamp>) -> I64`	Returns the millisecond.
`format_timestamp(<timestamp>, '< format >') -> String`	Converts the timestamp to a string.
`truncate_timestamp(<timestamp>, '< duration >') -> Timestamp`	Rounds the timestamp to an integer value.

Time functions

Time functions

Function	Description
`duration_days(<t1>, <t2>) -> I64`	Returns the difference in days.
`duration_hours(<t1>, <t2>) -> I64`	Returns the difference in hours.
`duration_minutes(<t1>, <t2>) -> I64`	Returns the difference in minutes.
`duration_seconds(<t1>, <t2>) -> I64`	Returns the difference in seconds.
`duration_milliseconds(<t1>, <t2>) -> I64`	Returns the difference in milliseconds.

Mathematical functions

Mathematical functions

Function	Description
`round(< operand >) -> I64`	Rounds the value to the nearest integer.
`ceil(< operand >) -> I64`	Rounds the value up.
`floor(< operand >) -> I64`	Rounds the value down.
`abs(< operand >) -> T`	Returns the absolute value of a number.
`pow(< operand >, '< power >') -> T`	Raises a number to a power.
`math_min(< array >) -> T`	Returns the minimum element of an array.
`math_max(< array >) -> T`	Returns the maximum element of an array
`math_avg(< array >) -> F64`	Calculates the average value of an array.

Data decoding and analysis functions

Data decoding and analysis functions

Function	Description
`decode_hex_integer(< string >) -> I64`	Converts a hex string to a number.
`decode_hex(< string >) -> String`	Decodes a hex string.
`decode_base64(< string >) -> String`	Decodes a Base64 string.
`decode_url(< string >) -> String`	Decodes a URL-encoded string.
`entropy(< string >) -> F64`	Calculates the Shannon entropy of a string.
`has_bit(< left_operand >, < position >) -> Bool`	Checks if the bit is set at the specified position.
`has_vulnerability(< asset_ID >, (<CVE>), [ severity ]) -> Bool`	Checks if an asset has a vulnerability.

Other functions

Other functions

Function	Description
`include('< predicate_ID >', '[ predicate_name ]')`	Uses predefined predicates from the selector-includes.yaml file.
`ti('< category >', < indicator >, '< field >')`	Retrieves a value from a specialized TI field (CyberTrace).
`with_selector(' correlation_rule_selector_tag ', < expression >)`	Can only be used in the `joinSelector` attribute of a correlation rule to distinguish between sets of events.
`template('< template >', [ argument 1], [ argument 2], ...) -> String`	Generates a string based on a template by interpolating the values of event fields or variables into it.
`conditional('< predicate >', <then>, <else>)`	Returns one of two values, depending on the result of the predicate
`has_ti_detect*()`	Checks for a CyberTrace triggering by category or indicator.
`has_ti_detect_with_category('< category >')`	Checks for a CyberTrace triggering by category.
`has_ti_detect_with_indicator(< indicator >)`	Checks for a CyberTrace triggering by indicator.
`has_ti_detect_with_category_and_indicator('< category >', < indicator >)`	Checks for a CyberTrace triggering by category and indicator.

Configuring event sources

This section provides information on configuring the receipt of events from various sources.

Configuring receipt of Auditd events

KUMA lets you monitor and audit the Auditd events on Linux devices.

Before configuring event receiving, make sure to create a new KUMA collector for the Auditd events.

Configuring the receipt of Auditd events involves the following steps:

1. Installing the KUMA collector in the network infrastructure.
2. Configuring the event source server.
3. Verifying receipt of Auditd events by the KUMA collector.

   You can verify that the Auditd event source server is configured correctly by searching for related events in the KUMA Console.

Installing KUMA collector for receiving Auditd events

After creating a collector, in order to configure event receiving using rsyslog, you must install a collector on the network infrastructure server intended for receiving events.

For details on installing the KUMA collector, refer to the Installing collector in the network infrastructure section.

Configuring the event source server

The rsyslog service is used to transmit events from the server to the KUMA collector.

To configure transmission of events from the server to the collector:

1. Make sure that the rsyslog service is installed on the event source server. To do it, run the command:

   ```
   systemctl status rsyslog.service
   ```

   If the rsyslog service is not installed on the server, install it by executing the following command:

   - for RPM-based distributions:

     ```
     yum install rsyslog
     ```

   - for Debian or Ubuntu-based distributions:

     ```
     apt-get install rsyslog
     ```

   Enable the service by executing the following command:

   ```
   systemctl enable rsyslog.service
   systemctl start rsyslog.service
   ```

2. In the /etc/rsyslog.d folder, create the audit.conf file with the following content:

   ```
   $ModLoad imfile
   $InputFileName /var/log/audit/audit.log
   $InputFileTag tag_audit_log:
   $InputFileStateFile audit_log
   $InputFileSeverity info
   $InputFileFacility local6
   $InputRunFileMonitor
   *.* @<KUMA collector IP address>:<KUMA collector port>
   ```

   > If you want to send events over TCP, instead of the last line in the file insert the following line:
   > `*.* @@<KUMA collector IP address>:<KUMA collector port>`.

3. Save the changes to the audit.conf file.

4. Restart the rsyslog service:

   ```
   systemctl restart rsyslog.service
   ```

The event source server is configured. Data about events is transmitted from the server to the KUMA collector.

Configuring receipt of KATA/EDR events

You can configure the receipt of Kaspersky Anti Targeted Attack Platform events in the KUMA SIEM system.

Before configuring event receipt, make sure to create a KUMA collector for the KATA/EDR events.

When creating a collector in the KUMA Console, make sure that the port number matches the port specified in step 4c of Configuring export of Kaspersky Anti Targeted Attack Platform events to KUMA, and that the connector type corresponds to the type specified in step 4d.

To receive Kaspersky Anti Targeted Attack Platform events using Syslog, in the collector Installation Wizard, at the **Event parsing** step, select the **[OOTB] KATA** normalizer.

Configuring the receipt of KATA/EDR events involves the following steps:

1. Configuring the forwarding of KATA/EDR events
2. Installing the KUMA collector in the network infrastructure
3. Verifying receipt of KATA/EDR events in the KUMA collector

   You can verify that the KATA/EDR event source server is configured correctly by searching for related events in the KUMA Console. Kaspersky Anti Targeted Attack Platform events are displayed as KATA in the table with search results.

Configuring export of KATA/EDR events to KUMA

To configure export of events from Kaspersky Anti Targeted Attack Platform to KUMA:

1. In a browser on any computer with access to the Central Node server, enter the IP address of the server hosting the Central Node component.

   A window for entering Kaspersky Anti Targeted Attack Platform user credentials opens.
2. In the user credentials entry window, select the **Local administrator** check box and enter the Administrator credentials.
3. Go to the **Settings** → **SIEM system** section.
4. Specify the following settings:
   a. Select the **Activity log** and **Detections** check boxes.
   b. In the **Host/IP** field, enter the IP address or host name of the KUMA collector.
   c. In the **Port** field, specify the port number to connect to the KUMA collector.
   d. In the **Protocol** field, select **TCP** or **UDP** from the list.
   e. In the **Host ID** field, specify the server host ID to be indicated in the SIEM systems log as a detection source.
   f. In the **Alert frequency** field, enter the interval for sending messages: from 1 to 59 minutes.
   g. Enable TLS encryption, if necessary.
   h. Click **Apply**.

Export of Kaspersky Anti Targeted Attack Platform events to KUMA is configured.

Creating KUMA collector for receiving KATA/EDR events

After configuring the event export settings, you must create a collector for Kaspersky Anti Targeted Attack Platform events in the KUMA Console.

For details on creating a KUMA collector, refer to Creating a collector.

When creating a collector in the KUMA Console, make sure that the port number matches the port specified in step 4c of Configuring export of Kaspersky Anti Targeted Attack Platform events to KUMA, and that the connector type corresponds to the type specified in step 4d.

To receive Kaspersky Anti Targeted Attack Platform events using Syslog, in the collector Installation Wizard, at the **Event parsing** step, select the **[OOTB] KATA** normalizer.

Installing KUMA collector for receiving KATA/EDR events

After creating a collector, to configure receiving Kaspersky Anti Targeted Attack Platform events, install a new collector on the network infrastructure server intended for receiving events.

For details on installing the KUMA collector, refer to the Installing collector in the network infrastructure section.

Integration with other solutions

In this section, you'll learn how to integrate KUMA with other solutions to enrich its functionality.

Integration with Kaspersky Security Center

You can create or edit Kaspersky Security Center integration settings in OSMP Console.

In OSMP Console, you can view the integration with selected Kaspersky Security Center Servers for one, several, or all KUMA tenants. If integration with Kaspersky Security Center is enabled, you can manually import assets, edit the automatic scheduled import interval, or temporarily disable scheduled import.

Configuring the data refresh interval for Kaspersky Security Center assets

KUMA imports the following device information received from Kaspersky Security Center Network Agents:

- Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
- Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset.

To configure the data refresh interval for asset data from Kaspersky Security Center:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant into which you want to import KSC assets information.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Assets settings**.
4. On the **KSC import** tab, make sure that the **State** toggle switch is turned on.
5. Specify intervals for automatic import of asset information and asset vulnerability information from Kaspersky Security Center:

   - Under **Hardware information**, in the **Import interval (hours)** field, enter the interval in hours for the automatic import of information about the basic attributes of assets. The default setting is 1 hour.
   - Under **Assets attributes**, in the **Import interval (hours)** field, enter the interval in hours for automatic import of information about other attributes of assets. The default setting is 12 hours.

     Importing the information about asset attributes (vulnerabilities, software, owners) may involve downloading a large amount of data, which may take a longer time to complete, we recommend setting a longer interval than for the hardware information import.
6. Click **Save**.

Kaspersky Security Center asset data update settings for the selected tenant are configured.

If the tenant you want is missing from the list of tenants, use the OSMP console to add it to the list of tenants.

Scheduled import of Kaspersky Security Center assets

To set up a schedule for importing Kaspersky Security Center assets:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.
2. Under **Integrations**, click **Kaspersky Security Center**.

   The **Kaspersky Security Center integration** window opens.

3. Select the tenant for which you want to schedule the import of Kaspersky Security Center assets.

   The **Kaspersky Security Center integration** window opens.

4. If necessary, clear the **Disabled** check box to enable integration with Kaspersky Security Center for the selected tenant. This check box is cleared by default.

   If you want to temporarily disable integration with Kaspersky Security Center for the selected tenant, select the **Disabled** check box. This turns off the scheduled import of Kaspersky Security Center assets.

5. In the **Data refresh interval** field, specify the time interval at which KUMA updates data on Kaspersky Security Center devices.

   The interval is specified in hours and must be an integer.

   The default time interval is 12 hours.

6. Click **Save**.

The specified settings for the scheduled import of Kaspersky Security Center assets for the selected tenant are applied.

Manual import of Kaspersky Security Center assets

KUMA imports the following device information received from Kaspersky Security Center Network Agents:

- Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
- Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

To manually import Kaspersky Security Center assets:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant into which you want to import KSC assets information.

   This opens the tenant properties window.

3. On the **Settings** tab, click **Assets settings**.
4. On the **KSC import** tab, make sure that the **State** toggle switch is turned on.
5. Specify intervals for automatic import of asset information and asset vulnerability information from Kaspersky Security Center:

   - To import information about the basic attributes of assets, under **Hardware information**, click the **Import** button.
   - To import information about other attributes of assets, under **Assets attributes**, click the **Import** button.

The *KSC assets import* task is created. Kaspersky Security Center assets for the specified tenant are imported regardless of the configured schedule.

Viewing the hierarchy of Kaspersky Security Center Servers

To view the hierarchy of Kaspersky Security Center Servers:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Integrations**, click **Kaspersky Security Center**.

   The **Kaspersky Security Center integration** window opens.

3. In the **Tenant** drop-down list, select the tenant for which you want to view the hierarchy.

   The **Connection parameters** window opens.

4. In the **Connection parameters** window, click **Load hierarchy**.

The hierarchy of Kaspersky Security Center Servers for the specified tenant is displayed in the **Connection parameters** window.

Importing events from the Kaspersky Security Center database

In KUMA, you can receive events from the Kaspersky Security Center SQL database. Events are received using the collector, which uses the following resources:

- Predefined connector: [OOTB] KSC MSSQL or [OOTB] KSC MySQL.
- Predefined [OOTB] KSC from SQL normalizer.

Configuring the import of events from Kaspersky Security Center involves the following steps:

1. Create a copy of the predefined connector.

   The settings of the predefined connector are not editable, therefore, to configure the connection to the database server, you must create a copy of the predefined connector.

2. Creating a collector:

   - In the web interface.
   - On the server.

To configure the import of events from Kaspersky Security Center:

1. Create a copy of the predefined connector corresponding to the type of database used by Kaspersky Security Center:

   a. In OSMP Console, in the **Monitoring** → **Resources** → **Connectors** section, find the relevant predefined connector in the folder hierarchy, select the check box next to that connector, and click **Duplicate**.

   b. This opens the **Create connector** window; in that window, on the **Basic settings** tab, in the **Default query** field, if necessary, replace the KAV database name with the name of the Kaspersky Security Center database you are using.

An example of a query to the Kaspersky Security Center SQL database

```
SELECT ev.event_id AS externalId, ev.severity AS severity, ev.task_display_name AS taskDisplayName,

    ev.product_name AS product_name, ev.product_version AS product_version,

     ev.event_type As deviceEventClassId, ev.event_type_display_name As event_subcode, ev.descr As
msg,

CASE

    WHEN ev.rise_time is not NULL THEN
DATEADD(hour,DATEDIFF(hour,GETUTCDATE(),GETDATE()),ev.rise_time )

      ELSE ev.rise_time

    END

  AS endTime,

  CASE

    WHEN ev.registration_time is not NULL

      THEN DATEADD(hour,DATEDIFF(hour,GETUTCDATE(),GETDATE()),ev.registration_time )

      ELSE ev.registration_time

    END

  AS kscRegistrationTime,

  cast(ev.par7 as varchar(4000)) as sourceUserName,

  hs.wstrWinName as dHost,

  hs.wstrWinDomain as strNtDom, serv.wstrWinName As kscName,

    CAST(hs.nlp / 256 / 256 / 256 % 256 AS VARCHAR) + '.' +

  CAST(hs.nlp / 256 / 256 % 256 AS VARCHAR) + '.' +

  CAST(hs.nlp / 256 % 256 AS VARCHAR) + '.' +

  CAST(hs.nlp % 256 AS VARCHAR) AS sourceAddress,

  serv.wstrWinDomain as kscNtDomain,

    CAST(serv.nlp / 256 / 256 / 256 % 256 AS VARCHAR) + '.' +

  CAST(serv.nlp / 256 / 256 % 256 AS VARCHAR) + '.' +

  CAST(serv.nlp / 256 % 256 AS VARCHAR) + '.' +

  CAST(serv.nlp % 256 AS VARCHAR) AS kscIP,
```

```
CASE
WHEN virus.tmVirusFoundTime is not NULL
    THEN DATEADD(hour,DATEDIFF(hour,GETUTCDATE(),GETDATE()),virus.tmVirusFoundTime )
    ELSE ev.registration_time
  END
AS virusTime,
virus.wstrObject As filePath,
virus.wstrVirusName as virusName,
virus.result_ev as result
FROM KAV.dbo.ev_event as ev
LEFT JOIN KAV.dbo.v_akpub_host as hs ON ev.nHostId = hs.nId
INNER JOIN KAV.dbo.v_akpub_host As serv ON serv.nId = 1
Left Join KAV.dbo.rpt_viract_index as Virus on ev.event_id = virus.nEventVirus
where registration_time >= DATEADD(minute, -191, GetDate())
```

c. Place the cursor in the **URL** field and in the displayed list, click ✎ in the line of the secret that you are using.

d. This opens the **Secret** window; in that window, in the **URL** field, specify the server connection address in the following format:

`sqlserver://user:password@kscdb.example.com:1433/database`

where:

- `user`—user account with public and db_datareader rights to the required database.
- `password`—user account password.
- `kscdb.example.com:1433`—address and port of the database server.
- `database`—name of the Kaspersky Security Center database. 'KAV' by default.

Click **Save**.

e. In the **Create connector** window, in the **Connection** section, in the **Query** field, replace the 'KAV' database name with the name of the Kaspersky Security Center database you are using.

You must do this if you want to use the ID column to which the query refers.

Click **Save**.

2. Install the collector in the web interface:

   a. Start the Collector Installation Wizard in one of the following ways:

      - In OSMP Console, in the **Monitoring** → **Resources** section, click **Add event source**.
      - In OSMP Console, in the **Monitoring** → **Resources** → **Collectors** section, click **Add collector**.

   b. At step 1 of the Installation Wizard, **Connect event sources**, specify the collector name and select the tenant.

   c. At step 2 of the Installation Wizard, **Transport**, select the copy of the connector that you created at step 1.

   d. At step 3 of the Installation Wizard, **Event parsing**, on the **Parsing schemes** tab, click **Add event parsing**.

   e. This opens the **Basic event parsing** window; in that window, on the **Normalization scheme** tab, in the **Normalizer** drop-down list, select **[OOTB] KSC from SQL** and click **OK**.

   f. If necessary, specify the other settings in accordance with your requirements for the collector. For the purpose of importing events, editing settings at the remaining steps of the Installation Wizard is optional.

   g. At step 8 of the Installation Wizard, **Setup validation**, click **Create and save service**.

      The lower part of the window displays the command that you must use to install the collector on the server. Copy this command to the clipboard.

   h. Close the Collector Installation Wizard by clicking **Save collector**.

3. Install the collector on the server.

   To do so, on the server on which you want to receive Kaspersky Security Center events, run the command that you copied to the clipboard after creating the collector in the web interface.

As a result, the collector is installed and can receive events from the SQL database of Kaspersky Security Center.

You can view Kaspersky Security Center events in the **Events** section of the web interface.

Integration with Kaspersky CyberTrace

Kaspersky CyberTrace (hereinafter CyberTrace) is a tool that integrates threat data streams with SIEM solutions. It provides users with instant access to analytics data, increasing their awareness of security decisions.

You can integrate CyberTrace with KUMA in one of the following ways:

- Integrate CyberTrace indicator search feature to enrich KUMA events with information from CyberTrace data streams.
- Integrate the entire CyberTrace web interface into KUMA to get full access to CyberTrace.

  CyberTrace console integration is available only if your CyberTrace license includes multi-user feature.

Integrating CyberTrace indicator search

To integrate CyberTrace indicator search:

1. Configure CyberTrace to receive and process KUMA requests.

   You can configure the integration with KUMA immediately after installing CyberTrace in the Quick Start Wizard or later in the CyberTrace web interface.

2. Create an event enrichment rule.

   In the enrichment rule, you can specify which data from CyberTrace you want to enrich the event with.

3. Create a collector to receive events that you want to enrich with CyberTrace data.

4. Link the enrichment rule to the collector.

5. Save and create the service:

   - If you linked the rule to a new collector, click **Save and create**, copy the collector ID in the opened window and use the copied ID to install the collector on the server using the command line interface.
   - If you linked the rule to an existing collector, click **Save and restart services** to apply the settings.

   The configuration of the integration of CyberTrace indicator search is complete and KUMA events will be enriched with CyberTrace data.

Example of testing data enrichment from CyberTrace

By default, KUMA does not test the connection with CyberTrace.

If you want to test the integration with CyberTrace and make sure that event enrichment is working, you can follow the steps of the following example or adapt the example to your situation. The example shows an integration test, which performs enrichment and shows that the event contains the specified test URL.

To run the test:

1. Create a test enrichment rule with parameters listed in the table below.

Setting	Value
Name	Test CT enrichment
Tenant	Shared
Source kind	cybertrace
URL	<URL of the cybertrace server to which you want to send requests>:9999
Mapping	KUMA field: RequestURL CyberTrace indicator: url
Debug	Enabled

1. Create a test collector with the following parameters:

   At step **2 Transport**, specify the http connector.

   At step **3 Parsing**, specify the normalizer and select the json parsing method, set the mapping of the RequestUrl – RequestUrl fields.

At step **6 Enrichment**, specify the 'Test CT enrichment' rule.

At step **7 Routing**, specify the storage where events must be sent.

2. Click **Create and save service**.

   A complete command for installing the collector is displayed in the window.

3. Click **Copy** to copy the command to the clipboard and run the command on the command line. Wait for the command to complete, return to the KUMA Console, and click **Save collector**.

   A test collector is created and the test enrichment rule is linked to the collector.

4. Use the command line interface to send a request to the collector, which will trigger an event, which will then be enriched with the test URL `http://fakess123bn.nu`. For example:

   ```
   curl --request POST \
     --url http://<ID of the host where the collector is installed>:<port of the collector>/input \
     --header 'Content-Type: application/json' \
     --data '{"RequestUrl":"http://fakess123bn.nu"}'
   ```

5. Go to the KUMA **Events** section and run the following query to filter event output and find the enriched event:

   ```
   SELECT * FROM `events` WHERE RequestUrl = 'http://fakess123bn.nu' ORDER BY Timestamp DESC LIMIT 250
   ```

   Result:

   Enrichment is successful, the event now has a **RequestURL** field with the `http://fakess123bn.nu` value, as well as a TI indicator and indicator category with CyberTrace data.

If the test did not result in enrichment, for example, if the TI indicator is missing, we recommend to do the following:

1. Check the settings of the collector and enrichment rules.

2. Download the collector logs using the following command and look for errors in the logs:

   ```
   tail -f /opt/kaspersky/kuma/collector/<collector ID>/log/collector
   ```

Configuring CyberTrace to receive and process requests

You can configure CyberTrace to receive and process requests from KUMA immediately after its installation in the Quick Start Wizard or later in the program web interface.

To configure CyberTrace to receive and process requests in the Quick Start Wizard:

1. Wait for the CyberTrace Quick Start Wizard to start after the program is installed.

   The **Welcome to Kaspersky CyberTrace** window opens.

2. In the **Select SIEM** drop-down list, select the type of SIEM system from which you want to receive data and click the **Next** button.

   The **Connection parameters** window opens.

3. Do the following:

   a. In the **Service listens on** settings block, select the **IP and port** option.

   b. In the **IP address** field, enter `0.0.0.0`.

c. In the **Port** field, enter the port for receiving events, the default port is `9999`.

d. Under **Service sends events to**, specify `127.0.0.1` in the **IP address or hostname** field and in the **Port** field, specify `9998`.

Leave the default values for everything else.

e. Click **Next**.

The **Proxy Settings** window opens.

4. If a proxy server is being used in your organization, define the settings for connecting to it. If not, leave all the fields blank and click **Next**.

The **Licensing Settings** window opens.

5. In the **Kaspersky CyberTrace license key** field, add a license key for CyberTrace.

6. In the **Kaspersky Threat Data Feeds certificate** field, add a certificate that allows you to download updated data feeds from servers, and click **Next**.

CyberTrace will be configured.

To configure CyberTrace to receive and process requests in the program web interface:

1. In the CyberTrace web interface, select **Settings** – **Service**.

2. In the **Connection Settings** block:

a. Select the **IP and port** option.

b. In the **IP address** field, enter `0.0.0.0`.

c. In the **Port** field, specify the port for receiving events, the default port is `9999`.

3. In the **Web interface** settings block, in the **IP address or hostname** field, enter `127.0.0.1`.

4. In the upper toolbar, click **Restart the CyberTrace Service**.

5. Select **Settings** – **Events format**.

6. In the **Alert events format** field, enter `%Date% alert=%Alert%%RecordContext%`.

7. In the **Detection events format** field, enter `Category=%Category%|MatchedIndicator=%MatchedIndicator%%RecordContext%`.

8. In the **Records context format** field, enter `|%ParamName%=%ParamValue%`.

9. In the **Actionable fields context format** field, enter `%ParamName%:%ParamValue%`.

CyberTrace will be configured.

After updating CyberTrace configuration you have to restart the CyberTrace server.

Creating event Enrichment rules

To create event enrichment rules:

1. In the main menu, go to **Monitoring** → **Resources and services** → **Enrichment rules**.
2. In the left part of the window, select or create a folder for the new rule.

   The list of available enrichment rules will be displayed.
3. Click **Create** to create a new rule.

   The enrichment rule window will be displayed.
4. Enter the rule configuration parameters:

   a. In the **Name** field, enter a unique name for the rule. The name must contain 1 to 128 Unicode characters.

   b. In the **Tenant** drop-down list, select the tenant that will own this resource.

   c. In the **Source kind** drop-down list, select **cybertrace**.

   d. Specify the **URL** of the CyberTrace server to which you want to connect. For example, *example.domain.com:9999*.

   e. If necessary, use the **Number of connections** field to specify the maximum number of connections to the CyberTrace server that can be simultaneously established by OSMP. By default, this value is equal to the number of vCPUs of the KUMA Core server.

   f. In the **RPS** field, enter the number of requests to the CyberTrace server per second that OSMP can make. The default value is `1000`.

   g. In the **Maximum number of events in enrichment queue** field, specify the maximum number of events stored in the enrichment queue for re-sending. The default value is `1000000`.

   h. In the **Timeout** field, specify the maximum number of seconds OSMP should wait for a response from the CyberTrace server. Until a response is received or the time expires, the event is not sent to the Correlator. If a response is received before the timeout, it is added to the `TI` field of the event and the event processing continues. The default value is `30`.

   i. Use the **Debug** drop-down list to indicate whether or not to enable logging of service operations. Logging is disabled by default.

   j. In the **Tags** drop-down list, select the tags for the event enrichment rule.

   k. If necessary, in the **Description** field, add up to 4,000 Unicode characters describing the resource.

l. Under **Mapping**, you must specify the fields of events to be checked via CyberTrace, and define the rules for mapping fields of KUMA events to CyberTrace indicator types:

- In the **KUMA field** column, select the field whose value must be sent to CyberTrace.
- In the **CyberTrace indicator** column, select the CyberTrace indicator type for every field you selected:
  - **ip**
  - **url**
  - **hash**

You must provide at least one string to the table. You can click the **Add** button to add a string, and can click the ✕ button to remove a string.

m. In the **Filter** section, you can specify conditions to identify events that will be processed using the enrichment rule. You can select an existing filter from the **Filter** drop-down list or **Create** a new filter.

Creating a filter in resources

All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

To create a filter:

1. In the **Filter** drop-down list, select **Create new**.
2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.
3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.
4. Under **Conditions**, specify the conditions that the events must meet:
   a. Click the **Add condition** button.
   b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.
   c. In the **Operator** drop-down list, select an operator.

      Filter operators

      - **=** means the left operand equals the right operand.
      - **<** means the left operand is less than the right operand.
      - **<=** means the left operand is less than or equal to the right operand.
      - **>** means the left operand is greater than the right operand.

- **>=** means the left operand is greater than or equal to the right operand.
- **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
- **contains** means the left operand contains values of the right operand.
- **startsWith** means the left operand starts with one of the values of the right operand.
- **endsWith** means the left operand ends with one of the values of the right operand.
- **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
- **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

  The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

  If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.
- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.
- **inContextTable** checks for the presence of the entry in the specified context table.
- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

5. Click the **Create** button.

A new enrichment rule will be created.

CyberTrace indicator search integration is now configured. You can now add the created enrichment rule to a collector. You must restart KUMA collectors to apply the new settings.

If any of the CyberTrace fields in the events details area contains "[{" or "}]" values, it means that information from CyberTrace data feed was processed incorrectly and it's possible that some of the data is not displayed. You can get all data feed information by copying the events **TI indicator** field value from KUMA and searching for it in the CyberTrace in the indicators section. All relevant information will be displayed in the **Indicator context** section of CyberTrace.

Integrating CyberTrace interface

You can integrate the CyberTrace web interface with OSMP Console. When this integration is enabled, OSMP Console includes a **CyberTrace** section that provides access to the CyberTrace web interface. You can configure the integration in the **Settings** → **KUMA** → **Open KUMA settings** → **Kaspersky CyberTrace** section of OSMP Console.

To integrate the CyberTrace web interface in OSMP Console:

1. In the main menu, go to **Monitoring** → **Resources and services** → **Secrets**.

   The list of available secrets will be displayed.

2. Click the **Create** button to create a new secret. This resource is used to store credentials of the CyberTrace server.

   The secret window is displayed.

3. Enter information about the secret:

   a. In the **Name** field, choose a name for the added secret. The name must contain 1 to 128 Unicode characters.

   b. In the **Tenant** drop-down list, select the tenant that will own this resource.

   c. In the **Type** drop-down list, select **credentials**.

   d. In the **User** and **Password** fields, enter credentials for your CyberTrace server.

   e. If necessary, select the tags for the secret from the **Tags** drop-down list.

   f. If necessary, in the **Description** field, add up to 4,000 Unicode characters describing the resource.

4. Click the **Create** button.

   The CyberTrace server credentials are now saved and can be used in other KUMA resources.

5. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

6. Under **Threat intelligence**, click **Kaspersky CyberTrace**.

   This opens the **Kaspersky CyberTrace integration** window.

7. Make the necessary changes to the following parameters:

   - **State**—enable the toggle switch if you want to integrate the CyberTrace web interface into OSMP Console.
   - **Host** (required)—enter the address of the CyberTrace server.
   - **Port** (required)—enter the port of the CyberTrace server; the default port for managing the web interface is 443.
   - In the **Secret** drop-down list, select the secret you created before.
   - In the **Allow hosts** drop-down list, select the hosts that support the CORS technology.
   - In the **Major version of CyberTrace** field, select the CyberTrace version. Possible values: **<5**, **≥ 5.0**. If version **≥ 5.0** is selected, requests are executed in the General tenant in CyberTrace and use the new version of the API provided by Kaspersky CyberTrace 5.0 and later. If you select **<5**, requests use the Kaspersky CyberTrace 4.x API. The default value is **<5**.

8. You can configure access to the CyberTrace web interface in the following ways:

   - Use hostname or IP when logging into OSMP Console.

     To do this, in the **Allow hosts** section, click **Add host** and in the field that is displayed, enter the IP or hostname of the device.

   - Use FQDN when logging into OSMP Console.

     If you are using the Mozilla Firefox browser to manage the console, the CyberTrace section may fail to display data. In this case, configure the data display (see below).

9. Click **Save**.

CyberTrace is now integrated with OSMP, and the **CyberTrace** section is displayed in OSMP Console.

*To configure the data display in the **CyberTrace** section when using the FQDN to log in to OSMP Console in Mozilla Firefox:*

1. Clear your browser cache.
2. In the browser's address bar, enter the FQDN of OSMP Console with port number.

   A window will open to warn you of a potential security threat.

3. Click the **Details** button.
4. In the lower part of the window, click the **Accept risk and continue** button.

   An exclusion is created for the URL of OSMP Console.

5. In the browser's address bar, enter the URL of OSMP Console with port number.

6. Go to the **CyberTrace** section.

   Data will be displayed in this section.

Updating CyberTrace deny list (Internal TI)

When the CyberTrace web interface is integrated into OSMP Console, you can update the CyberTrace denylist or **Internal TI** with information from KUMA events.

To update CyberTrace Internal TI:

1. Open the event details area from the events table, Alert window, or correlation event window and click the link on a domain, web address, IP address, or file hash.

   The context menu opens.

2. Select **Add to Internal TI of CyberTrace**.

The selected object is now added to the CyberTrace denylist.

Connecting over LDAP

LDAP connections are created and managed under **Settings** → **KUMA** → **Open KUMA settings** → **LDAP server** in OSMP Console. The **LDAP server integration by tenant** section shows the tenants for which LDAP connections were created. Tenants can be created or deleted.

If you select a tenant, the **LDAP server integration** window opens to show a table containing existing LDAP connections. Connections can be created or edited. In this window, you can change the frequency of queries sent to LDAP servers and set the retention period for obsolete data.

After integration is enabled, information about Active Directory accounts becomes available in the alert window, the correlation events detailed view window, and the incidents window. If you click an account name in the **Related users** section of the window, the **Account details** window opens with the data imported from Active Directory.

Data from LDAP can also be used when enriching events in collectors and in analytics.

Imported Active Directory attributes

The following account attributes can be requested from Active Directory:

- `accountExpires`
- `badPasswordTime`
- `cn`
- `co`
- `company`

- department
- description
- displayName
- distinguishedName
- division
- employeeID
- givenName
- l
- lastLogon
- lastLogonTimestamp
- Mail
- mailNickname
- managedObjects
- manager
- memberOf (this attribute can be used for search during correlation)
- mobile
- name
- objectCategory
- objectGUID (this attribute always requested from Active Directory even if a user doesn't specify it)
- objectSID
- physicalDeliveryOfficeName
- pwdLastSet
- sAMAccountName
- sAMAccountType
- sn
- streetAddress
- telephoneNumber

- `title`
- `userAccountControl`
- `UserPrincipalName`
- `whenChanged`
- `whenCreated`

For details about Active Directory attributes, please refer to the Microsoft documentation.

Enabling and disabling LDAP integration

You can enable or disable all LDAP connections of the tenant at the same time, or enable and disable an LDAP connection individually.

To enable or disable all LDAP connections of a tenant:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**, and then select the tenant for which you want to enable or disable all LDAP connections.

   The **LDAP server integration** window opens.

3. Enable or disable the **State** toggle switch.

4. Click **Save**.

To enable or disable a specific LDAP connection:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**, and then select the tenant for which you want to enable or disable all LDAP connections.

   The **LDAP server integration** window opens.

3. In the connections table, enable or disable the **State** toggle switch for the relevant connection.

4. Click **Save**.

Adding a tenant to the LDAP server integration list

To add a tenant to the list of tenants for integration with an LDAP server:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Click the **Add settings for a new tenant** button.

   The **LDAP server integration** window is displayed.

4. In the **Tenant** drop-down list, select the tenant that you need to add.

5. Click **Save**.

The selected tenant is added to the LDAP server integration list.

To delete a tenant from the list of tenants for integration with an LDAP server:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Select the check box next to the tenant that you need to delete, and click **Delete**.

4. Confirm deletion of the tenant.

The selected tenant is deleted from the LDAP server integration list.

Creating an LDAP server connection

To create a new LDAP connection to Active Directory:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Select or create a tenant for which you want to create a LDAP connection.

   The **LDAP server integration** window opens.

4. Click the **Add connection** button.

   The **Connection parameters** window opens.

5. Add a secret containing the account credentials for connecting to the Active Directory server. To do so:

   a. If you previously added a secret, in the **Secret** drop-down list, select the existing secret (with the **credentials** type).

      The selected secret can be changed by clicking the pencil icon ( ).

   b. If you want to create a new secret, click the plus icon ( ).

      The **Secret** window opens.

c. In the **Name** (required) field, enter the name of the secret containing 1 to 128 Unicode characters.

d. In the **User** and **Password** (required) fields, enter the account credentials for connecting to the Active Directory server.

You can enter the user name in one of the following formats: <user name>@<domain> or <domain><user name>.

e. In the **Description** field, enter a description of up to 4,000 Unicode characters.

f. Click **Save**.

6. In the **Name** (required) field, enter the unique name of the LDAP connection.

The length of the string must be 1 to 128 Unicode characters.

7. In the **URL** (required) field, enter the address of the domain controller in the format `<hostname or IP address of server>:<port>`.

> In case of server availability issues, you can specify multiple servers with domain controllers by separating them with commas. All of the specified servers must reside in the same domain.

8. If you want to use TLS encryption for the connection with the domain controller, select one of the following options from the **Type** drop-down list:

- **startTLS**.

  When the startTLS method is used, first it establishes an unencrypted connection over port 389, then it sends an encryption request. If the STARTTLS command ends with an error, the connection is terminated.

  > Make sure that port 389 is open. Otherwise, a connection with the domain controller will be impossible.

- **ssl**.

  When using SSL, an encrypted connection is immediately established over port 636.

- **insecure**.

When using an encrypted connection, it is impossible to specify an IP address as a URL.

9. If you enabled TLS encryption at the previous step, add a TLS certificate. To do this:

a. If you previously uploaded a certificate, select it from the **Certificate** drop-down list.

If no certificate was previously added, the drop-down list shows **No data**.

b. If you want to upload a new certificate, click the plus icon (+) on the right of the **Certificate** list.

The **Secret** window opens.

c. In the **Name** field, enter the name that will be displayed in the list of certificates after the certificate is added.

d. Click the **Upload certificate file** button to add the file containing the Active Directory certificate. X.509 certificate public keys in Base64 are supported.

e. If necessary, provide any relevant information about the certificate in the **Description** field.

f. Click **Save**.

The certificate will be uploaded and displayed in the **Certificate** list.

10. In the **Timeout in seconds** field, indicate the amount of time to wait for a response from the domain controller server.

    If multiple addresses are specified in the **URL** field, KUMA waits for a response from the first server for the specified number of seconds. If no response is received within this time, an attempt is made to connect to the next server. If none of the indicated servers responds during the specified amount of time, the connection will be terminated with an error.

11. In the **Base DN** field, enter the base distinguished name of the directory where the search request should be performed.

12. In the **Custom AD Account Attributes** field, specify the **additional attributes that you want to use to enrich events**.

    Before configuring event enrichment using custom attributes, make sure that custom attributes are configured in AD.

    To enrich events with accounts using custom attributes:

    1. Add **Custom AD Account Attributes** in the LDAP connection settings.

       Standard **imported attributes from AD** cannot be added as custom attributes. For example, if you add the standard `accountExpires` attribute as a custom attribute, KUMA returns an error when saving the connection settings.

       The following account attributes can be requested from Active Directory:

       - `accountExpires`
       - `badPasswordTime`
       - `cn`
       - `co`
       - `company`
       - `department`
       - `description`
       - `displayName`
       - `distinguishedName`
       - `division`
       - `employeeID`
       - `givenName`

- l
- lastLogon
- lastLogonTimestamp
- Mail
- mailNickname
- managedObjects
- manager
- memberOf (this attribute can be used for search during correlation)
- mobile
- name
- objectCategory
- objectGUID (this attribute always requested from Active Directory even if a user doesn't specify it)
- objectSID
- physicalDeliveryOfficeName
- pwdLastSet
- sAMAccountName
- sAMAccountType
- sn
- streetAddress
- telephoneNumber
- title
- userAccountControl
- UserPrincipalName
- whenChanged
- whenCreated

After you add custom attributes in the LDAP connection settings, the **LDAP attribute** to receive drop-down list in the collector automatically includes the new attributes. Custom attributes are identified by a question mark next to the attribute name. If you added the same attribute for multiple domains, the attribute is listed only once in the drop-down list. You can view the domains by moving your cursor over the question mark. Domain names are displayed as links. If you click a link, the domain is automatically added to **LDAP accounts mapping** if it was not previously added.

If you deleted a custom attribute in the LDAP connection settings, manually delete the row containing the attribute from the mapping table in the collector. Account attribute information in KUMA is updated each time you import accounts.

2. Import accounts.
3. In the collector, in the **LDAP mapping** table, define the rules for mapping KUMA fields to LDAP attributes.
4. Restart the collector.

   After the collector is restarted, KUMA begins enriching events with accounts.

13. Select the **Disabled** check box if you do not want to use this LDAP connection.

    This check box is cleared by default.

14. Click **Save**.

The LDAP connection to Active Directory will be created and displayed in the **LDAP server integration by tenant** window.

Account information from Active Directory will be requested immediately after the connection is saved, and then it will be updated at the specified frequency.

If you want to use multiple LDAP connections simultaneously for one tenant, you need to make sure that the domain controller address indicated in each of these connections is unique. Otherwise KUMA lets you enable only one of these connections. When checking the domain controller address, the application does not check whether the port is unique.

Creating a copy of an LDAP server connection

You can create an LDAP connection by copying an existing connection. In this case, all settings of the original connection are duplicated in the newly created connection.

To copy an LDAP connection:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Select the tenant for which you want to copy an LDAP connection.

   The **LDAP server integration** window opens.

4. Select the relevant connection.
5. In the opened **Connection parameters** window, click the **Duplicate connection** button.

   The New Connection window opens. The word `copy` will be added to the connection name.
6. If necessary, change the relevant settings.
7. Click **Save**.

The new connection is created.

If you want to use multiple LDAP connections simultaneously for one tenant, you need to make sure that the domain controller address indicated in each of these connections is unique. Otherwise KUMA lets you enable only one of these connections. When checking the domain controller address, the application does not check whether the port is unique.

Changing an LDAP server connection

To change an LDAP server connection:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.
2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.
3. Select the tenant for which you want to change the LDAP server connection.

   The **LDAP server integration** window opens.
4. Click the LDAP server connection that you want to change.

   The window with the settings of the selected LDAP server connection opens.
5. Make the necessary changes to the settings.
6. Click **Save**.

The LDAP server connection is changed. Restart the KUMA services that use LDAP server data enrichment for the changes to take effect.

Changing the data update frequency

KUMA queries the LDAP server to update account data. This occurs:

- Immediately after creating a new connection.
- Immediately after changing the settings of an existing connection.

- According to a regular schedule every several hours. Every 12 hours by default.
- Whenever a user creates a task to update account data.

When querying LDAP servers, a task is created in the **Task manager** section of the KUMA Console.

To change the schedule of KUMA queries to LDAP servers:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Select the relevant tenant.

   The **LDAP server integration** window opens.

4. In the **Data refresh interval** field, specify the required frequency in hours. The default value is 12.

The query schedule has been changed.

Changing the data storage period

Received user account data is stored in KUMA for 90 days by default if information about these accounts is no longer received from the Active Directory server. After this period, the data is deleted.

After KUMA account data is deleted, new and existing events are no longer enriched with this information. Account information will also be unavailable in alerts. If you want to view information about accounts throughout the entire period of alert storage, you must set the account data storage period to be longer than the alert storage period.

To change the storage period for the account data:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Select the relevant tenant.

   The **LDAP server integration** window opens.

4. In the **Data storage time** field, specify the number of days you need to store data received from the LDAP server.

The account data storage period is changed.

Starting account data update tasks

After a connection to an Active Directory server is created, tasks to obtain account data are created automatically. This occurs:

- Immediately after creating a new connection.
- Immediately after changing the settings of an existing connection.
- According to a regular schedule every several hours. Every 12 hours by default. The schedule can be changed.

Account data update tasks can be created manually. You can download data for all connections or for one connection of the required tenant.

To start an account data update task for all LDAP connections of a tenant:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Select the relevant tenant.

   The **LDAP server integration** window opens.

4. Click the **Import accounts** button.

A task to receive account data from the selected tenant is added to the **Task manager** section of the KUMA Console.

To start an account data update task for one LDAP connection of a tenant:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Select the relevant tenant.

   The **LDAP server integration** window opens.

4. Select the relevant LDAP server connection.

   The **Connection Settings** window opens.

5. Click the **Import accounts** button.

A task to receive account data from the selected connection of the tenant is added to the **Task manager** section of the KUMA Console.

Deleting an LDAP server connection

To delete LDAP connection to Active Directory:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the KUMA settings window.

2. Under **Integrations**, click **LDAP server**.

   The **LDAP server integration by tenant** window opens.

3. Select the tenant that owns the relevant LDAP connection.

   The **LDAP server integration** window opens.

4. Click the LDAP connection that you want to delete and click the **Delete** button.

5. Confirm deletion of the connection.

The LDAP connection to Active Directory will be deleted.

Kaspersky Industrial CyberSecurity for Networks integration

Kaspersky Industrial CyberSecurity for Networks (hereinafter referred to as "KICS for Networks") is an application designed to protect the industrial enterprise infrastructure from information security threats, and to ensure uninterrupted operation. The application analyzes industrial network traffic to identify deviations in the values of process parameters, detect signs of network attacks, and monitor the operation and current state of network devices.

KICS for Networks version 4.0 or later can be integrated with KUMA. After configuring integration, you can perform the following tasks in KUMA:

- Import asset information from KICS for Networks to KUMA.
- Send asset status change commands from KUMA to KICS for Networks.

> Unlike KUMA, KICS for Networks refers to assets as devices.

The integration of KICS for Networks and KUMA must be configured in both applications:

1. In KICS for Networks, you need to create a KUMA connector and save the communication data package of this connector.
2. In KUMA, the communication data package of the connector is used to create a connection to KICS for Networks.

> The integration described in this section applies to importing asset information. KICS for Networks can also be configured to send events to KUMA. To do so, you need to create a SIEM/Syslog connector in KICS for Networks, and configure a collector on the KUMA side.

Configuring integration in KICS for Networks

The application supports integration with KICS for Networks version 4.0 or later.

It is recommended to configure integration of KICS for Networks and KUMA after ending Process Control rules learning mode. For more details, please refer to the KICS for Networks documentation.

On the KICS for Networks side, integration configuration consists of creating a *KUMA-type connector*. In KICS for Networks, connectors are specialized application modules that enable KICS for Networks to exchange data with recipient systems, including KUMA. For more details on creating connectors, please refer to the documentation on KICS for Networks.

When a connector is added to KICS for Networks, a *communication data package* is automatically created for this connector. This is an encrypted configuration file for connecting to KICS for Networks that is used when configuring integration on the KUMA side.

Configuring integration in KUMA

It is recommended to configure integration of KICS for Networks and KUMA after ending Process Control rules learning mode. For more details, please refer to the KICS for Networks documentation.

To configure integration with KICS for Networks in KUMA:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select a tenant for which you want to create an integration with KICS for Networks.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Assets settings**.
4. On the **KICS/KATA import** tab, click the **Add** button.
5. This opens the **Create connection** window.
6. To enable or disable the connection, turn on or turn off the **State** toggle switch
7. Click the plus sign icon (+) and select the communication data package that was created in KICS for Networks.
8. In the **Communication data package password** field, enter the password of the communication data package.
9. In the **API version** field, enter the KICS/KATA API version that will be used to communicate with KICS/KATA. By default, version 4 is used.
10. Then click the **Add** button.

11. Turn on the **Enable response actions** toggle switch if you want to change the statuses of KICS for Networks assets by using KUMA response rules.
12. Click **Save**.

Integration with KICS for Networks is configured in KUMA, and the window shows the IP address of the node where the KICS for Networks connector will be running and its ID.

Enabling and disabling integration with KICS for Networks

To enable or disable KICS for Networks integration for a tenant:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant into which you want to import KICS/KATA assets.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Assets settings**.
4. On the **KICS/KATA import** tab, enable or disable the **State** toggle switch.
5. Click **Save**.

Changing the data update frequency

KUMA queries KICS for Networks to update its asset information. This occurs:

- Immediately after creating a new integration.
- Immediately after changing the settings of an existing integration.
- According to a regular schedule every several hours. This occurs every 3 hours by default.
- Whenever a user creates a task for updating asset data.

When querying KICS for Networks, a task is created in the **Task manager** section of the OSMP Console.

To edit the schedule for importing information about KICS for Networks assets:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant into which you want to import KICS/KATA assets.

   This opens the tenant properties window.
3. On the **Settings** tab, under **Analysis and response**, click **Assets settings**.
4. On the **KICS/KATA import** tab, in the **Import interval (hours)** field, specify the time interval at which OSMP updates data about KICS/KATA assets.

The import schedule has been changed.

Special considerations when importing asset information from KICS for Networks

Importing assets

Assets are imported according to the asset import rules. Only assets with the **Authorized** and **Unauthorized** statuses are imported.

KICS for Networks assets are identified by a combination of the following parameters:

- IP address of the KICS for Networks instance with which the integration is configured.
- KICS for Networks connector ID is used to configure the integration.
- ID assigned to the asset (or "device") in the KICS for Networks instance.

Importing vulnerability information

When importing assets, KUMA also receives information about active vulnerabilities in KICS for Networks. If a vulnerability has been flagged as Remediated or Negligible in KICS for Networks, the information about this vulnerability is deleted from KUMA during the next import.

Information about asset vulnerabilities is displayed in the localization language of KICS for Networks in the **Asset details** window under **Vulnerabilities**.

> In KICS for Networks, vulnerabilities are referred to as risks and are divided into several types. All types of risks are imported into KUMA.

Imported data storage period

If information about a previously imported asset is no longer received from KICS for Networks, the asset is deleted after 30 days.

Changing the status of a KICS for Networks asset

After configuring integration, you can change the statuses of KICS for Networks assets from KUMA. Statuses can be changed either automatically or manually.

Asset statuses can be changed only if you enabled a response in the settings for connecting to KICS for Networks.

Manually changing the status of a KICS for Networks asset

Users with the Main administrator, Administrator, and Analyst roles in the tenants available to them can manually change the statuses of assets imported from KICS for Networks.

To manually change a KICS for Networks asset status:

1. In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Click the asset that you want to edit.

   The **Asset details** area opens in the right part of the window.
3. In the **Status in KICS for Networks** drop-down list, select the status that you need to assign to the KICS for Networks asset. The *Authorized* or *Unauthorized* statuses are available.

The asset status is changed. The new status is displayed in KICS for Networks and in KUMA.

Automatically changing the status of a KICS for Networks asset

Automatic changes to the statuses of KICS for Networks assets are implemented using response rules. The rules must be added to the correlator, which will determine the conditions for triggering these rules.

Integration with Neurodat SIEM IM

Neurodat SIEM IM is an information security monitoring system.

You can configure the export of KUMA events to Neurodat SIEM IM. Based on incoming events and correlation rules, Neurodat SIEM IM automatically generates information security incidents.

To configure integration with Neurodat SIEM IM:

1. Connect to the Neurodat SIEM IM server over SSH using an account with administrative privileges.
2. Create a backup copy of the /opt/apache-tomcat-<server version>/conf/neurodat/soz_settings.properties configuration file.
3. In the /opt/apache-tomcat-<server version>/conf/neurodat/soz_settings.properties configuration file, edit the following settings as follows:

   - `kuma.on=true`

     This setting is an attribute of Neurodat SIEM IM interaction with KUMA.
   - `job_kuma=com.cbi.soz.server.utils.scheduler.KumaIncidentsJob`
   - `jobDelay_kuma=5000`
   - `jobPeriod_kuma=60000`

4. Save changes of the configuration file.

5. Run the following command to restart the tomcat service:

   ```
   sudo systemctl restart tomcat
   ```

6. Obtain a token for the user in KUMA. To do this:

   a. In the main menu, go to **Settings** → **API tokens**.

      This opens the **API tokens** window.

   b. Click the **Add token** button.

      The **Add token** window opens.

   c. If necessary, set the token expiration date:

      - Select the **No expiration date** check box.
      - In the **Expiration date** field, use the calendar to specify the date and time when the created token will expire.

   d. Click the **Generate** button.

      The **Token** field with an automatically generated token is displayed in the user details area. Copy it.

      When the window is closed, the token is no longer displayed. If you did not copy the token before closing the window, you will have to generate a new token.

   e. Click **Save**.

7. Log in to Neurodat SIEM IM using the 'admin' account or another account that has the Administrator role for the organization you are configuring or the Administrator role for all organizations.

8. In the **Administration** → **Organization structure** menu item, select or create an organization that you want to receive incidents from KUMA.

9. On the organization form, do the following:

   a. Select the **Configure integration with KUMA** check box.

   b. In the **KUMA IP address and port** field, specify the KUMA API address, for example, `https://192.168.58.27:7223/api/v1/`.

   c. In the **KUMA API key** field, specify the user token obtained at step 6.

   d. Save the organization information.

Integration with KUMA is configured.

Neurodat SIEM IM tests access to KUMA and, if successful, displays a message about being ready to receive data from KUMA.

Kaspersky Automated Security Awareness Platform

Kaspersky Automated Security Awareness Platform (hereinafter also referred to as "KASAP") is an online learning platform that allows users to learn the rules of information security and threats related to it in their daily work, as well as to practice using real examples.

KASAP can be integrated with KUMA. After configuring integration, you can perform the following tasks in KUMA:

- Change user learning groups.
- View information about the courses taken by the users and the certificates they received.

Integration between KASAP and KUMA includes configuring API connection to KASAP. The process takes place in both solutions:

1. In KASAP, create an authorization token and obtain an address for API requests.
2. In KUMA, specify the address for API requests in KASAP, add an authorization token for API requests, and specify the email address of the KASAP administrator to receive notifications.

Creating a token in KASAP and getting a link for API requests

In order to be authorized, the API requests from KUMA to KASAP must be signed by a token created in KASAP. Only the company administrators can create tokens.

Creating a token

To create a token:

1. Sign in to the KASAP web interface.
2. In the **Control panel** section, click **Import and synchronization**, and then open the **Open API** tab.
3. Click the **New token** button and select the API methods used for integration in the window that opens:
   - GET /openapi/v1/groups
   - POST /openapi/v1/report
   - PATCH /openapi/v1/user/:userid
4. Click the **Generate token** button.
5. Copy the token and save it in any convenient way. This token is required to configure integration in KUMA.

The token is not stored in the KASAP system in the open form. After you close the **Get token** window, the token is unavailable for viewing. If you close the window without copying the token, you will need to click the **New token** button again for the system to generate a new token.

The issued token is valid for 12 months. After this period, the token is revoked. The issued token is also revoked if it is not used for 6 months.

Getting a link for API requests

To get the link used in KASAP for API requests:

1. Log in to the KASAP platform console.
2. In the **Control panel** section, click the **Import and synchronization** button, and then open the **Open API** tab.
3. A link for accessing KASAP using the Open API is located at the bottom part of the window. Copy the link and save it in any convenient way. This link is required to configure integration in KUMA.

Configuring integration in KUMA

To configure KUMA integration with KASAP:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.

   This opens the **KUMA settings** window.
2. Under **Integrations**, click **Kaspersky Automated Security Awareness Platform**.

   The **Kaspersky Automated Security Awareness Platform** window opens.
3. In the **Secret** field click the plus icon (+) to create a secret of the **token** by entering the token received from KASAP:

   a. In the **Name** field, enter the name of the secret. Must contain 1 to 128 Unicode characters.

   b. In the **Token** field, enter the authorization token for API requests to KASAP.

   c. If necessary, add the secret description in the **Description** field.

   d. Click **Save**.
4. In the **KASAP Open API URL** field, specify the address used by KASAP for API requests.
5. In the **KASAP administrator email** field, specify the email address of the KASAP administrator who receives notifications when users are added to the learning groups using KUMA.
6. If necessary, in the **Proxy** drop-down list select the proxy server resource to be used to connect to KASAP.

7. To disable or enable integration with KASAP, select or clear the **Disabled** check box.

8. Click **Save**.

Integration with KASAP is configured in KUMA. When viewing information about alerts and incidents, you can select associated users to view which learning courses they have taken and to change their learning group.

Viewing information about the users from KASAP and changing learning groups

After configuring the integration between KASAP and KUMA, the following information from KASAP becomes available in alerts and incidents when you view data about associated users:

- The learning group to which the user belongs.
- The trainings passed by the user.
- The planned trainings and the current progress.
- The received certificates.

To view data about the user from KASAP:

1. In OSMP Console, in the **Alerts** or **Incidents** section, select the relevant alert or incident.

2. In the **Related users** section, click the desired account.

   The **Account details** window opens on the right side of the screen.

3. Select the **KASAP courses details** tab.

   The window displays information about the user from KASAP.

You can change the learning group of a user in KASAP.

To change a user learning group in KASAP:

1. In OSMP Console, in the **Alerts** or **Incidents** section, select the relevant alert or incident.

2. In the **Related users** section, click the desired account.

   The **Account details** window opens on the right side of the screen.

3. In the **Assign KASAP group** drop-down list, select the KASAP learning group you want to assign the user to.

4. Click **Apply**.

   The user is moved to the selected KASAP group, the KASAP company administrator is notified of the change in the learning group, and the study plan is recalculated for the selected learning group.

For details on learning groups and how to get started, refer to the KASAP documentation.

Sending notifications to Telegram

This integration is an example and may require additional configuration depending on the versions used and the specifics of the infrastructure.
The terms and conditions of premium technical support do not apply to this integration; support requests are processed without a guaranteed response time.

You can configure sending notifications to Telegram when KUMA correlation rules are triggered. This can reduce the response time to threats and, if necessary, make more persons informed.

Configure Telegram notifications involves the following steps:

1. Creating and configuring a Telegram bot

   A special bot sends notifications about triggered correlation rules. It can send notifications to a private or group Telegram chat.

2. Creating a script for sending notifications

   You must create a script and save it on the server where the correlator is installed.

3. Configuring notifications in KUMA

   Configure a KUMA response rule that starts a script to send notifications and add this rule to the correlator.

Creating and configuring a Telegram bot

To create and configure a Telegram bot:

1. In the Telegram application, find the BotFather bot and open a chat with it.
2. In the chat, click **Start**.
3. Create a new bot using the following command:

   ```
   /newbot
   ```

4. Enter the name of the bot.
5. Enter the login name of the bot.

   The bot is created. You receive a link to the chat that looks like t.me/<bot login> and a token for contacting the bot.

6. If you want to use the bot in a group chat, and not in private messages, edit privacy settings:

   a. In the BotFather chat, enter the command:

   ```
   /mybots
   ```

   b. Select the relevant bot from the list.

c. Click **Bot Settings** → **Group Privacy** and select **Turn off**.

The bot can now send messages to group chats.

7. To open a chat with the bot you created, use the t.me/<botlogin> link that you obtained at step 5, and click **Start**.

8. If you want the bot to send private messages to the user:

   a. In the chat with the bot, send any message.

   b. Follow the https://t.me/getmyid_bot link and click **Start**.

   c. The response contains the `Current chat ID`. You need this value to configure the sending of messages.

9. If you want the bot to send messages to the group chat:

   a. Add https://t.me/getmyid_bot to the group chat for receiving notifications from KUMA.

   The bot sends a message to the group chat, the message contains the `Current chat ID` value. You need this value to configure the sending of messages.

   b. Remove the bot from the group.

10. Send a test message through the bot. To do so, paste the following link into the address bar of your browser:

    `https://api.telegram.org/bot<token>/sendMessage?chat_id=<chat_id>&text=test`

    where `<token>` is the value obtained at step 5, and `<chat_id>` is the value obtained at step 8 or 9.

As a result, a test message should appear in the personal or group chat, and the JSON in the browser response should be free of errors.

Creating a script for sending notifications

To create a script:

1. In the console of the server on which the correlator is installed, create a script file and add the following lines to it:

```
#!/bin/bash
set -eu
CHAT_ID=<Current chat ID value obtained at step 8 or 9 of the Telegram bot setup instructions>
TG_TOKEN=<token value obtained at step 5 of the Telegram bot setup instructions>
RULE=$1
TEXT="<b>$RULE</b> rule triggered"
curl --data-urlencode "chat_id=$CHAT_ID" --data-urlencode "text=$TEXT" --data-urlencode "parse_mode=HTML" https://api.telegram.org/bot$TG_TOKEN/sendMessage
```

   If the correlator server does not have internet access, you can use a proxy server:

```
#!/bin/bash
set -eu
CHAT_ID=<Current chat ID value obtained at step 8 or 9 of the Telegram bot setup instructions>
TG_TOKEN=<token value obtained at step 5 of the Telegram bot setup instructions>
RULE=$1
TEXT="<b>$RULE</b> rule triggered."
PROXY=<address and port of the proxy server>
```

```
curl --proxy $PROXY --data-urlencode "chat_id=$CHAT_ID" --data-urlencode "text=$TEXT"
--data-urlencode "parse_mode=HTML" https://api.telegram.org/bot$TG_TOKEN/sendMessage
```

2. Save the script to the correlator directory at /opt/kaspersky/kuma/correlator/<ID of the correlator that must respond to events>/scripts/.

   For information about obtaining the correlator ID, see the Getting service identifier section.

3. Make the 'kuma' user the owner of the file and grant execution rights:

```
chown kuma:kuma /opt/kaspersky/kuma/correlator/<ID of the correlator that must
respond>/scripts/<script name>.sh
chmod +x /opt/kaspersky/kuma/correlator/<ID of the correlator that must
respond>/scripts/<script name>.sh
```

Configuring sending notifications in KUMA

To configure the sending of KUMA notifications to Telegram:

1. Create a response rule:

   a. In the main menu, go to **Monitoring** → **Resources and services** → **Response rules**, and then click **Add response rule**.

   b. This opens the **Create response rule** window; in that window, in the **Name** field, enter the name of the rule.

   c. In the **Tenant** drop-down list, select the tenant that owns the resource.

   d. In the **Type** drop-down list, select **Run script**.

   e. In the **Script name** field, enter the name of the script.

   f. In the **Script arguments** field, enter `{{.Name}}`.

   This passes the name of the correlation event as the argument of the script.

   g. Click **Save**.

2. Add the response rule to the correlator:

   a. In the main menu, go to **Monitoring** → **Resources and services** → **Correlators**, and then select the correlator in whose folder you placed the created script for sending notifications.

   b. In the steps tree, select **Response rules**.

   c. Then click the **Add** button.

   d. In the **Response rule** drop-down list, select the rule added at step 1 of these instructions.

   e. In the steps tree, select **Setup validation**.

   f. Click the **Save and restart services** button.

   g. Click **Save**.

Sending notifications about triggered KUMA rules to Telegram is configured.

UserGate integration

This integration is an example and may require additional configuration depending on the versions used and the specifics of the infrastructure.
The terms and conditions of premium technical support do not apply to this integration; support requests are processed without a guaranteed response time.

UserGate is a network infrastructure security solution that protects personal information from the risks of external intrusions, unauthorized access, viruses, and malware.

Integration with UserGate allows automatically blocking threats by IP address, URL, or domain name whenever KUMA response rules are triggered.

Configuring the integration involves the following steps:

1. Configuring integration in UserGate
2. Preparing a script for the response rule
3. Configuring the KUMA response rule

Configuring integration in UserGate

To configure integration in UserGate:

1. Connect to the UserGate web interface under an administrator account.
2. Go to **UserGate** → **Administrators** → **Administrator profiles**, and click **Add**.
3. In the **Profile settings** window, specify the profile name, for example, `API`.
4. On the **API Permissions** tab, add read and write permissions for the following objects:
   - content
   - core
   - firewall
   - nlists
5. Click **Save**.
6. In the **UserGate** → **Administrators** section, click **Add** → **Add local administrator**.
7. In the **Administrator properties** window, specify the login and password of the administrator.
   In the **Administrator profile** field, select the profile created at step 3.
8. Click **Save**.

9. In the address bar of your browser, after the address and port of UserGate, add `?features=zone-xml-rpc` and press **ENTER**.

10. Go to the **Network** → **Zones** section and for the zone of the interface that you want to use for API interaction, go to the **Access Control** tab and select the check box next to the **XML-RPC for management** service.

    If necessary, you can add the IP address of the KUMA correlator whose correlation rules must trigger blocking in UserGate, to the list of allowed addresses.

11. Click **Save**.

Preparing a script for integration with UserGate

To prepare a script for use:

1. Copy the ID of the correlator whose correlation rules you want to trigger blocking of URL, IP address, or domain name in UserGate:

   a. In the main menu, go to **Monitoring** → **Resources and services** → **Active services**.

   b. Select the check box next to the correlator whose ID you want to obtain, and click **Copy ID**.

      The correlator ID is copied to the clipboard.

2. Download the script:

   https://box.kaspersky.com/d/2dfd1d677c7547a7ac1e/

3. Open the script file and in the **Enter UserGate Parameters** section, in the **login** and **password** parameters, specify the credentials of the UserGate administrator account that was created at step 7 of configuring the integration in UserGate.

4. Place the downloaded script on the KUMA correlator server at the following path: /opt/kaspersky/kuma/correlator/<`correlator ID from step 1`>/scripts/.

5. Connect to the correlator server via SSH and go to the path from step 4:

   ```
   cd /opt/kaspersky/kuma/correlator/< correlator ID from step 1 >/scripts/
   ```

6. Run the following command:

   ```
   chmod +x ug.py && chown kuma:kuma ug.py
   ```

The script is ready to use.

Configuring a response rule for integration with UserGate

To configure a response rule:

1. Create a response rule:

   a. In the main menu, go to **Monitoring** → **Resources and services** → **Response rules**, and then click **Add response rule**.

   b. This opens the **Create response rule** window; in that window, in the **Name** field, enter the name of the rule.

c. In the **Tenant** drop-down list, select the tenant that owns the resource.

d. In the **Type** drop-down list, select **Run script**.

e. In the **Script name** field, enter the name of the script. `ug.py`.

f. In the **Script arguments** field, specify:

- one of the operations depending on the type of the object being blocked:
  - `blockurl` to block access by URL
  - `blockip` to block access by IP address
  - `blockdomain` to block access by domain name
- `-i {{< KUMA field from which the value of the blocked object must be taken, depending on the operation >}}`

  Example:
  `blockurl -i {{.RequetstUrl}}`

g. In the **Conditions** section, add conditions corresponding to correlation rules that require blocking in UserGate when triggered.

h. Click **Save**.

2. Add the response rule to the correlator:

a. In the main menu, go to **Monitoring** → **Resources and services** → **Correlators**, select the correlator that must respond and in whose directory you placed the script.

b. In the steps tree, select **Response rules**.

c. Then click the **Add** button.

d. In the **Response rule** drop-down list, select the rule added at step 1 of these instructions.

e. In the steps tree, select **Setup validation**.

f. Click **Save and reload services**.

g. Click **Save**.

The response rule is linked to the correlator and ready to use.

Integration with Kaspersky Web Traffic Security

This integration is an example and may require additional configuration depending on the versions used and the specifics of the infrastructure.
The terms and conditions of premium technical support do not apply to this integration; support requests are processed without a guaranteed response time.

You can configure integration with the Kaspersky Web Traffic Security web traffic analysis and filtering system (hereinafter also referred to as "KWTS").

Configuring the integration involves creating KUMA response rules that allow running KWTS tasks. Tasks must be created in advance in the KWTS web interface.

Configuring the integration involves the following steps:

1. Configuring integration in KWTS
2. Preparing a script for the response rule
3. Configuring the KUMA response rule

Configuring integration in KWTS

To prepare the integration in KWTS:

1. Connect to the KWTS web interface under an administrator account and create a role with permissions to view and create/edit a rule.

   For more details on creating a role, see the *Kaspersky Web Traffic Security Help*.

2. Assign the created role to a user with NTML authentication.

   You can use a local administrator account instead.

3. In the **Rules** section, go to the **Access** tab and click **Add rule**.

4. In the **Action** drop-down list, select **Block**.

5. In the **Traffic filtering** drop-down list, select the **URL** value, and in the field on the right, enter a nonexistent or known malicious address.

6. In the **Name** field, enter the name of the rule.

7. Enable the rule using the **Status** toggle switch.

8. Then click the **Add** button.

9. In the KWTS web interface, open the rule you just created.

10. Make a note of the ID value that is displayed at the end of the page address in the browser address bar.

    You must use this value when configuring the response rule in KUMA.

The integration is prepared on the KWTS side.

Preparing a script for integration with KWTS

To prepare a script for use:

1. Copy the ID of the correlator whose correlation rules you want to trigger blocking of URL, IP address, or domain name in KWTS:

   a. In the main menu, go to **Monitoring** → **Resources and services** → **Active services**.

   b. Select the check box next to the correlator whose ID you want to obtain, and click **Copy ID**.

   The correlator ID is copied to the clipboard.

2. Download the script and library:

   https://box.kaspersky.com/d/2dfd1d677c7547a7ac1e/

3. Place the downloaded script on the KUMA correlator server at the following path: /opt/kaspersky/kuma/correlator/<`correlator ID from step 1`>/scripts/.

4. Connect to the correlator server via SSH and go to the path from step 3:

   ```
   cd /opt/kaspersky/kuma/correlator/<correlator ID from step 1>/scripts/
   ```

5. Run the following command:

   ```
   chmod +x kwts.py kwtsWebApiV6.py && chown kuma:kuma kwts.py kwtsWebApiV6.py
   ```

The script is ready to use.

Configuring a response rule for integration with KWTS

To configure a response rule:

1. Create a response rule:

   a. In the main menu, go to **Monitoring** → **Resources and services** → **Response rules**, and then click **Add response rule**.

   b. This opens the **Create response rule** window; in that window, in the **Name** field, enter the name of the rule.

   c. In the **Tenant** drop-down list, select the tenant that owns the resource.

   d. In the **Type** drop-down list, select **Run script**.

   e. In the **Script name** field, enter the name of the script, kwts.py.

   f. In the **Script arguments** field, specify:

   - `--host` — address of the KWTS server.
   - `--username` — name of the user account created in KWTS or local administrator.
   - `--password` — KWTS user account password.

- `--rule_id` — ID of the rule created in KWTS.
- Specify one of the options depending on the type of the object being blocked:
  - `--url` — specify the field of the KUMA event from which you want to obtain the URL, for example, `{{.RequestUrl}}`.
  - `--ip` — specify the field of the KUMA event from which you want to obtain the IP address, for example, `{{.DestinationAddress}}`.
  - `--domain` — specify the field of the KUMA event from which you want to obtain the domain name, for example, `{{.DestinationHostName}}`.
- `--ntlm` — specify this option if the KWTS user was created with NTLM authentication.

  Example:
  ```
  --host <address> --username <user> --password <pass> --rule_id <id> --url {{.RequestUrl}}
  ```

g. In the **Conditions** section, add conditions corresponding to correlation rules that require blocking in KWTS when triggered.

h. Click **Save**.

2. Add the response rule to the correlator:

a. In the main menu, go to **Monitoring** → **Resources and services** → **Correlators**, select the correlator that must respond and in whose directory you placed the script.

b. In the steps tree, select **Response rules**.

c. Then click the **Add** button.

d. In the **Response rule** drop-down list, select the rule added at step 1 of these instructions.

e. In the steps tree, select **Setup validation**.

f. Click **Save and reload services**.

g. Click **Save**.

The response rule is linked to the correlator and ready to use.

Integration with Kaspersky Secure Mail Gateway

This integration is an example and may require additional configuration depending on the versions used and the specifics of the infrastructure.
The terms and conditions of premium technical support do not apply to this integration; support requests are processed without a guaranteed response time.

You can configure integration with the Kaspersky Secure Mail Gateway mail traffic analysis and filtering system (hereinafter also referred to as "KSMG").

Configuring the integration involves creating KUMA response rules that allow running KSMG tasks. Tasks must be created in advance in the KSMG web interface.

Configuring the integration involves the following steps:

1. Configuring integration in KSMG
2. Preparing a script for the response rule
3. **Configuring the KUMA response rule**

Configuring integration in KSMG

To prepare the integration in KSMG:

1. Connect to the KSMG web interface under an administrator account and create a role with permissions to view and create/edit a rule.

   For more details on creating a role, see the *Kaspersky Secure Mail Gateway Help*.

2. Assign the created role to a user with NTML authentication.

   You can use the 'Administrator' local administrator account.

3. In the **Rules** section, click **Create**.
4. In the left pane, select the **General** section.
5. Enable the rule using the **Status** toggle switch.
6. In the **Rule name** field, enter the name of the new rule.
7. Under **Mode**, select one of the message processing options that meets the criteria of this rule.
8. Under **Sender** on the **Email addresses** tab, enter a nonexistent or known malicious sender address.
9. Under **Recipient** on the **Email addresses** tab, specify the relevant recipients or the "*" character to select all recipients.
10. Click **Save**.
11. In the KSMG web interface, open the rule you just created.
12. Make a note of the ID value that is displayed at the end of the page address in the browser address bar.

    You must use this value when configuring the response rule in KUMA.

The integration is prepared on the KSMG side.

Preparing a script for integration with KSMG

To prepare a script for use:

1. Copy the ID of the correlator whose correlation rules must trigger the blocking of the IP address or email address of the message sender in KSMG:

   a. In the main menu, go to **Monitoring** → **Resources and services** → **Active services**.

   b. Select the check box next to the correlator whose ID you want to obtain, and click **Copy ID**.

   The correlator ID is copied to the clipboard.

2. Download the script and library:

   https://box.kaspersky.com/d/2dfd1d677c7547a7ac1e/

3. Place the downloaded script on the KUMA correlator server at the following path: /opt/kaspersky/kuma/correlator/<correlator ID from step 1>/scripts/.

4. Connect to the correlator server via SSH and go to the path from step 3:

   ```
   cd /opt/kaspersky/kuma/correlator/<correlator ID from step 1>/scripts/
   ```

5. Run the following command:

   ```
   chmod +x ksmg.py ksmgWebApiV2.py && chown kuma:kuma ksmg.py ksmgWebApiV2.py
   ```

The script is ready to use.

Importing asset information from RedCheck

This integration is an example and may require additional configuration depending on the versions used and the specifics of the infrastructure.
The terms and conditions of premium technical support do not apply to this integration; support requests are processed without a guaranteed response time.

RedCheck is a system for monitoring and managing the information security of an organization.

You can import asset information from RedCheck network device scan reports into KUMA.

Import is available from simple "Vulnerabilities" and "Inventory" reports in CSV format, grouped by hosts.

Imported assets are displayed in OSMP Console in the **Asset management** → **Assets (Devices)** → **Analysis and response** section. If necessary, you can edit the settings of assets.

Data is imported through the API using the redcheck-tool.py utility. The utility requires Python 3.6 or later and the following libraries:

- csv
- re

- json
- requests
- argparse
- sys

To import asset information from a RedCheck report:

1. Generate a network asset scan report in RedCheck in CSV format and copy the report file to the server where the script is located.

   For more details about scan tasks and output file formats, refer to the RedCheck documentation.

2. Create a file with the token for accessing the KUMA REST API.

   The account for which the token is created must satisfy the following requirements:

   - Administrator or Analyst role.
   - Access to the tenant into which the assets will be imported.
   - Rights to use API requests: GET /assets, GET /tenants, POST/assets/import.

3. Download the script:

   https://box.kaspersky.com/d/2dfd1d677c7547a7ac1e/

4. Copy the redcheck-tool.py tool to the server hosting the KUMA Core and make the tool's file executable:

   ```
   chmod +x <path to the redcheck-tool.py file>
   ```

5. Run the redcheck-tool.py utility:

   ```
   python3 redcheck-tool.py --kuma-rest <address and port of the KUMA REST API server> --token <API token> --tenant <name of the tenant in which the assets must be placed> --vuln-report <full path to the "Vulnerabilities" report file> --inventory-report <full path to the "Inventory" report file>
   ```

   Example:

   ```
   python3 --kuma-rest example.kuma.com:7223 --token 949fc03d97bad5d04b6e231c68be54fb --tenant Main --vuln-report /home/user/vuln.csv --inventory-report /home/user/inventory.csv
   ```

   You can use additional flags and commands for import operations. For example, the `-v` command displays an extended report on the received assets. A detailed description of the available flags and commands is provided in the "Flags and commands of redcheck-tool.py" table. You can also use the `--help` command to view information on the available flags and commands.

The asset information is imported from the RedCheck report to KUMA. The console displays information on the number of new and updated assets.

Example:

```
inventory has been imported for 2 host(s)
software has been imported for 5 host(s)
vulnerabilities has been imported for 4 host(s)
```

Example of extended import information:

```
[inventory import] Host: localhost Code: 200 Response: {'insertedIDs': {'0': '52ca11c6-a0e6-4dfd-8ef9-
bf58189340f8'}, 'updatedCount': 0, 'errors': []}
[inventory import] Host: 10.0.0.2 Code: 200 Response: {'insertedIDs': {'0': '1583e552-5137-4164-92e0-
01e60fb6edb0'}, 'updatedCount': 0, 'errors': []}
[software import][error] Host: localhost Skipped asset with FQDN localhost or IP 127.0.0.1
[software import] Host: 10.0.0.2 Code: 200 Response: {'insertedIDs': {}, 'updatedCount': 1, 'errors': []}
[vulnerabilities import] Host: 10.0.0.2 Code: 200 Response: {'insertedIDs': {}, 'updatedCount': 1, 'errors': []}
[vulnerabilities import] Host: 10.0.0.1 Code: 200 Response: {'insertedIDs': {'0': '0628f683-c20c-4107-abf3-
d837b3dbbf01'}, 'updatedCount': 0, 'errors': []}
[vulnerabilities import] Host: localhost Code: 200 Response: {'insertedIDs': {}, 'updatedCount': 1, 'errors': []}
[vulnerabilities import] Host: 10.0.0.3 Code: 200 Response: {'insertedIDs': {'0': 'ed01e0a8-dcb0-4609-ab2b-
91e50092555d'}, 'updatedCount': 0, 'errors': []}
inventory has been imported for 2 host(s)
software has been imported for 1 host(s)
vulnerabilities has been imported for 4 host(s)
```

The utility works as follows when importing assets:

- KUMA overwrites the data of assets imported through the API, and deletes information about their resolved vulnerabilities.
- KUMA skips assets with invalid data.

Flags and commands of redcheck-tool.py

Flags and commands	Mandatory	Description
`--kuma-rest <address and port of the KUMA server>`	Yes	Port 7223 is used for API requests by default. You can change the port if necessary.
`--token <token>`	Yes	The value of the option must contain only the token. The Administrator or Analyst role must be assigned to the user account for which the API token is being generated.
`--tenant <tenant name>`	Yes	Name of the KUMA tenant to which you want to import assets from the RedCheck report.
`--vuln-report <full path to the "Vulnerabilities" report>`	Yes	"Vulnerabilities" report file in CSV format.
`--inventory-report <full path to the "Inventory" report file>`	No	"Inventory" report file in CSV format.
`-v`	No	Display extended information about the import of assets.

Possible errors

Error message	Description
Tenant %w not found	The tenant name was not found.
Tenant search error: Unexpected status Code: %d	An unexpected HTTP response code was received while searching for the tenant.
Asset search error: Unexpected status Code: %d	An unexpected HTTP response code was received while searching for an asset.
[%w import][error] Host: %w Skipped asset with FQDNlocalhost or IP 127.0.0.1	When importing inventory/vulnerabilities information, host cfqdn=localhost or ip=127.0.0.1 was skipped.

Configuring receipt of Sendmail events

You can configure the receipt of Sendmail mail agent events in the KUMA SIEM system.

Configuring event receiving consists of the following steps:

1. Configuring Sendmail logging.
2. Configuring the event source server.
3. Creating a KUMA collector.

   To receive Sendmail events, use the following values in the Collector Installation Wizard:

   - At the **Event parsing** step, select the **[OOTB] Sendmail syslog** normalizer.
   - At the **Transport** step, select the **tcp** or **udp** connector type.
4. Installing KUMA collector.
5. Verifying receipt of Sendmail events in the KUMA collector

   You can verify that the Sendmail event source server is correctly configured in the Searching for related events section of OSMP Console.

Configuring Sendmail logging

By default, events of the Sendmail system are logged to syslog.

To make sure that logging is configured correctly:

1. Connect via SSH to the server on which the Sendmail system is installed.
2. Run the following command:

   ```
   cat /etc/rsyslog.d/50-default.conf
   ```

   The command should return the following string:

   ```
   mail.* -/var/log/mail.log
   ```

If logging is configured correctly, you can proceed to configuring the export of Sendmail events.

Configuring export of Sendmail events

Events are sent from the Sendmail mail agent server to the KUMA collector using the rsyslog service.

To configure transmission of Sendmail events to the collector:

1. Connect to the server where Sendmail is installed using an account with administrative privileges.
2. In the /etc/rsyslog.d/ directory, create the Sendmail-to-siem.conf file and add the following line to it:

   ```
   If $programname contains 'sendmail' then @<<IP address of the collector>:<port of the collector>>
   ```

   Example:

   ```
   If $programname contains 'sendmail' then @192.168.1.5:1514
   ```

   If you want to send events via TCP, the contents of the file must be as follows:

```
If $programname contains 'sendmail' then @@< <IP address of the collector> : <port of
the collector> >
```

3. Create a backup copy of the /etc/rsyslog.conf file.

4. Add the following lines to the /etc/rsyslog.conf configuration file:

   ```
   $IncludeConfig /etc/Sendmail-to-siem.conf
   $RepeatedMsgReduction off
   ```

5. Save your changes.

6. Restart the rsyslog service:

   ```
   sudo systemctl restart rsyslog.service
   ```

Configuring integration with an external SIEM system

OSMP can send information about alerts and user actions in the application web interface using Syslog protocol to an external SIEM system that your organization already uses.

The external SIEM system can be:

- Kaspersky Unified Monitoring and Analysis Platform (KUMA)
- A third-party SIEM system

To transmit data, you need to create a destination point of the tcp or udp type, depending on the chosen protocol. When transmitting data over TCP, you can use TLS encryption. To do this, specify a TLS certificate when creating the destination.

To upload a TLS certificate for encrypting the connection to a SIEM system:

1. In the window for creating a destination of the tcp type, select the **Advanced settings** tab.

2. In the **TLS mode** field, select one of the following values:

   - **Custom CA**

     Select this if you want to upload a certificate file. In the **Custom CA** field, specify the secret that contains the certificate file. You can select an existing secret or create a new secret. To create a secret, select **Create new** from the list and upload a TLS certificate in the displayed window.

   - **Custom PFX**

     Select this if you want to upload a certificate file in the PFX format. In the **PFX secret** field, specify the secret that contains the certificate file. You can select an existing secret or create a new secret. To create a secret, select **Create new** from the list and upload a PFX file that contains the TLS certificate in the displayed window.

3. Manage other destination settings as needed. Then click the **Create** button.

The uploaded TLS certificate will be used to encrypt the connection to the SIEM system.

Managing KUMA

This section describes the general settings of KUMA.

Configuring the KUMA Core

To configure KUMA Core settings:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Other**, click **Common**.

   This opens the **Common** window.

3. In the **Core settings** section, specify the following settings:

   - Use the **Debug** toggle switch to enable or disable system operation logging (debug mode). The toggle switch is turned off by default.
   - If debug mode is enabled, you can use the **Dump KSC HTTP Traffic** toggle switch to enable or disable the ability to dump HTTP traffic of Kaspersky Security Center.
   - If the dumping of HTTP traffic of Kaspersky Security Center is enabled, you can use the **Periodic dumping** toggle switch to enable or disable the dumping of Kaspersky Security Center HTTP requests and responses to the event log.

     After enabling the **Enable periodic dump** check box, specify the dump settings under **Dump settings**.
   - In the **Week start day** drop-down list, select the first day of the week to be used for the entire KUMA instance. The selected value is applied when selecting periods and specifying time intervals in all sections of KUMA. The default is **Monday**. Only a user with the Main administrator role can modify this setting. The selected value is saved in the KUMA Core settings.
   - In the **KUMA resources localization** drop-down list, select a localization language for KUMA resources imported from the repository. The default language is English. If this setting is changed, only new KUMA resources will be imported in the selected language. If you have previously imported resources in another language, such resources will remain unchanged. To change the language of previously imported resources, you need to re-import them from the repository.

     The **KUMA resources localization** setting is independent of the Kaspersky EDR Expert language setting. You can select different localization languages in these settings. In this case, for example, the language of the texts in the resource table may differ from the localization language of the interface.

     The **KUMA resources localization** setting does not affect manually created resources.
   - If necessary, click the **Reissue** button to reissue the AI service certificate and the internal CA certificate.

     After reissuing the AI service certificate, you must manually restart all services. To apply the new AI service certificate, you must restart the KUMA Core.

4. If you do not want to use a self-signed KUMA certificate, in the **External TLS pair** section, upload a certificate and key for the TLS pair.

   By clicking the **Update certificate** button, you can update the certificate for the TLS pair.

5. Under **Core properties**, specify the following settings:

   - Select the **Compacting SQLite** check box and specify the amount of disk space in GB. This allows you to reduce the size of the database for more efficient use of disk space.

     By default, the check box is selected, and the disk space is set to 10,000 GB.

   - In the **Activation tag** field, specify an applicable tag.

   - In the **Alert retention period, days** field, specify the retention period for alerts in days. You can specify any value greater than 0.

     The default retention period is 365 days.

   - In the **Asset bulk merge size** field, specify the number of assets in one group (batch) into which the total set of assets is split before the start of the merge. Each group of assets is sequentially processed by the program: assets are merged, verified and saved. If a value of 10 is specified, then 100 assets are split into 10 groups of 10 assets, and the groups are processed one by one. Specifying a smaller value yields smaller groups, which makes the merge faster because the application processes less data per step.

     You can specify any value greater than 0. The default setting is 10.

   - In the **Maximum number of services to be started simultaneously** field, specify the number of services that KUMA can start simultaneously.

     The default setting is 10.

     > Too many services running at the same time can slow down the processing of KUMA data.

   - In the **Correlation rule exclusions TTL, hours** field, specify the lifetime in hours for correlation rule exclusions. You can specify a value from 1 to 8760 (24*365) inclusive.

     The default setting is 72.

   - In the **Disk buffer size of service destination of Core (for sending events), MB** field, specify the size of the disk buffer on the Core that is allocated for each service. This buffer is used when internal events cannot be sent to correlators. You can set any buffer size greater than 0.

     The default setting is 1024 MB.

   - In the **Timeout of sending events via service destination of Core, seconds** field, specify the timeout for establishing the connection to the service when sending events. You can specify any timeout longer than 0 seconds.

     The default setting is 15 seconds.

   - In the **The hour of the day when Core is authorized to perform self-service tasks** field, specify the time (in UTC) when the Core can perform self-service operations. The KUMA Core performs such operations on a daily basis. You can specify a value from 0 to 23, inclusive.

     > We recommend performing KUMA Core maintenance during nighttime, when users are not using the functionality of the KUMA Core.

     The default setting is 1 (UTC time).

- In the **Max stored file size, MB** field, specify the maximum size of the compressed data of the downloaded GeoIP database and repository packages.

  The default setting is 300 MB.

- In the **Resource history retention period, days** field, specify the retention period for the resource changes history in days. You can set any value greater than or equal to 0.

  The default setting is 12 days.

- In the **Cluster request timeout from the UI, seconds** field, specify how long the KUMA web client must wait for a response after requesting the list of storages. You can set any value greater than 0.

  The default setting is 30 seconds.

- In the **Storage nodes health check timeout, seconds** field, specify the time to wait for a response after requesting an availability check of certain storage nodes. You can set any value greater than 0.

  The default setting is 30 seconds.

- If necessary, in the **KUMA UI balancer hostname and port** field, specify the host name and port of the KUMA user interface balancer.

  Given the distributed nature of the KUMA Core, multiple Core nodes can be configured to work as a cluster. You can configure the connection to the cluster through the balancer.

  > You can specify only one balancer URL.

  The balancer URL must be specified in the `hostname:port` format, where

  - `hostname` is the hostname of the balancer.
  - `port` is the port of the balancer.

  > Other balancer URL formats are not allowed.

6. Click **Save**.

Proxies

Proxy servers are used to store proxy server configuration settings, for example, in destinations. The http type is supported.

Available settings:

- **Name** (required)—unique name of the proxy server. Must contain 1 to 128 Unicode characters.
- **Tenant** (required)—name of the tenant that owns the resource.
- **Secret separately**—if this check box is selected, the window displays the required **URL** field in which you can specify the connection URL, and a **Secret** drop-down list with secrets of the 'credentials' type. In this way, you can view connection information without having to re-create a large number of connections if the password of the user account that you used for the connections changes. If the check box is cleared, the **URL** and **Secret** fields are not available. This check box is cleared by default.

- **URL** (required) is the field for specifying the URL of the connection. It is used together with a secret of the 'credentials' type. Available if the **Secret separately** check box is selected.
- **Secret** is a drop-down list for selecting an existing secret or creating a new secret of the 'credentials' type. The drop-down list is available if the **Secret separately** check box is selected.
- **Use URL from the secret** (required)—drop-down list to select a secret resource that stores URLs of proxy servers. If required, a secret can be created in the proxy server creation window by clicking the plus icon (+). You can change the selected secret by clicking the pencil icon ( ).
- **Do not use for domains**—one or more domains that require direct access.
- **Description**—up to 4,000 Unicode characters.

Connecting to an SMTP server

KUMA can be configured to send email notifications using an SMTP server. Users will receive notifications if the **Receive email notifications** check box is selected in their profile settings.

Only one SMTP server can be added to process KUMA notifications. An SMTP server connection is managed in OSMP Console under **Settings** → **KUMA** → **Open KUMA settings** → **Common** → **SMTP server settings**.

To configure SMTP server connection:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.
2. This opens the KUMA settings window.
3. Under **Other**, click **Common**.
4. This opens the **Common** window.
5. In the **SMTP server settings** block, change the relevant settings:
   - **Disabled**—select this check box if you want to disable connection to the SMTP server.
   - **Host** (required)—SMTP host in one of the following formats: hostname, IPv4, IPv6.
   - **Port** (required)—SMTP port. The value must be an integer from 1 to 65,535.
   - **From** (required)—email address of the message sender. For example, `kuma@company.com`.
   - **Alias for KUMA Core server**—name of the KUMA Core server that is used in your network. Must be different from the FQDN.
   - If necessary, use the **Secret** drop-down list to select a secret of the **credentials** type that contains the account credentials for connecting to the SMTP server.

     Add secret

To create a secret:

1. In the **Name** field, enter the name of the secret.
2. In the **User** and **Password** fields, enter the credentials of the user account that the Agent will use to connect to the connector.
3. If necessary, enter a description of the secret in the **Description** field.
4. Then click the **Create** button.

   The secret is added and displayed in the **Secret** drop-down list.

- Select the necessary frequency of notifications in the **Monitoring notifications interval** drop-down list.

  Notifications from the source about a monitoring policy triggering are repeated after the selected period until the status of the source becomes green again.

  If the **Notify once** setting is selected, you receive a notification about monitoring policy activation only once.

- Turn on the **Disable monitoring notifications** toggle button if you do not want to receive notifications about the state of event sources. The toggle switch is turned off by default.

- Click the **Test connection** button. KUMA will send a test message to the email address specified in the current user profile. The test message will be sent even if the **Receive email notifications** check box is not selected in the user profile.

  Check your email inbox. If the test message is delivered, the SMTP server is configured correctly. If an error occurs while sending the message, check the SMTP server settings. The error is displayed in the interface and also recorded in the KUMA Core log. If the message is sent but not delivered to the mailbox, check the SMTP server log for error messages.

  We recommend sending a test message each time you change the SMTP server settings or notification template.

6. Click **Save**.

The SMTP server connection is now configured, and users can receive email messages from KUMA.

Working with Kaspersky Security Center tasks

You can connect Kaspersky Security Center assets to KUMA and download database and application module updates to these assets, or run an anti-virus scan on them by using Kaspersky Security Center tasks. Tasks are started in the KUMA Console.

To run Kaspersky Security Center tasks on assets connected to KUMA, it is recommended to use the following script:

1. **Creating a user account in the Kaspersky Security Center Administration Console**

   The credentials of this account are used when creating a secret to establish a connection with Kaspersky Security Center, and can be used to create a task.

   For more details about creating a user account and assigning permissions to a user, please refer to the *Kaspersky Security Center Help Guide*.

2. **Creating KUMA tasks in Kaspersky Security Center**

3. [Configuring KUMA integration with Kaspersky Security Center]

4. **Importing asset information from Kaspersky Security Center into KUMA**

   All assets that are protected by this program are registered in Kaspersky Security Center. Information about assets protected by Kaspersky Security Center can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

   KUMA imports the following device information received from Kaspersky Security Center Network Agents:

   - Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
   - Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

   To import information about the Kaspersky Security Center assets:

   1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
   2. Click **Import**, and then select one of the following actions:
      - To import information about the basic attributes of assets, click **Import KSC assets**.

        This opens the **Import KSC assets** window.
      - To import information about other attributes of assets, click **Import KSC assets attributes**.

        This opens the **Import KSC assets attributes** window.
   3. In the drop-down list, select the tenant for which you want to perform the import.

      In this case, the program downloads information about all assets of all Kaspersky Security Center servers that have been configured to connect to the selected tenant.

      If you want to import information about all assets of all Kaspersky Security Center servers for all tenants, select **All**.
   4. Click the **Import** button.

   The asset information will be imported.

   Also, in a tenant properties window, you can schedule regular import of asset information or run import manually.

5. [Assigning a category to the imported assets]

   After import, the assets are automatically placed in the **Uncategorized devices** group. You can assign one of the existing categories to the imported assets, or create a category and assign it to the assets.

6. **Running tasks on assets**

   You can manually run tasks in the asset information or configure tasks to run automatically.

Creating KUMA tasks in Kaspersky Security Center

You can run the anti-virus database and application module update task, and the virus scan task on Kaspersky Security Center assets connected to KUMA. The assets must have Kaspersky Endpoint Security for Windows or Kaspersky Endpoint Security for Linux installed. The tasks are created in OSMP Console.

For more details about creating the *Update* and *Virus scan* tasks on the assets with Kaspersky Endpoint Security for Windows, refer to the *Kaspersky Endpoint Security for Windows Help Guide*.

For more details about creating the *Update* and *Virus scan* tasks on the assets with Kaspersky Endpoint Security for Linux, refer to the *Kaspersky Endpoint Security for Linux* Help Guide.

Task names must begin with "kuma" (not case-sensitive and without quotations). For example, `KUMA antivirus check`. Otherwise, the task is not displayed in the list of available tasks in the KUMA Console.

Starting Kaspersky Security Center tasks manually

You can manually run the anti-virus database, application module update task, and the anti-virus scan task on Kaspersky Security Center assets connected to KUMA. The assets must have Kaspersky Endpoint Security for Windows or Kaspersky Endpoint Security for Linux installed.

First, you need to configure the integration of Kaspersky Security Center with KUMA and create tasks in Kaspersky Security Center.

To manually start a Kaspersky Security Center task:

1. In the KUMA Console, go to the **Assets** section, and select the asset that was imported from Kaspersky Security Center.

   The **Asset details** window opens.

2. Click **OSMP response**.

   This button is displayed if the connection to the Kaspersky Security Center that owns the selected asset is enabled.

3. In the opened **Select task** window, select the check boxes next to the tasks that you want to start, and click the **Start** button.

Kaspersky Security Center starts the selected tasks.

Some types of tasks are available only for certain assets.

You can obtain vulnerability and software information only for assets running a Windows operating system.

Starting Kaspersky Security Center tasks automatically

You can configure the automatic start of the anti-virus database and application module update task and the virus scan task for Kaspersky Security Center assets connected to KUMA. The assets must have Kaspersky Endpoint Security for Windows or Kaspersky Endpoint Security for Linux installed.

First, you need to configure the integration of Kaspersky Security Center with KUMA and create tasks in Kaspersky Security Center.

Configuring automatic start of Kaspersky Security Center tasks includes the following steps:

Step 1. Adding a correlation rule

To add a correlation rule:

1. In the KUMA Console, select the **Resources** section.
2. Select **Correlation rules** and click the **Add correlation rule** button.
3. On the **General** tab, specify the following settings:
   a. In the **Name** field, define the rule name.
   b. In the **Tenant** drop-down list, select the tenant that owns the resource.
   c. In the **Type** drop-down list, select **simple**.
   d. In the **Propagated fields** field, add the following fields: DestinationAssetID.
   e. If required, define the values for the following fields:
      - In the **Rate limit** field, define the maximum number of times per second that the rule will be triggered.
      - In the **Severity** field, define the severity of alerts and correlation events that will be created as a result of the rule being triggered.
      - In the **Description** field, provide any additional information.
4. On the **Selectors** → **Settings** tab:
   a. In the **Filter** drop-down list, select **Create new**.
   b. In the **Conditions** field, click the **Add group** button.
   c. In the operator field for the group you added, select **AND**.
   d. Add a condition for filtering by the DeviceProduct field value:
      1. In the **Conditions** field, click the **Add condition** button.
      2. In the condition field, select **If**.

3. In the **Left operand** field, select event field.
4. In the **Event field** field, select DeviceProduct.
5. In the **Operator** field, select =.
6. In the **Right operand** field, select **constant**.
7. In the **Value** field, enter `OSMP`.

e. Add a condition for filtering by the Name field value:

1. In the **Conditions** field, click the **Add condition** button.
2. In the condition field, select **If**.
3. In the **Left operand** field, select event field.
4. In the event field, select Name.
5. In the **Operator** field, select =.
6. In the **Right operand** field, select **constant**.
7. In the **value** field, enter the name of the event. When this event is detected, the task is started automatically.

   For example, if you want the *Virus scan* task to start when Kaspersky Security Center registers the *Malicious object detected* event, specify this name in the **Value** field.

   You can view the event name in the **Name** field of the event details.

5. On the **Actions** tab, specify the following settings:

a. In the **Actions** section, open the **On every event** drop-down list.

b. Select the **Output** check box.

You do not need to fill in other fields.

6. Click **Save**.

The correlation rule will be created.

Step 2. Creating a correlator

You need to launch the Correlator Installation Wizard. At step 3 of the Wizard, you are required to select the correlation rule that you added by following this guide.

> The DeviceHostName field must display the domain name (FQDN) of the asset. If it is not displayed, create a DNS record for this asset and create a DNS enrichment rule at Step 4 of the Wizard.

Step 3. Adding a filter

To add a filter:

1. In the KUMA Console, select the **Resources** section.
2. Select **Filters** and click the **Add filter** button.
3. In the **Name** field, specify the filter name.
4. In the **Tenant** drop-down list, select the tenant that owns the resource.
5. In the **Conditions** field, click the **Add group** button.
6. In the operator field for the group you added, select **AND**.
7. Add a condition for filtering by the DeviceProduct field value:
    a. In the **Conditions** field, click the **Add condition** button.
    b. In the condition field, select **If**.
    c. In the **Left operand** field, select event field.
    d. In the **Event field** field, select Type.
    e. In the **Operator** field, select =.
    f. In the **Right operand** field, select **constant**.
    g. In the **Value** field, enter 3.
8. Add a condition for filtering by the Name field value:
    a. In the **Conditions** field, click the **Add condition** button.
    b. In the condition field, select **If**.
    c. In the **Left operand** field, select event field.
    d. In the event field, select Name.
    e. In the **Operator** field, select =.
    f. In the **Right operand** field, select **constant**.
    g. In the **Value** field, enter the name of the correlation rule created at Step 1.

Step 4. Adding a response rule

To add a response rule:

1. In the KUMA Console, select the **Resources** section.
2. Select **Response rules** and click the **Add response rule** button.
3. In the **Name** field, define the rule name.

4. In the **Tenant** drop-down list, select the tenant that owns the resource.
5. In the **Type** drop-down list, select **Response via OSMP**.
6. In the **Open Single Management Platform task** drop-down list, select the Kaspersky Security Center task you want to start.
7. In the **Event field** drop-down list, select the DestinationAssetID.
8. In the **Workers** field, specify the number of processes that the service can run simultaneously.

   By default, the number of work processes is the same as the number of virtual processors on the server where the correlator service is installed.

- In the **Description** field, you can add up to 4,000 Unicode characters.
- In the **Filter** drop-down list, select the filter added at Step 3 of this instruction.

To send requests to Kaspersky Security Center, you must ensure that Kaspersky Security Center is available over the UDP protocol.

If response rules are owned by the Shared tenant, then the tasks from the Kaspersky Security Center server to which the Main tenant is connected are displayed as Kaspersky Security Center tasks available for selection.

If a response rule has a selected task that is absent from the Kaspersky Security Center Server that the tenant is connected to, the task is not performed for assets of this tenant. This situation can arise, for example, when two tenants are using a common correlator.

Step 5. Adding a response rule to the correlator

To add a response rule to the correlator:

1. In the KUMA Console, select the **Resources** section.
2. Select **Correlators**.
3. In the list of correlators, select the correlator added at Step 2 of this instruction.
4. In the steps tree, select **Response rules**.
5. Then click the **Add** button.
6. In the **Response rule** drop-down list, select the rule added at step 4 of these instructions.
7. In the steps tree, select **Setup validation**.
8. Click the **Save and restart services** button.
9. Click **Save**.

The response rule will be added to the correlator.

The automatic start will be configured for the anti-virus database and application module update task and the virus scan task on Kaspersky Security Center assets connected to KUMA. The tasks are started when a threat is detected on the assets and KUMA receives the corresponding events.

Checking the status of Kaspersky Security Center tasks

In the KUMA Console, you can check whether a Kaspersky Security Center task was started or whether a search for events owned by the collector listening for Kaspersky Security Center events was completed.

To check the status of Kaspersky Security Center tasks:

1. In KUMA, select **Resources** → **Active services**.
2. Select the collector that is configured to receive events from the Kaspersky Security Center Server and click the **Go to Events** button.

   A new browser tab will open in the **Events** section of KUMA. The table displays events from the Kaspersky Security Center Server. The status of the tasks can be seen in the **Name** column.

Kaspersky Security Center event fields:

- **Name**—status or type of the task.
- **Message**—message about the task or event.
- **FlexString<number>Label**—name of the attribute received from Kaspersky Security Center. For example, `FlexString1Label=TaskName`.
- **FlexString<number>**—value of the FlexString<number>Label attribute. For example, `FlexString1=Download updates`.
- **DeviceCustomNumber<number>Label**—name of the attribute related to the task state. For example, `DeviceCustomNumber1Label=TaskOldState`.
- **DeviceCustomNumber<number>**—value related to the task state. For example, `DeviceCustomNumber1=1` means the task is executing.
- **DeviceCustomString<number>Label**—name of the attribute related to the detected vulnerability: for example, a virus name, affected application.
- **DeviceCustomString<number>**—value related to the detected vulnerability. For example, the attribute-value pairs `DeviceCustomString1Label=VirusName` and `DeviceCustomString1=EICAR-Test-File` mean that the EICAR test virus was detected.

KUMA logs

Component logs

By default, only errors are logged for all KUMA components. To receive detailed data in logs, configure **Debug** mode in the component settings.

The log is appended until it reaches 5 GB. When the log reaches 5 GB, it is archived and new events are written to a new log. Archives are kept in the log folder for 7 days, after 7 days the archive is deleted. A maximum of four archived logs are stored on the server at the same time. Whenever a new log archive is created, if the total number of archives becomes greater than four, the oldest log archive is deleted.

Debug mode is available for the following components:

Services:
• Storage
• Correlators
• Collectors
• Agents
	To enable it, use the **Debug** toggle switch in the settings of the service.
	
	Storage location: the service installation directory. For example, /opt/kaspersky/kuma/<service name>/log/<service name>. You can download the service logs from the KUMA Console, in the **Resources** → **Active services** section by selecting the desired service and clicking **Log**.
	
	Logs residing on Linux machines can be viewed by running the journalctl and tail command. For example:
	• Storage. To return the latest logs from the storage installed on the server, run the following command:
	`journalctl -f -u kuma-storage-< storage ID >`
	• Correlators. To return the latest logs from correlators installed on the server, run the following command:
	`journalctl -f -u kuma-correlator-< correlator ID >`
	• Collectors. To return the latest logs from a specific collector installed on the server, run the following command:
	`journalctl -f -u kuma-collector-< collector ID >`
	• Agents. To return the latest logs from an agent installed on the server, run the following command:
	`tail -f /opt/kaspersky/agent/< Agent ID >/log/agent`
	The activity of Agents on Windows machines is always logged if they are assigned the logon as a service permission. Data is specified in more detail when the **Debug** check box is selected. Agent logs on Windows machines can be viewed in the file located at the path %PROGRAMDATA%\Kaspersky Lab\KUMA\<Agent ID>\agent.log. Logs of Agents on Linux computers are stored in the agent installation directory.

Resources: • Connectors • Destinations • Enrichment rules	To enable it, use the **Debug** toggle switch in the settings of the service to which the resource is linked. The logs are stored on the machine hosting the installed service that uses the relevant resource. Detailed data for resources can be viewed in the log of the service linked to a resource.

KUMA notifications

Standard notifications

KUMA can be configured to send email notifications using an SMTP server. To do so, configure a connection to an SMTP server and select the **Receive email notifications** check box for users who should receive notifications.

KUMA automatically notifies users about the following events:

- A report was created (the users listed in the report template receive a notification).
- A task was performed (the users who created the task receive a notification).
- New resource packages are available. They can be obtained by updating the KUMA repository (the users whose email address is specified in the task settings are notified).

Editing a KUMA user profile

To edit a KUMA user profile:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Access**, click **Profile**.

   This opens the **Profile** window.

3. Specify the following settings:

   - In the **Time zone** field, select the time zone in which you want timestamps to be displayed in KUMA. The list is generated based on the settings of the user's operating system and takes into account daylight saving time. The timezone of the user's browser is used by default.
   - Select the **Use ISO 8601 format** check box to display timestamps in the ISO 8601 format (for example, 2026-02-08T17:35:27+03:00). This format is used in those sections of the KUMA web interface that use an abbreviated or full display of the date and time, and is applied throughout the KUMA system. The configured format is saved in the KUMA Core settings.
   - Select the **Receive email notifications** check box if you want the user to receive SMTP notifications from KUMA.
   - **Display non-printable characters**—select this check box if you want the KUMA web interface to display non-printing characters such as spaces, tab characters, and line breaks. If the **Display non-printable characters** check box is selected, you can press **`Ctrl/Command+*`** to enable or disable the display of non-printing characters.

Spaces and tab characters are displayed in all input fields (except **Description**), in normalizers, correlation rules, filters and connectors, and in SQL queries for searching events in the **Events** section. Spaces are displayed as dots. A tab character is displayed as a dash in normalizers, correlation rules, filters and connectors. In other fields, a tab character is displayed as one or two dots.

Line break characters are displayed in all input fields that support multi-line input, such as the event search field.

- In the **Space sets** drop-down list, select check boxes next to one or more space sets to which you want to grant access. If the user does not have a space set selected, access is granted to the default space set.

4. Click **Save**.

The KUMA user profile is modified.

Working with tenants

Tenants are displayed in the table under Settings → KUMA → Open KUMA settings → Tenants. You can sort the table by clicking on columns.

Available columns:

- **Name** is the name of the tenant.
- **EPS limit** is the EPS (events per second) quota allocated to the tenant out of the overall EPS quota determined by the license.
- **Description** is the description of the tenant.
- **Created** is the tenant creation date.
- **Updated** is the date and time when the tenant information was most recently modified.

You can export the list of tenants, for example, to display tenant names in Active lists or Context tables widgets. In such cases, export the list of tenants to then import it to a dictionary. To do so, click the **Export** → **For dictionary** button. The file with the list of tenants is downloaded to your computer.

You can also export all information from the table of tenants to a file. To do so, click the **Export** → **All fields** button. The file with the list of tenants is downloaded to your computer.

Managing certificates

This section describes how to work with certificates.

Downloading certificates

You can download the following certificates in the OSMP web interface:

- REST API CA certificate.

This certificate is used to authenticate the API server serving the KUMA public API. You can also use this certificate when importing data from MaxPatrol reports.

You can change the certificate if you want to use your company certificate and key instead of the self-signed web interface certificate.

Once downloaded, the certificate can be imported into the trust storage of the operating system or browser. After that, the client will trust the TLS certificate that was issued by OSMP and signed by the certification authority.

The downloaded CA certificate is not intended for editing. If you need to change the list of node names (SAN) or use a certificate from a corporate certification authority, you should issue a new TLS certificate and upload it to OSMP in the **Settings** → **KUMA** → **Open KUMA settings** → **Common** → **External TLS pair** section.

If the cluster contains multiple nodes running the KUMA Core service and direct connections to each node are expected, it is recommended to use a TLS certificate whose SAN includes the FQDNs of all KUMA Core nodes. Otherwise, the browser may display a warning that the node name does not match the certificate.

The FQDN of nodes in the Subject Alternative Names (SAN) field is specified at the stage of issuing a new TLS certificate. You do not need to modify the downloaded REST API CA certificate.

- Microservice CA certificate.

  This certificate is used for authentication when connecting log sources to passive collectors using TLS, but without specifying your own certificate.

- AI service certificate.

  This certificate is required to install the **AI-rating and AI-status of assets** service.

To download a certificate:

1. In the OSMP web interface, go to the **Resources and services** → **Active services** section.
2. In the toolbar, in the (⋮) menu select a command:
   - **Download REST API CA certificate**
   - **Download Microservice CA certificate**
   - **Download AI service certificate**

   The certificate is saved to the folder specified in your browser settings.

To copy the certificate fingerprint:

1. In the OSMP web interface, go to the **Resources and services** → **Active services** section.
2. In the toolbar, from the menu (⋮), select **Copy fingerprint**.

   The fingerprint certificate ID is copied to the clipboard. Use the fingerprint ID of the CA certificate as the value of the `--pair.fingerprint` option in the service installation command for validation of the KUMA Core certificate when the service connects to the KUMA Core for the first time.

Modifying the self-signed web interface certificate

You can use your company certificate and key instead of a self-signed web interface certificate. For example, if you want to replace a self-signed CA Core certificate with a certificate issued by an enterprise CA, you must provide an `external.cert` and an unencrypted `external.key` in PEM format.

The provided instruction shows how to replace a self-signed CA Core certificate with an enterprise certificate in PFX format. You can use the instructions as an example and adapt the steps according to your needs.

To replace the OSMP web interface certificate with a corporate certificate in PFX format:

1. If you are using a certificate and key in a PFX container, use OpenSSL to convert the PFX file to a certificate and an encrypted key in PEM format:

   ```
   openssl pkcs12 -in kumaWebIssuedByCorporateCA.pfx -nokeys -out external.cert
   ```

   ```
   openssl pkcs12 -in kumaWebIssuedByCorporateCA.pfx -nocerts -nodes -out external.key
   ```

   When carrying out the command, you are required to specify the PFX key password (Enter Import Password).

   You will receive the `external.cert` certificate and the `external.key` in PEM format.

2. If your `external.key` is not encrypted, make sure that the key is in PKCS#8 format. Kaspersky SIEM will not be able to process a key file if it starts with the `BEGIN RSA PRIVATE KEY` tag. In this case, convert the file using the command:

   ```
   openssl rsa -in rsa_private.key -outform PEM -out private.key
   ```

   The file produced by this command begins with the `BEGIN PRIVATE KEY` tag, and OSMP accepts such a key file.

3. In the OSMP web interface, open the **Settings** → **KUMA** → **Open KUMA settings** → **Common** section.

4. Under **External TLS pair**, upload the `external.cert` and the unencrypted `external.key` in PEM format.

5. Restart the KUMA Core:

   ```
   systemctl restart kuma-core
   ```

6. Refresh the web page or restart the browser that you are using to manage the OSMP web interface.

Your company certificate and key have been replaced.

Reissuing internal CA certificates

Only users with the Main administrator role may reissue an internal CA certificate.

To reissue and apply an internal CA certificate:

1. In the web interface, open the **Settings** → **KUMA** → **Open KUMA settings** → **General** section.

2. Under Core settings, click the **Reissue internal CA certificates** button.

3. Confirm the re-issue of certificates in the window that opens.

   CA certificates for KUMA services and CA certificates for ClickHouse are reissued. Reissued certificates must be applied.

4. Connect to the hosts where the collector and correlator services are deployed:

   a. Stop all services by running the following command:

   ```
   sudo systemctl stop kuma-<collector/correlator/metrics>-<service_ID>.service
   ```

   where:

   <service_ID> is the service ID copied from the OSMP web interface.

   b. Delete the `internal.cert` and `internal.key` files from the `/opt/kaspersky/kuma/<service type>/<service ID>/certificates` directories using the following commands:

   ```
   sudo rm -f /opt/kaspersky/kuma/<collector/correlator/metrics>/<service_ID>/certificates/internal.cert
   ```

   ```
   sudo rm -f /opt/kaspersky/kuma/<collector/correlator/metrics>/<service_ID>/certificates/internal.key
   ```

5. Connect to the hosts where storage services are deployed:

   a. Stop all storage services:

   ```
   sudo systemctl stop kuma-<storage>-<service_ID>.service
   ```

   b. Delete the `internal.cert` and `internal.key` files from the `/opt/kaspersky/kuma/storage/<service ID>/certificates` directories using the following commands:

   ```
   sudo rm -f /opt/kaspersky/kuma/storage/<service_ID>/certificates/internal.cert
   ```

   ```
   sudo rm -f /opt/kaspersky/kuma/storage/<service_ID>/certificates/internal.key
   ```

6. Delete all ClickHouse certificates from the `/opt/kaspersky/kuma/clickhouse/certificates` directory using the following commands:

   ```
   sudo rm -f /opt/kaspersky/kuma/clickhouse/certificates/internal.cert
   ```

   ```
   sudo rm -f /opt/kaspersky/kuma/clickhouse/certificates/internal.key
   ```

7. Connect to the hosts where agent services are deployed:

   a. Stop the services of Windows agents and Linux agents.

   b. Delete the `internal.cert` and `internal.key` files from working directories of the agents.

8. Restart the KUMA Core to apply the new CA certificates:

- To deploy on a single server and distributed deployment, run the following command:

```
sudo systemctl restart kuma-core-00000000-0000-0000-0000-000000000000.service
```

- To deploy in a Kubernetes cluster, run the following commands on any controller:

```
sudo k0s kubectl exec deployment/metrics -n kuma -- rm -rf /opt/kaspersky/kuma/metrics/certificates
```

```
sudo k0s kubectl rollout restart deployment metrics -n kuma
```

```
sudo k0s kubectl rollout restart deployment/core-deployment -n kuma
```

It is recommended to restart KUMA Core using the command, since restarting through the web interface affects only the restart of the KUMA Core bucket, and not KUMA Core entirely.

9. Restart all stopped services:

```
sudo systemctl start kuma-<collector/correlator/storage/metrics>-<service_ID>.service --pair.fingerprint
<CA_cert_ID>
```

where:

- <service_ID> is the service ID copied from the KUMA web interface.
- <CA_cert_ID> is the fingerprint ID of the CA certificate used for authentication when connecting the service.

  The `--pair.fingerprint` argument is optional. When creating a service, KUMA automatically adds this option to the installation command and specifies the fingerprint ID.
  You can install a service without specifying the `--pair.fingerprint` option. In this case, KUMA uses an `insecure` value by default, which skips the validation of the KUMA Core CA certificate when establishing a connection. If set to is `insecure`, the fingerprint does not need to be updated after the CA certificate is reissued.

  To make sure the KUMA Core CA certificate gets validated, we recommend keeping the `--pair.fingerprint` option with the fingerprint ID when installing the service. In this case, when reissuing the CA certificate, you need to copy the fingerprint ID from the **Resources and services** → **Active services** → menu (⋮) → **Copy fingerprint** section.

Internal CA certificates are applied.

Reissuing a certificate for a specific service

To reset a certificate for a specific service:

1. In the web interface, go to the **Resources and services** → **Active services** section.
2. Select the check box next to the service whose certificate you want to reissue.
3. In the toolbar or menu ⋮, select **Reset certificate**.

   This option cannot be used to renew the KUMA Core certificate. To update KUMA Core certificates, they must be reissued and an internal CA certificate must be applied.

4. Delete the old certificate in the service installation directory.

The solution will generate a new certificate automatically. You do not need to restart running services, the new certificate is applied automatically. A stopped service must be restarted to have the certificate applied.

Special considerations for deleting Windows agent certificates:

- If the agent has the green status, OSMP deletes the current certificate and generates a new one. The agent will continue operating with the new certificate.
- If the agent is in a red status, an error is displayed indicating that the agent is not running. In the `%PROGRAMDATA%\Kaspersky Lab\KUMA\agent\<agent ID>\certificates` agent installation directory, delete the `internal.cert` and `internal.key` files, then start the agent manually. When the agent starts, a new certificate is created automatically.

Special considerations for deleting Linux agent certificates:

- The certificate is reset via the web interface regardless of the agent status.
- In the `/opt/kaspersky/agent/<agent ID>/certificates` agent installation folder, delete `internal.cert` and `internal.key` files.
- Resetting the certificate stops the agent, therefore you must manually start the agent to resume its operation. When the agent starts, a new certificate is created automatically.

Working with geographic data

A list of mappings of IP addresses or ranges of IP addresses to geographic data can be uploaded to KUMA for use in event enrichment.

Geodata format

Geodata can be uploaded to KUMA as a CSV file in UTF-8 encoding. A comma is used as the delimiter. The first line of the file contains the field headers: `Network,Country,Region,City,Latitude,Longitude`.

CSV file description

Field header name in CSV	Field description	Example
`Network`	IP address in one of the following formats: • IP address • Range of IP addresses • IP address in CIDR format. IPv4 and IPv6 addresses can be mixed. Required field.	• `192.168.2.24` • `192.168.2.25-192.168.2.35` • `131.10.55.70/8` • `2001:DB8::0/120`
`Country`	Country designation used by your organization. For example, this could be its name or code. Required field.	• `Russia` • `RU`
`Region`	Regional designation used by your organization. For example, this could be its name or code.	• `Sverdlovsk Oblast` • `RU-SVE`
`City`	City designation used by your organization. For example, this could be its name or code.	• `Yekaterinburg` • `65701000001`
`Latitude`	Latitude of the described location in decimal format. This field can be empty, in which case the value 0 will be used when importing data into KUMA.	`56.835556`
`Longitude`	Longitude of the described location in decimal format. This field can be empty, in which case the value 0 will be used when importing data into KUMA.	`60.612778`

Converting geographic data from MaxMind to IP2Location

KUMA can use geodata from MaxMind, IP2Location, or others in a format compatible with these. The name of the file to be converted must match the following template: (GeoIP2|GeoLite2)-(City|Country)-Blocks-IPv(4|6).csv. However, you must convert the files you want to use to a format that KUMA supports. Conversion can be done using the script below. Make sure that the files do not contain duplicate records. For example, if a file has few columns, different records may contain data from the same network with the same geodata. Such files cannot be converted. To successfully perform the conversion, make sure that there are no duplicate rows and that every row has at least one unique field.

Download script

Python 2.7 or later is required to run the script.

Script start command:

```
python converter.py --type <type of geographic data being processed: "maxmind" or
"ip2location"> --out <directory where a CSV file containing geographic data in KUMA
format will be placed> --input <path to the ZIP archive containing geographic data from
MaxMind or IP2location>
```

When the script is run with the `--help` flag, help is displayed for the available script parameters: `python converter.py --help`

Command for converting a file containing a Russian database of IP address ranges from a MaxMind ZIP archive:

```
python converter.py --type maxmind --lang ru --input MaxMind.zip --out
geoip_maxmind_ru.csv
```

If the `--lang` parameter is not specified, the script receives information from the GeoLite2-City-Locations-en.csv file from the ZIP archive by default.

Absence of the `--lang` parameter for MaxMind is equivalent to the following command:

```
python converter.py --type maxmind --input MaxMind.zip --out geoip_maxmind.csv
```

Command for converting a file from an IP2Location ZIP archive:

```
python converter.py --type ip2location --input IP2LOCATION-LITE-DB11.CSV.ZIP --out
geoip_ip2location.csv
```

Command for converting a file from several IP2Location ZIP archives:

```
python converter.py --type ip2location --input IP2LOCATION-LITE-DB11.CSV.ZIP
IP2LOCATION-LITE-DB11.IPV6.CSV.ZIP --out geoip_ip2location_ipv4_ipv6.csv
```

The `--lang` parameter is not used for IP2Location.

Required sets of fields

The MaxMind source files GeoLite2-City-Blocks-IPv4.csv and GeoLite2-City-Blocks-IPv6.csv must contain the following set of fields:

network,geoname_id,registered_country_geoname_id,represented_country_geoname_id,
is_anonymous_proxy,is_satellite_provider,postal_code,latitude,longitude,accuracy_radius

Example set of source data:

```
network,geoname_id,registered_country_geoname_id,represented_country_geoname_id,
is_anonymous_proxy,is_satellite_provider,postal_code,latitude,longitude,accuracy_radius

1.0.0.0/24,2077456,2077456,,0,0,,-33.4940,143.2104,1000

1.0.1.0/24,1814991,1814991,,0,0,,34.7732,113.7220,1000
```

The remaining CSV files with the locale code must contain the following set of fields:

geoname_id,locale_code,continent_code,continent_name,country_iso_code,country_name,
subdivision_1_iso_code,subdivision_1_name,subdivision_2_iso_code,subdivision_2_name,
city_name,metro_code,time_zone,is_in_european_union

Example set of source data:

```
geoname_id,locale_code,continent_code,continent_name,country_iso_code,country_name,
subdivision_1_iso_code,subdivision_1_name,subdivision_2_iso_code,subdivision_2_name,
city_name,metro_code,time_zone,is_in_european_union

1392,de,AS,Asien,IR,Iran,02,Mazandaran,,,,,Asia/Tehran,0

7240,de,AS,Asien,IR,Iran,28,Nord-Chorasan,,,,,Asia/Tehran,0
```

The source IP2Location files must contain data on the network ranges, Country, Region, City, Latitude, and Longitude

Example set of source data:

```
"0","16777215","-","-","-","-","0.000000","0.000000","-","-"

"16777216","16777471","US","United States of America","California","Los
Angeles","34.052230","-118.243680","90001","-07:00"

"16777472","16778239","CN","China","Fujian","Fuzhou","26.061390","119.306110","350004","+
```

If the source files contain a different set of fields than the one indicated in this section, or if some fields are missing, the missing fields in the target CSV file will be empty after conversion.

Importing and exporting geographic data

If necessary, you can manually import and export geographic data into KUMA. Geographic data is imported and exported in a CSV file. If the geographic data import is successful, the previously added data is overwritten and an audit event is generated in KUMA.

To import geographic data into KUMA:

1. Prepare a CSV file containing geographic data.

   Geographic data received from MaxMind and IP2Location must be converted to a format supported by KUMA.

2. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

3. Under **Other**, click **Common**.

   This opens the **Common** window.

4. In the **GeoIP settings** settings block, click the **Import from file** button and select a CSV file containing geographic data.

   Wait for the geographic data import to finish. The data import is interrupted if the page is refreshed.

The geographic data is uploaded to KUMA.

To export geographic data from KUMA:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Other**, click **Common**.

   This opens the **Common** window.

3. In the **GeoIP settings** settings block, click the **Export** button.

Geographic data will be downloaded as a CSV file named geoip.csv (in UTF-8 encoding) based on the settings of your browser.

The data is exported in the same format as it was uploaded, with the exception of IP address ranges. If a range of addresses was indicated in the format `1.0.0.0/24` in a file imported into KUMA, the range will be displayed in the format `1.0.0.0-1.0.0.255` in the exported file.

Default mapping of geographic data

If you select the `SourceAddress`, `DestinationAddress` and `DeviceAddress` event fields as an IP address source when configuring a geographic data enrichment rule, the **Apply default mapping** button becomes available. You can click this button to add preconfigured mapping pairs of geographic data attributes and event fields as described below.

Default mappings for the SourceAddress event field

Geodata attribute	Event field
Country	`SourceCountry`
Region	`SourceRegion`
City	`SourceCity`
Latitude	`SourceLatitude`
Longitude	`SourceLongitude`

Default mappings for the DestinationAddress event field

Geodata attribute	Event field
Country	`DestinationCountry`
Region	`DestinationRegion`
City	`DestinationCity`
Latitude	`DestinationLatitude`
Longitude	`DestinationLongitude`

Default mappings for the DeviceAddress event field

Geodata attribute	Event field
Country	`DeviceCountry`
Region	`DeviceRegion`
City	`DeviceCity`
Latitude	`DeviceLatitude`
Longitude	`DeviceLongitude`

Working with the knowledge base

In the OSMP Console, you can find the **Knowledge base** section, which lets you organize Kaspersky package and resource management in a more visual way. In this section, you can view the available and installed packages and resources, evaluate the coverage of MITRE ATT&CK techniques by the installed resources, monitor the up-to-date status of resource versions, search and filter by specified parameters, and install individual resources or whole packages.

Packages contain sets of resources for configuring OSMP. Packages can be downloaded from the Kaspersky repository.

> If no packages from the repository have been downloaded thus far, the list of packages and resources in the **Knowledge base** section is empty. To get packages and resources available for installation, you need to configure updating of predefined resources.
> For more information on how to get resources from the repository, see the Updating resources section.

To open the **Knowledge base** section, in the OSMP Console, go to the **Monitoring** → **Resources and services** → **Knowledge base** section.

This section contains widgets that display summary information about packages and resources in your instance of the solution. To show or hide widgets, click the icon. The following widgets are available:

- **Package status** displays the number of packages with the following statuses:
  - **Available** means the package is available for installation.
  - **Installed** means the whole package is installed.
  - **Emergency** means the package contains high-priority resources that need to be installed as soon as possible.
  - **New** means the package was added to the repository less than three months ago and has not yet been installed or viewed by the user.

- **Resource status** displays the number of resources of various types with the following statuses:
  - **Available** means the resource is available for installation.
  - **Installed** means the resource is installed and does not need an update.
  - **Update required** mean a newer version is available for the resource in the repository.
- **MITRE Technique Coverage, {{ filter }}** displays information about the number or MITRE ATT&CK techniques covered or coverage percentage by the selected resources.

Widgets also act as filters for tables on the page. When you select a value in a widget, the table is automatically updated in accordance with the selected filter. For example, you can display only resources with the **Update required** status.

This section displays the following tabs:

- On the **Packages** tab, a list of packages with resources is displayed (this is the default tab).
- On the **Resources** tab, a list of individual resources is displayed.

You can use the **Search** field to search for packages or resources. The search is performed only on the currently opened tab. When you switch between tabs, the entered search query is kept and applied to the selected tab. In the **Search** field, you can enter the resource name, event source, event type, package name, or any substring.

To filter the contents of the **Packages** and **Resources** tabs, click the filter icon.

You can sort the table on the **Packages** and **Resources** tabs by clicking the column header of the relevant parameter and selecting **Ascending** or **Descending**. You can also filter the table by the **Resource kind** or **Status** columns by clicking the relevant column's heading and selecting the values that need to be displayed.

Viewing package details

To view available packages,

In the OSMP Console, open the **Monitoring** → **Resources and services** → **Knowledge base** section and go to the **Packages** tab (selected by default).

The **Packages** tab displays a table of available packages, which contains the following columns:

- **Name** is the name of the package.
- **Version** is the version of the package.
- **Release date** is the date when the package was released.
- **Resource kinds** are types of resources included in the package:
  - Active list
  - Context table
  - Normalizer

- Event aggregation rule
- Correlation rule
- Enrichment rule
- Dictionary
- Filter
- Notification template

- **Number of resources** is the number of resources in the package.
- **Status** is the status of the package.
  - **Available** means the package is available for installation.
  - **Installed** means the whole package is installed.
  - **Emergency** means the package contains high-priority resources that need to be installed as soon as possible.
  - **New** means the package is new and available for installation.
- **Description** is a description of the package.

To view information about a package, click its name. This opens a window with information about the package, which contains the **General** and **Change log** tabs.

The following information is displayed on the **General** tab:

- Package name
- Description
- Release date
- Version

This tab also contains the **Resources to be imported** section, which displays a list of resources included in the package. Here you can filter the resources and select only those that you need to install.

The **Change log** tab displays information about changes of the package.

Viewing resource details

To view available resources,

In the OSMP Console, open the **Monitoring** → **Resources and services** → **Knowledge base** section and go to the **Resources** tab.

The **Resources** tab displays a table of available resources, which contains the following columns:

- **Name**—the name of the resource.
- **Resource kind**—available types of resources:
  - Active list
  - Context table
  - Normalizer
  - Event aggregation rule
  - Correlation rule
  - Enrichment rule
  - Dictionary
  - Filter
  - Notification template
- **Installation date** is the date when the resource was installed in KUMA.
- **Tenant** is the tenant in which the resource is installed.

  If the same resource is installed for several tenants, it is displayed in the table as a group. To view the details of the resource in each tenant for which it is installed, expand the group.
- **Version** is the version of the resource.
- **Status** is the status of the resource.
  - **Available** means the resource is available for installation.
  - **Installed** means the resource is installed.
  - **Update required** mean a newer version is available for the resource.
- **Package names** lists packages that include this resource.
- **Vendor tags** are tags assigned by the vendor of the resource.
- **MITRE Techniques** are MITRE ATT&CK techniques associated with the resource.

To view information about a resource, click its name. This opens the resource information window, which contains the **General info** and **Linked resources** tabs.

On the **Linked resources** tab, you can view the resources linked to the selected resource. You can also view dependencies on the **Resources** tab by clicking the **Show dependencies** button.

Installing and updating packages and resources

Installing a package

A package gets the **Installed** status only if all resources it includes are installed.

To install the whole package:

1. Go to the **Monitoring** → **Resources and services** → **Knowledge base** → **Packages** section.
2. Do one of the following:
   - Select the check box next to the relevant package and click the **Install** button.
   - Click the name of the package to open a window, and in that window, click the **Install** button.
3. Select a tenant.
4. Click the **Install** button.
   After that, the resources are imported into OSMP and become available for further configuration.

Installing individual resources

To install individual resources from a package:

1. Go to the **Monitoring** → **Resources and services** → **Knowledge base** → **Resources** section.
2. Do one of the following:
   - Select the check box next to the relevant resources and click the **Install** button.
   - Click the name of the resource to open a window, and in that window, click the **Install** button.
3. Select a tenant.
4. Click the **Install** button.

Updating resources

If a new version is available for an installed resource, the resource gets the **Update required** status.

To update a resource:

1. Go to the **Monitoring** → **Resources and services** → **Knowledge base** → **Resources** section.
2. Select the check box next to one or more resources with the **Update required** status.
3. Click the **Update** button.

KUMA resources

Resources are KUMA components that contain parameters for implementing various functions: for example, establishing a connection with a given web address or converting data according to certain rules. These components are assembled in various combinations into resource sets for services which are further used as the basis for creating KUMA services.

Resources are contained in the **Resources** section of KUMA Console.

Under **Resources** and **Rules**, you can find the following types of resources:

- **Normalizers**—resources of this type contain rules for converting incoming events into the format used by KUMA. After processing in the normalizer, the raw event becomes normalized and can be processed by other KUMA resources and services.
- **Connectors**—resources of this type contain settings for establishing network connections.
- **Destinations**—resources of this type contain settings for forwarding events to a destination for further processing or storage.
- **Filters**—resources of this type contain conditions for rejecting or selecting individual events from the stream of events.
- **Active lists**—resources of this type are used by correlators for dynamic data processing when analyzing events according to correlation rules.
- **Dictionaries**—resources of this type are used to store keys and their values, which may be required by other KUMA resources and services.
- **Proxies**—resources of this type contain settings for using proxy servers.
- **Secrets**—resources of this type are used to securely store confidential information (such as credentials) that KUMA needs to interact with external services.
- **Context tables**—resources of this type are used by KUMA correlators for analyzing events in accordance with correlation rules.
- **Notification templates**—resources of this type are used when sending notifications about new alerts.
- **Correlation rules**—resources of this type contain rules for identifying event patterns that indicate threats. If the conditions specified in these resources are met, a correlation event is generated.
- **Aggregation rules**—resources of this type contain rules for combining several basic events of the same type into one aggregation event.

- **Enrichment rules**—resources of this type contain rules for supplementing events with information from third-party sources.
- **Response rules**—resources of this type are used in correlators to, for example, execute scripts or launch Kaspersky Security Center tasks when certain conditions are met.
- **Data collection and analysis rules**—resources of this type contain rules that allow scheduling SQL queries with aggregation functions to the storage. Data received from SQL queries is then used for correlation.

When you click a resource type, a window opens displaying a table with the available resources of this type. The resource table contains the following columns:

- **Name**—the name of a resource. Can be used to search for resources and sort them.
- **Updated**—the date and time of the last update of a resource. Can be used to sort resources.
- **Created by**—the name of the user who created a resource.
- **Description**—the description of a resource.

The maximum table size is not limited. If you want to select all resources, scroll to the end of the table and select the **Select all** check box, which selects all available resources in the table.

Resources can be organized into folders. The folder structure is displayed in the left part of the window: root folders correspond to tenants and contain a list of all resources of the tenant. All other folders nested within the root folder display the resources of an individual folder. When a folder is selected, the resources it contains are displayed as a table in the right pane of the window.

Resources can be created, edited, copied, moved from one folder to another, and deleted. Resources can also be exported and imported.

KUMA comes with a set of predefined resources, which can be identified by the `[OOTB]< resource_name >` name. OOTB resources are protected from editing.

If you want to adapt a predefined OOTB resource to your organization's infrastructure:

1. In the **Resources**-<resource type> section, select the OOTB resource that you want to edit.
2. In the upper part of the KUMA Console, click **Duplicate**, then click **Save**.

   A new resource named `[OOTB]< resource_name > - copy` is displayed in the web interface.
3. Edit the copy of the predefined resource as necessary and save your changes.

The adapted resource is available for use.

Operations with resources

To manage KUMA resources, you can create, move, copy, edit, delete, import, and export them. These operations are available for all resources, regardless of the resource type.

KUMA resources reside in folders. You can add, rename, move, or delete resource folders.

Creating, renaming, moving, and deleting resource folders

Resources can be organized into folders. The folder structure is displayed in the left part of the window: root folders correspond to tenants and contain a list of all resources of the tenant. All other folders nested within the root folder display the resources of an individual folder. When a folder is selected, the resources it contains are displayed as a table in the right pane of the window.

You can create, rename, move and delete folders.

To create a folder:

1. Select the folder in the tree where the new folder is required.
2. Click the **Add folder** button.

The folder will be created.

To rename a folder:

1. Locate required folder in the folder structure.
2. Hover over the name of the folder.
   The ... icon will appear near the name of the folder.
3. Open the ... drop-down list and select **Rename**.
   The folder name will become active for editing.
4. Enter the new folder name and press **ENTER**.

> The folder name cannot be empty.

The folder will be renamed.

To move a folder,

Drag and drop the folder to a required place in folder structure by clicking its name.

> Folders cannot be dragged from one tenant to another.

To delete a folder:

1. Locate required folder in the folder structure.
2. Hover over the name of the folder.
   The ... icon will appear near the name of the folder.

3. Open the ... drop-down list and select **Delete**.

   The conformation window appears.

4. Click the **OK** button.

The folder will be deleted.

> The program does not delete folders that contain files or subfolders.

Creating, duplicating, moving, editing, and deleting resources

You can create, move, copy, edit, and delete resources.

To create the resource:

1. In the main menu, go to **Monitoring** → **Resources** → **<resource type>**.
2. Select or create a folder where you want to add the new resource.

   Root folders correspond to tenants. For a resource to be available to a specific tenant, it must be created in the folder of that tenant.

3. Click the **Add <resource type>** button.

   The window for configuring the selected resource type opens. The available configuration parameters depend on the resource type.

4. Enter a unique resource name in the **Name** field.
5. Specify the required parameters (marked with a red asterisk).
6. If necessary, specify the optional parameters (not required).
7. Click **Save**.

The resource will be created and available for use in services and other resources.

To move the resource to a new folder:

1. In the main menu, go to **Monitoring** → **Resources** → **<resource type>**.
2. Find the required resource in the folder structure, and then select the check box near the resource you want to move. You can select multiple resources.

   The ⣿ icon appears near the selected resources.

3. Use the ⣿ icon to drag and drop resources to the required folder.

The resources will be moved to the new folders.

> You can only move resources to folders of the tenant in which the resources were created. Resources cannot be moved to another tenant's folders.

To copy the resource:

1. In the main menu, go to **Monitoring** → **Resources** → **<resource type>**.
2. Find the required resource in the folder structure, then select the check box next to the resource that you want to copy, and then click **Duplicate**.

   A window opens with the settings of the resource that you have selected for copying. The available configuration parameters depend on the resource type.

   The `<selected resource name> - copy` value is displayed in the **Name** field.
3. Make the necessary changes to the parameters.
4. Enter a unique name in the **Name** field.
5. Click **Save**.

The copy of the resource will be created.

To edit the resource:

1. In the main menu, go to **Monitoring** → **Resources** → **<resource type>**.
2. Find the required resource in the folder structure, and then select the resource.

   A window with the settings of the selected resource opens. The available configuration parameters depend on the resource type.
3. Make the necessary changes to the parameters.
4. Click **Save**.

The resource will be updated. If this resource is used in a service, restart the service to apply the new settings.

To delete the resource:

1. In the main menu, go to **Monitoring** → **Resources** → **<resource type>**.
2. Find the required resource in the folder structure.
3. Select the check box next to the resource that you want to delete and click **Delete**.

   A confirmation window opens.
4. Click the **OK** button.

The resource will be deleted.

Linking resources to services

You can now link resources (correlation rules, enrichment rules, response rules, aggregation rules, and destinations) to services such as collectors and correlators. The available services depend on the type of the selected resource.

To link a resource to a service:

1. In the main menu, go to **Monitoring** → **Resources and services** → **<resource name>** section.
2. Select the check box next to each resource that you want to link, and in the toolbar or menu (⋮), click **Link to service** → **Link to <service name>**.

   You can also link a resource to a service when editing resource settings. To do this, click the name of a resource, select the **Services** tab, and click **Link to service** → **Link to <service name>**.

   > When managing the settings of a correlation rule, you can use the **Correlators** tab to link the rule to correlators.

3. In the displayed **<service name>** window, select the check boxes next to the services that you need, and click **OK**.

The resource is linked to the service.

To unlink a resource from a service:

1. In the main menu, go to **Monitoring** → **Resources and services** → **<resource name>** section.
2. Click the resource and select the **Services** tab.

   > For correlation rules, the **Correlators** tab is displayed.

3. Select check boxes next to each service from which you want to unlink the resource.
4. Click **Delete** and confirm the unlinking from the service.

The resource is unlinked from the service.

Updating resources

The KUMA update subsystem provides mechanisms for receiving, storing, and applying resources required for event processing and threat detection. The subsystem includes two independent update mechanisms:

- **Repository update**–a mechanism for downloading resource packages with the ability to review, analyze, and import them into a tenant.
- **OSMP update**–an automatic mechanism for receiving and applying resources without user involvement and manual import.

Both mechanisms can use the following update sources:

- Kaspersky update servers.
- Custom source (repository or update mirror).

The update subsystem expands KUMA capabilities to respond to the changes in the threat landscape and the infrastructure. The possibility of using it without direct Internet access helps ensure the privacy of the data processed by the system.

Updating resources workflow

To update resources, perform the following steps:

1. Update the repository to deliver the resource packages to the repository. The repository update is available in two modes:
   - Automatic update
   - Manual update
2. Import the resource packages from the updated repository into the tenant.
3. Ensure that the updated resources are mapped after performing the import. If necessary, link the resources to collectors, correlators, or agents, and update the settings.

Repository update

Kaspersky regularly releases packages with resources that can be imported from the repository. You can specify an email address in the settings of the **Repository update** task. After the first execution of the task, KUMA starts sending notifications about the packages available for update to the specified address.

The repository update mechanism allows retrieving packages, reviewing their contents, and deciding whether to deploy them in the operating infrastructure. Repository update can be performed in automatic or manual mode.

If you have other Kaspersky applications in the infrastructure, you can connect KUMA to existing update mirrors.

To enable automatic update:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings**.
   This opens the KUMA settings window.
2. Under **Other**, click **Update settings**.
3. Under **Repository update**, configure the **Data refresh interval in hours**. The default value is 24 hours.
4. Specify the **Update source**. The following options are available:
   - Kaspersky update servers.
     You can view the list of servers in the Knowledge Base.

- Custom source:
  - The URL to the shared folder on the HTTP server.
  - The full path to the local folder on the host where the KUMA Core is installed.

    If a local folder is used, the kuma system user must have read access to this folder and its contents.

5. Specify the **Emails for notification** by clicking the **Add** button. The notifications that new packages or new versions of the packages imported into the tenant are available in the repository are sent to the specified email addresses.

   If you specify the email address of a KUMA user, the **Receive email notifications** check box must be selected in the user profile. For emails that do not belong to any KUMA user, the messages are received without additional settings. The settings for connecting to the SMTP server must be specified in all cases.

6. Click **Save**. The update task starts shortly. Then the task restarts according to the schedule.

To manually start the repository update:

1. To disable automatic updates, in the **Settings** → **KUMA** → **Open KUMA settings** → **Update settings** → **Repository update** section, turn on the **Disable automatic update** toggle switch. This toggle switch is turned off by default. You can also start a manual repository update without disabling automatic update. Starting an update manually does not affect the automatic update schedule.

2. Specify the **Update source**. The following options are available:
   - Kaspersky update servers.
   - Custom source:
     - The URL to the shared folder on the HTTP server.
     - The full path to the local folder on the host where the KUMA Core is installed.

       If a local folder is used, the kuma user must have access to this folder and its contents.

3. Specify the **Emails for notification** by clicking the **Add** button. The notifications that new packages or new versions of the packages imported into the tenant are available in the repository are sent to the specified email addresses.

   If you specify the email address of a KUMA user, the **Receive email notifications** check box must be selected in the user profile. For emails that do not belong to any KUMA user, the messages are received without additional settings. The settings for connecting to the SMTP server must be specified in all cases.

4. Click **Run update**. Thus, you simultaneously save the settings and manually start the **Repository update** task.

OSMP update

If supported by the license, the OSMP update mechanism automatically receives and applies resources. OSMP update is performed automatically in the background and does not require manual import, analysis, or approval of packages.

After the update is completed, new event fields and correlation rules become available for processing without additional configuration.

To configure OSMP update:

1. In the main menu, go to **Settings** → **KUMA** → **Open KUMA settings** → **Update settings**.
2. Specify the **Update source**. The following options are available:
   - Kaspersky update servers.
   - Custom source:
     - The URL to the shared folder on the HTTP server.
     - The full path to the local folder on the host where the KUMA Core is installed.

       If a local folder is used, the kuma user must have access to this folder and its contents. If a custom source is used, configure proxy settings if required.
3. Under **OSMP update**, in the **Data refresh interval, in minutes** field, specify the frequency of automatic update checks and downloads, in minutes. The default value is 30.
4. Click **Save**.

By default, the **Disable automatic update** toggle switch is turned off, and OSMP update runs automatically according to the interval specified in the **Data refresh interval, in minutes** field.

If you want to disable automatic OSMP updates, turn on the **Disable automatic update** toggle switch and click **Save**. In this case, automatic update checks and downloads are not performed. To start OSMP update manually, click **Run update**.

Configuring a custom source using Kaspersky Update Utility

You can update resources without internet access by using a custom update source via the Kaspersky Update Utility.

Configuration consists of the following steps:

1. Configuring a custom source using Kaspersky Update Utility:
   a. Installing and configuring Kaspersky Update Utility on one of the computers in the corporate LAN.
   b. Configuring copying of updates to a shared folder in Kaspersky Update Utility settings.
2. Configuring update of the KUMA repository from a custom source.

Configuring a custom source using Kaspersky Update Utility:

You can download the Kaspersky Update Utility distribution kit from the Kaspersky Technical Support website.

1. In Kaspersky Update Utility, enable the download of updates for KUMA:

   - Under **Applications** – **Perimeter control**, select the check box next to KUMA to enable the update capability.

   - If you work with Kaspersky Update Utility using the command line, add the following line to the [ComponentSettings] section of the updater.ini configuration file or specify the `true` value for an existing line:

     ```
     KasperskyUnifiedMonitoringAndAnalysisPlatform_XDR_1_1=true
     ```

2. In the **Downloads** section, specify the update source. By default, Kaspersky update servers are used as the update source.

3. In the **Downloads** section, in the **Update folders** group of settings, specify the shared folder for Kaspersky Update Utility to download updates to. The following options are available:

   - Specify the local folder on the host where Kaspersky Update Utility is installed. Deploy the HTTP server for distributing updates and publish the local folder on it. In OSMP Console, in the **Settings** → **KUMA** → **Open KUMA settings** → **Repository update** → **Custom source** section, specify the URL of the local folder published on the HTTP server.

   - Specify the local folder on the host where Kaspersky Update Utility is installed. Make this local folder available over the network. Mount the network-accessible local folder on the host where KUMA is installed. In OSMP Console, in the **Settings** → **KUMA** → **Open KUMA settings** → **Repository update** → **Custom source** section, specify the full path to the local folder.

For detailed information about working with Kaspersky Update Utility, refer to the Kaspersky Knowledge Base.

Exporting resources

If shared resources are hidden for a user, the user cannot export shared resources or resources that use shared resources.

To export resources:

1. In the main menu, go to **Monitoring** → **Resources** → **Correlation rules**.

2. Click **Export resources**.

   The **Export resources** window opens with the tree of all available resources.

3. In the **Password** field enter the password that must be used to protect exported data.

4. In the **Tenant** drop-down list, select the tenant whose resources you want to export.

5. Check boxes near the resources you want to export.

   If selected resources are linked to other resources, linked resources will be exported, too.

6. Click the **Export** button.

The resources in a password-protected file are saved on your computer using your browser settings. The Secret resources are exported blank.

Importing resources

To import resources:

1. In the main menu, go to **Monitoring** → **Resources**.

2. Click **Import resources**.

   The **Import resources** window opens.

3. In the **Tenant** drop-down list, select the tenant that will own the imported resources.

4. In the **Import source** drop-down list, select one of the following options:

   - **File**

     If you select this option, enter the password and click the **Import** button.

   - **Storage**

     If you select this option, a list of packages available for import is displayed. We recommend you to ensure that the repository update date is relatively recent and configure automatic updates if necessary.

     You can select one or more packages to import and click the **Import** button. The dependent resources of the Shared tenant are imported into the Shared tenant, the rest of the resources are imported into the selected tenant. You do not need special rights for the Shared tenant; you must only have the right to import in the selected tenant.

     Imported resources marked as **This resource is a part of the package. You can delete it, but it is impossible to edit** can only be deleted. To rename, edit or move an imported resource, make a copy of the resource using the **Duplicate** button and perform the desired actions with the copy of the resource. When importing future versions of the package, the duplicate is not updated because it is a separate object.

     Imported resources marked as **This resource is a part of the package** and located in the `Integration` directory can be edited. For example, you can edit exclusion filters for correlation rules in the `Integration` directory. Exclusion filters contain lists of conditions that prevent false positive triggering of correlation rules. Add conditions to exclusion filters before or while using correlation rules to reduce false positives depending on your network environment. Exclusion filters provided by Kaspersky are added to correlation rule selectors by default.

     When importing subsequent versions of the package, edited resources are not replaced with the corresponding resources from the package, which allows you to preserve your changes. Changes made to exclusion filters are applied permanently, unlike temporary exclusions.

     Resources from the repository are imported from the repository in the language specified in the KUMA resources localization setting in the KUMA Core settings section.

5. Resolve the conflicts between the resources imported from the file and the existing resources if they occur. Read more about resource conflicts below.

   a. If the name, type, and guid of an imported resource fully match the name, type, and guid of an existing resource, the **Conflicts** window opens with the table displaying the type and the name of the conflicting resources. Resolve displayed conflicts:

      - To replace the existing resource with a new one, click **Replace**.

        To replace all conflicting resources, click **Replace all**.

      - To leave the existing resource, click **Skip**.

        For dependent resources, that is, resources that are associated with other resources, the **Skip** option is not available; you can only **Replace** dependent resources.

        To keep all existing resources, click **Skip all**.

   b. Click the **Resolve** button.

   The resources are imported to KUMA. The Secret resources are imported blank.

Importing resources that use the extended event schema

If you import a normalizer that uses one or more fields of the extended event schema, KUMA automatically creates an extended schema field that is used in the normalizer.

If you import other types of resources that use fields of the extended event schema in their logic, the resources are imported successfully. To ensure the functioning of imported resources, you must create the corresponding fields of the extended event schema in a resource of the "normalizer" type.

If a normalizer that uses an extended event schema field is imported into KUMA and the same field already exists in KUMA, the previously created field is used.

About conflict resolving

When resources are imported into KUMA from a file, they are compared with existing resources; the following parameters are compared:

- Name and kind. If an imported resource's name and kind parameters match those of the existing one, the imported resource's name is automatically changed.

- If identifiers of two resources match, a conflict appears that must be resolved by the user. This could happen when you import resources to the same KUMA server from which they were exported.

When resolving a conflict you can choose either to *replace existing resource* with the imported one or to *keep exiting resource*, skipping the imported one.

Some resources are linked: for example, in some types of connectors, the connector secret must be specified. The secrets are also imported if they are linked to a connector. Such linked resources are exported and imported together.

Special considerations of import:

1. Resources are imported to the selected tenant.

2. If a linked resource was in the Shared tenant, it ends up in the Shared tenant when imported.

3. In the **Conflicts** window, the **Parent** column always displays the top-most parent resource among those that were selected during import.

4. If a conflict occurs during import and you choose to replace existing resource with a new one, it would mean that all the other resources linked to the one being replaced are automatically replaced with the imported resources.

Known errors:

1. The linked resource ends up in the tenant specified during the import, and not in the Shared tenant, as indicated in the **Conflicts** window, under the following conditions:

   a. The associated resource is initially in the Shared tenant.

   b. In the **Conflicts** window, you select **Skip** for all parent objects of the linked resource from the Shared tenant.

   c. You leave the linked resource from the Shared tenant for replacement.

2. After importing, the categories do not have a tenant specified in the filter under the following conditions:

   a. The filter contains linked asset categories from different tenants.

   b. Asset category names are the same.

   c. You are importing this filter with linked asset categories to a new server.

3. In Tenant 1, the name of the asset category is duplicated under the following conditions:

   a. in Tenant 1, you have a filter with linked asset categories from Tenant 1 and the Shared tenant.

   b. The names of the linked asset categories are the same.

   c. You are importing such a filter from Tenant 1 to the Shared tenant.

4. You cannot import conflicting resources into the same tenant.

   The *Import conflicting resources in the same tenant is not allowed* error means that the imported package contains conflicting resources from different tenants and cannot be imported into the Shared tenant.

   Solution: Select a tenant other than Shared to import the package. In this case, during the import, resources originally located in the Shared tenant are imported into the Shared tenant, and resources from the other tenant are imported into the tenant selected during import.

5. Only the Main administrator can import categories into the Shared tenant.

   The error *Only the Main administrator can import categories into the Shared tenant* means that the imported package contains resources with linked shared asset categories. The categories or resources with linked shared asset categories are displayed in the KUMA Core log. Path to the Core log:

   /opt/kaspersky/kuma/core/log/core

Solution. Choose one of the following options:

- Do not import resources to which shared categories are linked: clear the check boxes next to the relevant resources.
- Perform the import under a Main administrator account.

6. Only the general administrator can import resources into the Shared tenant.

   The error *Only the Main administrator can import resources into the Shared tenant* means that the imported package contains resources with linked shared resources. The resources with linked shared resources are displayed in the KUMA Core log. Path to the Core log:

   /opt/kaspersky/kuma/core/log/core

   Solution. Choose one of the following options:

   - Do not import resources that have linked resources from the Shared tenant, and the shared resources themselves: clear the check boxes next to the relevant resources.
   - Perform the import under a Main administrator account.

Tag management

To help manage resources, KUMA lets you add tags to resources. You can use tags to search for a component, as well as manage tags, link or unlink tags.

You cannot add tags to resources that are created from the interface of other resources. Tags can be added only from the resource's own card. You also cannot add tags to a resource that is not editable.

Tag management

The list of tags is displayed in the **Settings** → **KUMA** → **Open KUMA settings** → **Tags** section and is displayed as a table with the following columns: **Name**, **Tenant**, **Used in resources**.

In the **Tags** table, you can:

- Sort tags by **Name**, **Used in resources** fields.
- Filter by values of the **Tenant** field.
- Find a tag by the **Name** field.
- Go to the list of resources that have the selected tag.

Adding a tag

To add a tag:

1. In the main menu, go to **Monitoring** → **Resources and services**, and then select a resource.
2. In the panel above the table, click **Add**.
3. In the **Tags** field of the selected resource, add a new tag, or select a tag from the list.
4. Click the **Create** button.

   The new tag is added.

You can also add tags from existing ones.

When adding a tag, keep in mind the following special considerations:

- You can add multiple tags.
- A tag can contain characters of various alphabets (for example, Cyrillic, Latin, or Greek characters), numerals, underscores, and spaces.
- A tag may not contain any special characters other than the underscore and the space.
- You can enter the tag in uppercase or lowercase, but after saving, the tag is always displayed in lowercase.
- The tag inherits the tenant of the resource in which it is used.
- A tag is part of a resource and exists as long as the resource exists in which the tag was created or is used.
- Tags are unique within a tenant.
- Tags are imported or exported together with the resource as part of the resource.

Searching by tags

In the **Resources** section, you can search for resources:

- By tags
- By resource name

The search is performed across all resource types and services.

The search results display a list of resources and services.

To find resources by tags:

1. In the main menu, go to **Monitoring** → **Resources and services**, and then select a resource.
2. In the table of the resource, select the **Tags** column.
3. In the **Search** field that is displayed, enter or select a tag name.

   Searching by tag in the resource itself and in the list of resources returns full as well as partial matches of the entered text with the name of the tag.

Displays a list of resources if the specified tag is used in those resources.

In the list of resources, you can:

- Sort the list by name and type of resource or service.
- Filter resources or services by resource or service type, or by tag.
- Link or unlink tags.

Displaying tags while adding dependent resources

While adding a dependent resource, the tags of this resource are displayed in a drop-down list under **Filter settings**.

Resource tags that to not fit a single line are hidden. A special indicator lets you see that hidden tags exist.

The drop-down list can be filtered by resource name and by resource tags.

Linking and unlinking tags

To link tags to a resource or unlink tags from a resource:

1. In the main menu, go to **Monitoring** → **Resources and services**.
2. Select the **List** tab.
3. In the **Name** column, select the check boxes next to the relevant resources.
4. In the panel above the list, select the **Tags** tab.
5. Click **Link** or **Unlink**, select the tags that you need or create a new tag.

The selected tags are linked to or unlinked from the resources.

You can also link or unlink tags in the card of the resource.

Destinations

Destinations define network settings for sending normalized events. Collectors and correlators use destinations to describe where to send processed events. Typically, the destination points are the correlator and storage.

The settings of destinations are configured on two tabs: **Basic settings** and **Advanced settings**. The available settings depend on the selected type of destination:

- **internal**—used for receiving data from KUMA services using the 'internal' protocol.
- **nats-jetstream**—used for NATS communications.
- **tcp**—used for communications over TCP.
- **udp** – used for communication over UDP.
- **http**—used for HTTP communications.
- **diode**—used to transmit events using a data diode.
- **kafka**—used for Kafka communications.
- **file**—used for writing to a file.
- **storage**—used to transmit data to the storage.
- **correlator**—used to transmit data to the correlator.

Destination, internal type

Destinations of the **internal** type are used for receiving data from KUMA services using the 'internal' protocol. You can transfer the following data using the internal protocol:

- Internal data, such as event routes.
- File attributes. If while creating the collector at the Transport step of the Installation Wizard, you specified a connector of the file, 1c-xml, or 1c-log type, at the Event parsing step, in the **Mapping** table, you can pass the name of the file being processed by the collector or the path to the file in the KUMA event field. To do this, in the **Source** column, specify one of the following values:
  - `$kuma_fileSourceName` to pass the name of the file being processed by the collector in the KUMA event field.
  - `$kuma_fileSourcePath` to pass the path to the file being processed by the collector in the KUMA event field.

  When you use a **file**, **1c-xml**, or **1c-log** connector, the new variables in the normalizer will only work with **destinations of the internal type**.

Settings for a destination of the **internal** type are described in the following tables.

Basic settings tab

Setting	Description
Name	Unique name of the resource. The maximum length of the name is 128 Unicode characters. Required setting.
Tenant	The name of the tenant that owns the resource. Required setting.
State	This toggle switch enables sending events to the destination. This toggle switch is turned on by default.
Type	Destination type: **internal**. Required setting.
URL	URL (required)—a URL that you need to connect to. The following URL formats are supported: • `<host name>:<port number>` • `<IPv4 address>:<port number>` • `<IPv6 address>:<port number>` You can specify IPv6 addresses in the following format: `[<IPv6 address>%<interface>:<port number>]`, for example, `[fe80::5054:ff:fe4d:ba0c%eth0]:4222`. You can add multiple URLs and remove an URL. KUMA does not allow saving a resource or service if the URL field contains a tab or space character. To add an URL, click the **+ Add** button. To remove an URL, click the delete ✕ icon next to it. Required setting.
Tags	Tags for resource search. Optional setting.
Description	Description of the resource. The maximum length of the description is 4000 Unicode characters.

Advanced settings tab

Parameter	Description
Buffer size	Buffer size in bytes for accumulating events in the RAM of the server before sending them for further processing or storage. The value must be a positive integer. Default buffer size: 67,108,864 (64 MB), displayed as 0 in the interface.
Buffer flush interval	Interval (in seconds) for sending events to the destination. The default value is 1 second.
Disk buffer size limit	Size of the disk buffer in bytes. Default value: 10 GB, displayed as 0 in the interface.
Handlers	Number of handlers that the service can run simultaneously to process response rules in parallel. The value must be a positive integer up to 999.
Proxy server	The proxy server for the destination. You can select an existing proxy server or create a new proxy server. To create a new proxy server, select **Create new**. If you want to edit the settings of an existing proxy server, click the pencil icon next to it.
URL selection policy	Method of determining URLs to which events must be sent first if you added multiple URLs in the **URL** field on the **Basic settings** tab: • **Any** means events are sent to a randomly selected available URL as long as the URL accepts events. If the URL becomes unavailable, events are sent to another randomly selected available URL. This value is selected by default. • **Prefer first** means events are sent to the first added URL. If the URL becomes unavailable, events are sent to the next added available URL. If the first added URL becomes available again, events are sent to the first added URL again. • **Round robin** means events are evenly balanced among the available URLs. This method does not guarantee that events are evenly balanced among the URLs because the buffer may overflow or events may be sent to the destination. You can specify the buffer size in bytes in the **Buffer size limit** field; you can also specify the interval in seconds for sending events to the destination in the **Buffer flush interval** field.

Parameter	Description
Health check timeout	Interval, in seconds, for checking the health of the destination.
Disk buffer disabled	This toggle switch that enables the disk buffer. This toggle switch is turned on by default. The disk buffer is used if the collector cannot send normalized events to the destination. You can specify the size of the disk buffer in the **Disk buffer size limit** field. If the disk buffer runs out of free space, new normalized events will overwrite old normalized events, starting with the oldest.
Timeout	The time, in seconds, for which the destination waits for a response from another service or component.
Debug	The switch enables resource logging. The toggle switch is turned off by default.

Parameter	Description
Filter	Filter for determining which events must be processed by the resource. You can select an existing filter or create a new filter. To create a new filter, select **Create new**. If you want to edit the settings of an existing filter, click the pencil icon next to it. **How to create a filter?** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Parameter	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

nats-jetstream type

The **nats-jetstream** type is used for NATS communications.

Basic settings tab

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
The **State** toggle switch	Used when events must be sent to the destination. By default, sending events is enabled.
Type	Required setting. Destination type, **nats-jetstream**.
URL	Required setting. URL that you want to connect to.
Topic	Required setting. The topic of NATS messages. Must contain Unicode characters.
Delimiter	Specify a character that defines where one event ends and the other begins. By default, `\n` is used.

Setting	Description
Authorization	Type of authorization when connecting to the specified URL Possible values: • **disabled** is the default value. • **plain** — if this option is selected, you must indicate the secret containing user account credentials for authorization when connecting to the connector. **Add secret** *To create a secret:* 1. In the **Name** field, enter the name of the secret. 2. In the **User** and **Password** fields, enter the credentials of the user account that the Agent will use to connect to the connector. 3. If necessary, enter a description of the secret in the **Description** field. 4. Then click the **Create** button. The secret is added and displayed in the **Secret** drop-down list.
Description	Resource description: up to 4,000 Unicode characters.

Advanced settings tab

Parameter	Description
Compression	You can use Snappy compression. By default, compression is **disabled**.
Buffer size	Sets the size of the buffer. The default value is 1 KB, and the maximum value is 64 MB.
Disk buffer size limit	Size of the disk buffer in bytes. The default value is 10 GB.
Cluster ID	ID of the NATS cluster.
Output format	Format for sending events to an external destination. Available values: • JSON • CEF If the CEF format is selected, the sent event contains the CEF header and only non-empty fields.

Parameter	Description

TLS mode	Use of TLS encryption. Available values:
	• **Disabled** (default) means TLS encryption is not used.
	• **Enabled** means encryption is used, but the certificate is not verified.
	• **With verification**—use encryption with verification that the certificate was signed with the KUMA root certificate. The root certificate and key of KUMA are created automatically during program installation and are stored on the KUMA Core server in the folder /opt/kaspersky/kuma/core/certificates/.
	• **Custom CA** means encryption is used with verification that the certificate was signed by a Certificate Authority. The secret containing the certificate is selected from the **Custom CA** drop-down list, which is displayed when this option is selected.
	Creating a certificate signed by a Certificate Authority
	You can create a CA-signed certificate on the KUMA Core server (the following command examples use OpenSSL).
	To create a certificate signed by a Certificate Authority:
	1. Generate a key to be used by the Certificate Authority, for example:
	`openssl genrsa -out ca.key 2048`
	2. Create a certificate for the generated key, for example:
	`openssl req -new -x509 -days 365 -key ca.key -subj "/CN=< common host name of Certificate Authority >" -out ca.crt`
	3. Create a private key and a request to have it signed by the Certificate Authority, for example:
	`openssl req -newkey rsa:2048 -nodes -keyout server.key -subj "/CN=< common host name of KUMA server >" -out server.csr`
	4. Create the certificate signed by the Certificate Authority. You need to include the domain names or IP addresses of the server for which you are creating the certificate in the `subjectAltName` variable, for example:
	`openssl x509 -req -extfile <(printf "subjectAltName=DNS:domain1.ru,DNS:domain2.com,IP:192.168.0.1") -days 365 -in server.csr -CA ca.crt -CAkey ca.key -CAcreateserial -out server.crt`
	5. Upload the created `server.crt` certificate in the Open Single Management Platform web interface to a secret of the **certificate** type, then in the **Custom CA** drop-down list, select the secret of the **certificate** type.
	When using TLS, it is impossible to specify an IP address as a URL.

Delimiter	In the drop-down list, you can select the character to mark the boundary between events. By default, `\n` is used.
Buffer flush interval	Time (in seconds) between sending batches of data to the destination. The default value is `1 second`.
Number of handlers	This field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Debug	This toggle switch lets you specify whether resource logging must be enabled. The default value is **Disabled**.
Disk buffer disabled	Drop-down list that lets you enable or disable the disk buffer. By default, the disk buffer is enabled. The disk buffer is used if the collector cannot send normalized events to the destination. The amount of allocated disk space is limited by the value of the **Disk buffer size limit** setting. If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer.

Parameter	Description
Filter	In the **Filter** section, you can specify the criteria for identifying events that must be processed by the resource. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Parameter	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

Tcp type

The **tcp** type is used for TCP communications.

Basic settings tab

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
The **State** toggle switch	Used when events must be sent to the destination. By default, sending events is enabled.
Type	Required setting. Destination type, **tcp**.
URL	Required setting. URL that you want to connect to. Available formats: `host:port`, `IPv4:port`, `:port`. IPv6 addresses are also supported. When using IPv6 addresses, you must also specify the interface in the `[address%interface]:port` format. For example, `[fe80::5054:ff:fe4d:ba0c%eth0]:4222`).
Description	Resource description: up to 4,000 Unicode characters.

Advanced settings tab

Setting	Description
Compression	You can use Snappy compression. By default, compression is **disabled**.
Buffer size	Sets the size of the buffer. The default value is 1 KB, and the maximum value is 64 MB.
Timeout	The time (in seconds) to wait for a response from another service or component. The default value is `30`.
Disk buffer size limit	Size of the disk buffer in bytes. The default value is 10 GB.
Output format	Format for sending events to an external destination. Available values: • JSON • CEF If the CEF format is selected, the sent event contains the CEF header and only non-empty fields.
TLS mode	TLS encryption mode using certificates in pem x509 format. Available values: • **Disabled** means TLS encryption is not used. The default value. • **Enabled**—use encryption without certificate verification. • **Custom CA** means encryption is used, and a certificate that you provide as a file is verified. When you select this value, an additional parameter **Custom CA** is displayed. Use this parameter to specify the certificate. • **Custom PFX** means encryption is used, and a certificate that you provide in the PFX format is verified. When you select this value, an additional parameter **PFX secret** is displayed. Use this parameter to specify the certificate. When using TLS, it is impossible to specify an IP address as a URL.
Custom CA	This field allows you to select a secret of the certificate type that contains a certificate file. You can select an existing secret or create a new one. To create a new one, select the **Create** value, and then in the window that opens, upload the TLS certificate file.
PFX secret	This field allows you to select a secret of the pfx type that contains a certificate file. You can select an existing secret or create a new one. To create a new one, select the **Create** value, and then in the window that opens, upload the PFX file that contains the TLS certificate.
Delimiter	In the drop-down list, you can select the character to mark the boundary between events. By default, `\n` is used.
Buffer flush interval	Time (in seconds) between sending batches of data to the destination. The default value is `1 second`.
Number of handlers	This field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Debug	This toggle switch lets you specify whether resource logging must be enabled. The default value is **Disabled**.
Disk buffer disabled	Drop-down list that lets you enable or disable the disk buffer. By default, the disk buffer is enabled. The disk buffer is used if the collector cannot send normalized events to the destination. The amount of allocated disk space is limited by the value of the **Disk buffer size limit** setting. If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer.

Setting	Description
Filter	In this section, you can specify the criteria for identifying events that must be processed by the resource. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Setting	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

udp type

Destinations of the **udp** type are used for UDP communications. Settings for a destination of the **udp** type are described in the following tables.

Basic settings tab

Setting	Description
Name	Unique name of the resource. The maximum length of the name is 128 Unicode characters. Required setting.
Tenant	The name of the tenant that owns the resource. Required setting.
State	This toggle switch enables sending events to the destination. This toggle switch is turned on by default.
Type	Destination type, **udp**. Required setting.
URL	URL (required)—a URL that you need to connect to. The following URL formats are supported: • `< host name >:< port number >` • `< IPv4 address >:< port number >` • `< IPv6 address >:< port number >` You can specify IPv6 addresses in the following format: `[< IPv6 address >%< interface >:< port number >`, for example, `[fe80::5054:ff:fe4d:ba0c%eth0]:4222`. You can add multiple URLs and remove an URL. You cannot save a resource or service if the **URL** field contains a tab or space character. To add an URL, click the **+ Add** button. To remove an URL, click the delete ✕ icon next to it. Required setting.

Setting	Description
Tags	Tags for resource search. Optional setting.
Description	Description of the resource. The maximum length of the description is 4000 Unicode characters.

Advanced settings tab

Parameter	Description
Buffer size	Buffer size in bytes for accumulating events in the RAM of the server before sending them for further processing or storage. The value must be a positive integer. Default buffer size: 67,108,864 (64 MB), displayed as 0 in the interface.
Buffer flush interval	Interval (in seconds) for sending events to the destination. The default value is 1 second.
Disk buffer size limit	Size of the disk buffer in bytes. Default value: 10 GB, displayed as 0 in the interface.
Handlers	Number of handlers that the service can run simultaneously to process response rules in parallel. The value must be a positive integer up to 999.
Output format	Format in which events are sent to the destination: • **JSON**. • **CEF**. If this value is selected, the transmitted events contain the CEF header and only non-empty fields. • **Syslog-CEF**
TLS mode	TLS encryption mode. When using TLS encryption, you cannot specify an IP address in the **URL** field on the **Basic settings** tab. Available values: • **Disabled** means TLS encryption is not used. This value is selected by default. • **Enabled** means TLS encryption is used, but certificates are not verified. • **With verification** means TLS encryption is used with verification of the certificate signed with the KUMA root certificate. The root certificate and key of KUMA are created automatically during application installation and are stored on the KUMA Core server in the /opt/kaspersky/kuma/core/certificates/ directory. Obsolete encryption mode, deprecated.
Compression	Drop-down list for configuring Snappy compression: • **Disabled**. This value is selected by default. • **Use Snappy**.
URL selection policy	Method of determining URLs to which events must be sent first if you added multiple URLs in the **URL** field on the **Basic settings** tab: • **Any** means events are sent to a randomly selected available URL as long as the URL accepts events. If the URL becomes unavailable, events are sent to another randomly selected available URL. This value is selected by default. • **Prefer first** means events are sent to the first added URL. If the URL becomes unavailable, events are sent to the next added available URL. If the first added URL becomes available again, events are sent to the first added URL again. • **Round robin** means events are evenly balanced among the available URLs. This method does not guarantee that events are evenly balanced among the URLs because the buffer may overflow or events may be sent to the destination. You can specify the buffer size in bytes in the **Buffer size limit** field; you can also specify the interval in seconds for sending events to the destination in the **Buffer flush interval** field.
Delimiter	The character that marks the boundary between events: • **\n** • **\t** • **\0** If you do not select a value in this drop-down list, an empty value is selected by default. In this case, the connector does not split one event into several and passes it to the normalizer unchanged.
Disk buffer disabled	This toggle switch that enables the disk buffer. This toggle switch is turned on by default. The disk buffer is used if the collector cannot send normalized events to the destination. You can specify the size of the disk buffer in the **Disk buffer size limit** field. If the disk buffer runs out of free space, new normalized events will overwrite old normalized events, starting with the oldest.
Timeout	The time, in seconds, for which the destination waits for a response from another service or component.
Debug	The switch enables resource logging. The toggle switch is turned off by default.

Parameter	Description
Filter	Filter for determining which events must be processed by the resource. You can select an existing filter or create a filter. To create a new filter, select **Create new**. If you want to edit the settings of an existing filter, click the pencil icon next to it. **How to create a filter?** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Parameter	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

Http type

The **http** type is used for HTTP communications.

Basic settings tab

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
The **State** toggle switch	Used when events must be sent to the destination. By default, sending events is enabled.
Type	Required setting. Destination type, **http**.
URL	Required setting. URL that you want to connect to. Available formats: `host:port`, `IPv4:port`, `:port`. IPv6 addresses are also supported, however, when you use them, you must specify the interface as well: `[address%interface]:port`. Example: `[fe80::5054:ff:fe4d:ba0c%eth0]:4222`).

Setting	Description
Authorization	Type of authorization when connecting to the specified URL. Possible values: • **disabled** is the default value. • **plain** — if this option is selected, you must indicate the secret containing user account credentials for authorization when connecting to the connector. **Add secret** *To create a secret:* 1. In the **Name** field, enter the name of the secret. 2. In the **User** and **Password** fields, enter the credentials of the user account that the Agent will use to connect to the connector. 3. If necessary, enter a description of the secret in the **Description** field. 4. Then click the **Create** button. The secret is added and displayed in the **Secret** drop-down list.
Description	Resource description: up to 4,000 Unicode characters.

Advanced settings tab

Setting	Description
Compression	You can use Snappy compression. By default, compression is **disabled**.
Buffer size	Sets the size of the buffer. The default value is 1 KB, and the maximum value is 64 MB.
Timeout	The time (in seconds) to wait for a response from another service or component. The default value is `30`.
Disk buffer size limit	Size of the disk buffer in bytes. The default value is 10 GB.
Output format	Format for sending events to an external destination. Available values: • JSON • CEF If the CEF format is selected, the sent event contains the CEF header and only non-empty fields.

Setting	Description

TLS mode	Use of TLS encryption. Available values:
	• **Disabled** (default) means TLS encryption is not used.
	• **Enabled** means encryption is used, but the certificate is not verified.
	• **With verification**—use encryption with verification that the certificate was signed with the KUMA root certificate. The root certificate and key of KUMA are created automatically during program installation and are stored on the KUMA Core server in the folder /opt/kaspersky/kuma/core/certificates/.
	• **Custom CA** means encryption is used with verification that the certificate was signed by a Certificate Authority. The secret containing the certificate is selected from the **Custom CA** drop-down list, which is displayed when this option is selected.
	Creating a certificate signed by a Certificate Authority
	You can create a CA-signed certificate on the KUMA Core server (the following command examples use OpenSSL).
	To create a certificate signed by a Certificate Authority:
	1. Generate a key to be used by the Certificate Authority, for example:
	`openssl genrsa -out ca.key 2048`
	2. Create a certificate for the generated key, for example:
	`openssl req -new -x509 -days 365 -key ca.key -subj "/CN=< common host name of Certificate Authority >" -out ca.crt`
	3. Create a private key and a request to have it signed by the Certificate Authority, for example:
	`openssl req -newkey rsa:2048 -nodes -keyout server.key -subj "/CN=< common host name of KUMA server >" -out server.csr`
	4. Create the certificate signed by the Certificate Authority. You need to include the domain names or IP addresses of the server for which you are creating the certificate in the `subjectAltName` variable, for example:
	`openssl x509 -req -extfile <(printf "subjectAltName=DNS:domain1.ru,DNS:domain2.com,IP:192.168.0.1") -days 365 -in server.csr -CA ca.crt -CAkey ca.key -CAcreateserial -out server.crt`
	5. Upload the created `server.crt` certificate in the Open Single Management Platform web interface to a secret of the **certificate** type, then in the **Custom CA** drop-down list, select the secret of the **certificate** type.
	When using TLS, it is impossible to specify an IP address as a URL.

URL selection policy	From the drop-down list, you can select the method of deciding which URL to send events to if multiple URLs are specified. Available values: • **Any**. Events are sent to one of the available URLs as long as this URL receives events. If the connection is broken (for example, the receiving node is disconnected) a different URL will be selected as the events destination. • **Prefer first**. Events are sent to the first URL in the list of added addresses. If it becomes unavailable, events are sent to the next available node in sequence. When the first URL becomes available again, events start to be sent to it again. • **Balanced** means that packages with events are evenly distributed among the available URLs from the list. Because packets are sent either on a destination buffer overflow or on the flush timer, this URL selection policy does not guarantee an equal distribution of events to destinations.
Delimiter	In the drop-down list, you can select the character to mark the boundary between events. By default, \n is used.
Path	The path that must be added for the URL request. For example, if you specify the path `/input` and enter `10.10.10.10` for the URL, requests for `10.10.10.10/input` will be sent from the destination.
Buffer flush interval	Time (in seconds) between sending batches of data to the destination. The default value is `1 second`.
Number of handlers	The number of services that are processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Health check path	The URL for sending requests to obtain health information about the system that the destination resource is connecting to.
Health check timeout	Frequency of the health check in seconds.
Health Check Disabled	Check box that disables the health check.
Debug	This toggle switch lets you specify whether resource logging must be enabled. The default value is **Disabled**.
Disk buffer disabled	Drop-down list that lets you enable or disable the disk buffer. By default, the disk buffer is enabled. The disk buffer is used if the collector cannot send normalized events to the destination. The amount of allocated disk space is limited by the value of the **Disk buffer size limit** setting. If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer.

Setting	Description
Filter	In the **Filter** section, you can specify the criteria for identifying events that must be processed by the resource. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Setting	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

Diode type

The **diode** type is used to transmit events using a data diode.

Basic settings tab

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
The **State** toggle switch	Used when events must be sent to the destination. By default, sending events is enabled.
Type	Required setting. Destination type, **diode**.

Setting	Description
Data diode source directory	Required setting. The directory from which the data diode moves events. The path can contain up to 255 Unicode characters. **Limitations when using prefixes in paths on Windows servers** On Windows servers, absolute paths to directories must be specified. Directories with names matching the following regular expressions cannot be used: • `^[a-zA-Z]:\\Program Files` • `^[a-zA-Z]:\\Program Files \(x86\)` • `^[a-zA-Z]:\\Windows` • `^[a-zA-Z]:\\Program Files\\Kaspersky Lab\\KUMA` **Limitations when using prefixes in paths on Linux servers** Prefixes that cannot be used when specifying paths to files: • `/*` • `/bin` • `/boot` • `/dev` • `/etc` • `/home` • `/lib` • `/lib64` • `/proc` • `/root` • `/run` • `/sys` • `/tmp` • `/usr/*` • `/usr/bin/` • `/usr/local/*` • `/usr/local/sbin/` • `/usr/local/bin/` • `/usr/sbin/` • `/usr/lib/` • `/usr/lib64/` • `/var/*` • `/var/lib/` • `/var/run/` • `/opt/kaspersky/kuma/` These prefixes are used by the system as regular expressions for checking the path. The * character in prefixes matches any sequence of characters and must not be manually specified in the path itself if it is not part of a valid path. Files are available at the following paths: • `/opt/kaspersky/kuma/clickhouse/logs/` • `/opt/kaspersky/kuma/metrics/log/`

Setting	Description
Temporary directory	Directory in which events are prepared for transmission to the data diode. Events are stored in a file when a timeout (10 seconds by default) or a buffer overflow occurs. The prepared file is moved to the directory specified in the **Data diode source directory** field. The checksum (SHA256) of the file contents is used as the name of the file containing events. The temporary directory must be different from the data diode source directory.
Description	Resource description: up to 4,000 Unicode characters.

Advanced settings tab

Setting	Description
Compression	You can use Snappy compression. By default, compression is **disabled**. This setting must match for the connector and destination resources used to relay events from an isolated network segment via the data diode.
Buffer size	Sets the size of the buffer. The default value is 1 KB, and the maximum value is 64 MB.
Delimiter	In the drop-down list, you can select the character to mark the boundary between events. By default, `\n` is used. This setting must match for the connector and destination resources used to relay events from an isolated network segment via the data diode.
Buffer flush interval	Time (in seconds) between sending batches of data to the destination. The default value is `1 second`.
Number of handlers	This field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Debug	This toggle switch lets you specify whether resource logging must be enabled. The default value is **Disabled**.

Setting	Description
Filter	In the **Filter** section, you can specify the criteria for identifying events that must be processed by the resource. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Setting	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

Kafka type

The **kafka** type is used for Kafka communications.

Basic settings tab

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
The **State** toggle switch	Used when events must be sent to the destination. By default, sending events is enabled.
Type	Required setting. Destination type, **kafka**.
URL	Required setting. URL that you want to connect to. Available formats: `host:port`, `IPv4:port`, `:port`. IPv6 addresses are also supported, however, when you use them, you must specify the interface as well: `[address%interface]:port`. Example: `[fe80::5054:ff:fe4d:ba0c%eth0]:4222`). You can add multiple addresses by clicking the URL button.
Topic	Required setting. Subject of Kafka messages. Must contain from 1 to 255 of the following characters: a–z, A–Z, 0–9, ".", "_", "-".
Delimiter	Specify a character that defines where one event ends and the other begins. By default, `\n` is used.

Setting	Description
Authorization	Type of authorization when connecting to the specified URL Possible values: • **disabled** is the default value. • **PFX** — a certificate must be generated with a private key in PKCS#12 container format in an external Certificate Authority. Then the certificate must be exported from the key store and uploaded to the KUMA Console as a PFX secret. • **Add PFX secret** *To create a PFX secret:* 1. In the **Name** field, enter the name of the PFX secret. 2. Click **Upload PFX** and select the PKCS#12 container file to which you exported the PFX file with the private key. 3. In the **Password** field, enter the password of the PFX file that was set in the PFX Export Wizard. 4. Then click the **Create** button. The PFX secret is created and is displayed in the **PFX secret** drop-down list. • **plain** — you must indicate the secret containing user account credentials for authorization when connecting to the connector. **Add secret** *To create a secret:* 1. In the **Name** field, enter the name of the secret. 2. In the **User** and **Password** fields, enter the credentials of the user account that the Agent will use to connect to the connector. 3. If necessary, enter a description of the secret in the **Description** field. 4. Then click the **Create** button. The secret is added and displayed in the **Secret** drop-down list.
Description	Resource description: up to 4,000 Unicode characters.

Advanced settings tab

Parameter	Description
Buffer size	Sets the size of the buffer. The default value is 1 KB, and the maximum value is 64 MB.
Timeout	The time (in seconds) to wait for a response from another service or component. The default value is `30`.
Disk buffer size limit	Size of the disk buffer in bytes. The default value is 10 GB.
Output format	Format for sending events to an external destination. Available values: • JSON • CEF If the CEF format is selected, the sent event contains the CEF header and only non-empty fields.

Parameter	Description

TLS mode	Use of TLS encryption. Available values:
	• **Disabled** (default) means TLS encryption is not used.
	• **Enabled**—use encryption without certificate verification.
	• **With verification**—use encryption with verification that the certificate was signed with the KUMA root certificate. The root certificate and key of KUMA are created automatically during program installation and are stored on the KUMA Core server in the folder /opt/kaspersky/kuma/core/certificates/.
	• **Custom CA** means encryption is used with verification that the certificate was signed by a Certificate Authority. The secret containing the certificate is selected from the **Custom CA** drop-down list, which is displayed when this option is selected.
	Creating a certificate signed by a Certificate Authority
	You can create a CA-signed certificate on the KUMA Core server (the following command examples use OpenSSL).
	To create a certificate signed by a Certificate Authority:
	1. Generate a key to be used by the Certificate Authority, for example:
	`openssl genrsa -out ca.key 2048`
	2. Create a certificate for the generated key, for example:
	`openssl req -new -x509 -days 365 -key ca.key -subj "/CN=< common host name of Certificate Authority >" -out ca.crt`
	3. Create a private key and a request to have it signed by the Certificate Authority, for example:
	`openssl req -newkey rsa:2048 -nodes -keyout server.key -subj "/CN=< common host name of KUMA server >" -out server.csr`
	4. Create the certificate signed by the Certificate Authority. You need to include the domain names or IP addresses of the server for which you are creating the certificate in the `subjectAltName` variable, for example:
	`openssl x509 -req -extfile <(printf "subjectAltName=DNS:domain1.ru,DNS:domain2.com,IP:192.168.0.1") -days 365 -in server.csr -CA ca.crt -CAkey ca.key -CAcreateserial -out server.crt`
	5. Upload the created `server.crt` certificate in the Open Single Management Platform web interface to a secret of the **certificate** type, then in the **Custom CA** drop-down list, select the secret of the **certificate** type.
	When using TLS, it is impossible to specify an IP address as a URL.

Delimiter	In the drop-down list, you can select the character to mark the boundary between events. By default, `\n` is used.
Buffer flush interval	Time (in seconds) between sending batches of data to the destination. The default value is `1 second`.
Number of handlers	This field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Debug	This toggle switch lets you specify whether resource logging must be enabled. The default value is **Disabled**.
Disk buffer disabled	Drop-down list that lets you enable or disable the disk buffer. By default, the disk buffer is enabled. The disk buffer is used if the collector cannot send normalized events to the destination. The amount of allocated disk space is limited by the value of the **Disk buffer size limit** setting. If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer.

Parameter	Description
Filter	In this section, you can specify the criteria for identifying events that must be processed by the resource. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand. d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

Parameter	Description
	You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

File type

The **file** type is used for writing data to a file.

> If you delete a destination of the 'file' type used in a service, that service must be restarted.

Basic settings tab

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
The **State** toggle switch	Used when events must be sent to the destination. By default, sending events is enabled.
Type	Required setting. Destination type, **file**.

Setting	Description
URL	Required setting. Path to the file to which the events must be written. **Limitations when using prefixes in file paths** Prefixes that cannot be used when specifying paths to files: • `/*` • `/bin` • `/boot` • `/dev` • `/etc` • `/home` • `/lib` • `/lib64` • `/proc` • `/root` • `/run` • `/sys` • `/tmp` • `/usr/*` • `/usr/bin/` • `/usr/local/*` • `/usr/local/sbin/` • `/usr/local/bin/` • `/usr/sbin/` • `/usr/lib/` • `/usr/lib64/` • `/var/*` • `/var/lib/` • `/var/run/` • `/opt/kaspersky/kuma/` These prefixes are used by the system as regular expressions for checking the path. The * character in prefixes matches any sequence of characters and must not be manually specified in the path itself if it is not part of a valid path. Files are available at the following paths: • `/opt/kaspersky/kuma/clickhouse/logs/` • `/opt/kaspersky/kuma/metrics/log/`
Description	Resource description: up to 4,000 Unicode characters.

Advanced settings tab

Parameter	Description
Buffer size	Sets the size of the buffer. The default value is 1 KB, and the maximum value is 64 MB.
Disk buffer size limit	Size of the disk buffer in bytes. The default value is 10 GB.
Delimiter	In the drop-down list, you can select the character to mark the boundary between events. By default, \n is used.
Buffer flush interval	Time (in seconds) between sending batches of data to the destination. The default value is `1 second`.
Number of handlers	This field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Output format	Format for sending events to an external destination. Available values: • JSON • CEF If the CEF format is selected, the sent event contains the CEF header and only non-empty fields.
Debug	This toggle switch lets you specify whether resource logging must be enabled. The default value is **Disabled**.
Disk buffer disabled	Drop-down list that lets you enable or disable the disk buffer. By default, the disk buffer is enabled. The disk buffer is used if the collector cannot send normalized events to the destination. The amount of allocated disk space is limited by the value of the **Disk buffer size limit** setting. If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer.

Parameter	Description
Filter	In the **Filter** section, you can specify the criteria for identifying events that must be processed by the resource. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand. d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

Parameter	Description
	You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

Storage type

The **storage** type is used to transmit data to the storage.

Basic settings tab

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
The **State** toggle switch	Used when events must be sent to the destination. By default, sending events is enabled.
Type	Required setting. Destination type, **storage**.
URL	Required setting. URL that you want to connect to. Available formats: `host:port`, `IPv4:port`, `:port`. IPv6 addresses are also supported, however, when you use them, you must specify the interface as well: `[address%interface]:port`. Example: `[fe80::5054:ff:fe4d:ba0c%eth0]:4222`). You can add multiple addresses by clicking the **URL** button. The **URL** field supports search for services by FQDN, IP address, and name. Search string formats: • `<Search value>` —search is performed by FQDN, IP addresses, and service names. • `<First search value ending in one or more digits>:<second search value>` —the first value is used to search by the service FQDN or IP address, and the second value is used to search by port. • `:<value>` —search is performed by port.
Description	Resource description: up to 4,000 Unicode characters.

Advanced settings tab

Parameter	Description
Proxy server	Drop-down list for selecting a proxy server.
Buffer size	Sets the size of the buffer. The default value is 1 KB, and the maximum value is 64 MB.
Disk buffer size limit	Size of the disk buffer in bytes. The default value is 10 GB.
URL selection policy	Drop-down list in which you can select a method for determining which URL to send events to if several URLs have been specified: • **Any**. Events are sent to one of the available URLs as long as this URL receives events. If the connection is broken (for example, the receiving node is disconnected) a different URL will be selected as the events destination. • **Prefer first**. Events are sent to the first URL in the list of added addresses. If it becomes unavailable, events are sent to the next available node in sequence. When the first URL becomes available again, events start to be sent to it again. • **Balanced** means that packages with events are evenly distributed among the available URLs from the list. Because packets are sent either on a destination buffer overflow or on the flush timer, this URL selection policy does not guarantee an equal distribution of events to destinations.
Buffer flush interval	Time (in seconds) between sending batches of data to the destination. The default value is `1 second`.
Number of handlers	This field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Health check timeout	Frequency of the health check in seconds.
Debug	This toggle switch lets you specify whether resource logging must be enabled. The default value is **Disabled**.
Disk buffer disabled	Drop-down list that lets you enable or disable the disk buffer. By default, the disk buffer is enabled. The disk buffer is used if the collector cannot send normalized events to the destination. The amount of allocated disk space is limited by the value of the **Disk buffer size limit** setting. If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer.

Parameter	Description
Filter	In this section, you can specify the criteria for identifying events that must be processed by the resource. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand. d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

Parameter	Description
	You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

Correlator type

The **correlator** type is used to transmit data to the correlator.

Basic settings tab

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
The **State** toggle switch	Used when events must be sent to the destination. By default, sending events is enabled.
Type	Required setting. Destination type, **correlator**.
URL	Required setting. URL that you want to connect to. Available formats: `host:port`, `IPv4:port`, `:port`. IPv6 addresses are also supported, however, when you use them, you must specify the interface as well: `[address%interface]:port`. Example: `[fe80::5054:ff:fe4d:ba0c%eth0]:4222`). You can add multiple addresses by clicking the **URL** button. The **URL** field supports search for services by FQDN, IP address, and name. Search string formats: • `<Search value>` —search is performed by FQDN, IP addresses, and service names. • `<First search value ending in one or more digits>:<second search value>` —the first value is used to search by the service FQDN or IP address, and the second value is used to search by port. • `:<value>` —search is performed by port.
Description	Resource description: up to 4,000 Unicode characters.

Advanced settings tab

Parameter	Description
Proxy server	Drop-down list for selecting a proxy server.
Buffer size	Sets the size of the buffer. The default value is 1 KB, and the maximum value is 64 MB.
Disk buffer size limit	Size of the disk buffer in bytes. The default value is 10 GB.
URL selection policy	Drop-down list in which you can select a method for determining which URL to send events to if several URLs have been specified: • **Any**. Events are sent to one of the available URLs as long as this URL receives events. If the connection is broken (for example, the receiving node is disconnected) a different URL will be selected as the events destination. • **Prefer first**. Events are sent to the first URL in the list of added addresses. If it becomes unavailable, events are sent to the next available node in sequence. When the first URL becomes available again, events start to be sent to it again. • **Balanced** means that packages with events are evenly distributed among the available URLs from the list. Because packets are sent either on a destination buffer overflow or on the flush timer, this URL selection policy does not guarantee an equal distribution of events to destinations.
Buffer flush interval	Time (in seconds) between sending batches of data to the destination. The default value is `1 second`.
Number of handlers	This field is used to set the number of services processing the queue. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Health check timeout	Frequency of the health check in seconds.
Debug	This toggle switch lets you specify whether resource logging must be enabled. The default value is **Disabled**.
Disk buffer disabled	Drop-down list that lets you enable or disable the disk buffer. By default, the disk buffer is enabled. The disk buffer is used if the collector cannot send normalized events to the destination. The amount of allocated disk space is limited by the value of the **Disk buffer size limit** setting. If the disk space allocated for the disk buffer is exhausted, events are rotated as follows: new events replace the oldest events written to the buffer.

Parameter	Description
Filter	In the **Filter** section, you can specify the criteria for identifying events that must be processed by the resource. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand. d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

Parameter	Description
	You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when managing the settings of a destination and is used for linking to collectors and correlators.

To link a destination to a service, click the **Link to service** button → **Link to <service_name>**. This opens a window; in that window, select one or more services and click **OK**. The destination is linked to the selected services.

If necessary, you can unlink the destination from a service. To do this, select the check box next to the service, click **Delete** and confirm the unlinking from the service.

Predefined destinations

Destinations listed in the table below are included in the OSMP distribution kit.

Predefined destinations

Destination name	Description
[OOTB] Correlator	Sends events to a correlator.
[OOTB] Storage	Sends events to storage.

Normalizers

Normalizers are used for converting raw events that come from various sources in different formats to the KUMA event data model. Normalized events become available for processing by other KUMA resources and services.

A normalizer consists of the *main* event parsing rule and optional *additional event parsing rules*. By creating a main parsing rule and a set of additional parsing rules, you can implement complex event processing logic. Data is passed along the tree of parsing rules depending on the conditions specified in the **Extra normalization conditions** setting. The sequence in which parsing rules are created is significant: the event is processed sequentially and the processing sequence is indicated by arrows.

The following event normalization options are now available:

- 1 collector — 1 normalizer

  We recommend using this method if you have many events of the same type or many IP addresses from which events of the same type may originate. You can configure one collector with only one normalizer, which is optimal in terms of performance.

- 1 collector — multiple normalizers linked to IP

  This method is available for collectors with a connector of UDP, TCP, or HTTP type. If a UDP, TCP, or HTTP connector is specified in the collector at the 'Transport' step, then at the 'Event parsing' step, you can specify multiple IP addresses on the 'Parsing settings' tab and choose the normalizer that you want to use for events coming from the specified addresses. The following types of normalizers are available: `json`, `cef`, `regexp`, `syslog`, `csv`, `kv`, `xml`. For normalizers of the `syslog` and `regexp` types, you can specify extra normalization conditions depending on the value of the DeviceProcessName field.

A normalizer is created in several steps:

1. **Preparing to create a normalizer**

   A normalizer can be created in the OSMP Console:

   - In the **Monitoring** → **Resources** → **Normalizers** section.
   - When creating a collector, at the **Event parsing** step.

   Then parsing rules must be created in the normalizer.

2. **Creating the main parsing rule for an event**

   The main parsing rule is created by clicking the **Add event parsing** button. This opens the **Event parsing** window, where you can specify the settings of the main parsing rule:

   - Specify event parsing settings.
   - Specify event enrichment settings.

   The main parsing rule for an event is displayed in the normalizer as a dark circle. You can view or modify the settings of the main parsing rule by clicking this circle. When you hover the mouse over the circle, a plus sign is displayed. Click it to add the parsing rules.

   The name of the main parsing rule is used in KUMA as the normalizer name.

3. **Creating additional event parsing rules**

   Clicking the plus icon that is displayed when you hover the mouse over the circle or the block corresponding to the normalizer opens the **Additional event parsing** window where you can specify the settings of the additional parsing rule:

   - Specify the conditions for sending data to the new normalizer.
   - Specify event parsing settings.
   - Specify event enrichment settings.

   The additional event parsing rule is displayed in the normalizer as a dark block. The block displays the triggering conditions for the additional parsing rule, the name of the additional parsing rule, and the event field. When this event field is available, the data is passed to the normalizer. Click the block of the additional parsing rule to view or modify its settings.

   If you hover the mouse over the additional normalizer, a plus button appears. You can click this button to create a new additional event parsing rule. To delete a normalizer, use the button with the trash icon.

4. **Completing the creation of the normalizer**

   To finish the creation of the normalizer, click **Save**.

In the upper right corner, in the search field, you can search for additional parsing rules by name.

For normalizer resources, you can enable the display of control characters in all input fields except the **Description** field.

If, when changing the settings of a collector resource set, you change or delete conversions in a normalizer connected to it, the edits will not be saved, and the normalizer itself may be corrupted. If you need to modify conversions in a normalizer that is already part of a service, the changes must be made directly to the normalizer under **Monitoring** → **Resources** → **Normalizers** in OSMP Console.

Event parsing settings

You can configure the rules for converting incoming events to the KUMA format when creating event parsing rules in the normalizer settings window, on the **Normalization scheme** tab.

To define the event parsing settings:

1. In the **Resource version in the Kaspersky repository** field, the resource version number is specified.

   This field is not editable. Available only for resources provided by Kaspersky and used to manage resource updates.

2. In the **Name** field (required), enter the unique name of the parsing rule. Must contain 1 to 128 Unicode characters. The name of the main parsing rule is used as the name of the normalizer.

3. In the **Tenant** field (required), enter the name of the tenant that owns the resource.

   This setting is not available for extra parsing rules.

4. In the **Parsing method** drop-down list, select the type of events to receive. Depending on your choice, you can use the preconfigured rules for matching event fields or set your own rules. When you select some of the parsing methods, additional settings fields may need to be filled.

   Available parsing method: json.

   This parsing method is used to process JSON data where each object, including its nested objects, occupies a single line in a file.

   When processing files with hierarchically arranged data, you can access the fields of nested objects by specifying the names of the parameters dividing them by a period. For example, the `username` parameter from the string `"user": {"username": "system: node: example-01"}` can be accessed by using the `user.username` query.

   Files are processed line by line. Multi-line objects with nested structures may be normalized incorrectly.

   In complex normalization schemes where additional normalizers are used, all nested objects are processed at the first normalization level, except for cases when the extra normalization conditions are not specified and, therefore, the event being processed is passed to the additional normalizer in its entirety.

   Newline characters can be `\n` and `\r\n`. Strings must be UTF-8 encoded.

   If you want to send the raw event for advanced normalization, at each nesting level in the **Advanced event parsing** window, select **Yes** in the **Keep raw event** drop-down list.

5. In the **Keep raw event** drop-down list, specify whether to store the original raw event in the newly created normalized event. Available values:

   - **Don't save**—do not save the raw event. This is the default setting.
   - **Only errors**—save the raw event in the `Raw` field of the normalized event if errors occurred when parsing it. This value is convenient to use when debugging a service. In this case, every time an event has a non-empty `Raw` field, you know there was a problem.

     If fields containing the names `*Address` or `*Date*` do not comply with normalization rules, these fields are ignored. No normalization error occurs in this case, and the values of the fields are not displayed in the `Raw` field of the normalized event even if the **Keep raw event** → **Only errors** option was selected.

   - **Always**—always save the raw event in the `Raw` field of the normalized event.

   This setting is not available for extra parsing rules.

6. In the **Keep extra fields** drop-down list, choose whether you want to store the raw event fields in the normalized event if no mapping rules have been configured for them (see below). The data is stored in the `Extra` event field. Normalized events can be searched and filtered based on the data stored in the `Extra` field.

   Filtering based on data from the Extra event field

   Conditions for filters based on data from the **Extra** event field:

   - Condition—**If**.
   - Left operand—**event field**.
   - In this event field, you can specify one of the following values:
     - **Extra** field.
     - Value from the Extra field in the following format:

       `Extra.<field name>`

       For example, `Extra.app`.

       A value of this type is specified manually.

     - Value from the array written to the **Extra** field in the following format:

       `Extra.<field name>.<array element>`

       For example, `Extra.array.0`.

       The values in the array are numbered starting from 0.

       A value of this type is specified manually.

       To work with a value from the Extra field at depth 3 and below, use backquotes ``. For example, `Extra.lev1.lev2.lev3`.

   - Operator – =.
   - Right operand—**constant**.
   - Value—the value by which you need to filter events.

   By default, fields are not saved.

7. In the **Description** field, specify the resource description: up to 4,000 Unicode characters.

   This setting is not available for extra parsing rules.

8. In the **Event examples** field, you can provide an example of data that you want to process.

   This setting is not available for the following parsing methods: **netflow5**, **netflow9**, **sflow5**, **ipfix**, **sql**.

   The **Event examples** field is populated with data obtained from the raw event if the event was successfully parsed and the type of data obtained from the raw event matches the type of the KUMA field.

   For example, the value "192.168.0.1" enclosed in quotation marks is not displayed in the SourceAddress field, in this case the value 192.168.0.1 is displayed in the **Event examples** field.

9. In the **Mapping** table, configure the mapping of raw event fields to fields of the event in KUMA format:

   a. In the **Source** column, provide the name of the raw event field that you want to convert into the KUMA event field.

      For details about the field format, refer to the "Normalized event data model" article. For a description of the mapping, refer to the "Mapping fields of predefined normalizers" article.

      Clicking the button next to the field names in the **Source** column opens the **Conversion** window, in which you can click the **Add conversion** button to create rules for modifying the original data before they are written to the KUMA event fields.

      Available conversions

      Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

      Available conversions:

      - **lower**—is used to make all characters of the value lowercase
      - **upper**—is used to make all characters of the value uppercase
      - **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
      - **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.
      - **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
        - **Replace chars**—in this field you can specify the character sequence that should be replaced.
        - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
      - **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.
      - **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.
      - **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.

- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.
  - **Expression**—in this field you can specify the regular expression which results that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- Converting encoded strings to text:
  - **decodeHexString**—used to convert a HEX string to text.
  - **decodeBase64String**—used to convert a Base64 string to text.
  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.
- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.
- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.
- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

In the **Conversion** window, you can swap the added rules by dragging them by the ⣿ icon; you can also delete them using the ✕ icon.

b. In the **KUMA field** column, select the required KUMA event field from the drop-down list. You can search for fields by entering their names in the field.

Recommendations concerning the KUMA field column

We recommend that you configure the mapping for the following KUMA fields. Otherwise, you will not be able to view observables in alert details and incident details.

The recommended KUMA fields depend on the observable types:

- For observables of the MD5 hash and SHA256 types:
  - FileHash
- For observables of the URL type:
  - RequestUrl
- For observables of the IP address type:
  - DeviceCustomIPv6Address1
  - DeviceCustomIPv6Address2
  - DeviceCustomIPv6Address3
  - DeviceCustomIPv6Address4
  - DestinationTranslatedAddress
  - DeviceTranslatedAddress
  - DestinationAddress
  - DeviceAddress
  - SourceTranslatedAddress
  - SourceAddress
- For observables of the Domain name type:
  - DestinationDnsDomain
  - DeviceDnsDomain
  - DeviceNtDomain
  - DestinationNtDomain
  - SourceDnsDomain
  - SourceNtDomain
- For observables of the UserName type:
  - DestinationUserName
  - SourceUserName

- For observables of the HostName type:
  - DestinationHostName
  - DeviceHostName
  - SourceHostName

c. If the name of the KUMA event field selected at the previous step begins with `DeviceCustom*` or `Flex*`, you can add a unique custom label in the **Label** field.

New table rows can be added by using the **Add row** button. Rows can be deleted individually using the ✕ button or all at once using the **Clear all** button.

If you want KUMA to enrich events with asset information, and the asset information to be available in the alert card when a correlation rule is triggered, in the **Mapping** table, configure a mapping of host address and host name fields depending on the purpose of the asset. For example, the mapping can apply to SourceAddress and SourceHostName, or DestinationAddress and DestinationHostName fields. As a result of enrichment, the event card includes a SourceAssetID or DestinationAssetID field, and a link to the asset card. Also, as a result of enrichment, asset information is available in the alert card.

If you have loaded data into the **Event examples** field, the table will have an **Examples** column containing examples of values carried over from the raw event field to the KUMA event field.

If the size of the KUMA event field is less than the length of the value placed in it, the value is truncated to the size of the event field.

Extended event schema

When normalizing events, extended event schema fields can be used in addition to standard KUMA event schema fields. Information about the types of extended event schema fields is shown in the table below.

Using many unique fields of the extended event schema can reduce the performance of the system, increase the amount of disk space required for storing events, and make the information difficult to understand.

We recommend consciously choosing a minimal set of additional fields of the extended event schema that you want to use in normalizers and correlation.

To use extended event schema fields:

- Open an existing event normalizer or create a new event normalizer.
- Specify the basic settings of the normalizer.
- Click **Add row**.
- For the **Source** setting, enter the name of the source field in the raw event.
- For the **KUMA field** setting, enter the name of the extended event schema field that you are creating (see the table below). You can also use an existing field of the extended event schema.

Fields of the extended data model of normalized events:

Field name Specified in the KUMA field setting	Data type	Availability in the normalizer	Description
S.<field name>	String	All types	Field of the String type
N.<field name>	Number	All types	Field of the Number type
F.<field name>	Float	All types	Field of the Float type
SA.<field name>	Array of strings	KV, JSON	Field of the Array of strings type. The order of the array elements is the same as the order of the elements of the raw event.
NA.<field name>	Array of integers	KV, JSON	A field of the Array of integers type. The order of the array elements is the same as the order of the elements of the raw event.
FA.<field name>	Array of floats	KV, JSON	Field of the Array of floats type. The order of the array elements is the same as the order of the elements of the raw event.

The prefixes S., N., F., SA., NA., FA. are required when creating fields of the extended event schema; the prefixes must be strictly uppercase.

Replace < field name > with the field name. You may use letters of the English alphabet and numerals in the field name. The space character is not allowed.

- Click the **OK** button.
- Click **Save** to finish editing the event normalizer.

The normalizer is saved, and the additional field is created. After saving the normalizer, the additional field can be used in other normalizers.

Note: If the data in the fields of the raw event does not match the type of the KUMA field, the value is not saved during the normalization of events. For example, the string test cannot be written to the DeviceCustomNumber1 KUMA field of the Number type.

If you want to minimize the load on the storage server when searching events, preparing reports, and performing other operations on events in storage, use KUMA event schema fields as your first preference, extended event schema fields as your second preference, and the Extra fields as your last resort.

Extended event schema

You can use the extended event schema fields in normalizers for normalizing events and in other KUMA resources, for example, as widget fields or to filter and search for events. You can view the list of all extended event schema fields that exist in KUMA in the **Settings** → **KUMA** → **Open KUMA settings** → **Extended fields set** section. The list of extended event schema fields is the same for all tenants.

At the top of the section, the version number of the extended fields set is displayed. This version is used to manage extended fields updates.

Only users with the Main administrator, Tenant administrator, Tier 2 analyst, Tier 1 analyst, Junior analyst, Read shared resources, and Manage shared resources roles can view the table of extended event schema fields.

The **Extended event schema fields** table contains the following information:

- **Type**—Data type of the extended event schema field.

  Possible data types:

Type	Availability in the normalizer	Data type
S	All types	String.
N	All types	Number.
F	All types	Floating point number.
SA	KV, JSON	Array of strings. The order of the array elements is the same as the order of the elements of the raw event.
NA	KV, JSON	Array of integers. The order of the array elements is the same as the order of the elements of the raw event.
FA	KV, JSON	Array of floats. The order of the array elements is the same as the order of the elements of the raw event.

- **Field name**—Name of the extended event schema field, without a type.

  You can click the name to edit the settings of the extended event schema field.

- **Status**—Whether the extended event schema field can be used in resources.

  You can **Enable** or **Disable** the toggle switch to allow or forbid using this extended event schema field in new resources. However, a disabled field is still used in resource configurations that are already operational, until you manually remove the field from the configuration; the field also remains available in the list of table columns in the **Events** section for managing old events.

  Only a user with the Main administrator role can disable an extended event schema field.

- **Update date**—Date and time of the last modification of the extended event schema field.

- **Created by**—Name of the user that created the extended event schema field.

- **Dependencies**—the number of KUMA resources, dashboard layouts, reports, presets, and field sets for searching event sources that use the extended event schema field.

  You can click the number to open a pane with a table of all resources and other KUMA entities that are using this field. For each dependency, the table displays the name, tenant (only for resources), and type. Dependencies in the table are sorted by name. Clicking the name of a dependency takes you to its page (except for dashboard layouts, presets, and saved user queries).

  You can view the dependencies of an extended event schema field only for resources and entities to whose tenants you have access. If you do not have access to the tenant, its resources are not displayed in the table, but still count towards the number of dependencies.

- **Description**—Text description of the field.

By default, the table of extended event schema fields is sorted by update date in descending order. If necessary, you can sort the table by clicking a column heading and selecting **Ascending** or **Descending**; you can also use context search by field name.

By default, the following service extended event schema fields are automatically added to KUMA:

- `KL_EventRoute`, type `S` for storing information about the route of the event.

  You can use this field in normalizers, as a key or value in active lists, in enrichment rules, as a query field in data collection and analysis rules, in correlation rules. You cannot use this field to detect event sources.

- The following fields are added to a correlation event:

  - `KL_CorrelationRulePriority`, type `N`

  - `KL_SourceAssetDisplayName`, type `S`

- `KL_DestinationAssetDisplayName`, type `S`
- `KL_DeviceAssetDisplayName`, type `S`
- `KL_SourceAccountDisplayName`, type `S`
- `KL_DestinationAccountDisplayName`, type `S`

You cannot use this service fields to search for events.

You cannot edit, delete, export, or disable service fields. All extended event schema fields with the `KL_` prefix are service fields and can be managed only from Kaspersky servers. We do not recommend using the `KL_` prefix when adding new extended event schema fields.

Adding extended event schema fields

Users with the Main administrator, Tenant administrator, Tier 2 analyst, Tier 1 analyst, Junior analyst, Manage shared resources roles can add new extended event schema fields.

To add an extended event schema field:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Other**, click **Extended fields set**.

   This opens the **Extended fields set** window.

3. Click the **Add** button in the upper part of the table.

   This opens the **Create extended schema** pane.

4. Enable or disable the **Status** toggle switch to enable or disable this extended event schema field for resources.

   The toggle switch is enabled by default. A disabled field remains available in the list of table columns in the **Events** section for managing old events.

5. In the **Type** field, select the data type of the extended event schema field.

   Possible data types

Type	Availability in the normalizer	Data type
`S`	All types	String.
`N`	All types	Number.
`F`	All types	Floating point number.
`SA`	KV, JSON	Array of strings. The order of the array elements is the same as the order of the elements of the raw event.
`NA`	KV, JSON	Array of integers. The order of the array elements is the same as the order of the elements of the raw event.
`FA`	KV, JSON	Array of floats. The order of the array elements is the same as the order of the elements of the raw event.

6. In the **Name** field, specify the name of the extended event schema field.

Consider the following when naming extended event schema fields:

- The name must be unique within the KUMA instance.
- Names are case-sensitive. For example, `Field_name` and `field_name` are different names.
- You can use Latin, Cyrillic characters and numerals. Spaces or " ~ ` @ # $ % ^ & * ( ) + - [ ] { } | \ | / . " < > ; ! , : ? = characters are not allowed.
- If you want to use the extended event schema fields to search for event sources, you can only use Latin characters and numerals.
- The maximum length is 128 characters.

7. If necessary, in the **Description** field, enter a description for the extended event schema field.

   We recommend describing the purpose of the extended event schema field. Only Unicode characters are allowed in the description. The maximum length is 256 characters.

8. Click **Save**.

A new extended event schema field is added and displayed at the top of the table. An audit event is generated for the creation of the extended event schema field. If you have enabled the field, you can use it in normalizers and when configuring resources.

Editing extended event schema fields

Users with the Main administrator, Tenant administrator, Tier 2 analyst, Tier 1 analyst, Junior analyst, Manage shared resources roles can edit existing extended event schema fields.

To edit an extended event schema field:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Other**, click **Extended fields set**.

   This opens the **Extended fields set** window.

3. Click the name of the field that you want to edit.

   This opens the **Edit extended schema** pane. This pane displays the settings of the selected field, as well as the **Dependencies** table with a list of resources, dashboard layouts, reports, presets, and sets of fields for finding event sources that use this field. Only resources to whose tenants you have access are displayed. If the field is used by resources to whose tenant you do not have access, such resources are not displayed in the table. Resources in the table are sorted by name.

   Clicking the name of a resource or entity takes you to its page (except for dashboard resources, presets, and saved user queries).

4. Make the changes you need in the available settings.

   You can edit the **Type** and **Field name** settings only if the extended event schema field does not have dependencies. You can edit the **Status** and **Description** settings for any extended event scheme field. However, a field with the **Disabled** status is still used in resource configurations that are already operational, until you manually remove the field from the configuration; the field also remains available in the list of table columns in the **Events** section for managing old events.

Disabling an extended event schema field using the **Status** field requires the Main administrator role.

5. Click **Save**.

The extended event schema field is updated. An audit event is generated about the modification of the field.

Importing and exporting extended event schema fields

You can add multiple new extended event schema fields at once by importing them from a JSON file. You can also export all extended event schema fields with information about them to a file, for example, to propagate the list of fields to other KUMA instances to maintain resources.

Users with the Main administrator, Tenant administrator, Tier 2 analyst, Tier 1 analyst, Junior analyst, and Manage shared resources roles can import an export extended event schema fields. Users with the Read shared resources role can only export extended event schema fields.

To import extended event schema fields into KUMA from a file:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Other**, click **Extended fields set**.

   This opens the **Extended fields set** window.

3. Click the **Import** button.

4. This opens a window; in that window, select a JSON file with a list of extended event schema field objects.

   Example JSON file:

```
[
{"kind": "SA",
"name": "<fieldName1>",
"description": "<description1>",
"disabled": false},
{"kind": "N",
"name": "<fieldName2>",
"description": "<description2>",
"disabled": false},
....
{"kind": "FA",
"name": "<fieldNameX>",
"description": "<descriptionX>",
"disabled": false}
]
```

When importing fields from a file, their names are checked for possible conflicts with fields of the same type. If a field with the same name and type already exists in KUMA, such fields are not imported from the file.

Extended event schema fields are imported from the file to KUMA. An audit event about the import of fields is generated, and a separate audit event is generated for each added field.

To export extended event schema fields to a file:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Other**, click **Extended fields set**.

   This opens the **Extended fields set** window.

3. If you want to export specific extended event schema fields:

   a. Select the check boxes in the first column of the table for the required fields.

      You cannot select service fields.

   b. Click the **Export selected** button in the upper part of the table.

4. If you want to export all extended event schema fields, click the **Export all** button in the upper part of the table.

A JSON file with a list of extended event schema field objects and information about them is downloaded.

Deleting extended event schema fields

Only a user with the Main administrator role can delete extended event schema fields.

You can delete only those extended event schema fields that are not service fields, that have the **Disabled** status, and that are not used in KUMA resources and other entities (do not have dependencies). We recommend deleting extended event schema fields after enough time has passed to make sure that all events in which the field was used have been deleted from KUMA. When you delete a field, it is no longer displayed in event tips.

To delete extended event schema fields:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under **Other**, click **Extended fields set**.

   This opens the **Extended fields set** window.

3. Select the check boxes in the first column of the table next to one or more fields that you want to delete.

   To select all fields, you can select the check box in the heading of the first column.

4. Click the **Delete** button in the upper part of the table.

   The **Delete** button is active only if all selected fields are disabled and have no dependencies. If at least one field is enabled or has a dependency, the button is inactive.

   If you want to delete a field that is used in at least one KUMA resource (has a dependency), but you do not have access to its tenant, the **Delete** button is active when this field is selected, but an error is displayed when you try to delete it.

The selected fields are deleted. An audit event is generated about the deletion of the fields.

Using extended event schema fields in normalizers

When using extended event schema fields, the general limit for the maximum size of an event that can be processed by the collector is the same, 4 MB. Information about the types of extended event schema fields is shown in the table below (step 6 of the instructions).

Using many unique fields of the extended event schema can reduce the performance of the system, increase the amount of disk space required for storing events, and make the information difficult to understand.

We recommend consciously choosing a minimal set of additional fields of the extended event schema that you want to use in normalizers and correlation.

To use the fields of the extended event schema:

1. Open an existing normalizer or create a new normalizer.
2. Specify the basic settings of the normalizer.
3. Click **Add row**.
4. For the **Source** setting, enter the name of the source field in the raw event.
5. For the **KUMA field** setting, start typing the name of the extended event schema field and select the field from the drop-down list.

   The extended event schema fields in the drop-down list have names in the `<type>.<field name>` format.
6. Click the **Save** button to save the event normalizer.

The normalizer is saved with the selected extended event schema field.

If the data in the fields of the raw event does not match the type of the KUMA field, the value is not saved during the normalization of events if type conversion cannot be performed. For example, the string `test` cannot be written to the `DeviceCustomNumber1` KUMA field of the Number type.

If you want to minimize the load on the storage server when searching events, preparing reports, and performing other operations on events in storage, use KUMA event schema fields as your first preference, extended event schema fields as your second preference, and the `Extra` fields as your last resort.

Generating regular expressions with KIRA

You can automatically create one or more regular expressions based on examples of events for the normalizer with the **regexp** parsing method with the help of Kaspersky Investigation and Response Assistant. This functionality is available to users with the Main administrator, Tenant Administrator, Tier 2 Analyst, Tier 1 Analyst, and Junior Analyst roles.

To generate regular expressions:

1. Get a license with the AI module and activate the functionality in KUMA.
2. Configure KIRA integration using a third-party LLM provider (the **Custom** mode).
3. Start creating a normalizer or open the settings of an existing normalizer.
4. On the **Normalization scheme** tab, in the **Parsing method** drop-down list, select **regexp**.
5. In the **Event examples** field, add one or more example events from which you want to create a regular expression.

   You can add up to 10 one-liner events.
6. Click the **Generate regular expression with KIRA** button.
7. Confirm your request.

   After the request is processed, a window is displayed with the following information:

   - The number of tokens spent on the generation
   - Generated regular expressions with color highlighting of groups and corresponding snippets of example events.

   Each generated regular expression starts with the (?:ai)? group of characters.

   In the window with the created expressions, you can edit and copy the regular expression and apply the generation result by clicking the **Apply** button.

   > If the generation of the regular expression fails or does not produce the expected result, this may mean that the provider's model that you used was unable to correctly identify the components of the event or generate the regular expression. Try to start generation again. If the error recurs, add more similar examples to the **Event examples** field and restart the generation. When starting generation after an error, no additional tokens are spent.

   After applying the result, the generated regular expression is automatically added to the **Normalization** field. If multiple regular expressions have been generated, the appropriate number of fields is automatically generated for each expression. Regular expressions are added in the order in which they are generated, which you can change if necessary by dragging the expressions around by the ⠿ icon.
8. After applying the generated regular expressions, save the normalizer settings by clicking the **OK** button and then the **Save** button.

Enrichment in the normalizer

When creating event parsing rules in the normalizer settings window, on the **Enrichment** tab, you can configure the rules for adding extra data to the fields of the normalized event using enrichment rules. These enrichment rules are stored in the settings of the normalizer where they were created.

Enrichments are created by clicking the **Add enrichment** button. There can be more than one enrichment rule. You can delete enrichment rules by clicking the ✕ button.

Settings available in the enrichment rule settings block:

- **Source kind** (required)—drop-down list for selecting the type of enrichment. Depending on the selected type, advanced settings that will also need to be completed may be displayed.

  Available Enrichment rule source types:

  - **constant**

    This type of enrichment is used when a constant needs to be added to an event field. Settings of this type of enrichment:

    - In the **Constant** field, specify the value that should be added to the event field. The value may not be longer than 255 Unicode characters. If you leave this field blank, the existing event field value will be cleared.

    - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

    If you are using the event enrichment functions for extended schema fields of `String`, `Number`, or `Float` type with a constant, the constant is added to the field.

    If you are using the event enrichment functions for extended schema fields of `Array of strings`, `Array of numbers`, or `Array of floats` type with a constant, the constant is added to the elements of the array.

  - **dictionary**

    This type of enrichment is used if you need to add a value from the dictionary of the **Dictionary** type.

    When this type is selected in the **Dictionary name** drop-down list, you must select the dictionary that will provide the values. In the **Key fields** settings block, you have to click the **Add field** button and select the event fields whose values will be used for dictionary entry selection.

    If you are using event enrichment with the "Dictionary" type selected as the "Source kind" setting, and an array field is specified in the "Key enrichment fields" setting, when an array is passed as the dictionary key, the array is serialized into a string in accordance with the rules of serializing a single value in the TSV format.

    Example: The "Key enrichment fields" setting uses the SA.StringArrayOne extended schema field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b" and "c". The following value is passed to the dictionary as the key: ['a','b','c'].

    If the "Key enrichment fields" setting uses an extended schema array field and a regular event schema field, the field values are separated by the "|" character when the dictionary is queried.

    Example: The "Key enrichment fields" setting uses two fields: the SA.StringArrayOne extended schema field and the Code field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b", and "c"; the Code string field contains the character sequence "myCode". The following value is passed to the dictionary as the key: ['a','b','c']|myCode.

  - **table**

    This type of enrichment is used if you need to add a value from the dictionary of the **Table** type.

    When this enrichment type is selected in the **Dictionary name** drop-down list, select the dictionary for providing the values. In the **Key fields** group of settings, click the **Add field** button to select the event fields whose values are used for dictionary entry selection.

In the **Mapping** table, configure the dictionary fields to provide data and the event fields to receive data:

- In the **Dictionary field** column, select the dictionary field. The available fields depend on the selected dictionary resource.
- In the **KUMA field** column, select the event field to which the value is written. For some of the selected fields (`*custom*` and `*flex*`), in the **Label** column, you can specify a name for the data written to them.

New table rows can be added by clicking the **Add new element** button. Columns can be deleted by clicking the ✕ button.

- **event**

  This type of enrichment is used when you need to write a value from another event field to the current event field. Settings of this type of enrichment:

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.
  - In the **Source field** drop-down list, select the event field whose value will be written to the target field.
  - Clicking the 🔧 button opens the **Conversion** window in which you can, using the **Add conversion** button, create rules for modifying the original data before writing them to the KUMA event fields.

    Available conversions

    Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

    Available conversions:

    - **lower**—is used to make all characters of the value lowercase
    - **upper**—is used to make all characters of the value uppercase
    - **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
    - **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.
    - **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
      - **Replace chars**—in this field you can specify the character sequence that should be replaced.
      - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
    - **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.
    - **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.

- **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.

- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.

  - **Expression**—in this field you can specify the regular expression which results that should be replaced.

  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.

- Converting encoded strings to text:

  - **decodeHexString**—used to convert a HEX string to text.

  - **decodeBase64String**—used to convert a Base64 string to text.

  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.

- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.

- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.

- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

When using enrichment of events that have the **Event** selected as the **Source kind** setting and the fields of the extended event schema are used as arguments, the following special considerations apply:

- If the source field is an `Array of strings` field and the target field is a `String` field, the values are written to the target field in the TSV format.

  Example: The SA.StringArray extended event schema field contains values: "string1", "string2", "string3". An event enrichment operation is performed. The result of the operation is written to the DeviceCustomString1 event schema field. As a result of the operation, the DeviceCustomString1 field contains ["string1", "string2", "string3"].

- If the source field is an `Array of strings` field and the target field is an `Array of strings` field, the values of the source field are appended to the values of the target field and are placed in the target field, with commas (",") used as the separator character.

  Example: The SA.StringArrayOne extended event schema field contains values: "string1", "string2", "string3". An event enrichment operation is performed. The result of the operation is written to the SA.StringArrayTwo event schema field. As a result of the operation, the SA.StringArrayTwo field contains "string1", "string2", "string3".

- **template**

  This type of enrichment is used when you need to write a value obtained by processing Go templates into the event field. Settings of this type of enrichment:

  - In the **Template** field, enter the Go template.

    Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field from which the value must be passed to the script.

    Example: `Attack on {{.DestinationAddress}} from {{.SourceAddress}}`.

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

  To convert the data in an array field in a template into the TSV format, you must use the toString function.

  If you are using enrichment of events that have the **Template** type selected as the **Source kind** setting, in which the target field has the `String` type, and the source field is an extended event schema field containing an array of strings, you can use one of the following examples for the template.

  Example:

  {{.SA.StringArrayOne}}

  Example:

  {{- range $index, $element := . SA.StringArrayOne -}}

  {{- if $index}}, {{end}}"{{$element}}"{{- end -}}

- **Target field** (required)—drop-down list for selecting the KUMA event field that should receive the data.

  This setting is not available for the enrichment source of the **Table** type.

Conditions for sending data to an extra normalizer

When creating additional event parsing rules, you can specify the conditions. When these conditions are met, the events are sent to the created parsing rule for processing. Conditions can be specified in the **Additional event parsing** window, on the **Extra normalization conditions** tab. This tab is not available for the basic parsing rules.

Available settings:

- **Use raw event** — If you want to send a raw event for extra normalization, select **Yes** in the **Keep raw event** drop-down list. The default value is **No**. We recommend passing a raw event to normalizers of json and xml types. If you want to send a raw event for extra normalization to the second, third, etc nesting levels, at each nesting level, select **Yes** in the **Keep raw event** drop-down list.

- **Field to pass into normalizer**—indicates the event field if you want only events with fields configured in normalizer settings to be sent for additional parsing.

  If this field is blank, the full event is sent to the extra normalizer for processing.

- Set of filters—used to define complex conditions that must be met by the events received by the normalizer.

  You can use the **Add condition** button to add a string containing fields for identifying the condition (see below).

  You can use the **Add group** button to add a group of filters. Group operators can be switched between **AND**, **OR**, and **NOT**. You can add other condition groups and individual conditions to filter groups.

  You can swap conditions and condition groups by dragging them by the ⣿ icon; you can also delete them using the ✕ icon.

Filter condition settings:

- **Left operand** and **Right operand**—used to specify the values to be processed by the operator.

  In the left operand, you must specify the source field of events coming into the normalizer. For example, if the eventType - DeviceEventClass mapping is configured in the **Basic event parsing** window, then in the **Additional event parsing** window on the **Extra normalization conditions** tab, you must specify eventType in the left operand field of the filter. Data is processed only as text strings.

- Operators:

  - **=** – full match of the left and right operands.

  - **startsWith** – the left operand starts with the characters specified in the right operand.

  - **endsWith** – the left operand ends with the characters specified in the right operand.

  - **match** – the left operand matches the regular expression (RE2) specified in the right operand.

  - **in** – the left operand matches one of the values specified in the right operand.

The incoming data can be converted by clicking the 🔧 button. The **Conversion** window opens, where you can click the **Add conversion** button to create the rules for converting the source data before any actions are performed on them. In the **Conversion** window, you can swap the added rules by dragging them by the ⣿ icon; you can also delete them using the ✕ icon.

Available conversions

Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

Available conversions:

- **lower**—is used to make all characters of the value lowercase

- **upper**—is used to make all characters of the value uppercase

- **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
- **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.
- **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
  - **Replace chars**—in this field you can specify the character sequence that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.
- **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.
- **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.
- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.
  - **Expression**—in this field you can specify the regular expression which results that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- Converting encoded strings to text:
  - **decodeHexString**—used to convert a HEX string to text.
  - **decodeBase64String**—used to convert a Base64 string to text.
  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.
- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.
- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.
- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

Supported event sources

KUMA supports the normalization of events coming from systems listed in the table below. Normalizers for these systems are included in the distribution kit.

Supported event sources

System name	Normalizer name	Type	Normalizer description
1C EventJournal	[OOTB] 1C EventJournal Normalizer	xml	Designed for processing the event log of the 1C system. The event source is the 1C log.
1C TechJournal	[OOTB] 1C TechJournal Normalizer	regexp	Designed for processing the technology event log. The event source is the 1C technology log.
Absolute Data and Device Security (DDS)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
AhnLab Malware Defense System (MDS)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Ahnlab UTM	[OOTB] Ahnlab UTM	regexp	Designed for processing events from the Ahnlab system. The event sources are system logs, operation logs, connections, the IPS module.
AhnLabs MDS	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Alcatel AOS-W	[OOTB] Alcatel AOS-W syslog	regexp	Designed for processing some of the events received from Alcatel AOS-W 6.4 via syslog.
Alcatel Network Switch	[OOTB] Alcatel Network Switch syslog	Syslog	Designed for processing certain types of events received from Alcatel network switches via syslog.
Apache Cassandra	[OOTB] Apache Cassandra file	regexp	Designed for processing events from the logs of the Apache Cassandra database version 4.0.
Aruba ClearPass	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Atlassian Confluence	[OOTB] Atlassian Jira Confluence file	regexp	Designed for processing events of Atlassian Jira, Atlassian Confluence systems (Jira 9.12, Confluence 8.5) stored in files.

System name	Normalizer name	Type	Normalizer description
Atlassian Jira	[OOTB] Atlassian Jira Confluence file	regexp	Designed for processing events of Atlassian Jira, Atlassian Confluence systems (Jira 9.12, Confluence 8.5) stored in files.
Avanpost FAM	[OOTB] Avanpost FAM syslog	regexp	Designed for processing events of the Avanpost Federated Access Manager (FAM) 1.9 received via syslog.
Avanpost IDM	[OOTB] Avanpost IDM syslog	regexp	Designed for processing events of the Avanpost IDM system received via syslog.
Avanpost PKI	[OOTB] Avanpost PKI syslog CEF	Syslog	Designed for processing events received from Avanpost PKI 6.0 in CEF format via Syslog.
Avaya Aura Communication Manager	[OOTB] Avaya Aura Communication Manager syslog	regexp	Designed for processing some of the events received from Avaya Aura Communication Manager 7.1 via syslog.
Avigilon Access Control Manager (ACM)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Ayehu eyeShare	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Arbor Pravail	[OOTB] Arbor Pravail syslog	Syslog	Designed for processing events of the Arbor Pravail system received via syslog.
Aruba Aruba AOS-S	[OOTB] Aruba Aruba AOS-S syslog	regexp	Designed for processing certain types of events received from Aruba network devices with Aruba AOS-S 16.10 firmware via syslog. The normalizer supports the following types of events: accounting events, ACL events, ARP protect events, authentication events, console events, loop protect events.
Barracuda Cloud Email Security Gateway	[OOTB] Barracuda Cloud Email Security Gateway syslog	regexp	Designed for processing events from Barracuda Cloud Email Security Gateway via syslog.
Barracuda Networks NG Firewall	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Barracuda Web Security Gateway	[OOTB] Barracuda Web Security Gateway syslog	Syslog	Designed for processing some of the events received from Barracuda Web Security Gateway 15.0 via syslog.
BeyondTrust Privilege Management Console	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
BeyondTrust's BeyondInsight	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Bifit Mitigator	[OOTB] Bifit Mitigator Syslog	Syslog	Designed for processing events from the DDOS Mitigator protection system received via syslog.
Bloombase StoreSafe	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
BMC CorreLog	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Bricata ProAccel	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Brinqa Risk Analytics	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Broadcom Symantec Advanced Threat Protection (ATP)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Broadcom Symantec Endpoint Protection	[OOTB] Broadcom Symantec Endpoint Protection	regexp	Designed for processing events from the Symantec Endpoint Protection system.

System name	Normalizer name	Type	Normalizer description
Broadcom Symantec Endpoint Protection Mobile	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Broadcom Symantec Threat Hunting Center	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Brocade Fabric OS	[OOTB] Brocade Fabric OS syslog	Syslog	Designed for processing events of Brocade Fabric 9.1 received via syslog.
Canonical LXD	[OOTB] Canonical LXD syslog	Syslog	Designed for processing events received via syslog from the Canonical LXD system version 5.18.
Checkpoint	[OOTB] Checkpoint syslog	Syslog	[OOTB] Checkpoint syslog — designed for processing events received from the Checkpoint R81 firewall via the Syslog protocol.
Cisco Access Control Server (ACS)	[OOTB] Cisco ACS syslog	regexp	Designed for processing events of the Cisco Access Control Server (ACS) system received via syslog.
Cisco ASA	[OOTB] Cisco ASA and IOS syslog	Syslog	Designed for certain events of Cisco ASA and Cisco IOS devices received via syslog.
Cisco Email Security Appliance (WSA)	[OOTB] Cisco WSA AccessFile	regexp	Designed for processing the event log of the Cisco Email Security Appliance (WSA) proxy server, the access.log file.
Cisco ESA syslog	[OOTB] Cisco ESA syslog	Syslog	Designed for processing certain types of events received from Alcatel network switches via syslog.
Cisco Firepower Threat Defense	[OOTB] Cisco ASA and IOS Syslog	Syslog	Designed for processing events for network devices: Cisco ASA, Cisco IOS, Cisco Firepower Threat Defense (version 7.2) received via Syslog.
Cisco Identity Services Engine (ISE)	[OOTB] Cisco ISE syslog	regexp	Designed for processing events of the Cisco Identity Services Engine (ISE) system received via syslog.
Cisco IOS	[OOTB] Cisco ASA and IOS Syslog	Syslog	Designed for certain events of Cisco ASA and Cisco IOS devices received via syslog.
Cisco Netflow v5	[OOTB] NetFlow v5	netflow5	Designed for processing events from Cisco Netflow version 5.
Cisco NetFlow v9	[OOTB] NetFlow v9	netflow9	Designed for processing events from Cisco Netflow version 9.
Cisco Prime	[OOTB] Cisco Prime syslog	Syslog	Designed for processing events of the Cisco Prime system version 3.10 received via syslog.
Cisco Secure Email Gateway (SEG)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Cisco Secure Firewall Management Center	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Cisco Unified Communications Manager	[OOTB] Cisco Unified Communications Manager	regexp	Designed for processing event types from Cisco Unified Communications Manager 11.5.1.
Cisco WLC	[OOTB] Cisco WLC syslog	regexp	Normalizer for some types of events received from Cisco WLC network devices (2500 Series Wireless Controllers, 5500 Series Wireless Controllers, 8500 Series Wireless Controllers, Flex 7500 Series Wireless Controllers) via Syslog.
Cisco WSA	[OOTB] Cisco WSA file, [OOTB] Cisco WSA syslog	regexp	[OOTB] Cisco WSA file. This normalizer is designed for processing the event log of the Cisco WSA proxy server (versions 14.2, 15.0). The normalizer supports processing events generated using the following template: %t %e %a %w/%h %s %2r %A %H/%d %c %D %Xr %?BLOCK_SUSPECT_USER_AGENT,MONITOR_SUSPECT_USER_AGENT?%<User-Agent:%!%-%. %) %q %k %u %m [OOTB] Cisco WSA syslog. This normalizer is designed for processing events received from the Cisco WSA system (version 15.0) via Syslog.
Citrix NetScaler	[OOTB] Citrix NetScaler syslog	regexp	Designed for processing events received from the Citrix NetScaler 13.7 load balancer, Citrix ADC NS13.0.

System name	Normalizer name	Type	Normalizer description
Claroty Continuous Threat Detection	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
CloudPassage Halo	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Codemaster Mirada	[OOTB] Codemaster Mirada syslog	Syslog	Designed for processing events of the Codemaster Mirada system received via syslog.
CollabNet Subversion Edge	[OOTB] CollabNet Subversion Edge syslog	Syslog	Designed for processing events received from the Subversion Edge (version 6.0.2) system via syslog.
CommuniGate Pro	[OOTB] CommuniGate Pro	regexp	Designed to process events of the CommuniGate Pro 6.1 system sent by the KUMA agent via TCP.
Corvil Network Analytics	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Cribl Stream	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
CrowdStrike Falcon Host	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
CyberArk Privileged Threat Analytics (PTA)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
CyberPeak Spektr	[OOTB] CyberPeak Spektr syslog	Syslog	Designed for processing events of the CyberPeak Spektr system version 3 received via syslog.
Cyberprotect Cyber Backup	[OOTB] Cyberprotect Cyber Backup SQL [OOTB] Cyberprotect Cyber Backup syslog	sql, regexp	[OOTB] Cyberprotect Cyber Backup SQL is a normalizer designed to process events received by the connector from the database of the Cyber Backup system (version 16.5). [OOTB] Cyberprotect Cyber Backup syslog is a normalizer designed to process events received from the Cyber Backup system (version 17.2, 17.3, 18.5) via Syslog in CEF format. This package is available for KUMA version 3.2 or later.
DeepInstinct	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Delinea Secret Server	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Dell Network Switch	[OOTB] Dell Network Switch syslog	regexp	Designed for processing certain types of events received from Dell network switches via syslog.
Digital Guardian Endpoint Threat Detection	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
BIND DNS server	[OOTB] BIND syslog [OOTB] BIND file	Syslog regexp	[OOTB] BIND Syslog is designed for processing events of the BIND DNS server received via Syslog. [OOTB] BIND file is designed for processing event logs of the BIND DNS server.
Docsvision	[OOTB] Docsvision syslog	Syslog	Designed for processing audit events received from the Docsvision system via syslog.
Dovecot	[OOTB] Dovecot Syslog	Syslog	Designed for processing events of the Dovecot mail server received via syslog. The event source is POP3/IMAP logs.
Dragos Platform	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Dr.Web Enterprise Security Suite	[OOTB] Syslog-CEF	Syslog	Designed for processing Dr.Web Enterprise Security Suite 13.0.1 events in the CEF format.
EclecticIQ Intelligence Center	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.

System name	Normalizer name	Type	Normalizer description
Edge Technologies AppBoard and enPortal	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Eltex ESR	[OOTB] Eltex ESR syslog	Syslog	Designed to process part of the events received from Eltex ESR network devices via syslog.
Eltex MES	[OOTB] Eltex MES syslog	regexp	Designed for processing events received from Eltex MES network devices via syslog (supported device models: MES14xx, MES24xx, MES3708P).
ESET Protect	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Extreme Networks Summit Wireless Controller	[OOTB] Extreme Networks Summit Wireless Controller	regexp	Normalizer for certain audit events of the Extreme Networks Summit Wireless Controller (model: WM3700, firmware version: 5.5.5.0-018R).
Factor-TS Dionis NX	[OOTB] Factor-TS Dionis NX syslog	regexp	Designed for processing some audit events received from the Dionis-NX system (version 2.0.3) via syslog.
F5 Advanced Web Application Firewall	[OOTB] F5 Advanced Web Application Firewall syslog	regexp	Designed for processing audit events received from the F5 Advanced Web Application Firewall system via syslog.
F5 BigIP Advanced Firewall Manager (AFM)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
FFRI FFR yarai	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
FireEye CM Series	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
FireEye Malware Protection System	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Forcepoint NGFW	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Forcepoint SMC	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Fortinet FortiAnalyzer	[OOTB] Syslog-CEF	Syslog	Designed for processing events received from Fortinet FortiAnalyzer 7.0, 7.2 via syslog in CEF format.
Fortinet FortiADC	[OOTB] FortiADC syslog KV	regexp	Designed for processing event types received from Fortinet FortiADC 7.1 load balancers via Syslog in key-value format.
Fortinet FortiGate	[OOTB] Syslog-CEF	regexp	Designed for processing events received from Fortinet FortiGate 7.0, 7.2 via Syslog in CEF format.
Fortinet FortiGate	[OOTB] FortiGate syslog KV	Syslog	Designed for processing events from FortiGate firewalls (version 7.0) via Syslog. The event source is FortiGate logs in key-value format.
Fortinet Fortimail	[OOTB] Fortimail	regexp	Designed for processing events of the FortiMail email protection system. The event source is Fortimail mail system logs.
Fortinet FortiSOAR	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Fortinet FortiWeb	[OOTB] Syslog-CEF	Syslog	Designed for processing events from the Fortinet FortiWeb 7.6.1 system in CEF format.
FreeBSD	[OOTB] FreeBSD file	regexp	Designed for processing events of the FreeBSD operating system (version 13.1-RELEASE) stored in a file. The normalizer can process files produced by the praudit utility. Example: praudit -xl /var/audit/AUDITFILE >> file_name.log
FreeIPA	[OOTB] FreeIPA	json	Designed for processing events from the FreeIPA system. The event source is Free IPA directory service logs.
FreeRADIUS	[OOTB] FreeRADIUS syslog	Syslog	Designed for processing events of the FreeRADIUS system received via syslog. This normalizer supports events from FreeRADIUS version 3.0.

System name	Normalizer name	Type	Normalizer description
GajShield Firewall	[OOTB] GajShield Firewall syslog	regexp	Designed for processing part of the events received from the GajShield Firewall version GAJ_OS_Bulwark_Firmware_v4.35 via syslog.
Garda Monitor	[OOTB] Garda Monitor syslog	Syslog	Designed for processing events of the Garda Monitor system version 3.4 received via syslog.
Gardatech GardaDB	[OOTB] Gardatech GardaDB syslog	Syslog	Designed for processing events of the Gardatech Perimeter system version 5.3, 5.4 received via syslog.
Gardatech Perimeter	[OOTB] Gardatech Perimeter syslog	Syslog	Designed for processing events of the Gardatech Perimeter system version 5.3 received via syslog.
Gigamon GigaVUE	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
HAProxy	[OOTB] HAProxy syslog	Syslog	Designed for processing logs of the HAProxy system. The normalizer supports events of the HTTP log, TCP log, Error log type from HAProxy version 2.8.
HashiCorp Vault	[OOTB] HashiCorp Vault json	json	Designed for processing events received from the HashiCorp Vault system version 1.16 in JSON format. The normalizer package is available in KUMA 3.0 and later.
Huawei Eudemon	[OOTB] Huawei Eudemon	regexp	Designed for processing events from Huawei Eudemon firewalls. The event source is logs of Huawei Eudemon firewalls.
Huawei iManager 2000	[OOTB] Huawei iManager 2000 file	regexp	This normalizer supports processing some of the events of the Huawei iManager 2000 system, which are stored in the \client\logs\rpc, \client\logs\deploy\ossDeployment files.
Huawei USG	[OOTB] Huawei USG Basic	Syslog	Designed for processing events received from Huawei USG security gateways via syslog.
Huawei VRP	[OOTB] Huawei VRP syslog	regexp	Designed for processing some types of Huawei VRP system events received via syslog. The normalizer makes a partial selection of event data. The normalizer is available in KUMA 3.0 and later.
IBM InfoSphere Guardium	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Ideco UTM	[OOTB] Ideco UTM Syslog	Syslog	Designed for processing events received from Ideco UTM via syslog. This normalizer supports events of Ideco UTM 14.7, 14.10, 17.5.
Illumio Policy Compute Engine (PCE)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Imperva Incapsula	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Imperva SecureSphere	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Indeed Access Manager	[OOTB] Indeed Access Manager syslog	Syslog	Designed for processing events received from the Indeed Access Manager system via syslog.
Indeed PAM	[OOTB] Indeed PAM syslog	Syslog	Designed for processing events of Indeed PAM (Privileged Access Manager) version 2.6.
Indeed SSO	[OOTB] Indeed SSO xml	xml	Designed for processing events of the Indeed SSO (Single Sign-On) system. The normalizer supports KUMA 2.1.3 and later.
InfoWatch Person Monitor	[OOTB] InfoWatch Person Monitor SQL	sql	Designed for processing system audit events from the MS SQL database of InfoWatch Person Monitor 10.2.
InfoWatch Traffic Monitor	[OOTB] InfoWatch Traffic Monitor SQL	sql	Designed for processing events received by the connector from the database of the InfoWatch Traffic Monitor system.
Intralinks VIA	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
IPFIX	[OOTB] IPFIX	ipfix	Designed for processing events in the IP Flow Information Export (IPFIX) format.
Juniper JUNOS	[OOTB] Juniper - JUNOS	regexp	Designed for processing audit events received from Juniper network devices.

System name	Normalizer name	Type	Normalizer description
Kaspersky Anti Targeted Attack (KATA)	[OOTB] KATA	cef	Designed for processing alerts or events from the Kaspersky Anti Targeted Attack activity log.
Kaspersky CyberTrace	[OOTB] CyberTrace	regexp	Designed for processing Kaspersky CyberTrace events.
Kaspersky Endpoint Detection and Response (KEDR)	[OOTB] KEDR telemetry	json	Designed for processing Kaspersky EDR telemetry tagged by KATA. The event source is kafka, EnrichedEventTopic.
Kaspersky Endpoint Security for Linux	[OOTB] KESL syslog cef [OOTB] KESL json	Syslog, json	The [OOTB] KESL syslog cef normalizer is designed for processing events from Kaspersky Endpoint Security for Linux (KESL) 12.2 in CEF format via syslog. The [OOTB] KESL json normalizer is designed for processing events from Kaspersky Endpoint Security for Linux (KESL) 12.5 in JSON format.
KICS/KATA	[OOTB] KICS4Net v2.x	cef	Designed for processing KICS/KATA version 2.x events.
KICS/KATA	[OOTB] KICS4Net v3.x	Syslog	Designed for processing KICS/KATA version 3.x events.
KICS/KATA 4.2	[OOTB] Kaspersky Industrial CyberSecurity for Networks 4.2 syslog	Syslog	Designed for processing events received from the KICS/KATA 4.2 system via syslog.
Kaspersky KISG	[OOTB] Kaspersky KISG syslog	Syslog	Designed for processing events received from Kaspersky IoT Secure Gateway (KISG) 3.0 via syslog.
Kaspersky NGFW	[OOTB] Kaspersky NGFW CEF	cef	Designed for processing events received from the Kaspersky NGFW system version 1.0, 1.2 in CEF format.
Open Single Management Platform	[OOTB] KSC	cef	Designed for processing Open Single Management Platform events received in CEF format.
Open Single Management Platform	[OOTB] KSC from SQL	sql	Designed for processing events received by the connector from the database of the Open Single Management Platform system.
Kaspersky Security for Linux Mail Server (KLMS)	[OOTB] KLMS Syslog CEF	Syslog	Designed for processing events from Kaspersky Security for Linux Mail Server in CEF format via syslog.
Kaspersky Security for MS Exchange SQL	[OOTB] Kaspersky Security for MS Exchange SQL	sql	Normalizer for Kaspersky Security for Exchange (KSE) 9.0 events stored in the database.
Kaspersky Secure Mail Gateway (KSMG)	[OOTB] KSMG Syslog CEF	Syslog	Designed for processing events of Kaspersky Secure Mail Gateway version 2.0 in CEF format via Syslog.
Kaspersky Web Traffic Security (KWTS)	[OOTB] KWTS Syslog CEF	Syslog	Designed for processing events received from Kaspersky Web Traffic Security in CEF format via Syslog.
Kaspersky Web Traffic Security (KWTS)	[OOTB] KWTS (KV)	Syslog	Designed for processing events in Kaspersky Web Traffic Security for Key-Value format.
Kemptechnologies LoadMaster	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Kerio Control	[OOTB] Kerio Control	Syslog	Designed for processing events of Kerio Control firewalls.
KUMA	[OOTB] KUMA forwarding	json	Designed for processing events forwarded from KUMA.
LastLine Enterprise	[OOTB] LastLine Enterprise syslog cef	Syslog	Designed for processing events received from LastLine Enterprise 7.3, 8.1, 9.1 via syslog in CEF format.

System name	Normalizer name	Type	Normalizer description
Libvirt	[OOTB] Libvirt syslog	Syslog	Designed for processing events of Libvirt version 8.0.0 received via syslog.
Lieberman Software ERPM	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Linux	[OOTB] Linux audit and iptables Syslog v1	Syslog	Designed for processing events of the Linux operating system. This normalizer does not support processing events in the ENRICHED format.
Linux auditd	[OOTB] Linux auditd syslog for KUMA 3.2	Syslog	Designed for processing audit events (auditd package) of the Linux operating system received via syslog. The normalizer supports events that have been processed by a KUMA collector version 3.2 or later.
Linux auditd	[OOTB] Linux auditd file for KUMA 3.2	regexp	Designed for processing audit events (auditd package) of the Linux operating system saved to a file. The normalizer supports events that have been processed by a KUMA collector version 3.2 or later.
MariaDB	[OOTB] MariaDB Audit Plugin Syslog	Syslog	Designed for processing events coming from the MariaDB audit plug-in over syslog.
McAfee Endpoint DLP	[OOTB] McAfee Endpoint DLP syslog	Syslog	Designed for processing events received from McAfee Endpoint DLP Windows 11.10.200 via syslog.
Microsoft 365 (Office 365)	[OOTB] Microsoft Office 365 json	json	This normalizer is designed for processing Microsoft 365 events.
Microsoft Active Directory Federation Service (AD FS)	[OOTB] Microsoft Products for KUMA 3	xml	Designed for processing Microsoft AD FS events. The [OOTB] Microsoft Products for KUMA 3 normalizer supports this event source in KUMA 3.0.1 and later versions.
Microsoft Active Directory Domain Service (AD DS)	[OOTB] Microsoft Products for KUMA 3	xml	Designed for processing Microsoft AD DS events. The [OOTB] Microsoft Products for KUMA 3 normalizer supports this event source in KUMA 3.0.1 and later versions.
Microsoft Defender	[OOTB] Microsoft Products, [OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	Designed for processing Microsoft Defender events.
Microsoft DHCP	[OOTB] MS DHCP file	regexp	Designed for processing Microsoft DHCP server events. The event source is Windows DHCP server logs.
Microsoft DNS	[OOTB] DNS Windows	regexp	Designed for processing Microsoft DNS server events. The event source is Windows DNS server logs. The normalizer does not support processing debug log events with the **Details** option enabled.
Microsoft Exchange	[OOTB] Exchange CSV	csv	Designed for processing the event log of the Microsoft Exchange system. The event source is Exchange server MTA logs.
Microsoft Hyper-V	[OOTB] Microsoft Products, [OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	Designed for processing Microsoft Windows events. The event source is Microsoft Hyper-V logs: Microsoft-Windows-Hyper-V-VMMS-Admin, Microsoft-Windows-Hyper-V-Compute-Operational, Microsoft-Windows-Hyper-V-Hypervisor-Operational, Microsoft-Windows-Hyper-V-StorageVSP-Admin, Microsoft-Windows-Hyper-V-Hypervisor-Admin, Microsoft-Windows-Hyper-V-VMMS-Operational, Microsoft-Windows-Hyper-V-Compute-Admin.
Microsoft IIS	[OOTB] IIS Log File Format	regexp	The normalizer processes events in the format described at https://learn.microsoft.com/en-us/windows/win32/http/iis-logging. The event source is Microsoft IIS logs.
Microsoft Network Policy Server (NPS)	[OOTB] Microsoft Products, [OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	The normalizer is designed for processing events of the Microsoft Windows operating system. The event source is Network Policy Server events.

System name	Normalizer name	Type	Normalizer description
Microsoft SCCM	[OOTB] Microsoft SCCM file	regexp	Designed for processing events of the Microsoft SCCM system version 2309. This normalizer supports processing of some of the events stored in the AdminService.log file.
Microsoft SharePoint Server	[OOTB] Microsoft SharePoint Server diagnostic log file	regexp	The normalizer supports processing part of Microsoft SharePoint Server 2016 events stored in diagnostic logs.
Microsoft Sysmon	[OOTB] Microsoft Products, [OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	This normalizer is designed for processing Microsoft Sysmon module events.
Microsoft Windows 7, 8.1, 10, 11	[OOTB] Microsoft Products, [OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	Designed for processing part of events from the Security, System, Application logs of the Microsoft Windows operating system. The [OOTB] Microsoft Products via KES WIN normalizer supports a limited number of audit event types sent to KUMA by Kaspersky Endpoint Security 12.6 for Windows via Syslog.
Microsoft-Windows-PowerShell	[OOTB] Microsoft Products, [OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	Designed for processing Microsoft Windows PowerShell log events.
Microsoft-Windows-PowerShell-Operational	[OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	Designed for processing Microsoft Windows PowerShell-Operational log events. The [OOTB] Microsoft Products via KES WIN normalizer supports a limited number of audit event types sent to KUMA by Kaspersky Endpoint Security 12.6 for Windows via Syslog.
Microsoft → Windows → System log → Netlogon	[OOTB] Microsoft Products for KUMA 3 [OOTB] Microsoft Products via KES WIN NG for KUMA 3.2 [OOTB] Microsoft Products via KES WIN NG for KUMA 4.0.1	xml	Designed for processing Microsoft → Windows → System log → Netlogon log events in XML format.
Microsoft → Windows → TaskScheduler → Operational	[OOTB] Microsoft Products for KUMA 3 [OOTB] Microsoft Products via KES WIN NG for KUMA 3.2 [OOTB] Microsoft Products via KES WIN NG for KUMA 4.0.1	xml	Designed for processing Microsoft → Windows → TaskScheduler → Operational log events in XML format.

System name	Normalizer name	Type	Normalizer description
Microsoft → Windows → WinRM → Operational	[OOTB] Microsoft Products for KUMA 3 [OOTB] Microsoft Products via KES WIN NG for KUMA 3.2 [OOTB] Microsoft Products via KES WIN NG for KUMA 4.0.1	xml	Designed for processing Microsoft → Windows → WinRM → Operational log events in XML format.
Microsoft SQL Server	[Deprecated] [OOTB] Microsoft SQL Server xml	xml	Designed for processing events of MS SQL Server versions 2008, 2012, 2014, 2016. The normalizer supports KUMA 2.1.3 and later.
Microsoft Windows Remote Desktop Services	[OOTB] Microsoft Products, [OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	Designed for processing Microsoft Windows events. The event source is the log at Applications and Services Logs - Microsoft - Windows - TerminalServices-LocalSessionManager - Operational The [OOTB] Microsoft Products via KES WIN normalizer supports a limited number of audit event types sent to KUMA by Kaspersky Endpoint Security 12.6 for Windows via Syslog.
Microsoft Windows Server 2008 R2, 2012 R2, 2016, 2019, 2022	[OOTB] Microsoft Products, [OOTB] Microsoft Products for KUMA 3, [OOTB] Microsoft Products via KES WIN	xml	Designed for processing part of events from the Security, System logs of the Microsoft Windows Server operating system. The [OOTB] Microsoft Products via KES WIN normalizer supports a limited number of audit event types sent to KUMA by Kaspersky Endpoint Security 12.6 for Windows via Syslog.
Microsoft Windows XP/2003	[OOTB] SNMP. Windows {XP/2003}	json	Designed for processing events received from workstations and servers running Microsoft Windows XP, Microsoft Windows 2003 operating systems using the SNMP protocol.
Microsoft WSUS	[OOTB] Microsoft WSUS file	regexp	Designed for processing events of the Gardatech Perimeter system version 5.3, 5.4 received via syslog.
MikroTik	[OOTB] MikroTik syslog	regexp	Designed for events received from MikroTik devices via syslog.
Minerva Labs Minerva EDR	[OOTB] Minerva EDR	regexp	Designed for processing events from the Minerva EDR system.
MongoDb	[OOTB] MongoDb syslog	Syslog	Designed for processing part of events received from the MongoDB 7.0 database via syslog.
Multifactor Radius Server for Windows	[OOTB] Multifactor Radius Server for Windows syslog	Syslog	Designed for processing events received from the Multifactor Radius Server 1.0.2 for Microsoft Windows via Syslog.
MySQL 5.7	[OOTB] MariaDB Audit Plugin Syslog	Syslog	Designed for processing events coming from the MariaDB audit plugin over syslog.
NetApp ONTAP (AFF, FAM)	[OOTB] NetApp syslog, [OOTB] NetApp file	regexp	[OOTB] NetApp syslog — designed for processing events of the NetApp system (version — ONTAP 9.12) received via Syslog. [OOTB] NetApp file — designed for processing events of the NetApp system (version — ONTAP 9.12) stored in a file.
NetApp SnapCenter	[OOTB] NetApp SnapCenter file	regexp	Designed to process part of the events of the NetApp SnapCenter system (SnapCenter Server 5.0). This normalizer supports processing some of the events from the C:\Program Files\NetApp\SnapCenter WebApp\App_Data\log\napManagerWeb.*.log file. Types of supported events in xml format from the SnapManagerWeb.*.log file: SmDiscoverPluginRequest, SmDiscoverPluginResponse, SmGetDomainsResponse, SmGetHostPluginStatusRequest, SmGetHostPluginStatusResponse, SmGetHostRequest, SmGetHostResponse, SmRequest. The normalizer supports processing some of the events from the C:\Program Files\NetApp\SnapCenter WebApp\App_Data\log\audit.log file.
NetIQ Identity Manager	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.

System name	Normalizer name	Type	Normalizer description
NetScout Systems nGenius Performance Manager	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Netskope Cloud Access Security Broker	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Netwrix Auditor	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Nextcloud	[OOTB] Nextcloud syslog	Syslog	Designed for events of Nextcloud version 26.0.4 received via syslog. The normalizer does not save information from the Trace field.
Nexthink Engine	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Nginx	[OOTB] nginx regexp	regexp	Designed for processing Nginx web server log events.
NIKSUN NetDetector	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
One Identity Privileged Session Management	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
OpenLDAP	[OOTB] OpenLDAP	regexp	Designed for line-by-line processing of some events of the OpenLDAP 2.5 system in an auditlog.ldif file.
Open VPN	[OOTB] OpenVPN file	regexp	Designed for processing the event log of the OpenVPN system.
Oracle	[OOTB] Oracle Audit Trail	sql	Designed for processing database audit events received by the connector directly from an Oracle database.
OrionSoft Termit	[OOTB] OrionSoft Termit syslog	Syslog	Designed for processing events received from the OrionSoft Termit 2.2, 2.3, 2.4 system via Syslog.
Orion soft zVirt	[OOTB] Orion Soft zVirt syslog	regexp	Designed for processing events of the Orion soft zVirt 3.1 virtualization system.
PagerDuty	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Palo Alto Cortex Data Lake	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Palo Alto Networks NGFW	[OOTB] PA-NGFW (Syslog-CSV)	Syslog	Designed for processing events from Palo Alto Networks firewalls received via Syslog in CSV format.
Palo Alto Networks PANOS	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Parsec ParsecNET	[OOTB] Parsec ParsecNET	sql	Designed for processing events received by the connector from the database of the Parsec ParsecNET 3 system.
Passwork	[OOTB] Passwork syslog	Syslog	Designed for processing events received from the Passwork version 050219 system via Syslog.
Penta Security WAPPLES	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Positive Technologies ISIM	[OOTB] PTsecurity ISIM	regexp	Designed for processing events from the PT Industrial Security Incident Manager system.
Positive Technologies Network Attack Discovery (NAD)	[OOTB] PT NAD json	json	Designed for processing events coming from PT NAD in json format. This normalizer supports events from PT NAD version 11.1, 11.0.
Positive Technologies Sandbox	[OOTB] PTsecurity Sandbox	regexp	Designed for processing events of the PT Sandbox system.
Positive Technologies Web Application Firewall	[OOTB] PTsecurity WAF	Syslog	Designed for processing events from the PTsecurity (Web Application Firewall) system.

System name	Normalizer name	Type	Normalizer description
Postfix	[OOTB] Postfix syslog	regexp	The [OOTB] Postfix package contains a resource set for processing Postfix 3.6 events. It supports processing syslog events received over TCP. The package is available for KUMA 3.0 and newer versions.
PostgreSQL pgAudit	[OOTB] PostgreSQL pgAudit Syslog	Syslog	Designed for processing events of the pgAudit audit plug-in for the PostgreSQL database received via Syslog.
PowerDNS	[OOTB] PowerDNS syslog	Syslog	Designed for processing events of PowerDNS Authoritative Server 4.5 received via syslog.
Proftpd	[OOTB] Proftpd syslog	regexp	Designed for processing events received from Proftpd 1.3.8c via Syslog.
Proofpoint Insider Threat Management	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Proxmox	[OOTB] Proxmox file	regexp	Designed for processing events of the Proxmox system version 7.2-3 stored in a file. The normalizer supports processing of events in access and pveam logs.
PT NAD	[OOTB] PT NAD json	json	Designed for processing events coming from PT NAD in json format. This normalizer supports events from PT NAD version 11.1, 11.0.
QEMU - hypervisor logs	[OOTB] QEMU - Hypervisor file	regexp	Designed for processing events of the QEMU hypervisor stored in a file. QEMU 6.2.0 and Libvirt 8.0.0 are supported.
QEMU - virtual machine logs	[OOTB] QEMU - Virtual Machine file	regexp	Designed for processing events from logs of virtual machines of the QEMU hypervisor version 6.2.0, stored in a file.
Radware DefensePro AntiDDoS	[OOTB] Radware DefensePro AntiDDoS	Syslog	Designed for processing events from the DDOS Mitigator protection system received via Syslog.
Reak Soft Blitz Identity Provider	[OOTB] Reak Soft Blitz Identity Provider file	regexp	Designed for processing events of the Reak Soft Blitz Identity Provider system version 5.16, stored in a file.
RedCheck Desktop	[OOTB] RedCheck Desktop file	regexp	Designed for processing logs of the RedCheck Desktop 2.6 system stored in a file.
RedCheck WEB	[OOTB] RedCheck WEB file	regexp	Designed for processing logs of the RedCheck Web 2.6 system stored in files.
RED SOFT RED ADM	[OOTB] RED SOFT RED ADM syslog	regexp	Designed for processing events received from the RED ADM system (RED ADM: Industrial edition 1.1) via syslog. The normalizer supports processing: - Management subsystem events - Controller events
ReversingLabs N1000 Appliance	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Rubicon Communications pfSense	[OOTB] pfSense Syslog	Syslog	Designed for processing events from the pfSense firewall received via Syslog.
Rubicon Communications pfSense	[OOTB] pfSense w/o hostname	Syslog	Designed for processing events from the pfSense firewall. The Syslog header of these events does not contain a hostname.
SailPoint IdentityIQ	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
SecurityCode Continent 4	[OOTB] SecurityCode Continent 4 syslog	regexp	Designed for processing events of the SecurityCode Continent system version 4 received via syslog.
Sendmail	[OOTB] Sendmail syslog	Syslog	Designed for processing events of Sendmail version 8.15.2 received via syslog.
SentinelOne	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Skype for Business	[OOTB] Microsoft Products for KUMA 3	xml	Designed for processing some of the events from the log of the Skype for Business system, the Lync Server log.

System name	Normalizer name	Type	Normalizer description
Snort	[OOTB] Snort 3 json file	json	Designed for processing events of Snort version 3 in JSON format.
Sophos Central	[OOTB] Sophos Central syslog	Syslog	Designed for processing some events received from Sophos Central 1.2 via syslog in CEF format from the Sophos-Central-SIEM-Integration script.
Sonicwall TZ	[OOTB] Sonicwall TZ Firewall	Syslog	Designed for processing events received via Syslog from the SonicWall TZ firewall.
Solar WebProxy	[OOTB] Solar WebProxy syslog	regexp	Designed for processing events received from Solar WebProxy 4.2 in siem-log format via Syslog.
SolarWinds DameWare MRC	[OOTB] SolarWinds DameWare MRC xml	xml	This normalizer supports processing some of the DameWare Mini Remote Control (MRC) 7.5 events stored in the Application log of Windows. The normalizer processes events generated by the dwmrcs provider.
Sophos Firewall	[OOTB] Sophos Firewall syslog	regexp	Designed for processing events received from Sophos Firewall 20 via syslog.
Sophos XG	[OOTB] Sophos XG	regexp	Designed for processing events from the Sophos XG firewall.
Squid	[OOTB] Squid access Syslog	Syslog	Designed for processing events of the Squid proxy server received via the syslog protocol.
Squid	[OOTB] Squid access.log file	regexp	Designed for processing Squid log events from the Squid proxy server. The event source is access.log logs
Staffcop Enterprise	[OOTB] Staffcop Enterprise syslog CEF	regexp	Designed for processing events received from Staffcop Enterprise 5.4, 5.5 in CEF format via syslog.
S-Terra VPN Gate	[OOTB] S-Terra	Syslog	Designed for processing events from S-Terra VPN Gate devices.
Stormshield firewall	[OOTB] Stormshield firewall syslog	Syslog	Designed for processing events from Stormshield firewall 4.8 and 5.0 in key-value format via Syslog.
Suricata	[OOTB] Suricata json file	json	This package contains a normalizer for Suricata 7.0.1 events stored in a JSON file. The normalizer supports processing the following event types: flow, anomaly, alert, dns, http, ssl, tls, ftp, ftp_data, ftp, smb, rdp, pgsql, modbus, quic, dhcp, bittorrent_dht, rfb.
ThreatConnect Threat Intelligence Platform	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
ThreatQuotient	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Tionix Cloud Platform	[OOTB] Tionix Cloud Platform syslog	Syslog	Designed for processing events of the Tionix Cloud Platform system version 2.9 received via syslog. The normalizer makes a partial selection of event data. The normalizer is available in KUMA 3.0 and later.
Tionix VDI	[OOTB] Tionix VDI file	regexp	This normalizer supports processing some of the Tionix VDI system (version 2.8) events stored in the tionix_Intmov.log file.
TrapX DeceptionGrid	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Trend Micro Control Manager	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Trend Micro Deep Security	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Trend Micro NGFW	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Trustwave Application Security DbProtect	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Unbound	[OOTB] Unbound Syslog	Syslog	Designed for processing events from the Unbound DNS server received via syslog.

System name	Normalizer name	Type	Normalizer description
UserGate	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format received from the UserGate system via syslog.
Varonis DatAdvantage	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Veriato 360	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
ViPNet TIAS	[OOTB] ViPNet TIAS syslog	Syslog	Designed for processing events of ViPNet TIAS 3.8 received via Syslog.
VMware ESXi	[OOTB] VMware ESXi syslog	regexp	Designed for processing VMware ESXi events (support for a limited number of events from ESXi versions 5.5, 6.0, 6.5, 7.0) received via syslog.
VMWare Horizon	[OOTB] VMware Horizon - Syslog	Syslog	Designed for processing events received from the VMware Horizon 2106 system via syslog.
VMwareCarbon Black EDR	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Vmware vCenter	[OOTB] VMware vCenter API	xml	Designed for processing VMware vCenter 7 events received via API.
Vormetric Data Security Manager	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Votiro Disarmer for Windows	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Vsftpd	[OOTB] Vsftpd syslog	regexp	Designed for processing events received from Vsftpd 3.0.5 via Syslog.
Wallix AdminBastion	[OOTB] Wallix AdminBastion syslog	regexp	Designed for processing events received from the Wallix AdminBastion system via syslog.
WatchGuard - Firebox	[OOTB] WatchGuard Firebox	Syslog	Designed for processing WatchGuard Firebox events received via Syslog.
Webroot BrightCloud	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Winchill Fracas	[OOTB] PTC Winchill Fracas	regexp	Designed for processing events of the Windchill FRACAS failure registration system.
Yandex Browser corporate	[OOTB] Yandex Browser	json	Designed for processing events received from the corporate version of Yandex Browser 23 or 24.4.
Yandex Cloud	[OOTB] Yandex Cloud	regexp	Designed for processing a part of Yandex Cloud audit events. This normalizer supports processing audit log events of the configuration level: IAM (Yandex Identity and Access Management), Compute (Yandex Compute Cloud), Network (Yandex Virtual Private Cloud), Storage (Yandex Object Storage), Resourcemanager (Yandex Resource Manager).
Zabbix	[OOTB] Zabbix SQL	sql	Designed for processing events of Zabbix 6.4.
Zecurion DLP	[OOTB] Zecurion DLP syslog	regexp	Designed for processing events of the Zecurion DLP system version 12.0 received via Syslog.
ZEEK IDS	[OOTB] ZEEK IDS json file	json	Designed for processing logs of the ZEEK IDS system in JSON format. The normalizer supports events from ZEEK IDS version 1.8.
Zettaset BDEncrypt	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
Zscaler Nanolog Streaming Service (NSS)	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format.
IT-Bastion – SKDPU	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format received from the IT-Bastion SKDPU system via Syslog.
A-Real Internet Control Server (ICS)	[OOTB] A-real IKS syslog	regexp	Designed for processing events of the A-Real Internet Control Server (ICS) system received via syslog. The normalizer supports events from A-Real ICS version 7.0 and later.

System name	Normalizer name	Type	Normalizer description
Biznes Resheniya Compass	[OOTB] Biznes Resheniya Compass	regexp	Designed for processing audit event types of Biznes Resheniya Compass 6.7.7 and 6.7.8 received via Kafka.
Apache web server	[OOTB] Apache HTTP Server file	regexp	Designed for processing Apache HTTP Server 2.4 events stored in a file. The normalizer supports processing of events from the Application log in the Common or Combined Log formats, as well as the Error log. Expected format of the Error log events: `[%t] [%-m:%l] [pid %P:tid %T] [server\ %v] [client\ %a] %E: %M;\ referer\ %-{Referer}i`
Apache web server	[OOTB] Apache HTTP Server syslog	Syslog	Designed for processing events of the Apache HTTP Server received via syslog. The normalizer supports processing of Apache HTTP Server 2.4 events from the Access log in the Common or Combined Log format, as well as the Error log. Expected format of the Error log events: `[%t] [%-m:%l] [pid %P:tid %T] [server\ %v] [client\ %a] %E: %M;\ referer\ %-{Referer}i`
Lighttpd web server	[OOTB] Lighttpd syslog	Syslog	Designed for processing Access events of the Lighttpd system received via syslog. The normalizer supports processing of Lighttpd version 1.4 events. Expected format of Access log events: `$remote_addr $http_request_host_name $remote_user [$time_local] "$request" $status $body_bytes_sent "$http_referer" "$http_user_agent"`
IVK Kolchuga-K	[OOTB] Kolchuga-K Syslog	Syslog	Designed for processing events from the IVK Kolchuga-K system, version LKNV.466217.002, via syslog.
InfoTeCS ViPNet IDS	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format received from the infotecs ViPNet IDS system via syslog.
InfoTeCS ViPNet Coordinator	[OOTB] VipNet Coordinator Syslog	Syslog	Designed for processing events from the ViPNet Coordinator system received via syslog.
Kod Bezopasnosti —Continent	[OOTB][regexp] Continent IPS/IDS & TLS	regexp	Designed for processing events of Continent IPS/IDS device log.
Kod Bezopasnosti —Continent	[OOTB] Continent SQL	sql	Designed for getting events of the Continent system from the database.
Kod Bezopasnosti SecretNet 7	[OOTB] SecretNet SQL	sql	Designed for processing events received by the connector from the database of the SecretNet system.
Confident – Dallas Lock Unified Control Center	[OOTB] Confident Dallas Lock syslog CEF	regexp	Designed for processing events received from Dallas Lock Unified Control Center 4.0 in CEF format.
CryptoPro NGate	[OOTB] Ngate Syslog	Syslog	Designed for processing events received from the CryptoPro NGate system via Syslog.
H3C (Huawei-3Com) routers	[OOTB] H3C Routers syslog	regexp	Normalizer for some types of events received from H3C (Huawei-3Com) SR6600 network devices (Comware 7 firmware) via Syslog. The normalizer supports the standard event format (RFC 3164-compliant format).
NT Monitoring and Analytics	[OOTB] Syslog-CEF	Syslog	Designed for processing events in the CEF format received from the NT Monitoring and Analytics system via syslog.
BlueCoat proxy server	[OOTB] BlueCoat Proxy v0.2	regexp	Designed to process BlueCoat proxy server events. The event source is the BlueCoat proxy server event log.
SKDPU NT Access Gateway	[OOTB] Bastion SKDPU-GW	Syslog	Designed for processing events of the SKDPU NT Access gateway system received via Syslog.
Solar Dozor	[OOTB] Solar Dozor Syslog	Syslog	Designed for processing events received from the Solar Dozor system version 7.9 via syslog. The normalizer supports custom format events and does not support CEF format events.
-	[OOTB] Syslog header	Syslog	Designed for processing events received via Syslog. The normalizer parses the header of the Syslog event, the message field of the event is not parsed. If necessary, you can parse the message field using other normalizers.

Aggregation rules

Aggregation rules let you combine repetitive events of the same type and replace them with one common event. Aggregation rules support fields of the standard KUMA event schema as well as fields of the extended event schema. In this way, you can reduce the number of similar events sent to the storage and/or correlator, reduce the workload on services, conserve data storage space and licensing quota (EPS). An aggregation event is created when a time or number of events threshold is reached, whichever occurs first.

For aggregation rules, you can configure a filter and apply it only to events that match the specified conditions.

You can configure aggregation rules under **Monitoring** → **Resources** → **Aggregation rules**, and then select the created aggregation rule from the drop-down list in the collector settings. You can also configure aggregation rules directly in the collector settings.

Available aggregation rule settings

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
Threshold	Threshold on the number of events. After accumulating the specified number of events with identical fields, the collector creates an aggregation event and begins accumulating events for the next aggregated event. The default value is `100`.
Triggered rule lifetime	Required setting. Threshold on time in seconds. When the specified time expires, the accumulation of base events stops, the collector creates an aggregated event and starts obtaining events for the next aggregated event. The default value is `60`.
Description	Resource description: up to 4,000 Unicode characters.
Identical fields	Required setting. This drop-down list lists the fields of normalized events that must have identical values. For example, for network events, you can use SourceAddress, DestinationAddress, DestinationPort fields. In the aggregation event, these fields are populated with the values of the base events.
Unique fields	This drop-down list lists the fields whose range of values must be saved in the aggregated event. For example, if the DestinationPort field is specified under **Unique fields** and not **Identical fields**, the aggregated event combines base connection events for a variety of ports, and the DestinationPort field of the aggregated event contains a list of all ports to which connections were made.
Sum fields	In this drop-down list, you can select the fields whose values will be summed up during aggregation and written to the same-name fields of the aggregated event.

Setting	Description
Filter	Group of settings in which you can specify the conditions for identifying events that must be processed by this resource. You can select an existing filter from the drop-down list or **create** a new filter. In aggregation rules, do not use filters with the **TI** operand or the **TIDetect**, **inActiveDirectoryGroup**, or **hasVulnerability** operators. The Active Directory fields for which you can use the **inActiveDirectoryGroup** operator will appear during the enrichment stage (after aggregation rules are executed). **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Setting	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when you edit the settings of the created aggregation rule; on this tab, you can link the rule to a collector.

To link an aggregation rule to a collector, click the **Link to service** button → **Link to collector**. This opens a window; in that window, select one or more collectors and click **OK**. The aggregation rule is linked to the selected collectors and is applied in accordance with their configuration.

If necessary, you can unlink the aggregation rule from a collector. To do this, select the check box next to the collector, click **Delete** and confirm the unlinking from the service.

Predefined aggregation rules

The OSMP distribution kit includes aggregation rules listed in the table below.

Aggregation rule name	Description
[OOTB] Netflow 9	The rule is triggered after 100 events or 10 seconds. Events are aggregated by fields: • DestinationAddress • DestinationPort • SourceAddress • TransportProtocol • DeviceVendor • DeviceProduct The DeviceCustomString1 and BytesIn fields are summed up.

Enrichment rules

Event enrichment involves adding information to events that can be used to identify and investigate an incident.

Enrichment rules let you add supplementary information to event fields by transforming data that is already present in the fields, or by querying data from external systems. For example, suppose that a user name is recorded in the event. You can use an enrichment rule to add information about the department, position, and manager of this user to the event fields.

Enrichment rules can be used in the following KUMA services and features:

- Collector.
- Correlator.
- Normalizer.

Available enrichment rule settings are listed in the table below.

Basic settings tab

Setting	Description

Source kind	Required setting. Drop-down list for selecting the type of incoming events. Depending on the selected type, the following additional settings will be displayed: • **constant** This type of enrichment is used when a constant needs to be added to an event field. Settings of this type of enrichment: • In the **Constant** field, specify the value that should be added to the event field. The value may not be longer than 255 Unicode characters. If you leave this field blank, the existing event field value will be cleared. • In the **Target field** drop-down list, select the KUMA event field to which you want to write the data. If you are using the event enrichment functions for extended schema fields of `String`, `Number`, or `Float` type with a constant, the constant is added to the field. If you are using the event enrichment functions for extended schema fields of `Array of strings`, `Array of numbers`, or `Array of floats` type with a constant, the constant is added to the elements of the array. • **dictionary** This type of enrichment is used if you need to add a value from the dictionary of the **Dictionary** type. When this type is selected in the **Dictionary name** drop-down list, you must select the dictionary that will provide the values. In the **Key fields** settings block, you have to click the **Add field** button and select the event fields whose values will be used for dictionary entry selection. If you are using event enrichment with the "Dictionary" type selected as the "Source kind" setting, and an array field is specified in the "Key enrichment fields" setting, when an array is passed as the dictionary key, the array is serialized into a string in accordance with the rules of serializing a single value in the TSV format. Example: The "Key enrichment fields" setting uses the SA.StringArrayOne extended schema field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b" and "c". The following value is passed to the dictionary as the key: ['a','b','c']. If the "Key enrichment fields" setting uses an extended schema array field and a regular event schema field, the field values are separated by the "|" character when the dictionary is queried. Example: The "Key enrichment fields" setting uses two fields: the SA.StringArrayOne extended schema field and the Code field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b", and "c"; the Code string field contains the character sequence "myCode". The following value is passed to the dictionary as the key: ['a','b','c']|myCode. • **table** This type of enrichment is used if you need to add a value from the dictionary of the **Table** type. When this enrichment type is selected in the **Dictionary name** drop-down list, select the dictionary for providing the values. In the **Key fields** group of settings, click the **Add field** button to select the event fields whose values are used for dictionary entry selection. In the **Mapping** table, configure the dictionary fields to provide data and the event fields to receive data: • In the **Dictionary field** column, select the dictionary field. The available fields depend on the selected dictionary resource. • In the **KUMA field** column, select the event field to which the value is written. For some of the selected fields (`*custom*` and `*flex*`), in the **Label** column, you can specify a name for the data written to them. New table rows can be added by clicking the **Add new element** button. Columns can be deleted by clicking the ✕ button. • **event** This type of enrichment is used when you need to write a value from another event field to the current event field. Settings of this type of enrichment: • In the **Target field** drop-down list, select the KUMA event field to which you want to write the data. • In the **Source field** drop-down list, select the event field whose value will be written to the target field. • Under **Conversion**, you can create rules for modifying the original data before it is written to the KUMA event fields. The conversion type can be selected from the drop-down list. You can use the **Add conversion** and **Delete** buttons to add or delete a conversion, respectively. The order of conversions is important. **Available conversions** Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list. Available conversions: • **entropy** is used for converting the value of the source field using the information entropy calculation function and placing the conversion result in the target field of the float type. The result of the conversion is a number. Calculating the information entropy allows detecting DNS tunnels or compromised passwords, for example, when a user enters the password instead of the login and this password gets logged in plain text. • **lower**—is used to make all characters of the value lowercase

- **upper**—is used to make all characters of the value uppercase
- **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
- **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.
- **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
  - **Replace chars**—in this field you can specify the character sequence that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- **trim**—used to simultaneously remove the characters specified in the Chars field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a trim conversion with the Micromon value applied to Microsoft-Windows-Sysmon results in soft-Windows-Sys.
- **append** is used to add the characters specified in the Constant field to the end of the event field value. The field appears when this type of conversion is selected.
- **prepend**—used to prepend the characters specified in the Constant field to the start of the event field value. The field appears when this type of conversion is selected.
- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.
  - **Expression**—in this field you can specify the regular expression which results that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- Converting encoded strings to text:
  - **decodeHexString**—used to convert a HEX string to text.
  - **decodeBase64String**—used to convert a Base64 string to text.
  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.
- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.
- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

- **template**

This type of enrichment is used when you need to write a value obtained by processing Go templates into the event field. Settings of this type of enrichment:

- In the **Template** field, enter the Go template.

  Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field from which the value must be passed to the script.

  Example: `Attack on {{.DestinationAddress}} from {{.SourceAddress}}`.
- In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

To convert the data in an array field in a template into the TSV format, you must use the toString function.

If you are using enrichment of events that have the **Template** type selected as the **Source kind** setting, in which the target field has the `String` type, and the source field is an extended event schema field containing an array of strings, you can use one of the following examples for the template.

Example:

{{.SA.StringArrayOne}}

Example:

{{- range $index, $element := . SA.StringArrayOne -}}

{{- if $index}}, {{end}}"{{$element}}"{{- end -}}

- **dns**

  This type of enrichment is used to send requests to a private network DNS server to convert IP addresses into domain names or vice versa. IP addresses are converted to DNS names only for private addresses: 10.0.0.0/8, 172.16.0.0/12, 192.168.0.0/16, 100.64.0.0/10, fd00::/8.

  The settings of this type of enrichment are described in the table below.

  Parameters of enrichment type "dns"

Setting	Description
URL	URL of the DNS server to which you want to send requests. You can use the **Add URL** button to specify multiple URLs. If the **URL** setting is not specified, KUMA takes the list of DNS servers from the localhost's `/etc/resolv.conf` file. In this case, you need to enable the **Recursive queries** option. Otherwise, the enrichment will not occur.
Requests per second	Maximum number of queries sent to the DNS server per second. By default, this value is equal to the number of vCPUs of the KUMA Core server.
Workers	Number of handlers that the service can run simultaneously to process response rules in parallel. Specify a positive integer number from 0 to 999. If 0 is specified, the number of logical CPU cores is used. The default value is `1`.
Maximum number of events in enrichment queue	The maximum number of events to hold in the resubmission queue. The default value is `1,000,000`.
Timeout	The time to wait for a response from the DNS server (in seconds). The default value is `5`.
DNS mode override	Resolution method used: • **Forward DNS only** resolves a domain name to an IP address. • **Reverse DNS only** resolves an IP address to a domain name. • **Forward and reverse DNS** resolves a domain name to an IP address or an IP address to a domain name.
Cache TTL	The lifetime (in seconds) of values stored in the cache. The default value is `60` seconds.
Cache disabled	You can enable or disable caching using this setting. Caching is enabled by default.
Cache refresh disabled	If cache update is enabled, then upon expiry of the cache's TTL the collector sends repeated requests to the DNS server to update the data stored in the cache. This setting is available only when cache is enabled. By default, cache update is enabled.
Recursive queries	Allows a collector to send recursive queries to authoritative DNS servers for the purposes of enrichment. The default value is **Disabled**.

- **cybertrace**

  This type of enrichment is used to add information from CyberTrace data streams to event fields.

  Available settings:

  - **URL** (required)—in this field, you can specify the URL of a CyberTrace server to which you want to send requests.
  - **Number of connections**—maximum number of connections to the CyberTrace server that can be simultaneously established by KUMA. By default, this value is equal to the number of vCPUs of the KUMA Core server.
  - **RPS**—maximum number of requests sent to the server per second. The default value is `1000`.
  - **Timeout**—amount of time to wait for a response from the CyberTrace server, in seconds. The default value is `30`.
  - **Mapping** (required)—this settings block contains the mapping table for mapping KUMA event fields to CyberTrace indicator types. The **KUMA field** column displays the names of KUMA event fields, and the **CyberTrace indicator** column displays the types of CyberTrace indicators.

    Available types of CyberTrace indicators:

    - **ip**
    - **url**
    - **hash**

    In the mapping table, you must provide at least one string. You can click the **Add row** button to add a string, and can click the ✕ button to remove a string.

- **cybertrace-http**

  This type of enrichment is used to add information from CyberTrace data streams to event fields using the REST API.

  Available settings:

  - **URL** (required)—in this field, you can specify the URL of a CyberTrace server to which you want to send requests.
  - **Secret** (required) is a drop-down list in which you can select the secret which stores the credentials for the connection.
  - **Timeout**—amount of time to wait for a response from the CyberTrace server, in seconds. The default value is 30.

- **Key fields** (required) is the list of event fields used for enriching events with data from CyberTrace.
- **Maximum number of events in the enrichment queue**—maximum number of events stored in the enrichment queue for re-sending. The default value is 1000000000. After reaching 1 million events received from the CyberTrace server, events stop being enriched until the number of received events is reduced to less than 500,000.

> When the Queue figure reaches 1 million of received events, event enrichment stops, and events are recorded in the Storage unenriched until the Queue figure becomes less than 500 thousand events.

- **timezone**

  This type of enrichment is used in collectors and correlators to assign a specific timezone to an event. Timezone information may be useful when searching for events that occurred at unusual times, such as nighttime.

  When this type of enrichment is selected, the required timezone must be selected from the **Timezone** drop-down list.

  > Make sure that the required time zone is set on the server hosting the enrichment-utilizing service. For example, you can do this by using the `timedatectl list-timezones` command, which shows all time zones that are set on the server. For more details on setting time zones, please refer to your operating system documentation.

  When an event is enriched, the time offset of the selected timezone relative to Coordinated Universal Time (UTC) is written to the DeviceTimeZone event field in the `+-hh:mm` format. For example, if you select the **Asia/Yekaterinburg** timezone, the value `+05:00` will be written to the DeviceTimeZone field. If the enriched event already has a value in the DeviceTimeZone field, it will be overwritten.

  By default, if the timezone is not specified in the event being processed and enrichment rules by timezone are not configured, the event is assigned the timezone of the server hosting the service (collector or correlator) that processes the event. If the server time is changed, the service must be restarted.

  Permissible time formats when enriching the DeviceTimeZone field

  When processing incoming raw events in the collector, the following time formats can be automatically converted to the +-hh:mm format:

Time format in a processed event	Example
+-hh:mm	-07:00
+-hhmm	-0700
+-hh	-07

  If the date format in the `DeviceTimeZone` field differs from the formats listed above, the collector server timezone is written to the field when an event is enriched with timezone information. You can create custom normalization rules for non-standard time formats.

- **geographic data**

  This type of enrichment is used to add IP address geographic data to event fields. Learn more about linking IP addresses to geographic data.

  When this type is selected, under **Mapping geographic data to event fields**, you must specify from which event field the IP address will be read, select the required attributes of geographic data, and define the event fields in which geographic data will be written:

  1. In the **Event field with IP address** drop-down list, select the event field from which the IP address is read. Geographic data uploaded to KUMA is matched against this IP address.

     You can use the **Add event field with IP address** button to specify multiple event fields with IP addresses that require geographic data enrichment. You can delete event fields added in this way by clicking the **Delete event field with IP address** button.

     > When the `SourceAddress`, `DestinationAddress`, and `DeviceAddress` event fields are selected, the **Apply default mapping** button becomes available. You can click this button to add preconfigured mapping pairs of geographic data attributes and event fields.

  2. For each event field you need to read the IP address from, select the type of geographic data and the event field to which the geographic data should be written.

     You can use the **Add geodata attribute** button to add field pairs for **Geodata attribute** – **Event field to write to**. You can also configure different types of geographic data for one IP address to be written to different event fields. To delete a field pair, click ❌.

     - In the **Geodata attribute** field, select which geographic data corresponding to the read IP address should be written to the event. Available geographic data attributes: **Country**, **Region**, **City**, **Longitude**, **Latitude**.
     - In the **Event field to write to**, select the event field which the selected geographic data attribute must be written to.

     You can write identical geographic data attributes to different event fields. If you configure multiple geographic data attributes to be written to the same event field, the event will be enriched with the last mapping in the sequence.

Name	Required setting.

	Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
Debug	You can use this toggle switch to enable the logging of service operations. Logging is disabled by default.
Description	Resource description: up to 4,000 Unicode characters.

Filter

Group of settings in which you can specify the conditions for identifying events that must be processed by this resource. You can select an existing filter from the drop-down list or **create** a new filter.

Creating a filter in resources

All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

To create a filter:

1. In the **Filter** drop-down list, select **Create new**.
2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.
3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.
4. Under **Conditions**, specify the conditions that the events must meet:
   a. Click the **Add condition** button.
   b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.
   c. In the **Operator** drop-down list, select an operator.

      Filter operators

      - **=** means the left operand equals the right operand.
      - **<** means the left operand is less than the right operand.
      - **<=** means the left operand is less than or equal to the right operand.
      - **>** means the left operand is greater than the right operand.
      - **>=** means the left operand is greater than or equal to the right operand.
      - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
      - **contains** means the left operand contains values of the right operand.
      - **startsWith** means the left operand starts with one of the values of the right operand.
      - **endsWith** means the left operand ends with one of the values of the right operand.
      - **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
      - **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

        The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

        If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
      - **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

        If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.
      - The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
      - **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
      - **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
      - **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
      - The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.
      - **inContextTable** checks for the presence of the entry in the specified context table.
      - **intersect** checks for the presence in the left operand of the list items specified in the right operand.

   d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.
   e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

   You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when you edit the settings of the created enrichment rule; on this tab, you can link the rule to services, that is, correlators and collectors.

To link the enrichment rule to a collector or correlator, click the **Link to service** button → **Link to <service name>**. This opens a window; in that window, select one or more correlators or collectors and click **OK**. The enrichment rule is linked to the selected services and is applied in accordance with their configuration.

If necessary, you can unlink the aggregation rule from a service. To do this, select the check box next to the correlator or collector, click **Delete**, and confirm the unlinking from the service.

Predefined enrichment rules

The OSMP distribution kit includes enrichment rules listed in the table below.

Predefined enrichment rules

Enrichment rule name	Description
[OOTB] KATA alert	Used to enrich events received from KATA in the form of a hyperlink to an alert. The hyperlink is put in the DeviceExternalId field.

Correlation rules

Correlation rules are used to recognize specific sequences of processed events and to take certain actions after recognition, such as creating correlation events/alerts or interacting with an active list.

Correlation rules can be used in the following KUMA services and features:

- Correlator.
- Notification rule.
- Links of segmentation rules.
- Retroscan.

The available correlation rule settings depend on the selected type. Types of correlation rules:

- standard—used to find correlations between several events. Resources of this kind can create correlation events.

  This rule kind is used to determine complex correlation patterns. For simpler patterns you should use other correlation rule kinds that require less resources to operate.

- simple—used to create correlation events if a certain event is found.

- operational—used for operations with Active lists and context tables. This rule kind cannot create correlation events.

- periodical—used for detecting anomalous user activity based on accumulated data that is periodically analyzed. Anomalies are observed when the two metrics exceed thresholds: the **Relative Score** and the standard score (**Z-Score**).

  Rules of this type are available only when using the correlator-ng correlator. Such a rule cannot be created in the OSMP Console.

  When changing the correlator-ng configuration, you may need to delete the correlation/ and containers/ directories. Deleting these directories results in the loss of all accumulated correlator data, including statistics, correlation rule buckets, active lists, and context tables.

For these resources, you can enable the display of control characters in all input fields except the **Description** field.

If a correlation rule is used in the correlator and an alert was created based on it, any change to the correlation rule will not result in a change to the existing alert even if the correlator service is restarted. For example, if the name of a correlation rule is changed, the name of the alert will remain the same. If you close the existing alert, a new alert will be created and it will take into account the changes made to the correlation rule.

Standard correlation rules

Standard correlation rules are used to identify complex patterns in processed events.

The search for patterns is conducted by using buckets

Bucket is a data container that is used by the Correlation rule resources to determine if the correlation event should be created. It has the following functions:

- Group together events that were matched by the filters in the **Selectors** group of settings of the Correlation rule resource. Events are grouped by the fields that were selected by user in the **Identical fields** field.

- Determine the instance when the Correlation rule should trigger, affecting the events that are grouped in the bucket.

- Perform the actions that are selected in the **Actions** group of settings.

- Create correlation events.

Available states of the Bucket:

- `Empty`—the bucket has no events. This can happen only when it was created by the correlation rule triggering.
- `Partial Match`—the bucket has some of the expected events (recovery events are not counted).
- `Full Match`—the bucket has all of the expected events (recovery events are not counted). When this condition is achieved:
  - The Correlation rule triggers
  - Events are cleared from the bucket
  - The trigger counter of the bucket is updated
  - The state of the bucket becomes `Empty`
- `False Match`—this state of the Bucket is possible:
  - when the `Full Match` state was achieved but the join-filter returned false.
  - when **Recovery** check box was selected and the recovery events were received.

  When this condition is achieved the Correlation rule does not trigger. Events are cleared from the bucket, the trigger counter is updated, and the state of the bucket becomes `Empty`.

The correlation rule window contains the following tabs:

- **General**—used to specify the main settings of the correlation rule. On this tab, you can select the type of correlation rule.
- **Selectors**—used to define the conditions that the processed events must fulfill to trigger the correlation rule. Available settings vary based on the selected rule type.
- **Actions**—used to set the triggers that will activate when the conditions configured in the **Selectors** settings block are fulfilled. The Correlation rule resource must have at least one trigger. Available settings vary based on the selected rule type.
- **Correlators**—used for linking correlators. Available only for created correlation rules that are open for editing.

General tab

- **Resource version in the Kaspersky repository**—resource version number. This field is not editable. Available only for resources provided by Kaspersky and used to manage resource updates.
- **Name** (required)—a unique name for this type of resource. Must contain 1 to 128 Unicode characters.
- **Tenant** (required)—the tenant that owns the correlation rule.
- **Type** (required)—a drop-down list for selecting the type of correlation rule. Select **standard** if you want to create a standard correlation rule.

- **Identical fields** (required)—the event fields that should be grouped in a Bucket. The hash of the values of the selected fields is used as the Bucket key. If the selector (see below) triggers, the selected fields will be copied to the correlation event.

  If different selectors of the correlation rule use fields that have different values in events, do not specify these fields in the **Identical fields** section.

- **Unique fields**—event fields that should be sent to the Bucket. If this parameter is set, the Bucket will receive only unique events. The hash of the selected fields' values is used as the Bucket key.

  You can use local variables in the **Identical fields** and **Unique fields** sections. To access a variable, its name must be preceded with the "$" character.
  For an example of using local variables in these sections, refer to the rule provided with KUMA: R403_Access to malicious resources from a host with disabled protection or an out-of-date anti-virus database.

- **Rate limit**—maximum number of times a correlation rule can be triggered per second. The default value is 100.

  If correlation rules employing complex logic for pattern detection are not triggered, this may be due to the specific method used to count rule triggers in KUMA. In this case, try to increase the value of **Rate limit** to `1000000`, for example.

- **Window, sec** (required)—bucket lifetime, in seconds. Default value: 86,400 seconds (24 hours). This timer starts when the Bucket is created (when it receives the first event). The lifetime is not updated, and when it runs out, the **On timeout** trigger from the **Actions** group of settings is activated and the bucket is deleted. The **On every threshold** and **On subsequent thresholds** triggers can be activated more than once during the lifetime of the bucket.

- **Base events keep policy**—this drop-down list is used to specify which base events must be stored in the correlation event:

  - **first** (default value)—this option is used to store the first base event of the event collection that triggered creation of the correlation event.

  - **last**—this option is used to store the last base event of the event collection that triggered creation of the correlation event.

  - **all**—this option is used to store all base events of the event collection that triggered creation of the correlation event.

- **Priority**—base coefficient used to determine the importance of a correlation rule. The default value is **Low**.

- **Order by**—in this drop-down list, you can select the event field that will be used by the correlation rule selectors to track situational changes. This could be useful if you want to configure a correlation rule to be triggered when several types of events occur sequentially, for example.

- **Description**—the description of a resource. Up to 4,000 Unicode characters.

Selectors tab

A rule of the **standard** kind can have multiple selectors. You can add selectors by clicking the **Add selector** button and can remove them by clicking the **Delete selector** button. Selectors can be moved by clicking the ⣿ button.

For each selector, the following two tabs are available: **Settings** and **Local variables**.

The **Settings** tab contains the following settings:

- **Alias** (required)—unique name of the event group that meets the conditions of the selector. Must contain 1 to 128 Unicode characters.
- **Selector threshold (event count)** (required)—the number of events that must be received by the selector to trigger. The default value is 1.
- **Filter** (required)—used to set the criteria for determining events that should trigger the selector. You can select an existing filter from the drop-down list or create a new filter.

  Creating a filter in resources

  All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

  To create a filter:

  1. In the **Filter** drop-down list, select **Create new**.
  2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.
  3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.
  4. Under **Conditions**, specify the conditions that the events must meet:

     a. Click the **Add condition** button.

     b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.

     c. In the **Operator** drop-down list, select an operator.

        Filter operators

        - **=** means the left operand equals the right operand.
        - **<** means the left operand is less than the right operand.
        - **<=** means the left operand is less than or equal to the right operand.

- **>** means the left operand is greater than the right operand.
- **>=** means the left operand is greater than or equal to the right operand.
- **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
- **contains** means the left operand contains values of the right operand.
- **startsWith** means the left operand starts with one of the values of the right operand.
- **endsWith** means the left operand ends with one of the values of the right operand.
- **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
- **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

  The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

  If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.
- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.
- **inContextTable** checks for the presence of the entry in the specified context table.
- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Filtering based on data from the Extra event field

Conditions for filters based on data from the **Extra** event field:

- Condition—**If**.
- Left operand—**event field**.
- In this event field, you can specify one of the following values:
  - **Extra** field.
  - Value from the Extra field in the following format:

    `Extra.<field name>`

    For example, `Extra.app`.

    A value of this type is specified manually.
  - Value from the array written to the **Extra** field in the following format:

    `Extra.<field name>.<array element>`

    For example, `Extra.array.0`.

    The values in the array are numbered starting from 0.

    A value of this type is specified manually.

    To work with a value from the Extra field at depth 3 and below, use backquotes ``. For example, `Extra.lev1.lev2.lev3`.
- Operator – =.
- Right operand—**constant**.
- Value—the value by which you need to filter events.

The order of conditions specified in the selector filter of the correlation rule is significant and affects system performance. We recommend putting the most unique condition in the first place in the selector filter.

Consider two examples of selector filters that select successful authentication events in Microsoft Windows.

Selector filter 1:

Condition 1. DeviceProduct = Microsoft Windows

Condition 2. DeviceEventClassID = 4624

Selector filter 2:

Condition 1. DeviceEventClassID = 4624

Condition 2. DeviceProduct = Microsoft Windows

The order of conditions in Selector filter 2 is preferable because it causes less load on the system.

- **Recovery**—this check box must be selected when the Correlation rule must NOT trigger if a certain number of events are received from the selector. This check box is cleared by default.

Select the **Local variables** tab and click **Add variable** to declare variables that you want to use within the limits of this correlation rule.

In the selector of the correlation rule, you can use regular expressions conforming to the RE2 standard.

Using regular expressions in correlation rules is computationally intensive compared to other operations. Therefore, when designing correlation rules, we recommend limiting the use of regular expressions to the necessary minimum and using other available operations.

To use a regular expression, you must use the `match` comparison operator. The regular expression must be placed in a constant. The use of capture groups in regular expressions is optional. For the correlation rule to trigger, the field text matched against the regexp must exactly match the regular expression.

For a primer on syntax and examples of correlation rules that use regular expressions in their selectors, check the following rules that are provided with KUMA:

- R105_04_Suspicious PowerShell commands. Suspected obfuscation.
- R333_Suspicious creation of files in the autorun folder.

Actions tab

A rule of the **standard** kind can have multiple triggers.

- **On first threshold**—this trigger activates when the Bucket registers the first triggering of the selector during the lifetime of the Bucket.
- **On subsequent thresholds**—this trigger activates when the Bucket registers the second and all subsequent triggering of the selector during the lifetime of the Bucket.
- **On every threshold**—this trigger activates every time the Bucket registers the triggering of the selector.
- **On timeout**—this trigger activates when the lifetime of the Bucket ends, and is linked to the selector with the **Recovery** check box selected. In other words, this trigger activates if the situation detected by the correlation rule is not resolved within the defined amount of time.

Every trigger is represented as a group of settings with the following parameters available:

- **Output**—if this check box is selected, the correlation event is sent for post-processing: for external enrichment outside the correlation rule, for response, and to destinations.
- **Loop to correlator**—if this check box is selected, the created correlation event is processed by the rule chain of the current correlator. This allows hierarchical correlation.

  If the **Output** and **Loop to correlator** check boxes are set, the correlation rule is sent to post-processing first, and then to the selectors of the current correlation rule.
- **Do not create alert**—if this check box is selected, an alert is not created when this correlation rule is triggered. If you do not want to create an alert when a correlation rule is triggered, but you still want to send a correlation event to the storage, select the **Output** and **No alert** check boxes. If you select only the **No alert** check box, a correlation event is not saved in the storage.

- Under **Enrichment**, you can modify the fields of correlation events by using enrichment rules. These enrichment rules are stored in the correlation rule where they were created. You can create multiple enrichment rules. Enrichment rules can be added or deleted by clicking the **Add enrichment** or **Remove enrichment** buttons, respectively.

  - **Source kind**—you can select the type of enrichment in this drop-down list. Depending on the selected type, advanced settings that will also need to be completed may be displayed.

    Available types of enrichment:

    - **constant**

      This type of enrichment is used when a constant needs to be added to an event field. Settings of this type of enrichment:

      - In the **Constant** field, specify the value that should be added to the event field. The value may not be longer than 255 Unicode characters. If you leave this field blank, the existing event field value will be cleared.

      - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

      If you are using the event enrichment functions for extended schema fields of `String`, `Number`, or `Float` type with a constant, the constant is added to the field.

      If you are using the event enrichment functions for extended schema fields of `Array of strings`, `Array of numbers`, or `Array of floats` type with a constant, the constant is added to the elements of the array.

    - **dictionary**

      This type of enrichment is used if you need to add a value from the dictionary of the **Dictionary** type.

      When this type is selected in the **Dictionary name** drop-down list, you must select the dictionary that will provide the values. In the **Key fields** settings block, you have to click the **Add field** button and select the event fields whose values will be used for dictionary entry selection.

      If you are using event enrichment with the "Dictionary" type selected as the "Source kind" setting, and an array field is specified in the "Key enrichment fields" setting, when an array is passed as the dictionary key, the array is serialized into a string in accordance with the rules of serializing a single value in the TSV format.

      Example: The "Key enrichment fields" setting uses the SA.StringArrayOne extended schema field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b" and "c". The following value is passed to the dictionary as the key: ['a','b','c'].

      If the "Key enrichment fields" setting uses an extended schema array field and a regular event schema field, the field values are separated by the "|" character when the dictionary is queried.

      Example: The "Key enrichment fields" setting uses two fields: the SA.StringArrayOne extended schema field and the Code field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b", and "c"; the Code string field contains the character sequence "myCode". The following value is passed to the dictionary as the key: ['a','b','c']|myCode.

    - **table**

      This type of enrichment is used if you need to add a value from the dictionary of the **Table** type.

When this enrichment type is selected in the **Dictionary name** drop-down list, select the dictionary for providing the values. In the **Key fields** group of settings, click the **Add field** button to select the event fields whose values are used for dictionary entry selection.

In the **Mapping** table, configure the dictionary fields to provide data and the event fields to receive data:

- In the **Dictionary field** column, select the dictionary field. The available fields depend on the selected dictionary resource.
- In the **KUMA field** column, select the event field to which the value is written. For some of the selected fields (`*custom*` and `*flex*`), in the **Label** column, you can specify a name for the data written to them.

New table rows can be added by clicking the **Add new element** button. Columns can be deleted by clicking the ✕ button.

- **event**

  This type of enrichment is used when you need to write a value from another event field to the current event field. Settings of this type of enrichment:

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.
  - In the **Source field** drop-down list, select the event field whose value will be written to the target field.
  - Clicking the 🔧 button opens the **Conversion** window in which you can, using the **Add conversion** button, create rules for modifying the original data before writing them to the KUMA event fields.

    Available conversions

    Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

    Available conversions:

    - **lower**—is used to make all characters of the value lowercase
    - **upper**—is used to make all characters of the value uppercase
    - **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
    - **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.
    - **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
      - **Replace chars**—in this field you can specify the character sequence that should be replaced.
      - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
    - **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.

- **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.

- **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.

- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.

  - **Expression**—in this field you can specify the regular expression which results that should be replaced.

  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.

- Converting encoded strings to text:

  - **decodeHexString**—used to convert a HEX string to text.

  - **decodeBase64String**—used to convert a Base64 string to text.

  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

  If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.

- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.

- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.

- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

When using enrichment of events that have the **Event** selected as the **Source kind** setting and the fields of the extended event schema are used as arguments, the following special considerations apply:

- If the source field is an `Array of strings` field and the target field is a `String` field, the values are written to the target field in the TSV format.

  Example: The SA.StringArray extended event schema field contains values: "string1", "string2", "string3". An event enrichment operation is performed. The result of the operation is written to the DeviceCustomString1 event schema field. As a result of the operation, the DeviceCustomString1 field contains ["string1", "string2", "string3"].

- If the source field is an `Array of strings` field and the target field is an `Array of strings` field, the values of the source field are appended to the values of the target field and are placed in the target field, with commas (",") used as the separator character.

  Example: The SA.StringArrayOne extended event schema field contains values: "string1", "string2", "string3". An event enrichment operation is performed. The result of the operation is written to the SA.StringArrayTwo event schema field. As a result of the operation, the SA.StringArrayTwo field contains "string1", "string2", "string3".

- **template**

  This type of enrichment is used when you need to write a value obtained by processing Go templates into the event field. Settings of this type of enrichment:

  - In the **Template** field, enter the Go template.

    Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field from which the value must be passed to the script.

    Example: `Attack on {{.DestinationAddress}} from {{.SourceAddress}}`.

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

  To convert the data in an array field in a template into the TSV format, you must use the toString function.

  If you are using enrichment of events that have the **Template** type selected as the **Source kind** setting, in which the target field has the `String` type, and the source field is an extended event schema field containing an array of strings, you can use one of the following examples for the template.

  Example:

  {{.SA.StringArrayOne}}

  Example:

  {{- range $index, $element := . SA.StringArrayOne -}}

  {{- if $index}}, {{end}}"{{$element}}"{{- end -}}

- **Debug**—you can use this toggle switch to enable logging of service operations.

- **Description**—the description of a resource. Up to 4,000 Unicode characters.

- **Categorization** settings group—used to change the categories of assets indicated in events. There can be several categorization rules. You can add or delete them by clicking the **Add categorization** or **Remove categorization** buttons. Only reactive categories can be added to assets or removed from assets.

  - **Operation**—this drop-down list is used to select the operation to perform on the category:

    - **Add**—assign the category to the asset.

    - **Delete**—unbind the asset from the category.

  - **Event field**—event field that indicates the asset requiring the operation.

  - **Category ID**—the drop-down list displays a tree of categories, in which you can select a category to perform the operation on. Clicking the row expands the list.

- **Active lists update** group of settings—used to assign the trigger for one or more operations with active lists. You can click the **Add active list action** and **Delete active list action** buttons to add or delete operations with active lists, respectively.

  Available settings:

  - **Name** (required)—this drop-down list is used to select the Active list resources.

  - **Operation** (required)—this drop-down list is used to select the operation that must be performed:

    - **Sum**—add a constant, the value of a correlation event field, or the value of a local variable to the value of the active list.

    - **Get**—get the Active list entry and write the values of the selected fields into the correlation event.

    - **Set**—write the values of the selected fields of the correlation event into the Active list by creating a new or updating an existing Active list entry. When the Active list entry is updated, the data is merged and only the specified fields are overwritten.

    - **Delete**—delete the Active list entry.

  - **Key fields** (required)—this is the list of event fields used to create the Active list entry. It is also used as the Active list entry key.

    > The active list entry key depends on the available fields and does not depend on the order in which they are displayed in the KUMA Console.

  - **Mapping** (required for **Get** and **Set** operations)—used to map Active list fields with events fields. More than one mapping rule can be set.

    - The left field is used to specify the Active list field.

      > The field must not contain special characters or numbers only.

    - The middle drop-down list is used to select event fields.

    - The right field can be used to assign a constant to the Active list field is the **Set** operation was selected.

- Under Context table update, you can assign the trigger for one or more operations with context tables. You can click **Add context table action** or **Delete context table action** to add or delete operations with context tables.

- Available settings:

- Name (required)—this drop-down list is used to select context table resources.

- Operation (required)—this drop-down list is used to select the operation that must be performed.

- Sum—add a constant, the value of a correlation event field, or the value of a local variable to the value of the context table. This operation is used only for fields of number and float types.

- Set—write the values of the selected fields of the correlation event into the context table by creating a new or updating an existing context table entry. When the context table entry is updated, the data is merged and only the specified fields are overwritten.

- Get—get the fields of the context table and write the values of the specified fields into the correlation event. Table fields of the boolean type and lists of boolean values are excluded from mapping because the event does not contain boolean fields.

- Merge—append the value of a correlation event field, local variable, or constant to the current value of a field of the context table.

- Delete—delete the context table entry.

- Key fields (required)—this is the list of event fields used to create the context table entry. It is also used as the key of the context table entry. As a key field, you can specify an event field or a local variable declared on the **Selectors** tab.

- The composite key of the context table entry depends only on the values of fields and does not depend on the order in which they are displayed in the KUMA Console.

- Mapping (required for all operations except **Delete**)—used to map context table fields to event fields or variables. More than one mapping rule can be set. You can specify the same context table field multiple times.

- The left field is used to specify the context table field.

- The field must not contain a field name that is already used in the mapping, tab characters, special characters, or only numerals. The maximum number of characters is 128. The name cannot begin with an underscore.

- The middle drop-down list is used to select event fields or a local variable.

- The right field can be used to assign a constant to the context table field is the **Set** operation was selected. **Merge** or **Sum**. The maximum number of characters is 1,024.

Correlators tab

- **Add**—Used when editing the created correlation rule. You can click **Add** to open the **Correlators** window and select a correlator from the list. After you click **OK**, the rule is linked to the selected correlator. You can select multiple correlators at the same time. The rule is added to the end of the execution queue. If you want to move the rule up in the execution queue, go to **Resources** - **Correlator** - <selected correlator> - **Edit correlator** - **Correlation**, select the check box next to the relevant rule and click the **Move up** or **Move down** buttons to reorder the rules as necessary.

- **Delete**—Used to unlink the correlation rule from the correlator.

Simple correlation rules

Simple correlation rules are used to define simple sequences of events.

The correlation rule window contains the following settings tabs:

- **General**—used to specify the main settings of the correlation rule. On this tab, you can select the type of correlation rule.

- **Selectors**—used to define the conditions that the processed events must fulfill to trigger the correlation rule. Available settings vary based on the selected rule kind.

- **Actions**—used to set the triggers that will activate when the conditions configured in the **Selectors** settings block are fulfilled. A correlation rule must have at least one trigger. Available settings vary based on the selected rule type.

- **Correlators**—used for linking correlators. Available only for created correlation rules that are open for editing.

General tab

- **Resource version in the Kaspersky repository**—resource version number. This field is not editable. Available only for resources provided by Kaspersky and used to manage resource updates.

- **Name** (required)—a unique name for this type of resource. Must contain 1 to 128 Unicode characters.

- **Tenant** (required)—the tenant that owns the correlation rule.

- **Type** (required)—a drop-down list for selecting the type of correlation rule. Select **simple** if you want to create a simple correlation rule.

- **Propagated fields** (required)—event fields used for event selection. If the selector (see below) is triggered, these fields will be written to the correlation event.

- **Rate limit**—maximum number of times a correlation rule can be triggered per second. The default value is 100.

  If correlation rules employing complex logic for pattern detection are not triggered, this may be due to the specific method used to count rule triggers in KUMA. In this case, try to increase the value of **Rate limit** to `1000000`, for example.

- **Priority**—base coefficient used to determine the importance of a correlation rule. The default value is `Low`.

- **Description**—the description of a resource. Up to 4,000 Unicode characters.

Selectors tab

A rule of the **simple** kind can have only one selector for which the **Settings** and **Local variables** tabs are available.

The **Settings** tab contains settings with the **Filter** group of settings:

- **Filter** (required)—used to set the criteria for determining events that should trigger the selector. You can select an existing filter from the drop-down list or create a new filter.

  Creating a filter in resources

  All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

  To create a filter:

  1. In the **Filter** drop-down list, select **Create new**.
  2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.
  3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.
  4. Under **Conditions**, specify the conditions that the events must meet:
     a. Click the **Add condition** button.
     b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.
     c. In the **Operator** drop-down list, select an operator.

        Filter operators

        - **=** means the left operand equals the right operand.
        - **<** means the left operand is less than the right operand.

- **<=** means the left operand is less than or equal to the right operand.
- **>** means the left operand is greater than the right operand.
- **>=** means the left operand is greater than or equal to the right operand.
- **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
- **contains** means the left operand contains values of the right operand.
- **startsWith** means the left operand starts with one of the values of the right operand.
- **endsWith** means the left operand ends with one of the values of the right operand.
- **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
- **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

  The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

  If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
- **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

  If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.
- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.
- **inContextTable** checks for the presence of the entry in the specified context table.
- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Filtering based on data from the Extra event field

Conditions for filters based on data from the **Extra** event field:

- Condition—**If**.
- Left operand—**event field**.
- In this event field, you can specify one of the following values:
  - **Extra** field.
  - Value from the Extra field in the following format:

    `Extra.<field name>`

    For example, `Extra.app`.

    A value of this type is specified manually.
  - Value from the array written to the **Extra** field in the following format:

    `Extra.<field name>.<array element>`

    For example, `Extra.array.0`.

    The values in the array are numbered starting from 0.

    A value of this type is specified manually.

    To work with a value from the Extra field at depth 3 and below, use backquotes ``. For example, `Extra.lev1.lev2.lev3`.
- Operator – =.
- Right operand—**constant**.
- Value—the value by which you need to filter events.

The order of conditions specified in the selector filter of the correlation rule is significant and affects system performance. We recommend putting the most unique condition in the first place in the selector filter.

Consider two examples of selector filters that select successful authentication events in Microsoft Windows.

Selector filter 1:

Condition 1. DeviceProduct = Microsoft Windows

Condition 2. DeviceEventClassID = 4624

Selector filter 2:

Condition 1. DeviceEventClassID = 4624

Condition 2. DeviceProduct = Microsoft Windows

The order of conditions in Selector filter 2 is preferable because it causes less load on the system.

Select the **Local variables** tab and click **Add variable** to declare variables that you want to use within the limits of this correlation rule.

Actions tab

A rule of the **simple** kind can have only one trigger: **On every event**. It is activated every time the selector triggers.

Available parameters of the trigger:

- **Output**—if this check box is selected, the correlation event is sent for post-processing: for enrichment, for a response, and to destinations.
- **Loop to correlator**—if this check box is selected, the created correlation event is processed by the rule chain of the current correlator. This allows hierarchical correlation.

  If the **Output** and **Loop to correlator** check boxes are set, the correlation rule is sent to post-processing first, and then to the selectors of the current correlation rule.
- **Do not create alert**—if this check box is selected, an alert is not created when this correlation rule is triggered. If you do not want to create an alert when a correlation rule is triggered, but you still want to send a correlation event to the storage, select the **Output** and **No alert** check boxes. If you select only the **No alert** check box, a correlation event is not saved in the storage.
- **Enrichment** settings group—you can modify the fields of correlation events by using enrichment rules. These enrichment rules are stored in the correlation rule where they were created. You can create multiple enrichment rules. Enrichment rules can be added or deleted by clicking the **Add enrichment** or **Remove enrichment** buttons, respectively.
  - **Source kind**—you can select the type of enrichment in this drop-down list. Depending on the selected type, advanced settings that will also need to be completed may be displayed.

    Available types of enrichment:

    - **constant**

      This type of enrichment is used when a constant needs to be added to an event field. Settings of this type of enrichment:

      - In the **Constant** field, specify the value that should be added to the event field. The value may not be longer than 255 Unicode characters. If you leave this field blank, the existing event field value will be cleared.
      - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

      If you are using the event enrichment functions for extended schema fields of `String`, `Number`, or `Float` type with a constant, the constant is added to the field.

      If you are using the event enrichment functions for extended schema fields of `Array of strings`, `Array of numbers`, or `Array of floats` type with a constant, the constant is added to the elements of the array.

    - **dictionary**

      This type of enrichment is used if you need to add a value from the dictionary of the **Dictionary** type.

When this type is selected in the **Dictionary name** drop-down list, you must select the dictionary that will provide the values. In the **Key fields** settings block, you have to click the **Add field** button and select the event fields whose values will be used for dictionary entry selection.

If you are using event enrichment with the "Dictionary" type selected as the "Source kind" setting, and an array field is specified in the "Key enrichment fields" setting, when an array is passed as the dictionary key, the array is serialized into a string in accordance with the rules of serializing a single value in the TSV format.

Example: The "Key enrichment fields" setting uses the SA.StringArrayOne extended schema field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b" and "c". The following value is passed to the dictionary as the key: ['a','b','c'].

If the "Key enrichment fields" setting uses an extended schema array field and a regular event schema field, the field values are separated by the "|" character when the dictionary is queried.

Example: The "Key enrichment fields" setting uses two fields: the SA.StringArrayOne extended schema field and the Code field. The SA.StringArrayOne extended schema field contains 3 elements: "a", "b", and "c"; the Code string field contains the character sequence "myCode". The following value is passed to the dictionary as the key: ['a','b','c']|myCode.

- **table**

  This type of enrichment is used if you need to add a value from the dictionary of the **Table** type.

  When this enrichment type is selected in the **Dictionary name** drop-down list, select the dictionary for providing the values. In the **Key fields** group of settings, click the **Add field** button to select the event fields whose values are used for dictionary entry selection.

  In the **Mapping** table, configure the dictionary fields to provide data and the event fields to receive data:

  - In the **Dictionary field** column, select the dictionary field. The available fields depend on the selected dictionary resource.
  - In the **KUMA field** column, select the event field to which the value is written. For some of the selected fields (`*custom*` and `*flex*`), in the **Label** column, you can specify a name for the data written to them.

  New table rows can be added by clicking the **Add new element** button. Columns can be deleted by clicking the ✕ button.

- **event**

  This type of enrichment is used when you need to write a value from another event field to the current event field. Settings of this type of enrichment:

  - In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.
  - In the **Source field** drop-down list, select the event field whose value will be written to the target field.
  - Clicking the 🔧 button opens the **Conversion** window in which you can, using the **Add conversion** button, create rules for modifying the original data before writing them to the KUMA event fields.

    Available conversions

    Conversions are changes that can be applied to a value before it gets written to the event field. The conversion type is selected from a drop-down list.

Available conversions:

- **lower**—is used to make all characters of the value lowercase
- **upper**—is used to make all characters of the value uppercase
- **regexp** – used to convert a value using the regular expression RE2. When this conversion type is selected, the field appears where regular expression should be added.
- **substring**—is used to extract characters in the position range specified in the **Start** and **End** fields. These fields appear when this conversion type is selected.
- **replace**—is used to replace specified character sequence with the other character sequence. When this type of conversion is selected, new fields appear:
  - **Replace chars**—in this field you can specify the character sequence that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- **trim**—used to simultaneously remove the characters specified in the **Chars** field from the leading and end positions of the value. The field appears when this type of conversion is selected. For example, a **trim** conversion with the `Micromon` value applied to `Microsoft-Windows-Sysmon` results in `soft-Windows-Sys`.
- **append** is used to add the characters specified in the **Constant** field to the end of the event field value. The field appears when this type of conversion is selected.
- **prepend**—used to prepend the characters specified in the **Constant** field to the start of the event field value. The field appears when this type of conversion is selected.
- **replace with regexp**—is used to replace RE2 regular expression results with the character sequence.
  - **Expression**—in this field you can specify the regular expression which results that should be replaced.
  - **With chars**—in this field you can specify the characters sequence should be used instead of replaced characters.
- Converting encoded strings to text:
  - **decodeHexString**—used to convert a HEX string to text.
  - **decodeBase64String**—used to convert a Base64 string to text.
  - **decodeBase64URLString**—used to convert a Base64url string to text.

  When converting a corrupted string or if conversion error occur, corrupted data may be written to the event field.

  During event enrichment, if the length of the encoded string exceeds the size of the field of the normalized event, the string is truncated and is not decoded.

If the length of the decoded string exceeds the size of the event field into which the decoded value is to be written, such a string is truncated to fit the size of the event field.

- **hexToDecimal** converts a hexadecimal numeric value to its decimal representation. The conversion is applied to string or numeric fields containing hexadecimal values (including the 0x prefix, if present), and the result is stored in the target KUMA event field as an integer. The conversion returns a decimal number. For example, the value 0x00FF is converted to 255.

Conversions when using the extended event schema

Whether or not a conversion can be used depends on the type of extended event schema field being used:

- For an additional field of the `String` type, all types of conversions are available.
- For fields of the `Number` and `Float` types, the following types of conversions are available: regexp, substring, replace, trim, append, prepend, replaceWithRegexp, decodeHexString, decodeBase64String, decodeBase64URLString.
- For fields of `Array of strings`, `Array of numbers`, and `Array of floats` types, the following types of conversions are available: append, prepend.

When using enrichment of events that have the **Event** selected as the **Source kind** setting and the fields of the extended event schema are used as arguments, the following special considerations apply:

- If the source field is an `Array of strings` field and the target field is a `String` field, the values are written to the target field in the TSV format.

  Example: The SA.StringArray extended event schema field contains values: "string1", "string2", "string3". An event enrichment operation is performed. The result of the operation is written to the DeviceCustomString1 event schema field. As a result of the operation, the DeviceCustomString1 field contains ["string1", "string2", "string3"].

- If the source field is an `Array of strings` field and the target field is an `Array of strings` field, the values of the source field are appended to the values of the target field and are placed in the target field, with commas (",") used as the separator character.

  Example: The SA.StringArrayOne extended event schema field contains values: "string1", "string2", "string3". An event enrichment operation is performed. The result of the operation is written to the SA.StringArrayTwo event schema field. As a result of the operation, the SA.StringArrayTwo field contains "string1", "string2", "string3".

- **template**

  This type of enrichment is used when you need to write a value obtained by processing Go templates into the event field. Settings of this type of enrichment:

  - In the **Template** field, enter the Go template.

    Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field from which the value must be passed to the script.

Example: `Attack on {{.DestinationAddress}} from {{.SourceAddress}}`.

- In the **Target field** drop-down list, select the KUMA event field to which you want to write the data.

To convert the data in an array field in a template into the TSV format, you must use the toString function.

If you are using enrichment of events that have the **Template** type selected as the **Source kind** setting, in which the target field has the `String` type, and the source field is an extended event schema field containing an array of strings, you can use one of the following examples for the template.

Example:

{{.SA.StringArrayOne}}

Example:

{{- range $index, $element := . SA.StringArrayOne -}}

{{- if $index}}, {{end}}"{{$element}}"{{- end -}}

- **Debug**—you can use this toggle switch to enable logging of service operations.
- **Description**—the description of a resource. Up to 4,000 Unicode characters.
- **Filter** settings block—lets you select which events will be forwarded for enrichment. Configuration is performed as described above.

- **Categorization** settings group—used to change the categories of assets indicated in events. There can be several categorization rules. You can add or delete them by clicking the **Add categorization** or **Remove categorization** buttons. Only reactive categories can be added to assets or removed from assets.
  - **Operation**—this drop-down list is used to select the operation to perform on the category:
    - **Add**—assign the category to the asset.
    - **Delete**—unbind the asset from the category.
  - **Event field**—event field that indicates the asset requiring the operation.
  - **Category ID**—the drop-down list displays a tree of categories, in which you can select a category to perform the operation on. Clicking the row expands the list.
- **Active lists update** group of settings—used to assign the trigger for one or more operations with active lists. You can click the **Add active list action** and **Delete active list action** buttons to add or delete operations with active lists, respectively.

Available settings:

- **Name** (required)—this drop-down list is used to select the active list.
- **Operation** (required)—this drop-down list is used to select the operation that must be performed:
  - **Sum**—add a constant, the value of a correlation event field, or the value of a local variable to the value of the active list.
  - **Get**—get the Active list entry and write the values of the selected fields into the correlation event.
  - **Set**—write the values of the selected fields of the correlation event into the Active list by creating a new or updating an existing Active list entry. When the Active list entry is updated, the data is merged and only the specified fields are overwritten.
  - **Get**—get the Active list entry and write the values of the selected fields into the correlation event.
  - **Delete**—delete the Active list entry.
- **Key fields** (required)—this is the list of event fields used to create the Active list entry. It is also used as the Active list entry key.

  > The active list entry key depends on the available fields and does not depend on the order in which they are displayed in the KUMA Console.

- **Mapping** (required for **Get** and **Set** operations)—used to map Active list fields with events fields. More than one mapping rule can be set.
  - The left field is used to specify the Active list field.

    > The field must not contain special characters or numbers only.

  - The middle drop-down list is used to select event fields.
  - The right field can be used to assign a constant to the Active list field is the **Set** operation was selected.
- Under Context table update, you can assign the trigger for one or more operations with context tables. You can click **Add context table action** or **Delete context table action** to add or delete operations with context tables.
- Available settings:
- Name (required)—this drop-down list is used to select context table resources.
- Operation (required)—this drop-down list is used to select the operation that must be performed.
- Sum—add a constant, the value of a correlation event field, or the value of a local variable to the value of the context table. This operation is used only for fields of number and float types.
- Set—write the values of the selected fields of the correlation event into the context table by creating a new or updating an existing context table entry. When the context table entry is updated, the data is merged and only the specified fields are overwritten.

- Get—get the fields of the context table and write the values of the specified fields into the correlation event. Table fields of the boolean type and lists of boolean values are excluded from mapping because the event does not contain boolean fields.

- Merge—append the value of a correlation event field, local variable, or constant to the current value of a field of the context table.

- Delete—delete the context table entry.

- Key fields (required)—this is the list of event fields used to create the context table entry. It is also used as the key of the context table entry. As a key field, you can specify an event field or a local variable declared on the **Selectors** tab.

- The composite key of the context table entry depends only on the values of fields and does not depend on the order in which they are displayed in the KUMA Console.

- Mapping (required for all operations except **Delete**)—used to map context table fields to event fields or variables. More than one mapping rule can be set. You can specify the same context table field multiple times.

- The left field is used to specify the context table field.

- The field must not contain a field name that is already used in the mapping, tab characters, special characters, or only numerals. The maximum number of characters is 128. The name cannot begin with an underscore.

- The middle drop-down list is used to select event fields or a local variable.

- The right field can be used to assign a constant to the context table field is the **Set** operation was selected. **Merge** or **Sum**. The maximum number of characters is 1,024.

Correlators tab

- **Add**—Used when editing the created correlation rule. You can click **Add** to open the **Correlators** window and select a correlator from the list. After you click **OK**, the rule is linked to the selected correlator. You can select multiple correlators at the same time. The rule is added to the end of the execution queue. If you want to move the rule up in the execution queue, go to **Resources** - **Correlator** - <selected correlator> - **Edit correlator** - **Correlation**, select the check box next to the relevant rule and click the Move up or Move down buttons to reorder the rules as necessary.

- **Delete**—Used to unlink the correlation rule from the correlator.

Operational correlation rules

Operational correlation rules are used for working with active lists.

The correlation rule window contains the following tabs:

- **General**—used to specify the main settings of the correlation rule. On this tab, you can select the type of correlation rule.

- **Selectors**—used to define the conditions that the processed events must fulfill to trigger the correlation rule. Available settings vary based on the selected rule type.

- **Actions**—used to set the triggers that will activate when the conditions configured in the **Selectors** settings block are fulfilled. A correlation rule must have at least one trigger. Available settings vary based on the selected rule type.
- **Correlators**—used for linking correlators. Available only for created correlation rules that are open for editing.

General tab

- **Resource version in the Kaspersky repository**—resource version number. This field is not editable. Available only for resources provided by Kaspersky and used to manage resource updates.
- **Name** (required)—a unique name for this type of resource. Must contain 1 to 128 Unicode characters.
- **Tenant** (required)—the tenant that owns the correlation rule.
- **Type** (required)—a drop-down list for selecting the type of correlation rule. Select **operational** if you want to create an operational correlation rule.
- **Rate limit**—maximum number of times a correlation rule can be triggered per second. The default value is 100.

  If correlation rules employing complex logic for pattern detection are not triggered, this may be due to the specific method used to count rule triggers in KUMA. In this case, try to increase the value of **Rate limit** to `1000000`, for example.

- **Description**—the description of a resource. Up to 4,000 Unicode characters.

Selectors tab

A rule of the **operational** kind can have only one selector for which the **Settings** and **Local variables** tabs are available.

The **Settings** tab contains settings with the **Filter** group of settings:

- **Filter** (required)—used to set the criteria for determining events that should trigger the selector. You can select an existing filter from the drop-down list or create a new filter.

  Creating a filter in resources

  All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default.

To create a filter:

1. In the **Filter** drop-down list, select **Create new**.

2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default.

3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters.

4. Under **Conditions**, specify the conditions that the events must meet:

   a. Click the **Add condition** button.

   b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field.

   c. In the **Operator** drop-down list, select an operator.

   Filter operators

   - **=** means the left operand equals the right operand.
   - **<** means the left operand is less than the right operand.
   - **<=** means the left operand is less than or equal to the right operand.
   - **>** means the left operand is greater than the right operand.
   - **>=** means the left operand is greater than or equal to the right operand.
   - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
   - **contains** means the left operand contains values of the right operand.
   - **startsWith** means the left operand starts with one of the values of the right operand.
   - **endsWith** means the left operand ends with one of the values of the right operand.
   - **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
   - **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

     The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

     If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
   - **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

     If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.

- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.
- **inContextTable** checks for the presence of the entry in the specified context table.
- **intersect** checks for the presence in the left operand of the list items specified in the right operand.

d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default.

e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

You can add multiple conditions or a group of conditions.

5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button.

6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Filtering based on data from the Extra event field

Conditions for filters based on data from the **Extra** event field:

- Condition—**If**.
- Left operand—**event field**.
- In this event field, you can specify one of the following values:
  - **Extra** field.
  - Value from the Extra field in the following format:

    `Extra.<field name>`

    For example, `Extra.app`.

    A value of this type is specified manually.
  - Value from the array written to the **Extra** field in the following format:

    `Extra.<field name>.<array element>`

    For example, `Extra.array.0`.

The values in the array are numbered starting from 0.

A value of this type is specified manually.

To work with a value from the Extra field at depth 3 and below, use backquotes ``. For example, `Extra.lev1.lev2.lev3`.

- Operator – =.
- Right operand—**constant**.
- Value—the value by which you need to filter events.

On the **Local variables** tab, click **Add variable** to declare variables that you want to use within the limits of this correlation rule.

Actions tab

A rule of the **operational** kind can have only one trigger: **On every event**. It is activated every time the selector triggers.

Available parameters of the trigger:

- **Active lists update** settings group—used to assign the trigger for one or more operations with active lists. You can click the **Add active list action** and **Delete active list action** buttons to add or delete operations with active lists, respectively.

  Available settings:

  - **Name** (required)—this drop-down list is used to select the active list.
  - **Operation** (required)—this drop-down list is used to select the operation that must be performed:
    - **Sum**—add a constant, the value of a correlation event field, or the value of a local variable to the value of the active list.
    - **Set**—write the values of the selected fields of the correlation event into the Active list by creating a new or updating an existing Active list entry. When the Active list entry is updated, the data is merged and only the specified fields are overwritten.
    - **Delete**—delete the Active list entry.
  - **Key fields** (required)—this is the list of event fields used to create the Active list entry. It is also used as the Active list entry key.

    The active list entry key depends on the available fields and does not depend on the order in which they are displayed in the KUMA Console.

- **Mapping** (required for **Set** operation)—used to map active list fields with event fields. More than one mapping rule can be set.
  - The left field is used to specify the Active list field.

    The field must not contain special characters or numbers only.

  - The middle drop-down list is used to select event fields.
  - The right field can be used to assign a constant to the Active list field is the **Set** operation was selected.

- Under **Context table update**, you can assign the trigger for one or more operations with context tables. You can click **Add context table action** or **Delete context table action** to add or delete operations with context tables.

  Available settings:

  - **Name** (required)—this drop-down list is used to select context table resources.
  - **Operation** (required)—this drop-down list is used to select the operation that must be performed.
    - **Sum**—add a constant, the value of a correlation event field, or the value of a local variable to the value of the context table. This operation is used only for fields of number and float types.
    - **Set**—write the values of the selected fields of the correlation event into the context table by creating a new or updating an existing context table entry. When the context table entry is updated, the data is merged and only the specified fields are overwritten.
    - **Merge**—append the value of a correlation event field, local variable, or constant to the current value of a field of the context table.
    - **Delete**—delete the context table entry.
  - **Key fields** (required)—this is the list of event fields used to create the context table entry. It is also used as the key of the context table entry. As a key field, you can specify an event field or a local variable declared on the Selectors tab.

    The composite key of the context table entry depends only on the values of fields and does not depend on the order in which they are displayed in the KUMA Console.

  - **Mapping** (required for all operations except **Delete**)—used to map context table fields to event fields or variables. More than one mapping rule can be set. You can specify the same context table field multiple times.
    - The left field is used to specify the context table field.

      The field must not contain a field name that is already used in the mapping, tab characters, special characters, or only numerals. The maximum number of characters is 128. The name cannot begin with an underscore.

    - The middle drop-down list is used to select event fields or a local variable.
    - You can use the right field to assign a constant to the context table field. The maximum number of characters is 1024.

Correlators tab

- **Add**—Used when editing the created correlation rule. You can click **Add** to open the **Correlators** window and select a correlator from the list. After you click **OK**, the rule is linked to the selected correlator. You can select multiple correlators at the same time. The rule is added to the end of the execution queue. If you want to move the rule up in the execution queue, go to **Resources** - **Correlator** - <selected correlator> - **Edit correlator** - **Correlation**, select the check box next to the relevant rule and click the Move up or Move down buttons to reorder the rules as necessary.

- **Delete**—Used to unlink the correlation rule from the correlator.

Variables in correlators

If tracking values in event fields, active lists, or dictionaries is not enough to cover some specific security scenarios, you can use global and local *variables*. You can use them to take various actions on the values received by the correlators by implementing complex logic for threat detection. Variables can be declared in the correlator (*global variables*) or in the correlation rule (*local variables*) by assigning a function to them, then querying them from correlation rules as if they were ordinary event fields and receiving the triggered function result in response.

Usage scope of variables:

- When searching for grouping or unique field values in correlation rules.

- In the correlation rule selectors, in the filters of the conditions under which the correlation rule should be triggered.

- When enriching correlation events. Select **Event** as the source type.

- When filling active lists with values.

Variables can be queried the same way as event fields by preceding their names with the $ character.

Local variables in identical and unique fields

You can use local variables in the **Identical fields** and **Unique fields** sections of 'standard' type correlation rules. To use a local variable, its name must be preceded with the "$" character.

For an example of using local variables in the **Identical fields** and **Unique fields** sections, refer to the rule provided with KUMA: R403_Access to malicious resources from a host with disabled protection or an out-of-date anti-virus database.

Local variables in selector

To use a local variable in a selector:

1. Add a local variable to the rule.

2. In the **Correlation rules** window, go to the **General** tab and add the created local variable to the **Identical fields** section. Prefix the local variable name with a "$" character.

3. In **Correlation rules** window, go to the **Selectors** tab, select an existing filter or create a new filter and click **Add condition**.
4. Select the **event field** as the operand.
5. Select the local variable as the event field value and prefix the variable name with a "$" character.
6. Specify the remaining filter settings.
7. Click **Save**.

For an example of using local variables, refer to the rule provided with KUMA: R403_Access to malicious resources from a host with disabled protection or an out-of-date anti-virus database.

Local Variables in event enrichment

You can use 'standard' and 'simple' correlation rules to enrich events with local variables.

Enrichment with text and numbers

You can enrich events with text (strings). To do so, you can use functions that modify strings: to_lower, to_upper, str_join, append, prepend, substring, tr, replace, str_join.

You can enrich events with numbers. To do so, you can use the following functions: addition ("+"), subtraction ("-"), multiplication ("*"), division ("/"), round, ceil, floor, abs, pow.

You can also use regular expressions to manage data in local variables.

Using regular expressions in correlation rules is computationally intensive compared to other operations. Therefore, when designing correlation rules, we recommend limiting the use of regular expressions to the necessary minimum and using other available operations.

Timestamp enrichment

You can enrich events with timestamps (date and time). To do so, you can use functions that let you get or modify timestamps: now, extract_from_timestamp, parse_timestamp, format_timestamp, truncate_timestamp, time_diff.

Operations with active lists and tables

You can enrich events with local variables and data from active lists and tables.

To enrich events with data from an active list, use the active_list, active_list_dyn functions.

To enrich events with data from a table, use the table_dict, dict functions.

You can create conditional statements by using the 'conditional' function in local variables. In this way, the variable can return one of the values depending on what data was received for processing.

Enriching events with a local variable

To use a local variable to enrich events:

1. Add a local variable to the rule.
2. In the **Correlation rules** window, go to the **General** tab and add the created local variable to the **Identical fields** section. Prefix the local variable name with a "$" character.
3. In the **Correlation rules** window, go to the **Actions** tab, and under **Enrichment**, in the **Source kind** drop-down list, select **Event**.
4. From the **Target field** drop-down list, select the KUMA event field to which you want to pass the value of the local variable.
5. From the **Source field** drop-down list, select a local variable. Prefix the local variable name with a "$" character.
6. Specify the remaining rule settings.
7. Click **Save**.

Local variables in active list enrichment

You can use local variables to enrich active lists.

To enrich the active list with a local variable:

1. Add a local variable to the rule.
2. In the **Correlation rules** window, go to the **General** tab and add the created local variable to the **Identical fields** section. Prefix the local variable name with a "$" character.
3. In the **Correlation rules** window, go to the **Actions** tab and under **Active lists update**, add the local variable to the **Key fields** field. Prefix the local variable name with a "$" character.
4. Under **Mapping**, specify the correspondence between the event fields and the active list fields.
5. Click **Save**.

Properties of variables

Local and global variables

The properties of global variables differ from the properties of local variables.

Global variables:

- Global variables are declared at the correlator level and are applied only within the scope of this correlator.
- The global variables of the correlator can be queried from all correlation rules that are specified in it.

- In standard correlation rules, the same global variable can take different values in each selector.
- It is not possible to transfer global variables between different correlators.

Local variables:

- Local variables are declared at the correlation rule level and are applied only within the limits of this rule.
- In standard correlation rules, the scope of a local variable consists of only the selector in which the variable was declared.
- Local variables can be declared in any type of correlation rule.
- Local variables cannot be transferred between rules or selectors.
- A local variable cannot be used as a global variable.

Variables used in various types of correlation rules

- In **operational** correlation rules, on the **Actions** tab, you can specify all variables available or declared in this rule.
- In **standard** correlation rules, on the **Actions** tab, you can provide only those variables specified in these rules on the **General** tab, in the **Identical fields** field.
- In **simple** correlation rules, on the **Actions** tab, you can provide only those variables specified in these rules on the **General** tab, in the **Inherited Fields** field.

Requirements for variables

When adding a variable function, you must first specify the name of the function, and then list its parameters in parentheses. Basic mathematical operations (addition, subtraction, multiplication, division) are an exception to this requirement. When these operations are used, parentheses are used to designate the severity of the operations.

Requirements for function names:

- Must be unique within the correlator.
- Must contain 1 to 128 Unicode characters.
- Must not begin with the character $.
- Must be written in camelCase or CamelCase.

Special considerations when specifying functions of variables:

- The sequence of parameters is important.
- Parameters are separated by a comma: `,`.
- String parameters are passed in single quotes: `'`.
- Event field names and variables are specified without quotation marks.

- When querying a variable as a parameter, add the `$` character before its name.
- You do not need to add a space between parameters.
- In all functions in which a variable can be used as parameters, nested functions can be created.

Functions of variables

Operations with active lists and dictionaries

active_list and active_list_dyn

These functions allow you to receive information from an active list and dynamically generate a field name for an active list and key.

You must specify the parameters in the following sequence:

1. Active list name.
2. Expression that returns the field name of the active list
3. One or more expressions whose results make up the key

Usage example	Result
`active_list('Test', to_lower('DeviceHostName'), to_lower(DeviceCustomString2), to_lower(DeviceCustomString1))`	Gets the field value of the active list.

Use these functions to query the active list of the shared tenant from a variable. To do so, add the @Shared suffix after the name of the active list (case sensitive). For example, active_list('exampleActiveList@Shared', 'score', SourceAddress, SourceUserName).

table_dict

Gets information about the value in the specified column of a dictionary of the table type.

You must specify the parameters in the following sequence:

1. Dictionary name
2. Dictionary column name
3. One or more expressions whose results make up the dictionary string key

Usage example	Result
`table_dict('exampleTableDict', 'office', SourceUserName)`	Gets data from the `exampleTableDict` dictionary from the row with the `SourceUserName` key in the `office` column.
`table_dict('exampleTableDict', 'office', SourceAddress, to_lower(SourceUserName))`	Gets data from the `exampleTableDict` dictionary from a composite key string from the `SourceAddress` field value and the lowercase value of the `SourceUserName` field from the `office` column.

Use this function to access the dictionary of the shared tenant from a variable. To do so, add the `@Shared` suffix after the name of the active list (case sensitive). For example, `table_dict('exampleTableDict@Shared', 'office', SourceUserName)`.

dict

Gets information about the value in the specified column of a dictionary of the dictionary type.

You must specify the parameters in the following sequence:

1. Dictionary name.
2. One or more expressions whose results are used to generate the dictionary row key

Usage example	Result
`dict('exampleDictionary', SourceAddress)`	Gets data from `exampleDictionary` from the row with the `SourceAddress` key.
`dict('exampleDictionary', SourceAddress, to_lower(SourceUserName))`	Gets data from the `exampleDictionary` from a composite key string from the `SourceAddress` field value and the lowercase value of the `SourceUserName` field.

Use this function to access the dictionary of the shared tenant from a variable. To do so, add the `@Shared` suffix after the name of the active list (case sensitive). For example, `dict('exampleDictionary@Shared', SourceAddress)`.

Operations with context tables

context_table

Returns the value of the specified field in the base type (for example, integer, array of integers).

You must specify the parameters in the following sequence:

1. Name of the context table. The name must be specified.
2. Expression that returns the field name of context table.
3. Expression that returns the name of key field 1 of the context table.
4. Expression that returns the value of key field 1 of the context table.

The function must contain at least 4 parameters.

Usage example	Result
`context_table('tbl1', 'list_field1', 'key1', 'key1_val')`	`Get the value of the specified field. If the context table or context table field does not exist, an empty string is returned.`

len

Returns the length of a string or array.

The function returns the length of the array if the passed array is of one of the following types:

- array of integers
- array of floats

- array of strings
- array of booleans

If an array of a different type is passed, the data of the array is cast to the string type, and the function returns the length of the resulting string.

Usage examples
`len(context_table('tbl1', 'list_field1', 'key1', 'key1_val'))`
`len(DeviceCustomString1)`

distinct_items

Returns a list of unique elements in an array.

The function returns the list of unique elements of the array if the passed array is of one of the following types:

- array of integers
- array of floats
- array of strings
- array of booleans

If an array of a different type is passed, the data of the array is cast to the string type, and the function returns a string consisting of the unique characters from the original string.

Usage examples
`distinct_items(context_table('tbl1', 'list_field1', 'key1', 'key1_val'))`
`distinct_items(DeviceCustomString1)`

sort_items

Returns a sorted list of array elements.

You must specify the parameters in the following sequence:

1. Expression that returns the object of the sorting
2. Sorting order Possible values: `asc`, `desc`. If the parameter is not specified, the default value is `asc`.

The function returns the list of sorted elements of the array if the passed array is of one of the following types:

- array of integers
- array of floats
- array of strings

For a boolean array, the function returns the list of array elements in the original order.

If an array of a different type is passed, the data of the array is cast to the string type, and the function returns a string of sorted characters.

Usage examples
`sort_items(context_table('tbl1', 'list_field1', 'key1', 'key1_val'), 'asc')`
`sort_items(DeviceCustomString1)`

item

Returns the array element with the specified index or the character of a string with the specified index if an array of integers, floats, strings, or boolean values is passed.

You must specify the parameters in the following sequence:

1. Expression that returns the object of the indexing
2. Expression that returns the index of the element or character

The function must contain at least 2 parameters.

The function returns the array element with the specified index or the string character with the specified index if the index falls within the range of the array and the passed array is of one of the following types:

- array of integers
- array of floats
- array of strings
- array of booleans

If an array of a different type is passed and the index falls within the range of the array, the data is cast to the string type, and the function returns the string character with the specified index. If an array of a different type is passed and the index is outside the range of the array, the function returns an empty string.

Usage examples
`item(context_table('tbl1', 'list_field1', 'key1', 'key1_val'), 1)`
`item(DeviceCustomString1, 0)`

Operations with strings

to_lower

Converts characters in a string to lowercase. Supported for standard fields and extended event schema fields of the `string` type.

A string can be passed as a string, field name or variable.

Usage examples
`to_lower(SourceUserName)`

`to_lower('SomeText')`
`to_lower($otherVariable)`

to_upper

Converts characters in a string to uppercase. Supported for standard fields and extended event schema fields of the `string` type. A string can be passed as a string, field name or variable.

Usage examples
`to_upper(SourceUserName)`
`to_upper('SomeText')`
`to_upper($otherVariable)`

append

Adds characters to the end of a string. Supported for standard fields and extended event schema fields of the `string` type.

You must specify the parameters in the following sequence:

1. Original string
2. Added string

Strings can be passed as a string, field name or variable.

Usage examples	Usage result
`append(Message, '123')`	The string `123` is added to the end of this string from the `Message` field.
`append($otherVariable, 'text')`	The string `text` is added to the end of this string from the variable `otherVariable`.
`append(Message, $otherVariable)`	A string from `otherVariable` is added to the end of this string from the `Message` field.

prepend

Adds characters to the beginning of a string. Supported for standard fields and extended event schema fields of the `string` type.

You must specify the parameters in the following sequence:

1. Original string
2. Added string

Strings can be passed as a string, field name or variable.

Usage examples	Usage result
`prepend(Message, '123')`	The string `123` is added to the beginning of this string from the `Message` field.

`prepend($otherVariable, 'text')`	The string `text` is added to the beginning of this string from `otherVariable`.
`prepend(Message, $otherVariable)`	A string from `otherVariable` is added to the beginning of this string from the `Message` field.

substring

Returns a substring from a string. Supported for standard fields and extended event schema fields of the `string` type.

You must specify the parameters in the following sequence:

1. Original string.
2. Substring start position (natural number or 0).
3. Substring end position (optional).

Strings can be passed as a string, field name or variable. If the position number is greater than the original data string length, an empty string is returned.

Usage examples	Usage result
`substring(Message, 2)`	Returns a part of the string from the `Message` field: from 3 characters to the end.
`substring($otherVariable, 2, 5)`	Returns a part of the string from the `otherVariable` variable: from 3 to 6 characters.
`substring(Message, 0, len(Message) - 1)`	Returns the entire string from the `Message` field except the last character.

index_of

The `index_of` function returns the byte offset of a character or substring in a string; the first character in the string has index 0. If the function does not find the substring, the function returns a negative value.

If the string has non-ASCII characters, the returned byte offset will not correspond to the number of characters preceding the substring you are searching for.

The function accepts the following parameters:

- As source data, an event field, another variable, or a constant
- Any expression out of those that are available in local variables.

To use this function, you must specify the parameters in the following order:

1. Character or substring whose position you want to find.
2. String to be searched.

Usage examples	Usage result
`index_of('@', SourceUserName)`	The function looks for the `@` character in the `SourceUserName` field. The `SourceUserName` field contains the `user@example.com` string. Result = 4. The function returns the index of the first occurrence of the character in the string. The first character in the string has index 0.

`index_of('m', SourceUserName)`	The function looks for the `m` character in the `SourceUserName` field. The `SourceUserName` field contains the `user@example.com` string. Result = 8. The function returns the index of the first occurrence of the character in the string. The first character in the string has index 0.

last_index_of

The `last_index_of` function returns the position of the last occurrence of a character or substring in a string; the first character in the string has index 0. If the function does not find the substring, the function returns -9223372036854775808.

The function accepts the following parameters:

- As source data, an event field, another variable, or a constant
- Any expression out of those that are available in local variables.

To use this function, you must specify the parameters in the following order:

1. Character or substring whose position you want to find.
2. String to be searched.

Usage examples	Usage result
`last_index_of('m', SourceUserName)`	The function looks for the `m` character in the `SourceUserName` field. The `SourceUserName` field contains the `user@example.com` string. Result = 15. The function returns the index of the last occurrence of the character in the string. The first character in the string has index 0.

tr

Deletes the specified characters from the beginning and end of a string. Supported for standard fields and extended event schema fields of the `string` type.

You must specify the parameters in the following sequence:

1. Original string.
2. Substring to be deleted from the beginning and end of the original string (optional)

Strings can be passed as a string, field name or variable. If you do not specify a string to be deleted, spaces will be removed from the beginning and end of the original string.

Usage examples	Usage result
`tr(Message)`	Spaces have been removed from the beginning and end of the string from the `Message` field.
`tr($otherVariable, '_')`	If the `otherVariable` variable has the `_test_` value, the string `_test_` is returned.
`tr(Message, '@example.com')`	If the `Message` event field contains the string `user@example.com`, the string `user` is returned.

replace

Replaces all occurrences of the sequence of characters A in the string with the sequence of characters B. Supported for standard fields and extended event schema fields of the `string` type.

You must specify the parameters in the following sequence:

1. Original string.
2. Search string: sequence of characters to be replaced.
3. Replacement string: sequence of characters to replace the search string.

Strings can be passed as an expression.

Usage examples	Usage result
`replace(Name, 'UserA', 'UserB')`	Returns a string from the `Name` event field in which all occurrences of `UserA` are replaced with `UserB`.
`replace($otherVariable, ' text ', '_text_')`	Returns a string from `otherVariable` in which all occurrences of `' text'` are replaced with `'_text_'`.

regexp_replace

Replaces a sequence of characters that match a regular expression with a sequence of characters and regular expression capturing groups. Supported for standard fields and extended event schema fields of the `string` type.

You must specify the parameters in the following sequence:

1. Original string.
2. Search string: regular expression.
3. Replacement string: sequence of characters to replace the search string, and IDs of the regular expression capturing groups. A string can be passed as an expression.

Strings can be passed as a string, field name or variable. Unnamed capturing groups can be used.

In regular expressions used in variable functions, each backslash character must be additionally escaped. For example, `^example\\\\` must be used instead of the regular expression `^example\\`.

Usage examples	Usage result
`regexp_replace(SourceAddress, '([0-9]{1,3}).([0-9]{1,3}).([0-9]{1,3}).([0-9]{1,3})', 'newIP: $1.$2.$3.10')`	Returns a string from the `SourceAddress` event field in which the text `newIP` is inserted before the IP addresses. In addition, the last digits of the address are replaced with `10`.

regexp_capture

Gets the result matching the regular expression condition from the original string. Supported for standard fields and extended event schema fields of the `string` type.

You must specify the parameters in the following sequence:

1. Original string.

2. Search string: regular expression.

Strings can be passed as a string, field name or variable. Unnamed capturing groups can be used.

In regular expressions used in variable functions, each backslash character must be additionally escaped. For example, `^example\\\\` must be used instead of the regular expression `^example\\`.

Usage examples	Example values	Usage result
`regexp_capture(Message, '(\\\\d{1,3}\\\\.\\\\d{1,3}\\\\.\\\\d{1,3}\\\\.\\\\d{1,3})')`	`Message = 'Access from 192.168.1.1 session 1'` `Message = 'Access from 45.45.45.45 translated address 192.168.1.1 session 1'`	`'192.168.1.1'` `'45.45.45.45'`

template

Returns the string specified in the function, with variables replaced with their values. Variables for substitution can be passed in the following ways:

- Inside the string.

- After the string. In this case, inside the string, you must specify variables in the `{{index.<n>}}` notation, where <n> is the index of the variable passed after the string. The index is 0-based.

Usage examples
`template('Very long text with values of rule={{.DeviceCustomString1}} and {{.Name}} event fields, as well as values of {{index.0}} and {{index.1}} local variables and then {{index.2}}', $var1, $var2, $var10)`

Operations with timestamps

now function

Gets a timestamp in epoch format. Runs with no arguments.

Usage examples
`now()`

extract_from_timestamp

Gets atomic time representations (year, month, day, hour, minute, second, day of the week) from fields and variables with time in the epoch format.

The parameters must be specified in the following sequence:

1. Event field of the timestamp type, or variable.
2. Notation of the atomic time representation. This parameter is case sensitive.

   Possible variants of atomic time notation:

   - y refers to the year in number format.
   - M refers to the month in number notation.
   - d refers to the number of the month.
   - wd refers to the day of the week: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Sunday.
   - h refers to the hour in 24-hour format.
   - m refers to the minutes.
   - s refers to the seconds.
3. Time zone designation (optional).

   The parameter can be specified as a string (for example, `Europe/Moscow`) or as a variable (`$timezone`). The variable must be declared in the local variables of the correlation rule. The value of the variable must contain a string identifier for the time zone. It is also allowed to use variables derived from other variables and dictionary values.

   If this parameter is not specified, the time is calculated in UTC format.

Usage examples
`extract_from_timestamp(Timestamp, 'wd')`
`extract_from_timestamp(Timestamp, 'h')`
`extract_from_timestamp($otherVariable, 'h')`
`extract_from_timestamp(Timestamp, 'h', 'Europe/Moscow')`
`extract_from_timestamp(Timestamp, 'h', $timezone)`

Usage example: using a variable obtained from a dictionary

```
$key_timezone = 'timezone'

$timezone = dict('UEBA.Timezone', $key_timezone)

extract_from_timestamp(EndTime, 'h', $timezone)
```

In this example, the `$timezone` variable is derived from another variable and a dictionary value and is used as the `timezone` parameter.

parse_timestamp

Converts the time from RFC3339 format (for example, `2022-05-24 00:00:00`, `2022-05-24 00:00:00+0300`) to epoch format.

Usage examples
`parse_timestamp(Message)`
`parse_timestamp($otherVariable)`

format_timestamp

Converts the time from epoch format to RFC3339 format.

The parameters must be specified in the following sequence:

1. Event field of the timestamp type, or variable.
2. Time format notation: RFC3339.
3. (optional) Time zone notation. If this parameter is not specified, the time is calculated in UTC format.

Usage examples
`format_timestamp(Timestamp, 'RFC3339')`
`format_timestamp($otherVariable, 'RFC3339')`
`format_timestamp(Timestamp, 'RFC3339', 'Europe/Moscow')`

truncate_timestamp

Rounds the time in epoch format. After rounding, the time is returned in epoch format. Time is rounded down.

The parameters must be specified in the following sequence:

1. Event field of the timestamp type, or variable.
2. Rounding parameter:
   - 1s rounds to the nearest second.
   - 1m rounds to the nearest minute.
   - 1h rounds to the nearest hour.
   - 24h rounds to the nearest day.
3. (optional) Time zone notation. If this parameter is not specified, the time is calculated in UTC format.

Usage examples	Examples of rounded values	Usage result
`truncate_timestamp(Timestamp, '1m')`	1654631774175 (7 June 2022, 19:56:14.175)	1654631760000 (7 June 2022, 19:56:00)
`truncate_timestamp($otherVariable, '1h')`	1654631774175 (7 June 2022, 19:56:14.175)	1654628400000 (7 June 2022, 19:00:00)
`truncate_timestamp(Timestamp, '24h', 'Europe/Moscow')`	1654631774175 (7 June 2022, 19:56:14.175)	1654560000000 (7 June 2022, 0:00:00)

time_diff

Gets the time interval between two timestamps in epoch format.

The parameters must be specified in the following sequence:

1. Interval end time. Event field of the timestamp type, or variable.
2. Interval start time. Event field of the timestamp type, or variable.
3. Time interval notation:
   - ms refers to milliseconds.
   - s refers to seconds.
   - m refers to minutes.
   - h refers to hours.
   - d refers to days.

Usage examples
`time_diff(EndTime, StartTime, 's')`
`time_diff($otherVariable, Timestamp, 'h')`
`time_diff(Timestamp, DeviceReceiptTime, 'd')`

Mathematical operations

These are comprised of basic mathematical operations and functions.

Basic mathematical operations

Supported for integer and float fields of the extended event schema.

Operations:

- Addition
- Subtraction
- Multiplication
- Division
- Modulo division

Parentheses determine the sequence of actions

Available arguments:

- Numeric event fields
- Numeric variables
- Real numbers

  When modulo dividing, only natural numbers can be used as arguments.

Usage constraints:

- Division by zero returns zero.
- Mathematical operations on a number and a string return the number unchanged. For example, 1 + abc returns 1.
- Integers resulting from operations are returned without a dot.

Usage examples (Type=3; otherVariable=2; Message=text)	Usage result
`Type + 1`	4
`$otherVariable - Type`	-1
`2 * 2.5`	5
`2 / 0`	0
`Type * Message`	0
`(Type + 2) * 2`	10
`Type % $otherVariable`	1

round

Rounds numbers. Supported for integer and float fields of the extended event schema.

Available arguments:

- Numeric event fields
- Numeric variables
- Numeric constants

Usage examples (DeviceCustomFloatingPoint1=7.75; DeviceCustomFloatingPoint2=7.5 otherVariable=7.2)	Usage result
`round(DeviceCustomFloatingPoint1)`	8
`round(DeviceCustomFloatingPoint2)`	8
`round($otherVariable)`	7

ceil

Rounds up numbers. Supported for integer and float fields of the extended event schema.

Available arguments:

- Numeric event fields
- Numeric variables
- Numeric constants

Usage examples (DeviceCustomFloatingPoint1=7.15; otherVariable=8.2)	Usage result
ceil(DeviceCustomFloatingPoint1)	8
ceil($otherVariable)	9

floor

Rounds down numbers. Supported for integer and float fields of the extended event schema.

Available arguments:

- Numeric event fields
- Numeric variables
- Numeric constants

Usage examples (DeviceCustomFloatingPoint1=7.15; otherVariable=8.2)	Usage result
floor(DeviceCustomFloatingPoint1)	7
floor($otherVariable)	8

abs

Gets the modulus of a number. Supported for integer and float fields of the extended event schema.

Available arguments:

- Numeric event fields
- Numeric variables
- Numeric constants

Usage examples (DeviceCustomNumber1=-7; otherVariable=-2)	Usage result
abs(DeviceCustomFloatingPoint1)	7
abs($otherVariable)	2

pow

Exponentiates a number. Supported for integer and float fields of the extended event schema.

The parameters must be specified in the following sequence:

1. Base — real numbers.
2. Power — natural numbers.

Available arguments:

- Numeric event fields
- Numeric variables
- Numeric constants

Usage examples
`pow(DeviceCustomNumber1, DeviceCustomNumber2)`
`pow($otherVariable, DeviceCustomNumber1)`

str_join

Join multiple strings into one using a separator. Supported for integer and float fields of the extended event schema.

The parameters must be specified in the following sequence:

1. Separator. String.
2. String1, string2, stringN. At least 2 expressions.

Usage examples	Usage result
`str_join('|', to_lower(Name), to_upper(Name), Name)`	String.

conditional

Get one value if a condition is met and another value if the condition is not met. Supported for integer and float fields of the extended event schema.

The parameters must be specified in the following sequence:

1. Condition. String. The syntax is similar to the conditions of the Where statement in SQL. You can use the functions of the KUMA variables and references to other variables in a condition.
2. The value if the condition is met. Expression.
3. The value if the condition is not met. Expression.

Supported operators:

- `AND`
- `OR`
- `NOT`

- `=`
- `!=`
- `<`
- `<=`
- `>`
- `>=`
- `LIKE` (passes a RE2 regular expression, not an SQL expression)
- `ILIKE` (passes a RE2 regular expression, not an SQL expression)
- `BETWEEN`
- `IN`
- `IS NULL` (check for an empty value, such as 0 or an empty string)

Usage examples (the value depends on arguments 2 and 3)
`conditional('SourceUserName = \\'root\\' AND DestinationUserName = SourceUserName', 'match', 'no match')`
`conditional(`DestinationUserName ILIKE 'svc_.*'`, 'match', 'no match')`
`conditional(`DestinationUserName NOT LIKE 'svc_.*'`, 'match', 'no match')`

Operations for extended event schema fields

For extended event schema fields of the `string` type, the following operations are supported:

- `len`
- `to_lower`
- `to_upper`
- `append`
- `prepend`
- `substring`
- `tr`
- `replace`
- `regexp_replace`
- `regexp_capture`

For extended event schema fields of the integer or float type, the following kinds of operations are supported:

- Basic mathematical operations:
- `round`
- `ceil`
- `floor`
- `abs`
- `pow`
- `str_join`
- `conditional`

For extended event schema fields of the `array of integers`, `array of floats`, and `array of strings` types, KUMA supports the following functions:

- Get the i-th element of the array. Example: `item(<type>.someStringArray)`.
- Get an array of values. Example: `<type>.someStringArray`. Returns `["string1", "string2", "string3"]`.
- Get the count of elements in an array. Example: `len(<type>.someStringArray)`. Returns `["string1", "string2"]`.
- Get unique elements from an array. Example: `distinct_items(<type>.someStringArray)`.
- Generate a TSV string of array elements. Example: `to_string(<type>.someStringArray)`.
- Sort the elements of the array. Example: `sort_items(<type>.someStringArray)`.

  In the examples, instead of `<type>`, you must specify the array type: NA for an array of integers, FA for an array of floats, SA for an array of strings.

For fields of the `array of integers` and `array of floats` types, the following functions are supported:

- `math_min` — returns the minimum element of an array. Example: `math_min(NA.NumberArray)`, `math_min(FA.FloatArray)`.
- `math_max` returns the maximum element of an array. Example: `math_max(NA.NumberArray)`, `math_max(FA.FloatArray)`.
- `math_avg` — returns the average value of an array. Example: `math_avg(NA.NumberArray)`, `math_avg(FA.FloatArray)`.

Declaring variables

To declare variables, they must be added to a correlator or correlation rule.

To add a global variable to an existing correlator:

1. In the main menu, go to **Monitoring** → **Resources** → **Correlators**.
2. Select the resource set of the relevant correlator.

   The Correlator Installation Wizard opens.
3. Select the **Global variables** step of the Installation Wizard.
4. Click the **Add variable** button and specify the following parameters:
5. In the **Variable** window, enter the name of the variable.

   Variable naming requirements

   - Must be unique within the correlator.
   - Must contain 1 to 128 Unicode characters.
   - Must not begin with the character $.
   - Must be written in camelCase or CamelCase.
   - In the **Value** window, enter the variable function.

     Description of variable functions.

   Multiple variables can be added. Added variables can be edited or deleted by using the ✕ icon.
6. Select the **Setup validation** step of the Installation Wizard and click **Save**.

A global variable is added to the correlator. It can be queried like an event field by inserting the $ character in front of the variable name. The variable will be used for correlation after restarting the correlator service.

To add a local variable to an existing correlation rule:

1. In the main menu, go to **Monitoring** → **Resources** → **Correlation rules**.
2. Select the relevant correlation rule.

   The correlation rule settings window opens. The parameters of a correlation rule can also be opened from the correlator to which it was added by proceeding to the **Correlation** step of the Installation Wizard.
3. Click the **Selectors** tab.
4. In the selector, open the **Local variables** tab, click the **Add variable** button and specify the following parameters:

   - In the **Variable** window, enter the name of the variable.

     Variable naming requirements

     - Must be unique within the correlator.
     - Must contain 1 to 128 Unicode characters.

- Must not begin with the character $.
- Must be written in camelCase or CamelCase.

- In the **Value** window, enter the variable function.

  Description of variable functions.

Multiple variables can be added. Added variables can be edited or deleted by using the ✕ icon.

For standard correlation rules, repeat this step for each selector in which you want to declare variables.

5. Click **Save**.

The local variable is added to the correlation rule. It can be queried like an event field by inserting the $ character in front of the variable name. The variable will be used for correlation after restarting the correlator service.

Added variables can be edited or deleted. If the correlation rule queries an undeclared variable (for example, if its name has been changed), an empty string is returned.

If you change the name of a variable, you will need to manually change the name of this variable in all correlation rules where you have used it.

Predefined correlation rules

The OSMP distribution kit includes correlation rules listed in the table below.

Predefined correlation rules

Correlation rule name	Description
[OOTB] KATA alert	Used for enriching KATA events.
[OOTB] Successful Bruteforce	Triggers when a successful authentication attempt is detected after multiple unsuccessful authentication attempts. This rule works based on the events of the sshd daemon.
[OOTB][AD] Account created and deleted within a short period	Detects instances of creation and subsequent deletion of accounts on Microsoft Windows hosts.
[OOTB][AD] An account failed to log on from different hosts	Detects multiple unsuccessful attempts to authenticate on different hosts.
[OOTB][AD] Granted TGS without TGT (Golden Ticket)	Detects suspected Golden Ticket type attacks. This rule works based on Microsoft Windows events.
[OOTB][AD][Technical] 4768. TGT Requested	The technical rule used to populate the active list is [OOTB][AD] List of requested TGT. EventID 4768. This rule works based on Microsoft Windows events.
[OOTB][AD] Membership of sensitive group was modified	Works based on Microsoft Windows events.
[OOTB][AD] Multiple accounts failed to log on from the same host	Triggers after multiple failed authentication attempts are detected on the same host from different accounts.
[OOTB][AD] Possible Kerberoasting attack	Detects suspected Kerberoasting type attacks. This rule works based on Microsoft Windows events.
[OOTB][AD] Successful authentication with the same account on multiple hosts	Detects connections to different hosts under the same account. This rule works based on Microsoft Windows events.
[OOTB][AD] The account added and deleted from the group in a short period	Detects the addition of a user to a group and subsequent removal. This rule works based on Microsoft Windows events.
[OOTB][Net] Possible port scan	Detects suspected port scans. This rule works based on Netflow, Ipfix events.
[OOTB] EDR IOA alert	Monitors EDR events and creates an alert when detects an EDR event that has a sign of a triggered IOA rule and marked as an alert.

[OOTB] EDR IOA SB alert	Monitors EDR events and creates an alert when detects an EDR event that was received from Auto Sandbox Scan.
[OOTB] OSMP Scanner detects	Monitors security audit events generated by the IRP component and creates an alert when an event of one of the following types is received: "YARA Scan Host", "Sandbox Detect", "Antimalware Detect", "IOC Scan Host", "YARA Scan Server".
[OOTB] KEDR event monitoring	Monitors audit events and creates an alert when an event source monitoring policy triggers.
[OOTB] Multiple login attempts to OSMP console using the same account	Detects attempts to log in to the OSMP console using the same account and generates an alert if three unsuccessful authentication attempts occur.

Adding a temporary exclusion list for a correlation rule

Users that do not have the rights to edit correlation rules in the OSMP Console, can create a temporary list of exclusions (for example, create exclusions for false positives when managing alerts). A user with the rights to edit correlation rules can then add the exclusions to the rule and remove them from the temporary list.

To add exclusions to a correlation rule when managing alerts:

1. Go to the **Alerts** section and select an alert.
2. Click the **Find in events** button.

   Events of the alert are displayed on the events page.
3. Open the correlation event.

   This opens the event card in which each field has a (arrow) button that lets you add an exclusion.
4. Click the button and select **Add to exclusions** .

   A sidebar is displayed, containing the following fields: **Correlation rule**, **Exclusion**, **Alert**, **Comment**.
5. Click the **Create** button.

The exclusion rule is added.

The exclusion is added to the temporary list. This list is available to anyone with rights to read correlation rules: in the **Resources** → **Correlation rules** section, in the toolbar of the rule list, click the **List of exclusions** button. If you want to view the exclusions of a specific rule, open the card of the rule and select the **Exclusions** tab.

The exclusion list contains entries with the following parameters:

- `Exclusion`

  Exclusion condition.
- `Correlation rule`

  Name of the correlation rule.
- `Alert`

  Name of the alert from which the exclusion was added.
- `Tenant`

  The tenant to which the rule and the exclusion apply.

- `Condition`

  Generated automatically based on the selected field of the correlation event.

- `Creation date`

  Date and time when the exclusion was added.

- `Expires`

Date and time when the exclusion will be automatically removed from the list.

- `Created by`

  Name of the user that added the exclusion.

- `Comment`

After the exclusion is added, by default, the correlation rule takes the exclusion into account for 7 days. In the **Options** → **General** section, you can configure the duration of exclusions by editing the `corr_rule_exclusion_ttl_hours` parameter in the **Core properties** section. You can configure the lifetime of exclusions in hours and days. The minimum value is 1 hour, the maximum is 365 days. This setting is available only for users with the Main administrator role.

For fields from base events to be propagated to correlation events, these fields must be specified in the card of the correlation rule on the **General** tab, in the **Propagated fields** field. If the fields of base events are not mapped to the correlation event, these fields cannot be added to exclusions.

To remove exclusions from a correlation rule:

1. Go to the **Resources** → **Correlation rules** section.
2. In the toolbar of the rule list, click **List of exclusions** button.

   This opens the window with the list of exclusions.
3. Select the exclusions that you want to delete and click the **Delete** button.

Exceptions are deleted from the correlation rule.

KUMA generates an audit event whenever an exception is created or deleted. You can view the changes of event settings in the **Event details** window.

Sigma rules converter

The Sigma rule converter converts correlation rules into a format supported by OSMP and facilitates importing simple rules to be refined by an analyst.

The list of operating systems that support the Sigma rule converter is given in the Software requirements section.

To use the Sigma rule converter to convert correlation rules, follow these steps:

1. Install the Sigma rule converter. The following installation options are available:

   - **Installing the Sigma rule converter using docker and bash**

     This installation method is suitable for local installation of the converter web interface.

Installation requires the latest versions of bash and docker. For detailed information about deploying bash and docker, refer to the official documentation.

Astra Linux 1.7 is not supported.

To perform the installation:

1. Enter the directory with the extracted archive and execute one of the following commands:

   - To install the converter on the host with the address

     `0.0.0.0:8000`
     run the following command:

     ```
     ./run.sh
     ```

   - To install the converter on the host with the address

     `0.0.0.0:8888`
     run the following command:

     ```
     ./run.sh <port>
     ```

     where:
     <port> is the port (the default port is `8000`).

   - To install the converter on the host with the address

     `127.0.0.1:9999`
     run the following command:

     ```
     ./run.sh <IP address>:<port>
     ```

     where:

     - <IP address> is the IP address of the listening interface, by default

       `0.0.0.0`
       . Specify

       `127.0.0.1`
       to run only on the local interface.

     - <port> is the port.

   The converter is installed.

- **Installing the Sigma rule converter in an environment that allows running docker images**

  This installation method uses the provided container and lets you create a systemd service and deploy the web interface using Kubernetes.

Any containerization tool will do: docker, podman, cri-o. Installation involves downloading the container image and then running the image with a port specified.

To install the converter using podman:

1. Download the container image:

   ```
   podman load --input "kuma-sigma-converter-x.x.x.tar
   ```

2. Run the image in one of the following ways:

   - Run until Ctrl+C is pressed:

     ```
     podman run --name=kuma-converter -p "8000:8000" -e "PORT=8000" --rm -it kuma-sigma-converter:x.x.x
     ```

   - Run in the background:

     ```
     podman run --name=kuma-converter -p "8000:8000" -e "PORT=8000" --rm kuma-sigma-converter:x.x.x
     ```

   The converter is installed.

- **Installing the Sigma rule converter using Python 3.10 or later**

  This installation method is the most flexible and suitable for experienced users because it lets you adapt the converter to your specific needs. Unlike other methods, this method requires an internet connection to download Python packages.

  To install the converter:

  1. Make sure you have Python 3.10 or later installed.

  2. Install poetry for Python dependency management. For Ubuntu or Debian, you can use the package manager:

     ```
     sudo apt-get update
     sudo apt install pipx
     pipx install poetry
     ```

  3. Use poetry to configure and run the web interface of the Sigma rule converter:

     ```
     cd sigconverter.io
     poetry install
     poetry run ./run.py
     ```

  4. In the browser, navigate to the host where the web interface of the Sigma rule converter is installed. For a local installation, the address is http://127.0.0.1:8000 or http://0.0.0.0:8000.

  5. If necessary, you can specify the `HOST` and `PORT` environment variables to configure the listening interface and set the port number.

  The converter is installed.

  The Sigma rule converter is a plug-in for the pySigma framework, which means it

  pySigma-backend-kuma

can be used with other standard sigma tools, not just a custom version
sigconverter.io

. For example:
sigma-cli is a converter with a command line interface.

sigconverter.io is the original generic web interface.

The following are the README files for the libraries provided as source code:

src/pySigma/README.md for the industry—standard sigma conversion framework and library.

src/pySigma-backend-kuma/README.md—for the plug-in for pySigma that implements OSMP filter and query conversion.

src/sigconverter.io/README.md—web user interface.

After installation, log in to the web interface of the converter.

2. Adapt the correlation rule as necessary in the Sigma rule converter and copy or import the adapted rule into OSMP.

3. Restart the correlator to apply the changes.

Your adapted correlation is applied in the correlator.

Preparing a Sigma rule

To convert a Sigma rule to a correlation rule:

1. Before modifying the rule, make sure that the following requirements are satisfied:

   - The predefined normalizers use event enrichment `to lower case` for fields containing user names, host names, and process names, therefore we recommend converting the relevant fields to lower case in the source Sigma rule.

   - We do not recommend writing comments or additional information in the `contains` conditions and similar. If you need to leave a comment, we recommend using the # character, such comments do not affect the condition.

   - The rule must begin with the word `title` without hyphens before it.

2. Copy the correlation rule that you want to edit from the OSMP web interface, convert it to YML format, and paste it into the **rule.yml** tab of the converter. Select the settings in the drop-down lists as necessary. Fix any errors if necessary.

3. In the Sigma rule converter, in the **Backend** field, select **kuma**, in the **Format** field, select **default**, and leave the **Pipeline** field empty.

   The following values are available:

   - Backend: kuma, Format: default—ready-to-run SQL query without formatting.

   - Backend: kuma, format: SQL_formatted—ready-to-run SQL query with formatting.

- Backend: kuma_filter, Format: default—ready-to-use selector for the correlation rule.
- Backend: kuma_filter, Format: correlation—ready-to-import correlation rule in JSON format. To perform the import, you can use the REST API method /xdr/api/v3/kuma/resources/{kind}/create and specify the tenantID and the name of the tenant for the import.

4. Go to the tab of the **custom_pipeline.yml** converter and copy the example dictionary adapted for pySigma to that tab.

   Example dictionary adapted for pySigma

   Windows process_creation mapping

 EventID: DeviceEventClassID
 TaskName: SourceProcessName
```

```
rule_conditions:
- type: contains_detection_item
field: "EventID"
value: '4698'
```

The converted rule is displayed on the **query** tab. The result of the conversion is a `WHERE` clause for an SQL query.

You can copy the end result to OSMP if it is a query or a filter. If you want to use a rule in OSMP, you can import rules into OSMP one by one.

Examples of supported Sigma rule conversions

MITRE ATT&CK matrix coverage

If you want to assess the coverage of the MITRE ATT&CK matrix by your correlation rules:

1. Download the list of MITRE techniques from the official MITRE ATT&CK repository and import it into KUMA.
2. Map MITRE techniques to correlation rules.
3. Export correlation rules to MITRE ATT&CK Navigator.

As a result, you can visually assess the coverage of the MITRE ATT&CK matrix.

Importing the list of MITRE techniques

Only a user with the Main administrator role can import the list of MITRE techniques.

To import the list of MITRE ATT&CK techniques:

1. Download the list of MITRE ATT&CK techniques from the GitHub portal.

   KUMA supports only the MITRE ATT&CK technique list version 14.1.

2. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.
   This opens the KUMA settings window.
3. Under **Other**, click **Common**.
4. In the **MITRE technique list settings**, click **Import from file**.
   The file selection window opens.
5. Select the downloaded MITRE ATT&CK technique list and click **Open**.

The list of MITRE ATT&CK techniques is imported into KUMA. You can see the list of imported techniques and the version of the MITRE ATT&CK technique list by clicking **View list**.

Mapping MITRE techniques to correlation rules

To map MITRE ATT&CK techniques to correlation rules:

1. In the main menu, go to **Monitoring** → **Resources** → **Correlation rules**.
2. Click the name of the correlation rule to open the correlation rule editing window.
   This opens the correlation rule editing window.

3. On the **General** tab, clicking the **MITRE techniques** field opens a list of available techniques. For the convenience of searching, a filter is provided, in which you can enter the name of a technique or the ID of a technique or tactic. One or more MITRE ATT&CK techniques are available for linking to a correlation rule.

4. Click **Save**.

The MITRE ATT&CK techniques are mapped to the correlation rule. In the KUMA Console, in the **Monitoring** → **Resources** → **Correlation rules** section, the **MITRE techniques** column of the edited rule displays the ID of the selected technique, and when you hover over the ID, the full name of the technique is displayed, including the ID of the technique and tactic.

Exporting correlation rules to MITRE ATT&CK Navigator

To export correlation rules with mapped MITRE techniques to MITRE ATT&CK Navigator:

1. In the main menu, go to **Monitoring** → **Resources** → **Correlation rules**.

2. Click the ellipsis button (...) in the upper-right corner.

3. In the drop-down list, click **Export to MITRE ATT&CK Navigator**.

4. In the window that opens, select the correlation rules that you want to export.

5. Click **OK**.

   A file with exported rules is downloaded to your computer.

6. Upload the file from your computer to MITRE ATT&CK Navigator to assess the coverage of the MITRE ATT&CK matrix.

You can assess the coverage of the MITRE ATT&CK matrix.

Filters

Filters let you select events based on specified conditions.

The collector service uses filters to select events that you want to send to KUMA. That is, an event that matches the filter condition is sent to KUMA for further processing.

Filters can be used in the following KUMA services and features:

- Collector.
- Correlator.
- Storage.
- Correlation rules.
- Enrichment rules.

- Aggregation rules.
- Destinations.
- Response rules.
- Segmentation rules.

You can use standalone filters or built-in filters that are stored in the service or resource where they were created.

For these resources, you can enable the display of control characters in all input fields except the **Description** field.

Available settings for filters:

- **Name** (required)—a unique name for this type of resource. Must contain 1 to 128 Unicode characters. Inline filters are created in other resources or services and do not have names.
- **Tenant** (required)—name of the tenant that owns the resource.
- Description—up to 4,000 Unicode characters describing the filter.
- The **Conditions** group of settings lets you formulate filtering criteria by creating filter conditions and groups of filters, or by adding existing filters.

  To create filtering criteria, you can use *builder mode* or *source code mode*. The builder mode is used by default.

  In builder mode, you can create or edit filter criteria by selecting filter conditions and operators from drop-down lists.

  In source code mode, you can use text commands to create and edit search queries.

  You can freely switch between modes when creating filtering criteria. To switch to source code mode, click the **Code** button. When switching between modes, the created condition filters are preserved. If the filter code is not displayed on the **Code** tab after linking the created filter to the resource, go to the **Builder** tab and then go back to the **Code** tab. The filter code is displayed.

Creating conditions in builder mode

You can create filtering criteria in builder mode by clicking the following buttons:

- **Add condition** adds a string with fields for defining a condition.
- **Add group** adds a group of filters. Group operators can be switched between **AND**, **OR**, and **NOT**. You can add groups, conditions, and existing filters to groups of filters. Conditions placed in the **NOT** subgroup are combined with the **AND** operator.

To replace an operator in the created condition, click the operator that you want to replace and select the new operator from the drop-down list.

To delete an operator in the created condition, click the operator that you want to delete and press **Backspace**.

To alter the sequence of filter conditions, click ⣿ and drag and drop the condition to the new location.

Conditions, groups, and filters can be deleted by clicking the ✕ button.

Settings of conditions:

- **When** (required)—in this drop-down list, you can specify whether or not to use the inverted function of the operator.

- **Left operand** and **Right operand** (required)—used to specify the values that the operator will process. The available types depend on the selected operator.

  Operands of filters

  - **Event field**—used to assign an event field value to the operand. Advanced settings:

    - **Event field** (required)—this drop-down list is used to select the field from which the value for the operand should be extracted.

  - **Active list**—used to assign an active list record value to the operand. Advanced settings:

    - **Active list** (required)—this drop-down list is used to select the active list.

    - **Key fields** (required)—this is the list of event fields used to create the Active list entry and serve as the Active list entry key.

    - **Field** (required unless the **inActiveList** operator is selected)—used to enter the Active list field name from which the value for the operand should be extracted.

  - **Context table**—used to assign a context table value to the operand. Advanced settings:

    - **Context table name** (required)—this drop-down list is used to select a context table.

    - **key fields** (required)—a list of event fields or local variable that are used to create a context table record and serve as the key for the context table record.

    - **field**—used to enter the name of the context table field from which the operand value must be extracted.

    - **index**—used to enter the index of the list field of the table from which the operand value must be extracted.

  - **Dictionary**—used to assign a dictionary resource value to the operand. Advanced settings:

    - **Dictionary** (required)—this drop-down list is used to select the dictionary.

    - **Key fields** (required)—this is the list of the event fields used to form the dictionary value key.

  - **Constant**—used to assign a custom value to the operand. Advanced settings:

    - **Value** (required)—here you enter the constant that you want to assign to the operand.

  - **Table**—used to assign multiple custom values to the operand. Advanced settings:

    - **Dictionary** (required)—this drop-down list is used to select a **Table**-type dictionary.

    - **Key fields** (required)—this is the list of the event fields used to form the dictionary value key.

- **List**—used to assign multiple custom values to the operand. Advanced settings:
  - **Value** (required)—here you enter the list of constants that you want to assign to the operand. When you type the value in the field and press **ENTER**, the value is added to the list and you can enter a new value.
- **TI**—used to read the CyberTrace threat intelligence (TI) data from the events. Advanced settings:
  - **Feed** (required)—this field is used to specify the CyberTrace threat category.
  - **Key fields** (required)—this drop-down list is used to select the event field containing the CyberTrace threat indicators.
  - **Field** (required)—this field is used to specify the CyberTrace feed field containing the threat indicators.

- **Operator** (required)—used to select the condition operator.

  In this drop-down list, you can select the **do not match case** check box if the operator should ignore the case of values. This check box is ignored if the **inSubnet**, **inActiveList**, **inCategory**, **InActiveDirectoryGroup, hasBit**, **inDictionary** operators are selected. This check box is cleared by default.

  Filter operators

  - **=** means the left operand equals the right operand.
  - **<** means the left operand is less than the right operand.
  - **<=** means the left operand is less than or equal to the right operand.
  - **>** means the left operand is greater than the right operand.
  - **>=** means the left operand is greater than or equal to the right operand.
  - **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet).
  - **contains** means the left operand contains values of the right operand.
  - **startsWith** means the left operand starts with one of the values of the right operand.
  - **endsWith** means the left operand ends with one of the values of the right operand.
  - **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used.
  - **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list).

    The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list.

    If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`.
  - **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand.

    If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability.

- The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list.
- **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields.
- **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand.
- **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand.
- The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators.
- **inContextTable** checks for the presence of the entry in the specified context table.
- **intersect**—presence in the left operand of the list items specified in the right operand.

The available operand kinds depends on whether the operand is left (L) or right (R).

Available operand kinds for left (L) and right (R) operands

Operator	Event field type	Active list type	Dictionary type	Context table type	Table type	TI type	Constant type	List type
=	L,R	L,R	L,R	L,R	L,R	L,R	R	R
>	L,R	L,R	L,R	L,R (only when looking up a table value by index)	L,R	L	R	—
>=	L,R	L,R	L,R	L,R (only when looking up a table value by index)	L,R	L	R	—
<	L,R	L,R	L,R	L,R (only when looking up a table value by index)	L,R	L	R	—
<=	L,R	L,R	L,R	L,R (only when looking up a table value by index)	L,R	L	R	—
inSubnet	L,R	L,R	L,R	L,R	L,R	L,R	R	R
contains	L,R	L,R	L,R	L,R	L,R	L,R	R	R
startsWith	L,R	L,R	L,R	L,R	L,R	L,R	R	R
endsWith	L,R	L,R	L,R	L,R	L,R	L,R	R	R
match	L	L	L	L	L	L	R	R
hasVulnerability	L	L	L	L	L	—	—	—
hasBit	L	L	L	L	L	—	R	R
inActiveList	—	—	—	—	—	—	—	—
inDictionary	—	—	—	—	—	—	—	—
inCategory	L	L	L	L	L	—	R	R
inContextTable	—	—	—	—	—	—	—	—
inActiveDirectoryGroup	L	L	L	L	L	—	R	R
TIDetect	—	—	—	—	—	—	—	—

You can use hotkeys when managing filters. Hotkeys are described in the table below.

Hotkeys and their functions

Key	Function
e	Invokes a filter by the event field
d	Invokes a filter by the dictionary field
a	Invokes a filter by the active list field
c	Invokes a filter by the context table field
t	Invokes a filter by the table field
f	Invokes a filter
t+i	Invokes a filter using TI
Ctrl+Enter	Finish editing a condition

The usage of extended event schema fields `string`, `number`, or `float` types is the same as the usage of fields of the KUMA event schema.

When using filters with extended event schema fields of the `Array of strings`, `Array of numbers`, and `Array of floats` types, you can use the following operations:

- The `contains` operation returns `True` if the specified substring is present in the array, otherwise it returns `False`.
- The `match` operation matches the string against a regular expression.
- The `intersec` operation.

When using filters with extended event schema fields of the `Array of numbers` and `Array of floats` types, you can use the following comparison operations: `<`, `>`, `=`, `>=`, `<=`.

If you want to reference a specific element of an array in the filter, you can use the following syntax: `NA.<array name>.<index of the element>`

Arrays are 0-based.

Example:

`NA.ArrayOne.0` — access to the first element of the ArrayOne array of integers.

`FA.ArrayTwo.2` — access to the third element of the ArrayTwo array of floats.

Creating conditions in source code mode

The code editor mode allows you to quickly edit conditions, select and copy blocks of code.

On the right side of the builder, you can find the navigator, which lets you to navigate the filter code.

Line wrapping is performed automatically at **AND**, **OR**, **NOT** logical operators, or at commas that separate the items in the list of values.

Names of resources used in the filter are automatically specified. Fields containing the names of linked resources cannot be edited. The names of shared resource categories are not displayed in the filter if you do not have the **Access to shared resources** role.

The filters listed in the table below are included in the OSMP distribution kit.

Predefined filters

Filter name	Description
[OOTB][AD] A member was added to a security-enabled global group (4728)	Selects events of adding a user to an Active Directory security-enabled global group.
[OOTB][AD] A member was added to a security-enabled universal group (4756)	Selects events of adding a user to an Active Directory security-enabled universal group.
[OOTB][AD] A member was removed from a security-enabled global group (4729)	Selects events of removing a user from an Active Directory security-enabled global group.
[OOTB][AD] A member was removed from a security-enabled universal group (4757)	Selects events of removing a user from an Active Directory security-enabled universal group.
[OOTB][AD] Account Created	Selects Windows user account creation events.
[OOTB][AD] Account Deleted	Selects Windows user account deletion events.
[OOTB][AD] An account failed to log on (4625)	Selects Windows logon failure events.
[OOTB][AD] Successful Kerberos authentication (4624, 4768, 4769, 4770)	Selects successful Windows logon events and events with IDs 4769, 4770 that are logged on domain controllers.
[OOTB][AD][Technical] 4768. TGT Requested	Selects Microsoft Windows events with ID 4768.
[OOTB][Net] Possible port scan	Selects events that may indicate a port scan.
[OOTB][SSH] Accepted Password	Selects events of successful SSH connections with a password.
[OOTB][SSH] Failed Password	Selects attempts to connect over SSH with a password.

Active lists

The active list is a bucket for data that is used by KUMA correlators for analyzing events according to the correlation rules.

For example, for a list of IP addresses with a bad reputation, you can:

1. Create a correlation rule of the operational type and add these IP addresses to the active list.
2. Create a correlation rule of the standard type and specify the active list as filtering criteria.
3. Create a correlator with this rule.

   In this case, KUMA selects all events that contain the IP addresses in the active list and creates a correlation event.

You can fill active lists automatically using correlation rules of the simple type or import a file that contains data for the active list.

You can add, copy, or delete active lists.

Active lists can be used in the following KUMA services and features:

- Correlation rules.
- Dashboard.

The same active list can be used by different correlators. However, a separate entity of the active list is created for each correlator. Therefore, the contents of the active lists used by different correlators differ even if the active lists have the same names and IDs.

Only data based on correlation rules of the correlator are added to the active list.

You can add, edit, duplicate, delete, and export records in the active correlator sheet.

During the correlation process, when entries are deleted from active lists, service events are generated in the correlators. These events only exist in the correlators, and they are not redirected to other destinations. Correlation rules can be configured to track these events so that they can be used to identify threats. Service event fields for deleting an entry from the active list are described below.

Event field	Value or comment
`ID`	Event identifier
`Timestamp`	Time when the expired entry was deleted
`Name`	`"active list record expired"`
`DeviceVendor`	`"Kaspersky"`
`DeviceProduct`	`"KUMA"`
`ServiceID`	Correlator ID
`ServiceName`	Correlator name
`DeviceExternalID`	Active list ID
`DevicePayloadID`	Key of the expired entry
`BaseEventCount`	Number of deleted entry updates increased by one
`S.<active list field>`	Dropped-out entry of the active list in the following format: S.<active list field> = <value of active list field>

Viewing the table of active lists

To view the table of correlator active lists:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the correlator for which you want to view the active list.
4. Click the **Go to active lists** button.

   The **Correlator active lists** table is displayed.

The table contains the following data:

- **Name**—the name of the correlator list.
- **Records**—the number of record the active list contains.
- **Size on disk**—the size of the active list.
- **Directory**—the path to the active list on the KUMA Core server.

Adding active list

To add active list:

1. In the main menu, go to **Monitoring** → **Resources** → **Active lists**.
2. Click the **Add active list** button.
3. Do the following:
   a. In the **Name** field, enter a name for the active list.
   b. In the **Tenant** drop-down list, select the tenant that owns the resource.
   c. In the **TTL** field, specify time the record added to the active list is stored in it.
      When the specified time expires, the record is deleted. The time is specified in seconds.
      The default value is 0. If the value of the field is 0, the record is retained for 36,000 days (roughly 100 years).
   d. In the **Description** field, provide any additional information.
      You can use up to 4,000 Unicode characters.
      This field is optional.
4. Click **Save**.

The active list is added.

Viewing the settings of an active list

To view the settings of an active list:

1. In the main menu, go to **Monitoring** → **Resources** → **Active lists**.
2. In the **Name** column, select the active list whose settings you want to view.

This opens the active list settings window. It displays the following information:

- **ID**—identifier selected Active list.
- **Name**—unique name of the resource.
- **Tenant**—the name of the tenant that owns the resource.
- **TTL**—the record added to the active list is stored in it for this time. The value is specified in seconds.
- **Description**—any additional information about the resource.

Changing the settings of an active list

To change the settings of an active list:

1. In the main menu, go to **Monitoring** → **Resources** → **Active lists**.
2. In the **Name** column, select the active list whose settings you want to change.
3. Specify the values of the following parameters:
   - **Name**—unique name of the resource.
   - **TTL**—the record added to the active list is stored in it for this time. The value is specified in seconds. If the field is set to 0, the record is stored indefinitely.
   - **Description**—any additional information about the resource.

> The **ID** and **Tenant** fields are not editable.

Duplicating the settings of an active list

To copy an active list:

1. In the main menu, go to **Monitoring** → **Resources** → **Active lists**.
2. Select the check box next to the active lists you want to copy.
3. Click **Duplicate**.
4. Specify the necessary settings.
5. Click **Save**.

The active list is copied.

Deleting an active list

To delete an active list:

1. In the main menu, go to **Monitoring** → **Resources** → **Active lists**.
2. Select the check boxes next to the active lists you want to delete.
   To delete all lists, select the check box next to the **Name** column.

> At least one check box must be selected.

3. Click the **Delete** button.
4. Click **OK**.

The active lists are deleted.

Viewing records in the active list

To view the records in the active list:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the correlator for which you want to view the active list.
4. Click the **Go to active lists** button.

   The **Correlator active lists** table is displayed.
5. In the **Name** column, select the desired active list.

A table of records for the selected list is opened.

The table contains the following data:

- **Key** – the value of the record key.
- **Record repetitions** – total number of times the record was mentioned in events and identical records were downloaded when importing active lists to KUMA.
- **Expiration date** – date and time when the record must be deleted.

  If the **TTL** field had the value of 0 when the active list was created, the records of this active list are retained for 36,000 days (roughly 100 years).
- **Created** – the time when the active list was created.
- **Updated** – the time when the active list was last updated.

Searching for records in the active list

To find a record in the active list:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the correlator for which you want to view the active list.
4. Click the **Go to active lists** button.

   The **Correlator active lists** table is displayed.

5. In the **Name** column, select the desired active list.

   A window with the records for the selected list is opened.

6. In the **Search** field, enter the record key value or several characters from the key.

The table of records of the active list displays only the records with the key containing the entered characters.

Adding a record to an active list

To add a record to the active list:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the required correlator.
4. Click the **Go to active lists** button.

   The **Correlator active lists** table is displayed.

5. In the **Name** column, select the desired active list.

   A window with the records for the selected list is opened.

6. Click **Add**.

   The **Create record** window opens.

7. Specify the values of the following parameters:

   a. In the **Key** field, enter the name of the record.

   You can specify several values separated by the "|" character.

   > The **Key** field cannot be empty. If the field is not filled in, KUMA returns an error when trying to save the changes.

   b. In the **Value** field, specify the values for fields in the **Field** column.

   KUMA takes field names from the correlation rules with which the active list is associated. These names are not editable. You can delete these fields if necessary.

   c. Click the **Add new element** button to add more values.

   d. In the **Field** column, specify the field name.

   The name must meet the following requirements:

   - To be unique.
   - Do not contain tab characters.
   - Do not contain special characters except for the underscore character.

- The maximum number of characters is 128.

  The name must not begin with an underscore and contain only numbers.

e. In the **Value** column, specify the value for this field.

It must meet the following requirements:

- Do not contain tab characters.
- Do not contain special characters except for the underscore character.
- The maximum number of characters is 1024.

This field is optional.

8. Click **Save**.

The record is added. After saving, the records in the active list are sorted in alphabet order.

Duplicating records in the active list

To duplicate a record in the active list:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the correlator for which you want to view the active list.
4. Click the **Go to active lists** button.

   The **Correlator active lists** table is displayed.
5. In the **Name** column, select the desired active list.

   A window with the records for the selected list is opened.
6. Select the check boxes next to the record you want to copy.
7. Click **Duplicate**.
8. Specify the necessary settings.

   The **Key** field cannot be empty. If the field is not filled in, KUMA returns an error when trying to save the changes.

Editing the field names in the **Field** column is not available for the records that have been added to the active list before. You can change the names only for records added at the time of editing. The name must not begin with an underscore and contain only numbers.

9. Click **Save**.

The record is copied. After saving, the records in the active list are sorted in alphabet order.

Changing a record in the active list

To edit a record in the active list:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the correlator for which you want to view the active list.
4. Click the **Go to active lists** button.

   The **Correlator active lists** table is displayed.
5. In the **Name** column, select the desired active list.

   A window with the records for the selected list is opened.
6. Click the record name in the **Key** column.
7. Specify the required values.
8. Click **Save**.

The record is overwritten. After saving, the records in the active list are sorted in alphabet order.

Restrictions when editing a record:

- The record name is not editable. You can change it by importing the same data with a different name.
- Editing the field names in the **Field** column is not available for the records that have been added to the active list before. You can change the names only for records added at the time of editing. The name must not begin with an underscore and contain only numbers.
- The values in the **Value** column must meet the following requirements:
  - Do not contain Cyrillic characters.
  - Do not contain spaces or tabs.
  - Do not contain special characters except for the underscore character.
  - The maximum number of characters is 128.

Deleting records from the active list

To delete records from the active list:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the correlator for which you want to view the active list.
4. Click the **Go to active lists** button.
   The **Correlator active lists** table is displayed.
5. In the **Name** column, select the desired active list.
   A window with the records for the selected list is opened.
6. Select the check boxes next to the records you want to delete.
   To delete all records, select the check box next to the **Key** column.

   > At least one check box must be selected.

7. Click the **Delete** button.
8. Click **OK**.

The records will be deleted.

Import data to an active list

To import active list:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the correlator for which you want to view the active list.
4. Click the **Go to active lists** button.
   The **Correlator active lists** table is displayed.
5. Point the mouse over the row with the desired active list.
6. Click ... to the left of the active list name.
7. Select **Import**.
   The active list import window opens.
8. In the **File** field select the file you want to import.

9. In the **Format** drop-down list select the format of the file:
   - **csv**
   - **tsv**
   - **internal**
10. Under **Key field**, enter the name of the column containing the active list record keys.
11. Click the **Import** button.

    The data from the file is imported into the active list. The records included in the list before are saved.

Data imported from a file is not checked for invalid characters. If you use this data in widgets, widgets are displayed incorrectly if invalid characters are present in the data.

Exporting data from the active list

To export active list:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. Select the check box next to the correlator for which you want to view the active list.
4. Click the **Go to active lists** button.

   The **Correlator active lists** table is displayed.
5. Point the mouse over the row with the desired active list.
6. Click ... to the left of the desired active list.
7. Click the **Export** button.

   The active list is downloaded in the JSON format using your browsers settings. The name of the downloaded file reflects the name of active list.

Predefined active lists

The active lists listed in the table below are included in the OSMP distribution kit.

Predefined active lists

Active list name	Description
[OOTB][AD] End-users tech support accounts	This active list is used as a filter for the "[OOTB][AD] Successful authentication with same user account on multiple hosts" correlation rule. Accounts of technical support staff may be added to the active list. Records are not deleted from the active list.
[OOTB][AD] List of requested TGT. EventID 4768	This active list is populated by the "[OOTB][AD][Technical] 4768. TGT Requested" rule, this active list is also used in the selector of the "[OOTB][AD] Granted TGS without TGT (Golden Ticket)" rule. Records are removed from the list 10 hours after they are recorded.

[OOTB][AD] List of sensitive groups	This active list is used as a filter for the "[OOTB][AD] Membership of sensitive group was modified" correlation rule. Critical domain groups, whose membership must be monitored, can be added to the active list. Records are not deleted from the active list.
[OOTB][Linux] CompromisedHosts	This active list is populated by the [OOTB] Successful Bruteforce by potentially compromised Linux hosts rule. Records are removed from the list 24 hours after they are recorded.

Dictionaries

Description of parameters

Dictionaries are resources storing data that can be used by other KUMA resources and services.

Dictionaries can be used in the following KUMA services and features:

- Collector.
- Correlation rules.
- Normalizers.

Available settings:

- **Name** (required)—a unique name for this type of resource. Must contain 1 to 128 Unicode characters.
- **Tenant** (required)—name of the tenant that owns the resource.
- **Description**—up to 4,000 Unicode characters describing the resource.
- **Type** (required)—type of dictionary. The selected type determines the format of the data that the dictionary can contain:
  - You can add key-value pairs to the **Dictionary** type.

    It is not recommended to add more than 50,000 entries to dictionaries of this type.

    > When adding lines with the same keys to the dictionary, each new line will overwrite the existing line with the same key. This means that only one line will be added to the dictionary.

  - Data in the form of complex tables can be added to the **Table** type. You can interact with this type of dictionary by using the REST API.
- **Values** settings block—contains a table of dictionary data:

For the **Dictionary** type, this block displays a list of **Key**—**Value** pairs. You can click the + button to add rows to the table. You can delete rows by clicking the × button that appears when you hover your mouse cursor over a row. In the **Key** field, you may optionally specify a unique value: up to 128 Unicode characters, the first character may not be $. In the **Value** field, you may optionally specify a value: up to 255 Unicode characters, the first character may not be $. You may add one or more **Key**–**Value** pairs.

- For the **Table** type, this block displays a table containing data. You can click the + button to add rows and columns to the table. You can delete rows and columns by clicking the × buttons that are displayed when you hover your mouse cursor over a row or a column header. Column headers can be edited.

If the dictionary contains more than 5,000 entries, they are not displayed in the KUMA Console. To view the contents of such dictionaries, the contents must be exported in CSV format. If you edit the CSV file and import it back into KUMA, the dictionary is updated.

Importing and exporting dictionaries

You can import or export dictionary data in CSV format (in UTF-8 encoding) by clicking the **Import CSV** or **Export CSV** buttons.

The format of the CSV file depends on the dictionary type:

- **Dictionary** type:

  ```
  {KEY},{VALUE}\n
  ```

- **Table** type:

  ```
  {Column header 1}, {Column header N}, {Column header N+1}\n
  {Key1}, {ValueN}, {ValueN+1}\n
  {Key2}, {ValueN}, {ValueN+1}\n
  ```

  The keys must be unique for both the CSV file and the dictionary. In tables, the keys are specified in the first column. Keys must contain 1 to 128 Unicode characters.

  Values must contain 0 to 256 Unicode characters.

During an import, the contents of the dictionary are overwritten by the imported file. When imported into the dictionary, the resource name is also changed to reflect the name of the imported file.

If the key or value contains comma or quotation mark characters (, and "), they are enclosed in quotation marks (") when exported. Also, quotation mark character (") is shielded with additional quotation mark (").

If incorrect lines are detected in the imported file (for example, invalid separators), these lines will be ignored during import into the dictionary, and the import process will be interrupted during import into the table.

Interacting with dictionaries via API

You can use the REST API to read the contents of **Table**-type dictionaries. You can also modify them even if these resources are being used by active services. This lets you, for instance, configure enrichment of events with data from dynamically changing tables exported from third-party applications.

Predefined dictionaries

The dictionaries listed in the table below are included in the OSMP distribution kit.

Predefined dictionaries

Dictionary name	Type	Description
[OOTB] Ahnlab. Severity	dictionary	Contains a table of correspondence between a priority ID and its name.
[OOTB] Ahnlab. SeverityOperational	dictionary	Contains values of the SeverityOperational parameter and a corresponding description.
[OOTB] Ahnlab. VendorAction	dictionary	Contains a table of correspondence between the ID of the operation being performed and its name.
[OOTB] Cisco ISE Message Codes	dictionary	Contains Cisco ISE event codes and their corresponding names.
[OOTB] DNS. Opcodes	dictionary	Contains a table of correspondence between decimal opcodes of DNS operations and their IANA-registered descriptions.
[OOTB] IANAProtocolNumbers	dictionary	Contains the port numbers of transport protocols (TCP, UDP) and their corresponding service names, registered by IANA.
[OOTB] Juniper - JUNOS	dictionary	Contains JUNOS event IDs and their corresponding descriptions.
[OOTB] KEDR. AccountType	dictionary	Contains the ID of the user account type and its corresponding type name.
[OOTB] KEDR. FileAttributes	dictionary	Contains IDs of file attributes stored by the file system and their corresponding descriptions.
[OOTB] KEDR. FileOperationType	dictionary	Contains IDs of file operations from the KATA API and their corresponding operation names.
[OOTB] KEDR. FileType	dictionary	Contains modified file IDs from the KATA API and their corresponding file type descriptions.
[OOTB] KEDR. IntegrityLevel	dictionary	Contains the SIDs of the Microsoft Windows INTEGRITY LEVEL parameter and their corresponding descriptions.
[OOTB] KEDR. RegistryOperationType	dictionary	Contains IDs of registry operations from the KATA API and their corresponding values.
[OOTB] Linux. Sycall types	dictionary	Contains Linux call IDs and their corresponding names.
[OOTB] MariaDB Error Codes	dictionary	The dictionary contains MariaDB error codes and is used by the [OOTB] MariaDB Audit Plugin syslog normalizer to enrich events.
[OOTB] Microsoft SQL Server codes	dictionary	Contains MS SQL Server error IDs and their corresponding descriptions.
[OOTB] MS DHCP Event IDs Description	dictionary	Contains Microsoft Windows DHCP server event IDs and their corresponding descriptions.
[OOTB] S-Terra. Dictionary MSG ID to Name	dictionary	Contains IDs of S-Terra device events and their corresponding event names.
[OOTB] S-Terra. MSG_ID to Severity	dictionary	Contains IDs of S-Terra device events and their corresponding Severity values.
[OOTB] Syslog Priority To Facility and Severity	table	The table contains the **Priority** values and the corresponding **Facility and Severity** field values.
[OOTB] VipNet Coordinator Syslog Direction	dictionary	Contains direction IDs (sequences of special characters) used in ViPNet Coordinator to designate a direction, and their corresponding values.
[OOTB] Wallix EventClassId - DeviceAction	dictionary	Contains Wallix AdminBastion event IDs and their corresponding descriptions.
[OOTB] Windows.Codes (4738)	dictionary	Contains operation codes present in the MS Windows audit event with ID 4738 and their corresponding names.
[OOTB] Windows.Codes (4719)	dictionary	Contains operation codes present in the MS Windows audit event with ID 4719 and their corresponding names.
[OOTB] Windows.Codes (4663)	dictionary	Contains operation codes present in the MS Windows audit event with ID 4663 and their corresponding names.
[OOTB] Windows.Codes (4662)	dictionary	Contains operation codes present in the MS Windows audit event with ID 4662 and their corresponding names.

[OOTB] Windows. EventIDs and Event Names mapping	dictionary	Contains Windows event IDs and their corresponding event names.
[OOTB] Windows. FailureCodes (4625)	dictionary	Contains IDs from the **Failure Information\Status** and **Failure Information\Sub Status** fields of Microsoft Windows event 4625 and their corresponding descriptions.
[OOTB] Windows. ImpersonationLevels (4624)	dictionary	Contains IDs from the **Impersonation level** field of Microsoft Windows event 4624 and their corresponding descriptions.
[OOTB] Windows. KRB ResultCodes	dictionary	Contains Kerberos v5 error codes and their corresponding descriptions.
[OOTB] Windows. LogonTypes (Windows all events)	dictionary	Contains IDs of user logon types and their corresponding names.
[OOTB] Windows_Terminal Server. EventIDs and Event Names mapping	dictionary	Contains Microsoft Terminal Server event IDs and their corresponding names.
[OOTB] Windows. Validate Cred. Error Codes	dictionary	Contains IDs of user logon types and their corresponding names.
[OOTB] ViPNet Coordinator Syslog Direction	dictionary	Contains direction IDs (sequences of special characters) used in ViPNet Coordinator to designate a direction, and their corresponding values.
[OOTB] Syslog Priority To Facility and Severity	table	Contains the Priority values and the corresponding Facility and Severity field values.

Response rules

Response rules let you initiate automatic running of Kaspersky Security Center tasks, Threat Response actions for Kaspersky Endpoint Detection and Response, KICS for Networks, Active Directory, and running a custom script for specific events.

Automatic execution of Kaspersky Security Center tasks, Kaspersky Endpoint Detection and Response tasks, and KICS for Networks and Active Directory tasks in accordance with response rules is available when integrated with the relevant programs.

You can configure response rules under **Monitoring → Resources → Response rules**, and then select the created response rule from the drop-down list in the correlator settings. You can also configure response rules directly in the correlator settings.

Response rules for Kaspersky Security Center

You can configure response rules to automatically start tasks of anti-virus scan and updates on Kaspersky Security Center assets.

When creating and editing response rules for Kaspersky Security Center, you need to define values for the following settings.

General tab

Response rule settings

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
Type	Required setting, available if KUMA is integrated with Kaspersky Security Center. Response rule **osmptasks**.
Open Single Management Platform task	Required setting. Name of the Kaspersky Security Center task to run. Tasks must be created beforehand, and their names must begin with "`KUMA`". For example, `KUMA antivirus check` (not case-sensitive and without quotation marks). You can use KUMA to run the following types of Kaspersky Security Center tasks: • Update • Virus scan
Event field	Required setting. Defines the event field of the asset for which the Kaspersky Security Center task should be started. Possible values: • SourceAssetID • DestinationAssetID • DeviceAssetID
Workers	The number of processes that the service can run simultaneously. By default, the number of workers is the same as the number of virtual processors on the server where the service is installed.
Description	Description of the response rule. You can add up to 4,000 Unicode characters.

Setting	Description
Filter	Used to define the conditions for the events to be processed using the response rule. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Setting	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

To send requests to Kaspersky Security Center, you must ensure that Kaspersky Security Center is available over the UDP protocol.

If response rules are owned by the Shared tenant, then the tasks from the Kaspersky Security Center server to which the Main tenant is connected are displayed as Kaspersky Security Center tasks available for selection.

If a response rule has a selected task that is absent from the Kaspersky Security Center Server that the tenant is connected to, the task is not performed for assets of this tenant. This situation can arise, for example, when two tenants are using a common correlator.

Services tab

This tab is displayed only when you edit the settings of the created response rule; on this tab, you can link the rule to correlators.

To link a response rule to a correlator, click the **Link to service** button → **Link to correlator**. This opens a window; in that window, select one or more correlators and click **OK**. The response rule is linked to the selected correlators and is applied in accordance with their configuration.

If necessary, you can unlink the response rule from a service. To do this, select the check box next to the relevant correlator, click **Delete**, and confirm the unlinking from the service.

Response rules for a custom script

You can create a script containing commands to be executed on the KUMA server when selected events are detected and configure response rules to automatically run this script. In this case, the program will run the script when it receives events that match the response rules.

The script file is stored on the server where the correlator service using the response resource is installed: /opt/kaspersky/kuma/correlator/<Correlator ID>/scripts. The `kuma` user of this server requires the permissions to run the script.

When creating and editing response rules for a custom script, you need to define values for the following parameters.

General tab

Response rule settings

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
Type	Required setting. Response rule type, **script**.
Timeout	The number of seconds allotted for the script to finish. If this amount of time is exceeded, the script is terminated.
Script name	Required setting. Name of the script file. If the response resource is attached to the correlator service but there is no script file in the /opt/kaspersky/kuma/correlator/<Correlator ID>/scripts folder, the correlator will not work.
Script arguments	Arguments or event field values that must be passed to the script. If the script includes actions taken on files, you should specify the absolute path to these files. Parameters can be written with quotation marks ("). Event field names are passed in the `{{.EventField}}` format, where `EventField` is the name of the event field which value must be passed to the script. Example: `-n "\"usr\": {{.SourceUserName}}"`
Workers	The number of processes that the service can run simultaneously. By default, the number of workers is the same as the number of virtual processors on the server where the service is installed.
Description	Description of the resource. You can add up to 4,000 Unicode characters.

Setting	Description
Filter	Used to define the conditions for the events to be processed using the response rule. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand. d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

Setting	Description
	You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when you edit the settings of the created response rule; on this tab, you can link the rule to correlators.

To link a response rule to a correlator, click the **Link to service** button → **Link to correlator**. This opens a window; in that window, select one or more correlators and click **OK**. The response rule is linked to the selected correlators and is applied in accordance with their configuration.

If necessary, you can unlink the response rule from a service. To do this, select the check box next to the relevant correlator, click **Delete**, and confirm the unlinking from the service.

Response rules for KICS for Networks

You can configure response rules to automatically trigger response actions on KICS for Networks assets. For example, you can change the asset status in KICS for Networks.

When creating and editing response rules for KICS for Networks, you need to define values for the following settings.

General tab

Response rule settings

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
Type	Required setting. Response rule type, **kics**.
Event field	Required setting. Specifies the event field for the asset for which response actions must be performed. Possible values: • SourceAssetID • DestinationAssetID • DeviceAssetID

Setting	Description
KICS for Networks task	Response action to be performed when data is received that matches the filter. The following types of response actions are available: • **Change asset status to Authorized**. • **Change asset status to Unauthorized**. When a response rule is triggered, KUMA will send KICS for Networks an API request to change the status of the specified device to **Authorized** or **Unauthorized**.
Workers	The number of processes that the service can run simultaneously. By default, the number of workers is the same as the number of virtual processors on the server where the service is installed.
Description	Description of the resource. You can add up to 4,000 Unicode characters.

Setting	Description
Filter	Used to define the conditions for the events to be processed using the response rule. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand.

Setting	Description
	d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**. You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when you edit the settings of the created response rule; on this tab, you can link the rule to correlators.

To link a response rule to a correlator, click the **Link to service** button → **Link to correlator**. This opens a window; in that window, select one or more correlators and click **OK**. The response rule is linked to the selected correlators and is applied in accordance with their configuration.

If necessary, you can unlink the response rule from a service. To do this, select the check box next to the relevant correlator, click **Delete**, and confirm the unlinking from the service.

Response rules for Kaspersky Endpoint Detection and Response

You can configure response rules to automatically trigger response actions on Kaspersky Endpoint Detection and Response assets. For example, you can configure automatic asset network isolation.

When creating and editing response rules for Kaspersky Endpoint Detection and Response, you need to define values for the following settings.

General tab

Response rule settings

Setting	Description
Event field	Required setting. Specifies the event field for the asset for which response actions must be performed. Possible values: • SourceAssetID • DestinationAssetID • DeviceAssetID

Setting	Description
Task type	Response action to be performed when data is received that matches the filter. The following types of response actions are available: • Enable network isolation. When selecting this type of response, you need to define values for the following setting: • **Isolation timeout**—the number of hours during which the network isolation of an asset will be active. You can indicate from 1 to 9,999 hours. If necessary, you can **add an exclusion for network isolation**. *To add an exclusion for network isolation:* a. Click the **Add exclusion** button. b. Select the direction of network traffic that must not be blocked: • Inbound. • Outbound. • Inbound/Outbound. c. In the **Asset IP** field, enter the IP address of the asset whose network traffic must not be blocked. d. If you selected **Inbound** or **Outbound**, specify the connection ports in the **Remote ports** and **Local ports** fields. e. If you want to add more than one exclusion, click **Add exclusion** and repeat the steps to fill in the **Traffic direction**, **Asset IP**, **Remote ports** and **Local ports** fields. f. If you want to delete an exclusion, click the **Delete** button under the relevant exclusion. When adding exclusions to a network isolation rule, Kaspersky Endpoint Detection and Response may incorrectly display the port values in the rule details. This does not affect application performance. For more details on viewing a network isolation rule, please refer to the *Kaspersky Anti Targeted Attack Platform Help Guide*. • Disable network isolation. • Add prevention rule. When selecting this type of response, you need to define values for the following settings: • **Event fields to extract hash from**—event fields from which KUMA extracts SHA256 or MD5 hashes of files that must be prevented from running. The selected event fields, as well as the values selected in **Event field**, must be added to the propagated fields of the correlation rule. • **File hash #1**—SHA256 or MD5 hash of the file to be blocked. At least one of the above fields must be completed. • Delete prevention rule. • Start application When selecting this type of response, you need to define values for the following settings: • **File path**—path to the file of the process that you want to start. • **Command line parameters**—parameters with which you want to start the file. • **Working directory**—directory in which the file is located at the time of startup. When a response rule is triggered for users with the Main administrator role, the **Run program** task will be displayed in the **Task manager** section of the program console. In the Created by column of the **task table**, **Scheduled task** is displayed for this task. You can view task completion results. All of the listed operations can be performed on assets that have Kaspersky Endpoint Agent for Windows. On assets that have Kaspersky Endpoint Agent for Linux, the program can only be started. At the software level, the capability to create prevention rules and network isolation rules for assets with Kaspersky Endpoint Agent for Linux is unlimited. KUMA and Kaspersky Endpoint Detection and Response do not provide any notifications about unsuccessful application of these rules.
Workers	The number of processes that the service can run simultaneously. By default, the number of workers is the same as the number of virtual processors on the server where the service is installed.
Description	Description of the response rule. You can add up to 4,000 Unicode characters.

Setting	Description
Filter	Used to define the conditions for the events to be processed using the response rule. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand. d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

Setting	Description
	You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when you edit the settings of the created response rule; on this tab, you can link the rule to correlators.

To link a response rule to a correlator, click the **Link to service** button → **Link to correlator**. This opens a window; in that window, select one or more correlators and click **OK**. The response rule is linked to the selected correlators and is applied in accordance with their configuration.

If necessary, you can unlink the response rule from a service. To do this, select the check box next to the relevant correlator, click **Delete**, and confirm the unlinking from the service.

Active Directory response rules

Active Directory response rules define the actions to be applied to an account if a rule is triggered.

When creating and editing response rules using Active Directory, specify the values for the following settings.

General tab

Response rule settings

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource.
Type	Required setting. Response rule type, **Response via Active Directory**.
Account ID source	Event field from which the Active Directory account ID value is taken. Possible values: • SourceAccountID • DestinationAccountID

Setting	Description
AD command	Command that is applied to the account when the response rule is triggered. Available values: • **Add account to group** The Active Directory group to move the account from or to. In the mandatory field **Distinguished name**, you must specify the full path to the group. For example, CN = Team, OU = Groups, OU = ExchangeObjects, DC = example, DC = com. Only one group can be specified within one operation. • **Remove account from group** The Active Directory group to move the account from or to. In the mandatory field **Distinguished name**, you must specify the full path to the group. For example, CN = Team, OU = Groups, OU = ExchangeObjects, DC = example, DC = com. Only one group can be specified within one operation. • Reset account password If your Active Directory domain allows selecting the **User cannot change password** check box, resetting the user account password as a response will result in a conflict of requirements for the user account: the user will not be able to authenticate. The domain administrator will need to clear one of the check boxes for the affected user account: **User cannot change password** or **User must change password at next logon**. • Block account

Setting	Description
Filter	Used to define the conditions for the events to be processed using the response rule. You can select an existing filter from the drop-down list or create a new filter. **Creating a filter in resources** All fields of a KUMA event have a default value. For all numeric fields, the default value is 0. For all string fields, the default value is an empty string. An event not having a field means the field has the default value. Therefore, an event can trigger a filter even if the event does not have the field specified in the filter. For example, if you specify a `DestinationPort <= 1024` condition in the filter, but the event does not contain the `DestinationPort` field, the filter is triggered anyway because `DestinationPort = 0` by default. *To create a filter:* 1. In the **Filter** drop-down list, select **Create new**. 2. If you want to keep the filter as a separate resource, select the **Save filter** check box. In this case, you will be able to use the created filter in various services. This check box is cleared by default. 3. If you selected the **Save filter** check box, enter a name for the created filter resource in the **Name** field. Maximum length of the name: 128 Unicode characters. 4. Under **Conditions**, specify the conditions that the events must meet: a. Click the **Add condition** button. b. In the **Left operand** and **Right operand** drop-down lists, specify the search parameters. Depending on the data source selected in the **Right operand** field, fields of additional parameters for identifying the value to be passed to the filter may be displayed. For example, when you select **active list**, you must specify the name of the active list, the entry key, and the entry key field. c. In the **Operator** drop-down list, select an operator. **Filter operators** • **=** means the left operand equals the right operand. • **<** means the left operand is less than the right operand. • **<=** means the left operand is less than or equal to the right operand. • **>** means the left operand is greater than the right operand. • **>=** means the left operand is greater than or equal to the right operand. • **inSubnet** means the left operand (IP address) is in the subnet of the right operand (subnet). • **contains** means the left operand contains values of the right operand. • **startsWith** means the left operand starts with one of the values of the right operand. • **endsWith** means the left operand ends with one of the values of the right operand. • **match** means the left operand matches the regular expression of the right operand. The RE2 regular expressions are used. • **hasBit** checks whether the left operand (string or number) contains bits whose positions are listed in the right operand (in a constant or in a list). The value to be checked is converted to binary and processed right to left. Chars are checked whose index is specified as a constant or a list. If the value being checked is a string, then an attempt is made to convert it to integer and process it in the way described above. If the string cannot be converted to a number, the filter returns `False`. • **hasVulnerability** checks whether the left operand contains an asset with the vulnerability and vulnerability severity specified in the right operand. If you do not specify the ID and severity of the vulnerability, the filter is triggered if the asset in the event being checked has any vulnerability. • The **inActiveList** operator has only one operand. Its values are selected in the **Key fields** field and are compared with the entries in the active list selected from the Active List drop-down list. • **inDictionary** checks whether the specified dictionary contains an entry defined by the key composed with the concatenated values of the selected event fields. • **inCategory** means the asset in the left operand is assigned at least one of the asset categories of the right operand. • **inActiveDirectoryGroup** means the Active Directory account in the left operand belongs to one of the Active Directory groups in the right operand. • The **TIDetect** operator is used to find events using CyberTrace Threat Intelligence (TI) data. This operator can be used only on events that have completed enrichment with data from CyberTrace Threat Intelligence. In other words, it can only be used in collectors at the destination selection stage and in correlators. • **inContextTable** checks for the presence of the entry in the specified context table. • **intersect** checks for the presence in the left operand of the list items specified in the right operand. d. If you want the operator to be case-insensitive, select the **do not match case** check box. This check box does not apply to the **InSubnet**, **InActiveList**, **InCategory**, or **InActiveDirectoryGroup** operators. This check box is cleared by default. e. If you want to add a negative condition, from the **If** drop-down list, select **If not**.

Setting	Description
	You can add multiple conditions or a group of conditions. 5. If you have added multiple conditions or groups of conditions, choose a selection condition (**and**, **or**, **not**) by clicking the **AND** button. 6. If you want to add existing filters that are selected from the **Select filter** drop-down list, click the **Add filter** button. You can view the nested filter settings by clicking the button.

Services tab

This tab is displayed only when you edit the settings of the created response rule; on this tab, you can link the rule to correlators.

To link a response rule to a correlator, click the **Link to service** button → **Link to correlator**. This opens a window; in that window, select one or more correlators and click **OK**. The response rule is linked to the selected correlators and is applied in accordance with their configuration.

If necessary, you can unlink the response rule from a service. To do this, select the check box next to the relevant correlator, click **Delete**, and confirm the unlinking from the service.

Data collection and analysis rules

Data mining rules are used for detecting incidents by analyzing events saved in the OSMP database.

In contrast to streaming correlation and retrospective scanning, data mining rules involve the preprocessing of data using SQL queries (including additional calculations, grouping and aggregation using SQL) and running regularly on a schedule. With correctly configured data mining rules, the SIEM can help you detect advanced threats.

To manage the section, you need one of the following roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

When creating or editing data collection and analysis rules, you need to specify the settings listed in the table below.

Settings of data mining rules

Setting	Description
Name	Required setting. Unique name of the resource. Must contain 1 to 128 Unicode characters.
Tenant	Required setting. The name of the tenant that owns the resource. If you have access to only one tenant, this field is filled in automatically. If you have access to multiple tenants, the name of the first tenant from your list of available tenants is inserted. You can select any tenant from this list.

Setting	Description
SQL	Required setting. The SQL query must contain an aggregation function with a LIMIT and/or a data grouping with a LIMIT. You must use a LIMIT value between 1 and 10,000. Examples of SQL queries • A query containing only an aggregation function: `SELECT count(DeviceCustomFloatingPoint1) AS `Aggregate` FROM `events` WHERE Type = 1 ORDER BY Aggregate DESC LIMIT 10` • A query containing only data grouping: `SELECT SourceAddress, DeviceCustomFloatingPoint1 FROM `events` WHERE Type = 1 GROUP BY SourceAddress, DeviceCustomFloatingPoint1 ORDER BY DeviceCustomFloatingPoint1 DESC LIMIT 10` • A query containing an aggregation function and data grouping: `SELECT SourceAddress, sum(DeviceCustomFloatingPoint1) FROM `events` WHERE Type = 1 GROUP BY SourceAddress, DeviceCustomFloatingPoint1 ORDER BY DeviceCustomFloatingPoint1 DESC LIMIT 10` • A query containing an expression using aggregation functions: `SELECT stddevPop(DeviceCustomFloatingPoint1) + avg(DeviceCustomFloatingPoint1) AS `Aggregate` FROM `events` WHERE Type = 1 ORDER BY Aggregate DESC LIMIT 10`
Query interval	Required setting. The interval for executing the SQL query. You can specify the interval in minutes, hours, and days. The minimum interval is 1 minute. The default timeout of the SQL query is equal to the interval that you specify in this field. If the execution of the SQL query takes longer than the timeout, an error occurs. In this case, we recommend increasing the interval. For example, if the interval is 1 minute, and the query takes 80 seconds to execute, we recommend setting the interval to at least 90 seconds.
Tags	Optional setting. Tags for resource search.
Depth	Optional setting. Expression for the lower bound of the interval for searching events in the database. To select a value from the list or to specify the depth as a relative interval, place the cursor in the field. For example, if you want to find all events from one hour ago to now, set the relative interval of now-1h.
Description	Optional setting. Description of data collection and analysis rules.
Mapping	Settings of the mapping the fields of an SQL query result to KUMA events: **Source field** is the field from the SQL query result that you want to convert into a KUMA event. **Event field** is the KUMA event field. You can select one of the values in the list by placing the mouse cursor in this field. **Label** is a unique custom label for event fields that begin with `DeviceCustom*`. You can add new table rows or delete table rows. To add a new table row, click **Add mapping**. To delete a row, select the check box next to the row and click the button. If you do not want to fill in the fields manually, you can click the **Update mapping from SQL** button. The field mapping table is populated with the values of the SQL query fields, including aliases (if any). For example, if the value of an SQL query field is `SourceAddress` and this value is the same as the name of an event field, this value is inserted into in the **Event field** column in the field mapping table. Clicking the **Update mapping from SQL** button again does not refresh the table, and fields from the SQL query are added to it again.

You can create a data collection and analysis rule in one of the following ways:

- In the **Dashboard** → **Resources and services** → **Data mining rules** section.

1. In the **Dashboard** → **Threat Hunting** section.

*To create a data collection and analysis rule in the **Threat Hunting** section:*

1. Create or generate an SQL query and click the **Create data mining rule** button.

   A new browser tab for creating a data collection and analysis rule is opened in the browser with pre-filled **SQL query** and **Depth** fields. The field mapping table is also be populated automatically if you did not use an asterisk (*) in the SQL query.

2. Fill in the required fields.

   If necessary, you can change the value in the **SQL query period** field.

3. Save the settings.

   The data collection and analysis rule is saved and is available in the **Monitoring → Resources and services → Data collection and analysis rules** section. For a data mining rule to be applied, you need to create a schedule for it.

Virtual Administration Server

Virtual Administration Server (also referred to as *virtual Server*) is a component of Kaspersky EDR Expert intended for managing anti-virus protection of the network of a client organization.

A virtual Administration Server is a special case of a secondary Administration Server and has the following restrictions as compared to a physical Administration Server:

- A virtual Administration Server can be created only on a primary Administration Server.
- A virtual Administration Server relies on the database of the primary Administration Server. Data backup and restoration tasks, as well as update, scan and download tasks, are not supported on a virtual Administration Server.
- A virtual Administration Server does not support creation of secondary Administration Servers (including virtual servers).

In addition, virtual Administration Server has the following restrictions:

- In the virtual Administration Server properties window, the number of sections is limited.
- To install Kaspersky applications remotely on client devices managed by the virtual Administration Server, you must make sure that Network Agent is installed on one of the client devices, in order to ensure communication with the virtual Administration Server. Upon first connection to the virtual Administration Server, the device is automatically assigned as a distribution point, thus functioning as a connection gateway between the client devices and the virtual Administration Server.
- A virtual Server can poll the network only through distribution points.
- To restart a malfunctioning virtual Server, Kaspersky EDR Expert restarts the primary Administration Server and all virtual Administration Servers.
- Users created on a virtual Server cannot be assigned a role on the Administration Server.

The administrator of a virtual Administration Server has all privileges on this particular virtual Server.

Connectors

Connectors are used for establishing connections between KUMA services and receiving events actively and passively.

The program has the following connector types available:

- tcp—used to receive data over TCP passively.
- udp—used to receive data over UDP passively.
- netflow—used to passively receive events in the NetFlow format.
- sflow—used to passively receive events in the SFlow format.
- nats-jetstream—used for communication with the NATS message broker.
- kafka—used for communication with the Apache Kafka data bus.
- http—used for receiving events over HTTP.
- sql—used for selecting data from a database.
  The program supports the following types of SQL databases:
  - SQLite.
  - MSSQL.
  - MySQL.
  - PostgreSQL.
  - Cockroach.
  - Oracle.
  - Firebird.
  - ClickHouse
- file—used to retrieve data from a text file.
- 1c-log and 1c-xml are used to receive data from 1C logs.
- diode—used for unidirectional data transfer in industrial ICS networks using data diodes.
- ftp—used to receive data over the File Transfer Protocol.
- sftp—used to receive data over the Secure File Transfer Protocol.
- nfs—used to receive data over the Network File System protocol.
- wmi—used to obtain data using Windows Management Instrumentation.
- wec—used to receive data using Windows Event Forwarding (WEF) and Windows Event Collector (WEC), or local operating system logs of a Windows host.
- snmp—used to receive data using the Simple Network Management Protocol.
- snmp-trap—used to receive data using Simple Network Management Protocol traps (SNMP traps).

- kata/edr—used to receive KEDR data via the API.
- vmware—used to receive VMware vCenter data via the API.
- elastic—used to receive Elasticsearch data.
- etw—used to receive extended DNS server logs.
- universalAPI—used to receive data from any REST APIs that support JSON responses. Filtering by unique ID and iteration mode are supported.
- smb—used to receive data over the SMB (Server Message Block) protocol.
- http-streaming—used for receiving streamed events over HTTP. The connector processes the request body in parts, which reduces memory usage.

Viewing connector settings

To view connector settings:

1. In the main menu, go to **Monitoring** → **Resources** → **Connectors**.
2. In the folder structure, select the folder containing the relevant connector.
3. Select the connector whose settings you want to view.

The settings of connectors are displayed on two tabs: **Basic settings** and **Advanced settings**. For a detailed description of each connector settings, please refer to the *Connector settings* section.

Adding a connector

You can enable the display of non-printing characters for all entry fields except the **Description** field.

To add a connector:

1. In the main menu, go to **Monitoring** → **Resources** → **Connectors**.
2. In the folder structure, select the folder in which you want the connector to be located.

   Root folders correspond to tenants. To make a connector available to a specific tenant, the resource must be created in the folder of that tenant.

   If the required folder is absent from the folder tree, you need to create it.

   By default, added connectors are created in the **Shared** folder.
3. Click the **Add connector** button.

4. Define the settings for the selected connector type.

   The settings that you must specify for each type of connector are provided in the *Connector settings* section.

5. Click **Save**.

Connector settings

This section describes the settings of all connector types supported by KUMA.

kata/edr type

When creating this type of connector, you need to define values for the following settings:

Basic settings tab:

- **Name** (required)—a unique name for this type of resource. Must contain 1 to 128 Unicode characters.
- **Tenant** (required)—name of the tenant that owns the resource.
- **Type** (required)—connector type, **kata/edr**.
- **URL** (required)—URL at which telemetry can be received from the KATA/EDR server. The URL must include the host and the port; the default port is 443. If KATA/EDR is deployed in a cluster, you can specify multiple URLs to ensure high availability of the connection.
- **Secret** (required) is a drop-down list in which you can select the secret which stores the credentials for connecting to the KATA/EDR server. You can select the secret resource from the drop-down list or create one by clicking the plus icon (+). When creating a secret, you can specify a user certificate and private key, or automatically generate a new self-signed certificate and private key. The selected secret can be changed by clicking the pencil icon ( ).
- **External ID**—ID for external systems. KUMA generates an ID in this field automatically.
- **Description**—resource description: up to 4,000 Unicode characters.

Advanced settings tab:

- **Debug**—a toggle switch that lets you specify whether resource logging must be enabled. By default, this toggle switch is in the **Disabled** position.
- **Character encoding**—the source character encoding setting for conversion to UTF-8. We only recommend configuring a conversion if you find invalid characters in the fields of the normalized event. Default value: not selected.
- **Number of events**—maximum number of events in one request. By default, the value set on the KATA/EDR server is used.
- **Events fetch timeout** is the time in seconds to wait for receipt of events from the KATA/EDR server. The default value is 0, which means that the value specified on the KATA/EDR server is used.

- **Client timeout** is the time in seconds to wait for a response from the KATA/EDR server. Default value: 1,800 s; displayed as 0.

- **KEDRQL filter**—filter of requests to the KATA/EDR server. For more details on the query language, please refer to the KEDR Help.

Secrets

Secrets are used to securely store sensitive information such as user names and passwords that must be used by KUMA to interact with external services. If a secret stores account data such as user login and password, when the collector connects to the event source, the user account specified in the secret may be blocked in accordance with the password policy configured in the event source system.

Secrets can be used in the following KUMA services and features:

- Collector (when using TLS encryption).

- Connector (when using TLS encryption).

- Destinations (when using TLS encryption or authorization).

- Proxy servers.

Available settings:

- **Name** (required)—a unique name for this type of resource. Must contain 1 to 128 Unicode characters.

- **Tenant** (required)—name of the tenant that owns the resource.

- **Type** (required)—the type of secret.

  When you select the type in the drop-down list, the parameters for configuring this secret type also appear. These parameters are described below.

- **Description**—up to 4,000 Unicode characters.

Depending on the secret type, different fields are available. You can select one of the following secret types:

- **credentials**—this type of secret is used to store account credentials required to connect to external services, such as SMTP servers. If you select this type of secret, you must fill in the **User** and **Password** fields. If the **Secret** resource uses the 'credentials' type to connect the collector to an event source, for example, a database management system, the user account specified in the secret may be blocked in accordance with the password policy configured in the event source system.

  When changing a previously saved secret of the credentials type, the user name and password fields are displayed empty. The values of these fields are preserved, you do not need to enter them again.

- **token**—this secret type is used to store tokens for API requests. Tokens are used when connecting to IRP systems, for example. If you select this type of secret, you must fill in the **Token** field.

- **ktl**—this secret type is used to store Kaspersky Threat Intelligence Portal account credentials. If you select this type of secret, you must fill in the following fields:
  - **User** and **Password** (required fields)—user name and password of your Kaspersky Threat Intelligence Portal account.
  - **PFX file** (required)—lets you upload a Kaspersky Threat Intelligence Portal certificate key.
  - **PFX password** (required)—the password for accessing the Kaspersky Threat Intelligence Portal certificate key.
- **urls**—this secret type is used to store URLs for connecting to SQL databases and proxy servers. In the **Description** field, you must provide a description of the connection for which you are using the secret of **urls** type.

  You can specify URLs in the following formats: hostname:port, IPv4:port, IPv6:port, :port.
- **pfx**—this type of secret is used for importing a PFX file containing certificates. If you select this type of secret, you must fill in the following fields:
  - **PFX file** (required)—this is used to upload a PFX file. The file must contain a certificate and key. PFX files may include CA-signed certificates for server certificate verification.
  - **PFX password** (required)—this is used to enter the password for accessing the certificate key.
- **kata/edr**—this type of secret is used to store the certificate file and private key required when connecting to the Kaspersky Endpoint Detection and Response server. If you select this type of secret, you must upload the following files:
  - Certificate file—KUMA server certificate.

    The file must be in PEM format. You can upload only one certificate file.
  - Private key for encrypting the connection—KUMA server RSA key.

    The key must be without a password and with the PRIVATE KEY header. You can upload only one key file.

    > You can generate certificate and key files by clicking the ⬇ button.
- **snmpV1**—this type of secret is used to store the value of **Community** (for example, `public` or `private`) that is required for interaction over the Simple Network Management Protocol.
- **snmpV3**—this type of secret is used for storing data required for interaction over the Simple Network Management Protocol. If you select this type of secret, you must fill in the following fields:
  - **User**—user name indicated without a domain.
  - **Security Level**—security level of the user.
    - **NoAuthNoPriv**—messages are forwarded without authentication and without ensuring confidentiality.
    - **AuthNoPriv**—messages are forwarded with authentication but without ensuring confidentiality.
    - **AuthPriv**—messages are forwarded with authentication and ensured confidentiality.

    Additional settings depending on the selected level may be displayed.

- **Password**—SNMP user authentication password. This field becomes available when the **AuthNoPriv** or **AuthPriv** security level is selected.
- **Authentication Protocol**—the following protocols are available: MD5, SHA, SHA224, SHA256, SHA384, SHA512. This field becomes available when the **AuthNoPriv** or **AuthPriv** security level is selected.
- **Privacy Protocol**—protocol used for encrypting messages. Available protocols: DES, AES. This field becomes available when the **AuthPriv** security level is selected.
- **Privacy password**—encryption password that was set when the SNMP user was created. This field becomes available when the **AuthPriv** security level is selected.

- **certificate**—this secret type is used for storing certificate files. Files are uploaded to a resource by clicking the **Upload certificate file** button. X.509 certificate public keys in Base64 are supported.
- **ssh private key**—this secret type is used in a SFTP connector for connecting to a SFTP server. If you select this type of secret, you must specify a user name and a file containing a private SSH key.

Predefined secrets

The secrets listed in the table below are included in the OSMP distribution kit.

Predefined secrets

Secret name	Description
[OOTB] Continent SQL connection	Stores confidential data and settings for connecting to the APKSh Kontinent database. To use it, you must specify the login name and password of the database.
[OOTB] KSC MSSQL connection	Stores confidential data and settings for connecting to the MS SQL database of Kaspersky Security Center (KSC). To use it, you must specify the login name and password of the database.
[OOTB] KSC MySQL Connection	Stores confidential data and settings for connecting to the MySQL database of Kaspersky Security Center (KSC). To use it, you must specify the login name and password of the database.
[OOTB] Oracle Audit Trail SQL Connection	Stores confidential data and settings for connecting to the Oracle database. To use it, you must specify the login name and password of the database.
[OOTB] SecretNet SQL connection	Stores confidential data and settings for connecting to the MS SQL database of the SecretNet system. To use it, you must specify the login name and password of the database.

Context tables

A *context table* is a container for a data array that is used by KUMA correlators for analyzing events in accordance with correlation rules. You can create context tables in the **Monitoring** → **Resources** section. The context table data is stored only in the correlator to which it was added using filters or actions in correlation rules.

You can populate context tables automatically using correlation rules of 'simple' and 'operational' types or import a file with data for the context table.

You can add, copy, and delete context tables, as well as edit their settings.

Context tables can be used in the following KUMA services and features:

- Correlation rules.
- Dashboard.

The same context table can be used in multiple correlators. However, a separate entity of the context table is created for each correlator. Therefore, the contents of the context tables used by different correlators are different even if the context tables have the same name and ID.

Only data based on correlation rules of the correlator are added to the context table.

You can add, edit, delete, import, and export records in the context table of the correlator.

During the correlation process, when entries are deleted from context tables, service events are generated in the correlators. These events only exist in the correlators, and they are not redirected to other destinations. Service events are sent for processing by correlation rules of that correlator which uses the context table. Correlation rules can be configured to track these events so that they can be used to identify threats.

Service event fields for deleting an entry from a context table are described below.

Event field	Value or comment
`ID`	Event ID
`Timestamp`	Time when the expired entry was deleted
`Name`	`"context table record expired"`
`DeviceVendor`	`"Kaspersky"`
`DeviceProduct`	`"KUMA"`
`ServiceID`	Correlator ID
`ServiceName`	Correlator name
`DeviceExternalID`	Context table ID
`DevicePayloadID`	Key of the expired entry
`BaseEventCount`	Number of updates for the deleted entry, incremented by one
`FileName`	Name of the context table.

`S.<context table field>`
`SA.<context table field>`
`N.<context table field>`
`NA.<context table field>`
`F.<context table field>`
`FA.<context table field>`
	Depending on the type of the entry that dropped out from the context table, the dropped-out context table entry is recorded in the corresponding type of event:
	for example, S.<`context table field`>=<`context table field value`>
	SA.<`context table field`>=<`array of context table field values`>
	
	Context table records of the boolean type have the following format:
	S.<`context table field`> = true/false
	SA.<`context table field`> = false,true,false

Viewing the list of context tables

To view the context table list of the correlator:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. In the context menu of the correlator for which you want to view context tables, select **Go to context tables**.

   The **Correlator context tables** list is displayed.

The table contains the following data:

- **Name**—name of the context table.
- **Size on disk**—size of the context table.
- **Directory**—path to the context table on the KUMA correlator server.

Adding a context table

To add a context table:

1. In the main menu, go to **Monitoring** → **Resources** → **Context tables**.
2. In the **Context tables** window, click **Add**.

   This opens the **Create context table** window.
3. In the **Name** field, enter a name for the context table.
4. In the **Tenant** drop-down list, select the tenant that owns the resource.
5. In the **TTL** field, specify time the record added to the context table is stored in it.

   When the specified time expires, the record is deleted. The time is specified in seconds. The maximum value is `31536000` (1 year).

   The default value is `0`. If the value of the field is 0, the record is stored indefinitely.
6. In the **Description** field, provide any additional information.

   You can use up to 4,000 Unicode characters.

   This field is optional.
7. In the **Schema** section, specify which fields the context table has and the data types of the fields.

   Depending on the data type, a field may or may not be a key field. At least one field in the table must be a key field. The names of all fields must be unique.

To add a table row, click **Add** and fill in the table fields:

a. In the **Name** field, enter the name of the field. The maximum length is 128 characters.

b. In the **Type** drop-down list, select the data type for the field.

Possible field data types

Possible data types of context table fields

Field data type	Can be a key field	Comment
Integer	Yes	—
Float	Yes	—
String	Yes	—
Boolean	Yes	—
Timestamp	Yes	For a field of this type, it is checked that the field value is greater than or equal to zero. No other operations are provided.
IP address	Yes	For a field of this type, it is checked that the field value corresponds to the IPv4, IPv6 format. No other operations are provided.
Integer list	No	—
Float list	No	—
List of strings	No	—
Boolean list	No	—
Timestamp list	No	For a field of this type, it is checked that each item in the list is greater than or equal to zero. No other operations are provided.
IP list	No	For a field of this type, it is checked that each item of the list corresponds to the IPv4, IPv6 format. No other operations are provided.

c. If you want to make a field a key field, select the **Key field** check box.

A table can have multiple key fields. Key fields are chosen when the context table is created, uniquely identify a table entry and cannot be changed.

If a context table has multiple key fields, each table entry is uniquely identified by multiple fields (composite key).

8. Add the required number of context table rows.

After saving the context table, the schema cannot be changed.

9. Click **Save**.

The context table is added.

Viewing context table settings

To view the context table settings:

1. In the main menu, go to **Monitoring** → **Resources** → **Context tables**.
2. In the list in the **Context tables** window, select the context table whose settings you want to view.

   This opens the context table settings window. It displays the following information:

- **Name**—unique name of the resource.
- **Tenant**—the name of the tenant that owns the resource.
- **TTL**—the record added to the context table is stored in it for this duration. The value is specified in seconds.
- **Description**—any additional information about the resource.
- **Schema** is an ordered list of fields and their data types, with key fields marked.

Editing context table settings

To edit context table settings:

1. In the main menu, go to **Monitoring** → **Resources** → **Context tables**.
2. In the list in the **Context tables** window, select the context table whose settings you want to edit.
3. Specify the values of the following parameters:

   - **Name**—unique name of the resource.
   - **TTL**—the record added to the context table is stored in it for this duration. The value is specified in seconds.
   - **Description**—any additional information about the resource.
   - **Schema** is an ordered list of fields and their data types, with key fields marked. If the context table is not used in a correlation rule, you can edit the list of fields.

     If you want to edit the schema in a context table that is already being used in a correlation rule, follow the steps below.

   The **Tenant** field is not available for editing.
4. Click **Save**.

To edit the settings of the context table previously used by the correlator:

1. Export data from the table.
2. Copy and save the path to the file with the data of the table on the disk of the correlator. This path is specified in the **Directory** column in the **Correlator context tables** window. You will need this path later to delete the file from the disk of the correlator.
3. Delete the context table from the correlator.
4. Edit context table settings as necessary.
5. Delete the file with data of the table on the disk of the correlator at the path from step 2.
6. Add the context table in which you edited the settings to the correlator.
7. To restart the correlator, in the **Resources** → **Active services** section, in the list of services, select the check box next to the relevant correlator, click the three-dots icon on the toolbar and in the displayed menu, select **Restart**.
8. Adapt the fields in the exported table (see step 1) so that they match the fields of the table that you uploaded to the correlator at step 6.
9. Import the adapted data into the context table.

Duplicating context table settings

To copy a context table:

1. In the main menu, go to **Monitoring** → **Resources** → **Context tables**.
2. Select the check box next to the context table that you want to copy.
3. Click **Duplicate**.
4. Specify the necessary settings.
5. Click **Save**.

The context table is copied.

Deleting a context table

You can delete only those context tables that are not used in any of the correlators.

To delete a context table:

1. In the main menu, go to **Monitoring** → **Resources** → **Context tables**.
2. Select the check boxes next to the context tables that you want to delete.

   To delete all context tables, select the check box next to the **Name** column.

At least one check box must be selected.

3. Click the **Delete** button.
4. Click **OK**.

The context tables are deleted.

Viewing context table records

To view a list of context table records:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. In the context menu of the correlator for which you want to view the context table, select **Go to context tables**.

   This opens the **Correlator context tables** window.
4. In the **Name** column, select the relevant context table.

The list of records for the selected context table is displayed.

The list contains the following data:

- **Key** is the composite key of the record. It is comprised by one or more values of key fields, separated by the "|" character. If one of the key field values is absent, the separator character is still displayed.

  For example, a record key consists of three fields: `DestinationAddress`, `DestinationPort`, and `SourceUserName`. If the last two fields do not contain values, the record key is displayed as follows: `43.65.76.98| | `.
- **Record repetitions** is the total number of times the record was mentioned in events and identical records were downloaded when importing context tables to KUMA.
- **Expiration date** – date and time when the record must be deleted.

  If the **TTL** field had the value of 0 when the context table was created, the records of this context table are retained for 36,000 days (approximately 100 years).
- **Updated** is the date and time when the context table was updated.

Searching context table records

To find a record in the context table:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.

3. In the context menu of the correlator in whose context table you want to find a record, select **Go to context tables**.

   This opens the **Correlator context tables** window.

4. In the **Name** column, select your context table.

   This opens a window with the records of the selected context table.

5. In the **Search** field, enter the record key value or several characters from the key.

The list of context table records displays only the records whose key contains the entered characters.

If the your search query matches records with empty key values, the text <Nothing found> is displayed in the widget on the **Dashboard**. We recommend clarifying the conditions of your search query.

Adding a context table record

To add a record to the context table:

1. In the main menu, go to **Monitoring** → **Resources**.

2. In the **Services** section, click the **Active services** button.

3. In the context menu of the correlator to whose context table you want to add a record, select **Go to context tables**.

   This opens the **Correlator context tables** window.

4. In the **Name** column, select the relevant context table.

   The list of records for the selected context table is displayed.

5. Click **Add**.

   The **Create record** window opens.

6. In the **Value** field, specify the values for fields in the **Field** column.

   KUMA takes field names from the correlation rules with which the context table is associated. These names are not editable. The list of fields cannot be edited.

   If you do not specify some of the field values, the missing fields, including key fields, are populated with default values. The key of the record is determined from the full set of fields, and the record is added to the table. If an identical key already exists in the table, an error is displayed.

   List of default field values

Field type	Default value
Integer	0
Float	0.0
String	""
Boolean	false
IP address	"0.0.0.0"
Timestamp	0
Integer list	[]
Float list	[]

List of strings	[]
Boolean list	[]
Timestamp list	[]
IP list	[]

7. Click **Save**.

The record is added.

Editing a context table record

To edit a record in the context table:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. In the context menu of the correlator for which you want to edit the context table, select **Go to context tables**.

   This opens the **Correlator context tables** window.
4. In the **Name** column, select the relevant context table.

   The list of records for the selected context table is displayed.
5. Click on the row of the record that you want to edit.
6. Specify your values in the **Value** column.
7. Click **Save**.

The record is overwritten.

Restrictions when editing a record:

- The value of the key field of the record is not available for editing. You can change it by exporting and importing a record.
- Field names in the **Field** column are not editable.
- The values in the **Value** column must meet the following requirements:
  - greater than or equal to 0 for fields of the **Timestamp** and **Timestamp list** types.
  - IPv4 or IPv6 format for fields of the **IP address** and **IP list** types.
  - is **true** or **false** for a **Boolean** field.

Deleting a context table record

To delete records from a context table:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. In the context menu of the correlator from whose context table you want to delete a record, select **Go to context tables**.

   This opens the **Correlator context tables** window.
4. In the **Name** column, select the relevant context table.

   The list of records for the selected context table is displayed.
5. Select the check boxes next to the records you want to delete.

   To delete all records, select the check box next to the **Key** column.

   > At least one check box must be selected.
6. Click the **Delete** button.
7. Click **OK**.

The records will be deleted.

Importing data into a context table

To import data to a context table:

1. In the main menu, go to **Monitoring** → **Resources**.
2. In the **Services** section, click the **Active services** button.
3. In the context menu of the correlator to whose context table you want to import data, select **Go to context tables**.

   This opens the **Correlator context tables** window.
4. Select the check box next to your context table and click **Import**.

   This opens the context table data import window.
5. Click **Add** and select the file that you want to import.

6. In the **Format** drop-down list select the format of the file:

   - **csv**
   - **tsv**
   - **internal**

7. Click the **Import** button.

   The data from the file is imported into the context table. Records that previously existed in the context table are preserved.

When importing, KUMA checks the uniqueness of each record's key. If a record already exists, its fields are populated with new values obtained by merging the previous values with the field values of the imported record.

If no record existed in the context table, a new record is created.

Data imported from a file is not checked for invalid characters. If you use this data in widgets, widgets are displayed incorrectly if invalid characters are present in the data.

Exporting data from a context table

To export data from a context table:

1. In the main application window, go to the **Resources and services** → **Active services** section.
2. Select the correlator whose context table you want to export, and in the toolbar or in the menu (⋮), click **Go to context tables**.

   This opens the **Correlator context tables** window.

3. Select the check box next to the context table that you want to export.

   You cannot export multiple context tables at the same time. Each table must be exported separately.

4. Click the **Export** button and select a format from the **Format** drop-down list:

   - **internal**

     The context table is exported in JSON format.

   - **csv**
   - **tsv**

5. Click the **Export** button.

   The context table is downloaded to your device in the selected format. The name of the exported file follows the following template: <context_table_name>_<export date (YYYY-MM-DD)>_<export time (HH-MM-SS)>. Exported data in the file is sorted by the **Key** field.

When exporting in JSON (**internal**) format:

- The order of the fields in the file is not defined.
- Fields of the array type are exported to a file as an array of values, for example: `["val1","val2","val3","val4"]`.
- The date and time format in the field of the **Timestamp** type depends on the selected application interface language:
  - Russian: DD.MM.YYYY HH:MM:SS, for example: `18.02.2025 16:09:58`
  - English: YYYY-MM-DD HH:MM:SS, for example: `2025.02.18 16:09:58`

When exporting in CSV and TSV formats:

- The first line of the file contains field names, and the subsequent lines contain the data.
- In the CSV format, the comma is used as a field separator, and in TSV format, the tabulation character.

You can also export data into the context table in the context table settings window.

Building a hierarchy of OSMP instances

You can arrange Open Single Management Platform (OSMP) instances into a two-level hierarchy, with the parent instance at the top. This enables you to distribute the settings from the parent instance to the child ones, while maintaining the settings of child instances.

For example, User A and User B have deployed OSMP. Each user has an independent instance of OSMP and manages their own instance of the OSMP Console.

To enable data exchange between the instances, User A and User B have to arrange their instances into a hierarchy. For this, User A, the user of the future child instance, sends a connection request to the future parent instance; and user B, the user of the future parent instance, approves the request.

If necessary, you can disconnect the child instance.

After you build a hierarchy, the entities of the instances are managed in the hierarchy as follows:

- **Administration Servers**

  Within the hierarchy of instances, you have to manually assign a secondary Administration Server.

- **Tenants**

  The tenant hierarchy of the child instance is built into the tenant hierarchy of the parent instance. Tenant settings and integration tenant settings of the child instance can be edited from both the child and the parent instance. Tenant settings and integration tenant settings of the parent instance can be edited from the parent instance only.

  On the parent instance, you can view the tenant hierarchy of the child instance; and create, edit, and delete tenants on the child instance; but you cannot delete the child instance Root tenant.

- **Assets (devices) and asset categories**

  Settings of the parent and the child instances are independent from each other. If you make changes in the parent instance, the changes are not applied to the child instance, and vice versa.

  The assets of the parent instance are not displayed in the child instance. In the child instance, the asset categories of the parent instance are available for viewing, for linking to child instance assets, and for performing response actions on assets of the child instance. For example, on both a parent and child instance there is an NNN asset category. If you run a response action for the NNN category from the child instance, only the child instance assets fall under the response action. However, you cannot edit the parent instance categories, assign these categories to the child instance devices, or create subcategories of the inherited categories.

  On the parent instance, asset categories of the child instance are displayed. If you select an asset category, the child instance assets are displayed. You can perform response actions for the assets of the child instance categories. If there is no connection to the child instance, the user of the parent instance is able to initiate a response action that will be performed on the child instance devices once the connection is reestablished. If you delete a category from the parent instance, then on the child instance this category becomes local and moved to the Categorized assets category on the child instance Root tenant. You cannot delete an asset category if it is used by KUMA resources. Assets categories of the child instance cannot be used by KUMA resources of the parent instance.

- **Users and user roles**

  All users are managed from the parent instance. Users and roles are replicated from the parent instance into the child instance (except the admin account). In the child instance, existing users are deleted, and user roles remain without being replicated into the parent instance.

The admin account is unique to each OSMP instance and is not replicated between instances. Therefore, the following actions cannot be performed under the admin account of the parent instance:

- Managing events of the child instance in **Threat hunting** section of the parent instance
- Viewing information about the resources of child instances from the parent instance
- Viewing and managing the services of child instances from the parent instance

- **Files**

  Files downloaded and obtained as a result of response actions performed on a child instance are displayed in the table of files on the parent instance with the following icon in the **Tenant** field: (⛁). When on the parent instance you open the details of the child instance file, you are redirected to the child instance for further operations with the file.

- **KUMA entities**

  - **Events**

    Child instance events are stored on the child instance, and parent instance events are stored on the parent instance. On the parent instance, you can perform a search of the child instances events.

  - **Correlation rules and IOA rules**

    IOA rules are converted into KUMA correlation rules after the hierarchy is built.

    There are the following modes of working with correlation rules in the hierarchy:

    - **Local**. If the correlation rule is created on the child instance, it is managed on the child instance. If the correlation rule is inherited from the parent instance, then on the child instance you can only add exclusions to the correlation rule and cannot edit the rule.

      The correlation rules and their exclusions are only applied to the devices connected to the child instance Administration Server.

    - **Global**. The correlation rules are created on the parent instance. The rules and their exclusions are applied to the child instance devices that you specified while configuring the rules settings.

  - **Exclusions from correlation rules**

    Temporary exclusions added to correlation rules on the parent instance are not inherited. On the child instance, you can add a temporary exclusion to the inherited correlation rules. Filters are inherited with correlation rules.

- **Alerts and Incidents**

  Alerts and incidents of the child instance are replicated to the parent instance and displayed in both the child and the parent instance. Alerts and incidents of the parent instance are displayed in the parent instance only. On the parent instance, you cannot edit, link, and merge the child instance alerts or incidents.

  When deleting alerts or an incident on the child instance, they are deleted from the parent instance as well.

  Alerts and incidents settings, as well as their retention period, are not inherited. If the retention period expires, and an alert or incident is deleted on the child instance, the corresponding event is sent to the parent incident, and then the alert or incident is deleted on the parent instance as well.

- **Incident types**, **workflows**, **and SLA**

To avoid data inconsistency, incident types, workflows, and SLA are copied to the child instance as a single bundle.

- **SLA**

  On the child instance, you cannot create an SLA. When trying to view the child SLA from the parent instance, you are redirected to the child instance.

- **Workflow**

  In a child instance, you can create workflows as well as view and apply workflows inherited from the parent instance. When trying to view a workflow of a child instance from the parent instance, you are redirected to the child instance. On the parent instance, you can delete a parent instance workflow; if the workflow has no linked entities on the parent instance, the workflow is no longer displayed and after 90 days is completely deleted. You cannot delete a workflow with linked entities.

- **Incident types**

  Incident types are inherited from the parent instance, where they have disabled status. If a default incident type is inherited, in the child instance this incident type is not default.

  On the child instance, you can create new incident types, as well as view and apply the inherited incident types. You cannot edit the inherited incident types. Also, you can use default the attribute both to the inherited incident types and ones created locally on the child instance.

- **Aggregation rules**

  Manually created aggregation rules are inherited from the parent instance. Predefined aggregation rules are not inherited.

  On the parent instance, you can view all aggregation rules of the child instance. The ability to edit the rules is defined by your EDR role.

  On the child instance, the inherited aggregation rules are displayed at the top of the rules table in the order as they were displayed on the parent instance. By default, the rules are disabled when inherited. You can view, enable, and disable the inherited aggregation rules.

  The enabled aggregation rules will be applied in accordance with their priority: the higher the rule is in the table, the higher its priority.

- **Segmentation rules**

  Manually created segmentation rules are inherited from the parent instance. Predefined segmentation rules are not inherited.

  On the parent instance, you can view all segmentation rules of the child instance. The ability to edit the rules is defined by your EDR role.

  On the child instance, the inherited segmentation rules are displayed at the top of the rules table in the order as they were displayed on the parent instance. By default, the rules are disabled when inherited. You can view, enable, and disable the inherited segmentation rules.

  The enabled segmentation rules will be applied in accordance with their priority: the higher the rule is in the table, the higher its priority.

- **Prevention rules**

  Prevention rules are inherited from the parent instance.

  On the parent instance, you can view and edit the child instance prevention rules, as well as apply the child instance rules to the child instance assets. You cannot apply the child instance prevention rules for the parent instance assets.

On the child instance, you can view the prevention rules inherited from the parent instance. You can neither edit these rules, nor add or delete the child instance assets in the prevention rules inherited from the parent instance.

- **YARA and IOC rules**

  The lists of YARA and IOC rules are inherited from the parent instance.

  On the parent instance, you can view and edit the child instance rules, as well as apply the child instance rules to the child instance assets. You cannot apply the child instance rules to the parent instance assets.

  On the child instance, you can view YARA and IOC rules inherited from the parent instance but you cannot edit these rules. To run response actions, you can use both the rules of the child instance and the ones inherited from the parent instance.

- **Sandbox rules**

  Sandbox rules are inherited from the parent instance.

  On the parent instance, you can view and edit the child instance Sandbox rules, as well as apply the child instance rules to the child instance assets.

  On the child instance, you can view the Sandbox rules inherited from the parent instance but you cannot edit these rules.

- **Playbooks**

  From the parent instance, you can create playbooks on the child instance, and manually launch playbooks for alerts and incidents of the child instance.

- **Licensing**

  License management and licensing configuration are handled by instances independently from each other and not inherited within the hierarchy of instances.

  A license key is added to each instance separately. You can add the same license key to all the instances.

- **Policies and tasks**

  Policies and tasks are inherited from the parent instance.

- KSN/KPSN settings, credentials, and notifications templates are not inherited.

Connecting a child instance to the parent instance

The user of a future child instance sends a connection request, and the user of the future parent instance approves the request.

Both users must have the Main Administrator EDR role in their instances.
If you send a connection request to an instance that serves as a child instance in another hierarchy, the request will be canceled.
The maximum number of child instances that a parent instance can have is 150.

Sending a connection request from the child instance

To send a connection request:

1. On the future child instance, in the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed on the screen.

2. In the toolbar, click the **Request connection** button.

3. In the right pane that opens, do the following:

   - In the **API URL of parent instance** field, specify the address of the parent instance public API, for example: `https://api.xdr-hier-1.kuma.example.com`.

   - In the **Fingerprint of the parent instance certificate** filed, specify the hash of the parent instance certificate.

     You can click **Get fingerprint** to insert the hash of the parent instance certificate into the **Fingerprint of the parent instance certificate** filed. If the parent instance has a chain of certificates, Kaspersky EDR Expert uses an intermediate certificate. We do not recommend that you use the leaf certificate because it is rotated more often than an intermediate one. After the specified certificate is rotated, you need to restore the instance hierarchy.

   - In the **API token** field, specify the public API token for external integrations.

     > The API token must be generated in advance on the parent instance.
     > When configuring token parameters, the GET:/api/hierman/v1/* and POST:/api/hierman/v1/* API methods are required for building the hierarchy of instances.

   - If necessary, configure the following settings:

     - In the **API URL of child instance** field, specify the address of the child instance public API, for example: *https://api.xdr-hier-2.kuma.example.com.*

     - In the **Select tenants to share SIEM resources** section, select the check boxes next to the tenants whose SIEM resources you want to be visible in the parent instance.

4. Click the **Request** button.

   The pane closes.

5. In the confirmation dialog box, click **Request**.

   The confirmation dialog box closes, and the **Your connection request is pending approval** status message is displayed on the screen.

After the user on the parent instance approves or declines the request, you receive an email notification and the status message displayed on the screen also changes.

If the user on the parent instance approves the request, the ID of the parent instance and the name of the parent instance tenant are displayed in the child instance.

Approving a connection request from the parent instance

Once the user of the child instance sends a connection request, you receive a corresponding email notification.

To approve the connection request:

1. In the main menu, go to **Settings** → **Tenants**.
2. At the top of the page, click the **View requests** link that is displayed in the message about pending connection requests.
3. In the **Connection requests** pane that opens, click the **Approve** button for a request that you want to approve.
4. In the **Approve connection request** pane that opens, do the following:
   - In the **Root tenant name** field, specify a new name for the child instance tenant to be connected.
   - In the **Root tenant name** section, from the tenant hierarchy of the parent instance, select a tenant to be assigned as a parent for the tenant of child instance.
   - Click the **Approve** button.

     The pane closes.

The child instance is added to the tenant hierarchy of the parent instance. A corresponding message is displayed on the screen.

Restarting the active services on the child instance

After the connection between the child and parent instances is established, restart the active services on the child instance. After that, the active services of the child instance are displayed on the parent instance.

Results

You can now manage the tenant tree of the child instance as follows:

- View the child instance tenant tree
- Create tenants on the child instance
- Edit tenants on the child instance
- Delete tenants from the child instance except for the Root tenant
- Disconnect the child instance

The user of the child instance can view, edit, and delete tenants of the child instance only.

Assigning a secondary Administration Server within the hierarchy of OSMP instances

After you build a hierarchy of OSMP instances, you have to manually establish a "primary/secondary" relationship by manually assigning secondary Administration Server.

To assign a secondary Administration Server that is available for connection through OSMP Console:

1. On the future primary Administration Server, make sure that port 13000 is available for receipt of connections from secondary Administration Servers.

2. In the main menu, click the Administration Server name to open the properties window, and then click the **Administration Servers** tab.

3. Select the check box next to the name of the administration group to which you want to add the Administration Server.

4. In the menu line, click **Connect secondary Administration Server**.

   The Add secondary Administration Server wizard starts. Proceed through the wizard by using the **Next** button.

5. Specify the connection settings for future secondary Administration Server:

   - **Connect primary Administration Server to secondary Administration Server in DMZ**

     Select this option if the secondary Administration Server is in a demilitarized zone (DMZ).

     If this option is selected, the primary Administration Server initiates connection to the secondary Administration Server. Otherwise, the secondary Administration Server initiates connection to the primary Administration Server.

   - **Secondary Administration Server address (optional)**

     Specify the IP address or the domain name of the secondary Administration Server.

     This parameter is required if the **Connect primary Administration Server to secondary Administration Server in DMZ** option is enabled.

   - **Secondary Administration Server display name**

     A name by which the secondary Administration Server will be displayed in the hierarchy. If you want, you can enter the IP address as a name, or you can use a name like, for example, "Secondary Server for group 1".

   - **Administration Server SSL port**

     Specify the number of the SSL port on the primary Administration Server. The default port number is 13000.

     Port 13000 is used for the root Administration Server; this port number cannot be changed.

   - **Administration Server API port**

     The number of the port that Web Console will use for receiving connections from the secondary Administration Server over OpenAPI. The default port number is 13299.

While building the hierarchy, Web Console connects to the future secondary Server, requests credentials, retrieves the public certificate, and performs the initial setup.

After the hierarchy of Administration Server is built, port 13299 will no longer be used. Administration Servers will interact over port 13000.

6. Specify the certificate of the future secondary Server.

   If the **Secondary Administration Server address (optional)** parameter is selected, you have to either click the **Get from secondary Administration Server** button to obtain the certificate or click **Browse for the certificate file** and add the certificate manually.

7. Specify the address of the future primary Server.

8. If the connection to the future primary Administration Server is performed through a proxy server, select the **Use proxy server** check box and specify the connection settings.

9. Specify the credentials of the user who has access rights to the future secondary Administration Server.

10. If two-factor authentication is enabled and configured, specify a secret key generated by the authenticator app.

11. Save the settings.

12. Switch to the future secondary Administration Server and open its properties window.

13. On the **General** tab, go to the **Hierarchy of Administration Servers** section and do the following:

    - Select the **This Administration Server is secondary in the hierarchy** check box.
    - In the **Primary Administration Server address** field, specify the network name of the future primary Administration Server.
    - Select the previously saved file with the certificate of the future primary Administration Server by clicking Browse.
    - If necessary, select the **Connect primary Administration Server to secondary Administration Server in DMZ** check box.
    - If the connection to the future primary Administration Server is performed through a proxy server, select the **Use proxy server** check box and specify the connection settings.

14. Save the settings.

The "primary/secondary" hierarchy of Administration Servers is built. The primary Administration Server starts receiving connection from the secondary Administration Server using port 13000. The tasks and policies from the primary Administration Server are received and applied. The secondary Administration Server is displayed on the primary Administration Server, in the administration group where it was added.

Disconnecting a child instance from a parent instance

After a child instance is disconnected from its parent instance, you cannot connect the child instance to another hierarchy.

Initiating disconnection from a parent instance

To disconnect a child instance:

1. On the parent instance, in the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed on the screen.

2. Select the check box next to the child instance Root tenant to be disconnected.

3. In the toolbar, click the **Disconnect** button, and then in the confirmation dialog box that is displayed, click **Disconnect**.

   The child instance is disconnected from the parent instance, and an appropriate message is displayed on the screen. The user of the child instance will be notified by email.

If a child instance is turned off at the moment of disconnection, the instance will be disconnected forcibly. Anyway, to complete the disconnection, turn on the child instance, and then follow the instructions below to disconnect the child instance from the parent one.

When you disconnect instances, Kaspersky EDR Expert creates an audit event `Disconnecting an SCN from PCN`. For both cases—when the child instance is turned on or turned off at the moment of disconnection, the audit event is the same.

For diagnostics purposes, if a child instance is turned off at the moment of disconnection, Kaspersky EDR Expert adds an error to the hierman component log files, for example the "disconnect on secondary failed" error. Use the value of the `trace_id` field in the audit event to find the errors in the log files.

Initiating disconnection from a child instance

To disconnect a child instance:

1. On the child instance, in the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed on the screen.

2. Select the check box next to the Root tenant to be disconnected.

3. In the toolbar, click the **Disconnect** button, and then in the confirmation dialog box that is displayed, click **Disconnect**.

   The child instance is disconnected from the parent instance, and an appropriate message is displayed on the screen. The user of the parent instance will be notified by email.

Disconnection results

As a result of the child instance disconnection, the OSMP hierarchy is broken.

In the parent instance:

- The resources and settings of the disconnected instance are deleted.
- The child instance data replicated to the parent instance is now deleted from the parent instance.

On the child instance:

- Information about the parent instance is deleted, and the parent instance is not displayed in the child instance tenant hierarchy.
- Management of the child instance tenant hierarchy goes back to the child instance.
- The Identity and Access Manager remains available in the read-only mode.

  The users of the child instance are still able to sign in to the instance, but cannot perform any other actions (create users, assign rights, change a password, etc.).

  The users created on the child instance before the instance was connected to the hierarchy are deleted from the child instance.
- The entities inherited from the parent instance are immediately deleted from the child instance if the entities have no linked objects on the parent instance. Otherwise, the entity is no longer displayed on the child instance but remains available in the read-only mode for 90 days. After this period, the entity is deleted.
- Asset categories inherited from the parent instance are now managed on the child instance.
- The services managed by the parent instance are deleted.

Distribution of the correlation rules in the hierarchy

OSMP supports centralized management and distribution of correlation rules among OSMP instances that are combined into a hierarchy.

You can create correlation rules on the parent OSMP instance and automatically propagate them to child instances. On the child instances of OSMP, inherited correlation rules are used without the possibility of modification. To make changes, you need to create a local copy of the inherited rule (duplicate the correlation rule). After that, changes are made only to the local copy. Resource paths on the parent and child instances of OSMP are different because the folders have different names; however, the resources themselves and the changes they contain are synchronized.

Centralized management ensures unified use of correlation rules across distributed infrastructures with multiple instances of OSMP, reduces the cost of rule maintenance, and supports consistent threat detection.

Key terms

A *global rule* is a correlation rule created on the parent OSMP instance and propagated to child instances.

A *local rule* is a rule created on a child OSMP instance.

An *inherited correlator* is a correlator service on the child OSMP instance that uses a correlator configuration created on the parent instance.

An *inherited resource* is a resource that is obtained from the parent OSMP instance in the hierarchy.

Prerequisites

For the rule inheritance mechanism to work, the following conditions must be met:

1. The hierarchy of OSMP instances is configured.
   OSMP instances are organized into a hierarchy with one parent instance and one or more child instances.
2. The child OSMP instance is connected to the parent OSMP instance.

What the functionality can do

The parent OSMP instance can do the following:

- Create global correlation rules and propagate such rules to child OSMP instances.
- View resources and services created on child OSMP instances.

The following operations are available in the **Active services** section:

- Adding a service
- Updating service settings
- Restarting a service
- Deleting a service of a child instance
- Viewing service events
- Viewing active lists
- Viewing context tables
- Viewing sections
- Downloading logs and dumps
- Copying the service ID
- Copying the cluster ID
- Resetting a certificate

The child OSMP instance can do the following:

- Use inherited rules without being able to edit them
- Create a local copy of a global rule

The following operations are available for inherited services in the **Active services** section:

- Viewing service logs
- Updating service settings
- Viewing service configuration

Limitations

For inherited correlation rules on child OSMP instances, rules cannot be edited or deleted, linking to services cannot be changed, correlator settings cannot be modified.

To edit an inherited correlation rule, you need to create a duplicate rule on the child OSMP instance.

The duplicate becomes an editable local resource.

Life cycle of rules

Updating a parent rule

Changes are not automatically propagated after a global rule is modified. If you want to apply the changes, you need to restart the correlator service or

update service settings.

After that, the changes are applied to child OSMP instances.

Deleting a rule on the parent instance

If a global rule is deleted on the parent OSMP instance, the inherited rule is not automatically deleted on the child OSMP instance. The inherited rule becomes a local resource and the child OSMP instance gains full rights to this resource.

Duplicating a rule

If a global rule is duplicated on the child OSMP instance, a local copy of the rule is created and the child OSMP instance gains full rights to it (read, write, delete).

Exporting and importing

An inherited rule can be exported or imported into another OSMP instance.

After import, such a rule becomes a local resource that can be edited.

Temporary interruption of connectivity

If the connection between OSMP instances is temporarily interrupted, packets up to 64 MB are transmitted immediately, and larger packets are rejected with an error.

When the connection is restored, the child instances receive the missing changes.

Breakup of the hierarchy

If a child instance becomes orphaned from the hierarchy, its inherited services become local, inherited rules become local and available for editing and deletion.

Use cases

You can do the following:

- Distribute the global correlator configuration along with the global correlation rule
- Distribute the global correlation rule for local use
- Duplicate an inherited correlation rule on a child instance
- View correlation rules created on child OSMP instances

Distributing global correlator configuration along with global correlation rules

To distribute global rules to child OSMP instances as part of the inherited correlator:

1. On the parent OSMP instance:

    a. Create a global correlation rule:

        1. Go to the **Resources and services** → **Correlation rules** section.
        2. Create a correlation rule.
        3. In the settings of the correlation rule, enable the **Enable inheritance on secondary nodes** toggle switch.
        4. In the drop-down list, specify a tenant or several tenants of child OSMP instances to which you want to distribute the rule.
        5. Save the correlation rule.

    The created correlation rule must be linked to a correlator service.

b. Create a correlator service that will be inherited on child OSMP instances and link the global correlation rule:

1. Go to the **Resources and services** → **Correlators** section.
2. Create a correlator and in the Installation Wizard, at the **General** step, enable the **Enable inheritance on secondary nodes** toggle switch.
3. In the drop-down list, specify a tenant or several tenants of child OSMP instances to which you want to distribute the correlator configuration.
4. At the **Correlation** step of the Installation Wizard, link the global correlation rule.
5. Save the settings of the correlator service.

After you save the settings, the configuration of the correlator service and the global correlation rule are saved on the parent OSMP instance and propagated to child OSMP instances. Further configuration and installation of the correlator service is performed on child OSMP instances.

2. On the child OSMP instance:

a. Go to the **Resources and services** → **Correlators** section and open the inherited correlator service in the table of services.

1. In the Installation Wizard of the correlator, at the **Routing** step, specify the destination:

- The storage in which events and alerts will be saved.
- The correlator on the parent OSMP instance for further processing of events.

1. At the **Setup validation** step, click **Create and save service**.
2. Copy the installation command under **Recommended command for correlator installation** and install the correlator service on the host of the child OSMP instance.

As a result, on the child OSMP instance:

- A copy of the correlation rule is created.
- Associated dependent resources are created.
- An inherited correlator configuration is created. Resources used inside the correlator are also inherited, even if they are not inherited separately, for example, response rules.
- The correlation rule and the configuration of the correlator service are available in read mode with the ability to specify destination points.
- The service is displayed on the parent OSMP instance in the **Active services** section with indication of it being an inherited service.
- Changes made on the parent OSMP instance are automatically inherited down the hierarchy.

Distributing global correlation rules for local use

To distribute global rules to child OSMP instances and link them to the local correlator:

1. On the parent OSMP instance:

   a. Go to the **Resources and services** → **Correlation rules** section.

   b. Create a correlation rule.

   c. In the settings of the correlation rule, enable the **Enable inheritance on secondary nodes** toggle switch.

   d. In the drop-down list, specify a tenant or several tenants of child OSMP instances to which you want to distribute the rule.

   e. Fill in the rest of the required fields.

   f. Save the rule.

   The created global correlation rule is propagated to the child OSMP instances. The inherited correlation rule must be linked to a correlator service.

2. On the child OSMP instance:

   a. Go to the **Resources and services** → **Correlators** section.

   b. Create a correlator service or open the settings of an existing service.

   c. In the Installation Wizard of the correlator, at the **Correlation** step, link the global correlation rule to the local correlator service.

   d. Manage the rest of the required settings:

   e. At the **Setup validation** step, do one of the following:

      - If you want to create a correlator, click **Save and create service**, then use the generated command to install the service on the host in the child OSMP instance.

      - If you want to update the settings of an active correlator, click **Save and update service configurations**.

As a result, on the child OSMP instance:

- A copy of the correlation rule is created.
- The correlator service is displayed in the parent OSMP instance in the **Active services** section and can be viewed.
- Changes made to the correlation rule on the parent OSMP instance are automatically inherited down the hierarchy.

Inherited correlation rules are read-only.

If you need to edit a rule for local use, duplicate the correlation rule and use the local copy independently of the parent OSMP instance.

Duplicating the inherited correlation rules for local use

Prerequisites:

- The hierarchy of OSMP instances is configured.
- The child OSMP instance is connected to the parent instance.
- A correlation rule has been created on the parent OSMP instance.
- Inheritance of the global correlation rule is configured on the child OSMP instance.

To duplicate inherited correlation rules for local use:

1. On the child OSMP instance, go to the **Resources and services** → **Correlation rules** section.
2. In the table of correlation rules, find the inherited rule and select the check box next to it.
3. In the toolbar or in the menu (⋮), click **Duplicate**.
4. Enter a new name for the correlation rule.
5. Save the copy of the correlation rule.
6. Open the created local copy of the correlation rule.
7. Make the necessary changes.
8. Save the correlation rule.

As a result, the local copy of the correlation rule on the child OSMP instance becomes independent of the parent OSMP instance, and you can edit, delete, export, and change dependent resources of the local copy.

Limitations:

After duplication, changes made to the parent rule are not applied to such a local copy and are not synchronized.

Viewing resources and services created in child OSMP instances

Prerequisites:

- The hierarchy of OSMP instances is configured.
- The child OSMP instance is connected to the parent OSMP instance.
- Resources or services are created on the child OSMP instance.

To view resources created on child OSMP instances:

1. On the parent OSMP instance, go to the **Resources and services** → **Correlation rules** section.
2. Open the list of resources.
3. View the minimally available information:
   - ID.
   - Name.
   - Tenant ID
   - Tenant name.
   - Remote tenant (tenant of the child OSMP instance) indicator
   - Rule type
   - Last update (date)
   - Tags
   - MITRE techniques.
   - Package name (if the resource was obtained through Kaspersky update servers)
   - Description
   - Path to the resource

     The folders on the parent and child instances will have different names, therefore, the paths will be different. However, changes will be synchronized where applicable.

To view full information, open the card of the correlation rule.

To view correlator services created on child OSMP instances:

1. On the parent OSMP instance, go to the **Resources and services** → **Active services** section.
2. In the table of services, open a service for viewing.

As a result, on the parent OSMP instance:

- Resources and services of child instances are displayed.
- Resources and services are read-only.
- Search and filtering is available.
- The full information about a correlation rule is loaded directly from the child OSMP instance when the resource card is opened.

The following actions with resources of child OSMP instances are not available on the parent OSMP instance:

- Duplication
- Deletion
- Viewing the list of dependencies
- Assigning tags
- Linking to correlators
- Assigning and viewing the list of exclusions
- Viewing the version history
- Using the resources in correlators of the parent instance

Folder behavior when distributing resources in the hierarchy

Resources are associated with the folder path at the time of distribution. If you do not rename or move folders manually, routing will not change. Changes to the folder structure are not synchronized between the OSMP instances.

When distributing resources in the hierarchy, the following rules apply:

1. Only folders that contain at least one distributed resource are transferred.
2. Folders are mapped between instances by their full path.
3. Folder IDs are not transferred: on the target instance, folders are created with the new IDs.
4. During import, the existing folder structure is not replaced, but is merged with the imported one.
5. Folder operations (creation, renaming, and moving) are not synchronized directly. Changes become visible only after distributing the resources located in the corresponding folders.

Creating a folder

A new folder created on a child instance does not become visible on the parent OSMP instance until at least one distributed resource is created in that folder.

Renaming a folder

Renaming a folder does not automatically update the folder structure on other OSMP instances.

After renaming, the following behavior is expected:

- Resources distributed before the folder name was changed remain associated with the old path.
- Resources distributed after the renaming use the new path.

Example

Initial state:

- Parent instance: folder A contains resource R1.
- The R1 resource is inherited by the child instance.

Change:

- On the child instance, folder A is renamed to B.
- A new resource R2 is created in folder B and distributed to the parent instance.

Result:

- On the parent instance, R1 is located in folder A; R2 is located in folder B.
- On the child instance: R1 and R2 are located in folder B.

Each resource is associated with the folder path that existed at the time of the resource distribution. Therefore, to maintain stable routing, it is recommended not to rename or move folders manually.

Combining OSMP instances into a hierarchy

This section describes how to combine OSMP instances into hierarchy.

Prerequisites
At least two OSMP instances are required: a parent and a child instance.

In this section, the following domain names are used as examples:

- For the parent instance:
  - Web interface: `console.edrparent.organization.acme`
  - API: `api.edrparent.organization.acme`

- For the child instance:
  - Web interface: `console.edrchild1.organization.acme`
  - API: `api.edrchild1.organization.acme`
- For all instances:
  - Two-way communication with port 443 at the IP address of each instance must be established.
  - API domain names of child instances must be available to the parent instance, and the API domain of the parent instance must be available to all child instances.

Preparing the parent instance

1. In the main menu of the future parent instance, go to the **Settings** → **API tokens** section and click the **Add token** button.
2. In the **Name** field, enter a name for the API token (for example, `edrparenthierarchy`).

   You can revoke this token at a later time, after completing the connection to the child node.
3. In the **Expiration date** field, specify the token expiration date. When setting this date, take into account the minimum time required to finish building the hierarchy (at least one day).
4. In the **API methods** section, select check boxes by the following methods:
   - **GET:/api/hierman/v1/***
   - **POST:/api/hierman/v1/***
5. Click **Generate**, then **Copy and close**.

   The API token will be created and copied to the clipboard. Save it securely, as you will not be able to copy it later.
6. Get the fingerprint of the certificate to verify the connection to the instance. To do this, open the API domain of the parent instance (`api.edrparent.organization.acme`) in your browser and view the certificate details.

   Make sure the fingerprint was received from a trusted source. Check its IP address to make sure the domain has not been spoofed.

Steps for each child instance

1. Go to the web interface of the future child instance (in this example, `console.edrchild1.organization.acme`).
2. In the main menu, go to **Settings** → **Tenants**.
3. In the toolbar, click the **Request connection** button.

4. In the right pane that opens, do the following:

   - In the **API URL of parent instance** field, specify the API address of the parent instance (in this example, `api.edrparent.organization.acme`).
   - In the **Fingerprint of the parent instance certificate** filed, specify the hash of the parent instance certificate.
   - In the **API token** field, specify the API token that was created earlier in the parent instance.

5. Click the **Request** button.

   If all fields are filled in correctly, the *Your request has been sent* message is displayed.

6. Navigate to the **parent** instance (`console.edrparent.organization.acme` in this example).

7. In the main menu, go to **Settings** → **Tenants**.

   The *Awaiting connection request* message is displayed. If the message does not appear, refresh the page.

8. Click **View request**.

   This opens a window with details of the child instance.

9. Carefully check the filled in fields and the address. In particular, pay attention to the **Certificate fingerprint** field: its value must be verified by using a trusted source of the child instance's certificate. Check the IP address to make sure that the domain (`api.edrchild1.organization.acme` in this example) has not been spoofed.

10. If all the fields are filled in properly, click the **Approve** button.

11. In the **Approve connection request** pane that opens, do the following:

    - In the **Root tenant name** field, specify a new name for the child instance tenant to be connected. The root tenant of the child instance is registered with the parent instance with this name.
    - In the **Root tenant name** section, from the tenant hierarchy of the parent instance, select a tenant to be assigned as a parent for the tenant of child instance.
    - Click the **Approve** button.

      The pane closes. The child instance is added to the tenant hierarchy of the parent instance. The *Root tenant connected to the instance* message is displayed on the screen.

12. After refreshing the page, you will see a new node with a hierarchy of child instances in the tree of tenants.

Reparing an instance hierarchy after certificate rotation

When you build a hierarchy of OSMP instances, you specify the certificate of the parent instance in the **Fingerprint of the parent instance certificate** field. After the specified certificate is rotated, the hierarchy is broken. For example, this may happen for the following reasons:

- You upgraded Kaspersky EDR Expert from a previous version or updated it within the same major version.
- The certificate is replaced automatically after its expiration date.
- You replaced the certificate manually.

When a hierarchy is broken, OSMP adds the following error to the log files of the hierman component: 'no certificate in chain matches expected thumbprint'.

To repair an instance hierarchy after certificate rotation:

1. On the administrator host of the parent OSMP instance, run the following command:

```
./kdt invoke hierman --action hiermanRepairTrust
```

2. Run the same command on the administrator hosts of the child OSMP instances included in the hierarchy.

The hierarchy is repared.

OSMP Console interface

Kaspersky EDR Expert is managed through the OSMP Console interface.

The OSMP Console window contains the following items:

- Main menu in the left part of the window
- Upper pane in the upper part of the window
- Work area in the right part of the window

Main menu

The main menu contains the following sections:

- **Administration Server**. Displays the name of the Administration Server that you are currently connected to. You can open the Administration Server properties by clicking the Administration Server name.
- **Console navigation**. Displays the main menu map. Most of the displayed sections can be added to bookmarks or set as a home page. By default, **Console navigation** is set as a home page. You can change these settings.
- **Monitoring**. Provides an overview of your infrastructure, protection statuses, and statistics, including threat hunting, alerts and incidents, and playbooks. Also, this section allows you to add and configure KUMA resources and services.
- **Asset management**. Contains tools for assets and hardware management, and Kaspersky application policies.
- **Tasks**. Contains tools for creating and running tasks.
- **Users & roles**. Allows you to manage users and roles, configure user rights by assigning roles to the users, and associate policy profiles with roles.
- **Repositories**. Provides you access to application repositories.
- **Software management**. Allows you to manage Kaspersky and third-party applications, as well as installation packages and patches.
- **Operations**. Contains a variety of operations, including application licensing, viewing, and managing encrypted drives and encryption events.
- **Discovery & deployment**. Allows you to poll the network to discover client devices, and distribute the devices to administration groups manually or automatically. This section also contains the Protection deployment wizard.

- **Marketplace**. Contains information about the entire range of Kaspersky business solutions and allows you to select the ones you need, and then proceed to purchase those solutions at the Kaspersky website.

- **Settings**. Contains settings to integrate Kaspersky EDR Expert with other Kaspersky applications and allows you to create API tokens. It also contains settings related to displaying interface elements depending on features being used, as well as to interface language. Also, from this section you can open the KUMA settings window that contains parameters for KUMA configuration, including KUMA configuration settings, KUMA integration settings, license key management, and access options.

If necessary, you can minimize the main menu to icons by clicking the chevron sign (<<) at the bottom of the screen.

Upper pane

The upper pane is always displayed in all console sections and cannot be hidden.

The left side of the pane contains the application name and logo. If you click the application name or logo, the OSMP Console home page opens.

On the right side of the pane, the following settings are displayed:

- Notification icon (🔔). If you click the icon, a pane with notifications opens.

- The menu of your account. Contains a link to Kaspersky EDR Expert Help. It also allows you to sign out of Kaspersky EDR Expert, view your work status, the OSMP Console version and the list of installed management web plug-ins.

Work area

The work area displays the information you choose to view in the sections of the OSMP Console interface window. It also contains control elements that you can use to configure how the information is displayed.

Changing the language of the OSMP Console interface

You can select the language of the OSMP Console interface.

To change the interface language:

1. In the main menu, go to **Settings** → **Language**.

2. Select one of the supported localization languages.

Changing the OSMP Console home page

The home page is displayed after you sign in to OSMP Console.

By default, the **Console navigation section** is set as the home page. If necessary, you can change the home page.

To change the home page:

1. In **Console navigation** section, hover the mouse cursor over the item that you want to set as the home page.
2. After the home (⌂) icon is displayed, click the icon.

   The home page is changed. A corresponding message is displayed on the screen. The item selected as the home page is marked with the house (⌂) icon.

> The **Marketplace** and **Settings** sections cannot be set as the home page.

Adding and removing bookmarks

You can add frequently used sections of OSMP Console to bookmarks to access them quickly from the **Bookmarks** section in the main menu.

> If you did not add any section to bookmarks, the **Bookmarks** section is not displayed in the main menu.

You can add to bookmarks only the sections that display pages. For example, if you go to **Asset management → Assets (Devices)**, a page with the table of devices opens, which means you can add this section to bookmarks. If a window or no element is displayed after you select the section in the main menu, then you cannot add such a section to bookmarks.

To add a section to bookmarks:

1. In the main menu, hover the mouse cursor over the section you want to pin.
2. After the bookmark (🔖) icon is displayed, click the icon.

   The section is displayed in the **Bookmarks** section.

To remove a section from bookmarks:

1. In the main menu, go to the **Bookmarks** section.
2. Hover the mouse cursor over the section you want to remove, and then click the bookmark (🔖) icon.

   The section is removed from bookmarks.

You can also add and remove sections from bookmarks in the **Console navigation** section by hovering the mouse cursor over them and clicking the bookmark (☐) icon. The selected item will be marked with the bookmark (🔖) icon and displayed in the **Bookmarks** section in the main menu. If you want to remove the item from the bookmarks, click the bookmark (🔖) icon.

The **Bookmarks** section is displayed only in the main menu. It is never displayed on the **Console navigation** page.

New KEDR navigation

Navigation in KEDR 8.3 significantly differs from navigation in KEDR 7.1; changes in navigation are listed in the table below.

KEDR navigation changes

Navigation in KEDR 7.1	Navigation in KEDR 8.3
Dashboard	**Monitoring → Dashboard** **Monitoring → Dashboard → Analysis and response**
Alerts	**Monitoring → Alerts**.
Threat Hunting	**Monitoring → Threat hunting**
Tasks	**Monitoring → Response history** **Asset management → Assets (Devices)** **Asset management → Assets (Devices) → Analysis and response**
Prevention → Prevention rules	**Monitoring → Resources and services → Prevention rules**
Prevention → Presets	Unavailable, we recommend using playbooks instead of presets.
Custom rules → TAA	**Monitoring → Resources and services → Correlation rules**
Custom rules → IOC	**Monitoring → Resources and services → IOC rules**
Custom rules → YARA	**Monitoring → Resources and services → YARA rules**
Custom rules → Sandbox	**Monitoring → Resources and services → Sandbox rules**
Storage → Files	**Operations → Repositories → Files**
Storage → Quarantine	**Operations → Repositories → Quarantine**
Assets	**Asset management → Assets (Devices)**
Reports	**Dashboard → Reports**
Settings → Users → Users	**Users & roles → Users & groups** **Settings → Tenants** → select a tenant → **Access rights**
Settings → Exclusions → TAA	Kaspersky Endpoint Security web plug-in.
Settings → Endpoint Agents → IOC scanning schedule	**Settings → Tenants** → select a tenant → **Settings → Scanning settings → IOC scanning schedule**
Settings → Endpoint Agents → Send files to Sandbox automatically	**Settings → Tenants** → select a tenant → **Settings → Scanning settings → Sandbox**
Settings → Notifications	**Settings → Tenants** → select a tenant → **Settings → Email templates**
Settings → KSN/KPSN and MDR → Participation in KSN/KPSN	**Settings → Kaspersky Security Network**
Settings → KSN/KPSN and MDR → MDR integration	**Monitoring → MDR**
Settings → Passwords for archives	**Settings → Tenants** → select a tenant → **Settings → Scanning settings → Archives**
Sandbox servers	**Settings → Tenants** → select a tenant → **Settings → Sandbox servers**

Threat detection

Kaspersky EDR Expert uses alerts and incidents as work items that are to be processed by analysts.

The **Alerts** and **Incidents** sections are displayed in the main menu if the following conditions are met:

- You have a license key for Kaspersky EDR Expert.
- You are connected to the root Administration Server in OSMP Console.
- You have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 1 analyst, Tier 2 analyst, SOC manager, Approver, Auditor.

Working with alerts

This section contains general information about alerts, their properties, typical life cycle, and connection with incidents. The instructions that are provided will help you analyze the alert table, change alert properties according to the current state in the life cycle, and combine alerts into incidents by linking or unlinking the alerts.

The **Alerts** section is displayed in the main menu if the following conditions are met:

- You have a license key for Kaspersky EDR Expert.
- You are connected to the root Administration Server in OSMP Console.
- You have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 1 analyst, Tier 2 analyst, SOC manager, Approver, Auditor.

About alerts

An *alert* is an event in the organization's IT infrastructure that was marked by Kaspersky EDR Expert as unusual or suspicious, and that may pose a threat to the security of the organization's IT infrastructure.

Kaspersky EDR Expert generates an alert when an EPP application (for example, Kaspersky Endpoint Security for Windows) detects certain activity in the infrastructure that corresponds to conditions defined in the detection rules.

The alert is created within 30 seconds after the KUMA correlation event has occurred. You receive a corresponding email notification if you previously configured notifications templates.

You can also create an alert manually from a set of events.

After detection, Kaspersky EDR Expert adds alerts to the alert table as work items that are to be processed by analysts. You cannot delete alerts. You can only close these.

Incidents can be assigned only to analysts who have the access right to read and modify alerts and incidents.

You can manage alerts as work items by using the following alert properties:

- **Alert status.**

  Possible values: **New**, **In progress**, **Closed**, or **In incident**.

  The alert status shows the current state of the alert in its life cycle. You can change the status as you like, with the following exceptions:

  - You cannot return closed alerts to the status **In progress**. Closed alerts can only be returned to the status *New*, and then the status can be changed to **In progress**.
  - You cannot set the **In incident** status manually. The alerts gain this status when they are linked to an incident.
  - You can only set the **Closed** status to a linked alert. To set the **New** or **In progress** status, you first must unlink the alert from the incident.

- **Alert severity level.**

  Possible values: **Low**, **Medium**, **High**, or **Critical**.

  The alert severity shows the impact this alert may have on computer security or corporate LAN security based on Kaspersky experience. The severity is defined automatically and cannot be changed manually.

- **Alert assignee**

  This is an alert owner, the analyst who is responsible for the alert investigation and process. You can change the assignee of an alert at any time. You cannot change the assignee of closed alerts.

You can combine and link alerts to bigger work items called *incidents*. You can link alerts to incidents manually, or enable the rules to create incidents and link alerts automatically. By using incidents, analysts can investigate multiple alerts as a single issue. When you link a currently unlinked alert to an incident, the alert loses its current status and gains the status **In incident**. You can link a currently linked alert to another incident. In this case, the **In incident** status of the alert is kept. You can link a maximum of 200 alerts to an incident.

Each alert has *alert details* that provide all of the information related to the alert. You can use this information to investigate the alert, track the events that preceded the alert, view detection artifacts, affected assets, or link the alert to an incident.

Alert data model

The structure of an alert is represented by fields that contain values (see the table below). Some fields are objects or arrays of objects with their own set of fields (for example, the `Assignee` and `Assets` fields).

Alert

Field	Value type	Required	Description
`InternalID`	String	Yes	Internal alert ID, in the UUID format. The field value may match the `SourceID` value.
`ID`	Integer	Yes	Short internal alert ID.
`TenantID`	String	Yes	ID of the tenant that the alert is associated with, in the UUID format.

`CreatedAt`	String	Yes	Date and time of the alert generation, in the RFC 3339 format.
`UpdatedAt`	String	Yes	Date and time of the last alert change, in the RFC 3339 format.
`StatusChangedAt`	String	No	Date and time of the last alert status change, in the RFC 3339 format.
`Severity`	String	Yes	Severity of the alert. Possible values: • `critical` • `high` • `medium` • `low`
`IntegrationID`	String	Yes	ID of the Kaspersky application management plug-in that is integrated in OSMP.
`IntegrationCompatibilityVersion`	String	Yes	Version of the Kaspersky application management plug-in that is integrated in OSMP.
`SourceID`	String	No	Unique alert identifier in the integrated component.
`SourceCreatedAt`	String	No	Date and time of the alert generation in the integrated component, in the RFC 3339 format.
`FirstEventTime`	String	Yes	Date and time of the first telemetry event related to the alert, in the RFC 3339 format.
`LastEventTime`	String	Yes	Date and time of the last telemetry event related to the alert, in the RFC 3339 format.
`DetectSource`	String	No	Component that detects and generates the alert.
`DetectionTechnologies`	Array of strings	No	Triggered detection technology.
`State`	String	Yes	Alert status. Possible values: • `new` • `inProgress` • `inIncident` • `closed`
`StatusResolution`	String	No	Resolution of the alert status. Possible values: • `truePositive` • `falsePositive` • `lowPriority` • `merged`
`IncidentID`	String	No	Internal ID of the incident associated with the alert.
`IncidentLinkType`	String	No	Way to add an alert to an incident. Possible values: • `manual` • `auto`
`Assignee`	`Assignee` object	No	Operator to whom the alert is assigned.
`MITRETactics`	Array of `MITRETactic` objects	No	MITRE tactics related to all triggered IOA rules in the alert.
`MITRETechniques`	Array of `MITRETechnique` objects	No	MITRE techniques related to all triggered IOA rules in the alert.
`Observables`	Array of `Observable` objects	No	Observables related to the alert.
`Assets`	Array of `Asset` objects	No	Assets affected by the alert.
`Rules`	Array of `Rule` objects	No	Triggered correlation rules, on the basis of which the alert is generated.
`OriginalEvents`	Array of objects	No	Events, on the basis of which the alert is generated.

`ExternalRef`	String	Yes	Link to an entity in an external system (for example, a link to a Jira ticket).
`Extra`	Object	No	Data related to the alert, in the JSON format. This data is obtained from managed Kaspersky applications when events are transformed into alerts. This field is not used in the interface.
`AdditionalData`	Object	No	Additional information about the alert, in the JSON format. This information can be filled in by a user or a playbook.
`IsCII`	Boolean	Yes	Indicator that the affected asset (a device or an account) is an object of critical information infrastructure.
`Name`	String	Yes	The name of the alert.
`Attachments`	Array of `UnkeyedAttachment` objects	No	Attachments related to the incident.

Assignee

Field	Value type	Required	Description
`ID`	String	Yes	User account ID of the operator to whom the alert is assigned.
`Name`	String	Yes	Name of the operator to whom the alert is assigned.

MITRETactic

Field	Value type	Required	Description
`ID`	String	Yes	ID of the MITRE tactic related to all triggered IOA rules in the alert.
`Name`	String	Yes	Name of the MITRE tactic related to all triggered IOA rules in the alert.

MITRETechnique

Field	Value type	Required	Description
`ID`	String	Yes	ID of the MITRE technique related to all triggered IOA rules in the alert.
`Name`	String	Yes	Name of the MITRE technique related to all triggered IOA rules in the alert.

Observable

Field	Value type	Required	Description
`Type`	String	Yes	Observable type Possible values: • `ip` • `md5` • `sha256` • `url` • `domain` • `userName` • `hostName`
`Value`	String	Yes	Value of the observable object.
`Details`	String	No	Additional information about the observable object.

Rule

Field	Value type	Required	Description
`ID`	String	Yes	ID of the triggered rule.
`Name`	String	No	Name of the triggered rule.
`Severity`	String	No	Severity of the triggered rule. Possible values: • `critical` • `high` • `medium` • `low`
`Confidence`	String	No	Confidence level of the triggered rule. Possible values: • `high` • `medium` • `low`
`Custom`	Boolean	No	Indicator that the alert is based on custom rules.

Asset

Field	Value type	Required	Description
`Type`	String	Yes	Type of the affected asset (a device or an account). Possible values: • `host` • `user`
`ID`	String	Yes	ID of the affected asset (a device or an account).
`Name`	String	No	The name of the affected device that the alert is associated with (if `Type` is set to `host`). The user name of the affected user account associated with events, on the basis of which the alert is generated (if `Type` is set to `user`).

`IsAttacker`	Boolean	No	Indicator that the affected asset (a device or an account) is an attacker.
`IsVictim`	Boolean	No	Indicator that the affected asset (a device or an account) is a victim.
`CIICategory`	String	No	Category of importance of the affected asset (a device or an account) that is an object of critical information infrastructure. Possible values: • `notCII` • `ciiWithoutCategory` • `ciiFirstCategory` • `ciiSecondCategory` • `ciiThirdCategory`

UnkeyedAttachment

Field	Value type	Required	Description
`AttachmentID`	String	Yes	Attachment ID, in the UUID format.
`Name`	String	Yes	Attachment name.
`CreatedAt`	String	Yes	Date and time of the attachment creation, in the UTC format.
`UpdatedAt`	String	Yes	Date and time of the last attachment change, in the UTC format.
`CreatedBy`	String	Yes	Indicator that the affected asset (a device or an account) is a victim.
`Size`	Integer	Yes	Attachment size, specified in bytes.
`State`	String	Yes	Attachment status that indicates whether the attachment upload is in progress, completed, or aborted with an error. Possible values: • `completed` • `error` • `uploading`
`Description`	String	No	Attachment description.
`StatusCode`	String	No	Text of the status that is displayed to a user (for example, an error message that is displayed when the attachment upload fails).

Viewing the alert table

The alert table is displayed in the **Monitoring** → **Alerts** section and provides you with an overview of all alerts registered by Kaspersky EDR Expert. By default, the table displays the alerts related to all of the tenants to which you have access rights. If necessary, you can configure the alert table.

To configure the alert table, do any of the following:

- Apply tenant filter:

  a. Click the link next to the **Tenant filter** setting.

  The tenant filter opens.

  b. Select the check boxes next to the required tenants.

- Filter the data of the alerts table using one of the following methods:
  - Use the main filter:
    a. Click the filter ( ) icon.
    b. On the **Filters** tab, specify and apply the filter criterion in the invoked menu.
  - Filter out rescanned alerts:
    a. Click the header of the **Name** column.
    b. Check either **Only rescanned alerts** or **Exclude rescanned alerts** box.
  - Use a cell context filter to quickly add a new filter condition:
    a. Find the cell that contains the value that you want to add as a filter condition. Note that some columns do not have a cell context filter.
    b. Left-click the value in the cell.
    c. In the list that opens, select one of the following actions:
      - **Add to filter** to add the value in the filter condition.
      - **Exclude from filter** to exclude the value from the filter condition.
      - **Copy** to copy the value to the clipboard.
- If you want to hide or display a column, click the settings ( ) icon, and then select the necessary column.

The alert table is configured and displays the data you need.

The alert table has the following columns:

- **Registered**. The date and time when the alert was added to the alert table.
- **Updated**. The date and time of the last change from the alert history.
- **Alert ID**. Unique ID of the alert.
- **Status**. The current status of the alert.
- **Incident link type**. Way to add an alert to an incident.
- **Severity**. Severity of the alert.
- **Name**. The name of the alert.
- **Detected**. One or multiple categories of detected objects. For example, when Kaspersky EDR Expert detects a file infected with the Trojan-Downloader.JS.Cryptoload.ad virus, the **Detected** field shows the Trojan-Downloader.JS.Cryptoload.ad category for this alert.

- **Affected assets**. The devices and users that were affected by the alert.

  From the moment an asset is added to OSMP, it takes approximately 2 minutes before the solution can start enriching events with this asset. For example, if a correlation event occurs within two minutes after adding an asset, this asset is not displayed in the generated alert.

- **Assigned**. The current assignee of the alert.
- **Observables**. Detection artifacts, for example IP addresses or MD5 hashes of files.
- **Details**. Brief summary of the alert.
- **Status changed**. The date and time of the last alert status change.
- **Tenant**. The name of the tenant in which the alert was detected.
- **External reference**. The alert number in an external system.
- **CII object**. An indicator showing whether alert is associated with the assets related to the CII objects.
- **Technology**. Names of the modules or components that generated the alert while scanning.

  Possible values in this column:

  - IOA
  - SB (Sandbox)
  - AM (Anti-Malware Engine)
  - IOC
  - YARA
  - KUMA

Special considerations for event aggregation in alerts triggered by IOA rules

If Kaspersky EDR Expert has created an alert triggered by an IOA rule, and if the same IOA rule is triggered by other events on this or other hosts during the same day, Kaspersky EDR Expert aggregates those events in the same alert. If the alert is already closed, Kaspersky EDR Expert reopens it. The event aggregation period ends at 00:00 the next day.

Viewing alert details

Alert details are a page in the interface that contains all of the information related to the alert, including the alert properties.

To view alert details:

1. In the main menu, go to **Monitoring** → **Alerts**.
2. In the alert table, click the ID of the required alert.

   The alert details are displayed.

If necessary, you can refresh the information in the alert details by clicking the refresh (↻) icon next to the alert name.

The toolbar in the upper part of the alert details allows you to perform the following actions:

- Edit the **External reference** field value
- Assign the alert to an analyst
- Change the alert status
- Link the alert to an incident
- Unlink the alert from the incident
- Select a playbook
- Create a new incident and link the alert to it

Depending on alert type, alert details contain the following sections:

- **Summary**

  Depending on alert type, the summary section may contain the following alert properties:

  - **Analyst**. An analyst to which the alert is assigned.
  - **Name**. The name of the alert. If the alert name is not specified, this field is not displayed.
  - **Tenant**. The name of the tenant in which the alert was detected.
  - **Assets**. The number of user accounts and devices related to the alert.
  - **Severity**. Possible values: **Low**, **Medium**, **High**, or **Critical**. The alert severity shows the impact this alert may have on computer security or corporate LAN security based on Kaspersky experience.
  - **Rules**. The rules that were triggered to detect the alert. By clicking the ellipsis icon next to the rule name, you can open the context menu. Use this menu to learn more details about the rule, find alerts or incidents that were detected by the same rule, or search the rule triggering events in **Threat hunting** for the period between the first and the last event of the alert.

    When you click **Go to Threat hunting** in the menu, the **Threat hunting** section opens in the same tab. The section title displays the ID and name of the alert from which you drilled down here. If you want to open the **Threat Hunting** section in a new browser tab, press and hold the `Ctrl` key and in the menu, click the **Go to Threat hunting** section.

- **Registered**. The date and time when the alert was added to the alert table.
- **First event**. A date and time of the first event related to the alert.
- **Last event**. A date and time of the most recent event related to the alert.
- **External reference**. Link to an entity in an external system (for example, a link to a Jira ticket). You can click the **Edit** button at the top to specify the external reference. If the alert was created from a Kaspersky Endpoint Detection and Response alert, a link to this alert is displayed in the field.
- **Linked to**. The incident to which the alert is linked.
- **MITRE tactic**. A tactic or several tactics detected in the alert. You can open the context menu by clicking a MITRE tactic name. By using the context menu, you can do the following:
  - View detailed information about a MITRE tactic in Kaspersky TIP by clicking the **Find in Kaspersky TIP** button.
  - View detailed information about a MITRE tactic in the MITRE ATT&CK knowledge base by clicking the **Find in MITRE ATTCK** button.
  - Copy the MITRE tactic name.
- **MITRE technique**. A technique or several techniques detected in the alert. You can open the context menu by clicking a MITRE technique name. By using the context menu, you can do the following:
  - View detailed information about a MITRE technique in Kaspersky TIP by clicking the **Find in Kaspersky TIP** button.
  - View detailed information about a MITRE technique in the MITRE ATT&CK knowledge base by clicking the **Find in MITRE ATTCK** button.
  - Copy the MITRE technique name.
- **Correlation rules**. The correlation rules that were triggered to detect a threat and create the alert.
- **IOA rules**. The IOA rules that were triggered to detect a threat and create the alert. You can open the context menu by clicking an IOA rule name. By using the context menu, you can do the following:
  - View detailed information about that IOA rule by clicking the **Open properties** button.
  - View related events by clicking the **Go to Threat hunting** button.

    You will be redirected to the **Threat hunting** section that displays only the events tracked by this IOA rule. The default time interval from which to display the events is 24 hours. The section title displays the ID and name of the alert from which you drilled down here.
  - Find similar incidents.
  - View detailed information about an IOA rule in Kaspersky TIP by clicking the **Find in Kaspersky TIP** button.
  - Copy the IOA rule name.
- **Technology**. Detection technology used to detect a threat.

- **Detection source**. The source from which the detected object came. For example, if a file is sent to Sandbox for scanning from some host, this host is the detection source.

- **Additional data**. Additional information on the alert. You can edit a value in this field only by using a playbook. The field is displayed if you added a value.

- **Scan result**

  The **Scan result** section contains information about the file that was scanned and the scan results that triggered the alert creation.

- **IOC scan results**

  The **IOC scan result** section contains information about IOC rules that were triggered during the scan.

  By clicking the IOC rule name, you can view the detailed information about the IOC rule.

  By clicking **View report** in the **Scan results** column, you can view the detailed information about scan results, including network and system information, processes and files involved when scanning.

- **Kaspersky Sandbox scan results**

  The **Kaspersky Sandbox scan result** section contains information about the results of processing objects in Sandbox including the following:

  - Number of detected objects and their types.

  - Number of extracted files and their types.

  - Hash sums of the detected objects.

  By clicking **Export results**, you can view the detailed information about the results of object processing in operating systems available on Sandbox, including the following:

  - Diagrams with detection statistics.

  - A graph containing a tree of object activity.

  - MITRE tactics and techniques (see the MITRE ATT&CK knowledge base).

  - A list of suspicious activities in an operating system.

  - Screenshots of the file execution in an operating system.

  - System activities.

  - Network activities.

  To get the full information in the Sandbox scan results window, switch between operating systems and between the results obtained in **Quick scan mode** and **Full logging mode**.

- **YARA scan results**

  The **YARA scan result** section contains information about the results of YARA scanning on a host.

By clicking **View report** in the **Scan results** column, you can view the detailed information about scan results. To get the full information in the YARA scan results window, switch between the **Processes & memory dump**, **Files** and **Rule condition** tabs.

- **Scanned files**

  In the **Scanned files** section, you can find information about the files that were scanned. To learn more about threats detected in files on Kaspersky Threat Intelligence Portal, click the threat name in the **Verdict** column.

- **Detailed information**

  In the **Details** section, you can track the telemetry events related to the alert.

  The event table displays the search result that you define through an SQL query.

  The toolbar of the event table allows you to perform the following actions:

  - **Download events**. You can click this button to download information about related events as a CSV file (in UTF-8 encoding).

  - **Find in Threat hunting**. You can click this button to open the **Threat hunting** section. This section allows you to search through all of the events related to the tenants that you have access to, and not only the events related to the current alert. The section title displays the ID and name of the alert from which you drilled down here.

    By default, the opened event table in the section contains all of the events that occurred during the time period between the first and the last event of the alert. For example, you can run a search query to find all of the events in which the device was affected.

    In the **Threat hunting** section, you can link events to alerts manually. This might be helpful if you discover that some events relate to an alert, but they were not linked to the alert automatically. For details, refer to the instructions on linking or unlinking events to or from alerts.

    You can go back to the incident details by clicking **Alert investigation** or by clicking the back button in your browser.

  - **Unlink from alert**. You can select an event or several events in the table, and then click this button to unlink the selected events from the alert.

- **Assets**

  In the **Assets** section, you can do the following:

  - View the devices and users affected by or involved in the alert.

  - Perform response actions. To do this, select the check box next to the asset, and then in the **Select response action** drop-down list, select the required response action.

  - Export information about affected assets to a CSV file by clicking the **Export to CSV** button.

  - Connect to the asset by using the remote terminal. To do this, click the **Open remote terminal** button.

  The asset table contains the following columns:

  - **Asset type**

    Possible values: device or user.

  - **Asset name**

  - **Asset ID**

- **Has signs of**

  Possible values: attacker or victim.

- **Authorization status**

  This parameter is only applied to device asset type. A device authorization status is defined by KICS for Networks. You can change the authorization status by applying the corresponding response action to a device.

- **Administration Server**

  The Administration Server that manages the device.

- **Administration Group**

  The administration group to which the device belongs.

- **Categories**

  Asset categories which include the asset.

- **Archived**

  Archival status of the asset. Possible values: Yes or No.

By clicking a user name or a device name, you can:

- View the user or the device properties.

  > To view the list of alerts or incidents related to the device, in the device properties window, click the **Show related** button and select either **Alerts** or **Incidents**, depending on what you want to view.

- Copy the user name or the device name in the clipboard.
- Search the user name or the device ID in other alerts.
- Search the user name or the device ID in other incidents.
- Search the user name or the device ID in **Threat hunting** for the period between the first and the last event of the alert.

  > When after clicking a user name or a device name you select **Go to Threat hunting** in the menu, the **Threat hunting** section opens in the same tab. The section header displays the ID and name of the alert from which you drilled down here. If you want to open the **Threat Hunting** section in a new browser tab, press and hold the `Ctrl` key and in the menu, click the **Go to Threat hunting** section.

By clicking a user ID or a device ID, you can:

- View the user or the device properties.

  > To view the list of alerts or incidents related to the device, in the device properties window, click the **Show related** button and select either **Alerts** or **Incidents**, depending on what you want to view.

- Copy the user ID or the device ID in the clipboard.

- Search the user ID or the device ID in other alerts.
- Search the user ID or the device ID in other incidents.
- Search the user ID or the device ID in **Threat hunting** for the period between the first and the last event of the alert.

  When after clicking a user ID or a device ID you select **Go to Threat hunting** in the menu, the **Threat hunting** section opens in the same tab. The section header displays the ID and name of the alert from which you drilled down here. If you want to open the **Threat Hunting** section in a new browser tab, press and hold the `Ctrl` key and in the menu, click the **Go to Threat hunting** section.

From the moment an asset is added to OSMP, it takes approximately 2 minutes before the solution can start enriching events with this asset. For example, if a correlation event occurs within two minutes after adding an asset, this asset is not displayed in the generated alert.

- **Files**

  The **Files** section contains files obtained through response actions or manually added to this alert. You can upload, download, delete files related to the alert, or edit the files' description.

  You can upload files of any extension. Duplicate file names are allowed. The maximum number of files that you can attach to the incident and the maximum total file size you can specify in the configuration file.

  Default limitations:

  - The number of files cannot exceed 100 per alert.
  - Total file size cannot exceed 25 MB per alert.

  To upload files, click the **Upload** button and select one or multiple files. If you attempt to upload files exceeding the limitations, the **Uploading files** panel displaying a warning message will open. In this panel, you can remove files from the upload queue until the warning message disappears and click the **Upload** button to upload files. If you ignore the warning message, upload will fail and the file list will include files that could not be uploaded with a warning icon next to the file names.

  After you click the **Upload** button, the pane is closed, and the uploaded file is displayed in the table of files both in the alert details and in the **Files** section of the main menu. When uploading a large file or multiple files, you have to refresh the table so it displays the new files. If the file uploading is in progress, the **Name or full path** column displays the loading spinner, and the **Size** column shows how much of the total file size is already uploaded.

  Click a file to open the **Edit file** panel that displays file details. In this panel, you can edit file description.

  Use check boxes to select a file or multiple files. Select one or more files and click the **Download** button to download them as an archive in the ZIP format. The archive is protected with the password *infected*. Select a file or multiple files and click the **Delete** button to delete the selected files.

  The **Write** permission in the **Alerts and incidents** functional area is required to upload and delete files and edit file descriptions. The **Read** permission in the **Alerts and incidents** functional area is required to download files.

- **Observables**

  In the **Observables** section, you can:

  - View observables related to an alert.
  - Export information about the related observables to a CSV file by clicking the **Export to CSV** button.

- Search the table of observables by data from the **Value** column.

  To do this, start entering the data of the desired observable in the search field. If there are no matches with values of observables from the **Value** column, an empty table is displayed.

The observables may include:

- MD5 hash
- URL
- Domain name
- SHA256
- UserName
- HostName
- Local IP address
- Remote IP address

  The following private IP addresses are not included in the observables related to the alert:
  From 10.0.0.0 to 10.255.255.255 with the subnet mask 255.0.0.0 or /8
  From 172.16.0.0 to 172.31.255.255 with the subnet mask 255.240.0.0 or /12
  From 192.168.0.0 to 192.168.255.255 with the subnet mask 255.255.0.0 or /16
  From 100.64.0.0 to 100.127.255.255 with the subnet mask 255.192.0.0 or /10

  To include private IP addresses in the observables, run the following commands on the administrator host:

  ```
  k0s kubectl -n irp set env deploy/transformer -c transformer
  OSMP_TRANSFORMER_FILTER_PRIVATE_IPS_DISABLED=true
  ```

  ```
  k0s kubectl -n irp set env deploy/incident -c incident
  OSMP_FILTER_PRIVATE_IPS_DISABLED=true
  ```

- Local Port
- Remote Port
- System Process ID
- Unique PID
- Full name of a file

By clicking a link in the **Value** column, you can:

- Search the observable value in **Threat hunting** for the period between the first and the last event of the alert.

  When after clicking a link in the **Value** column you select **Go to Threat hunting** in the menu, the **Threat hunting** section opens on the same tab. The section title displays the ID and name of the alert from which you drilled down here. If you want to open the **Threat Hunting** section in a new browser tab, press and hold the `Ctrl` key and in the menu, click the **Go to Threat hunting** section.

- Search the observable value in other alerts.
- Search the observable value in other incidents.
- Copy the observable value in the clipboard.

The toolbar of this section contains the following buttons:

- **Request status from Kaspersky TIP**. Use this button to obtain detailed information about the selected observable from Kaspersky Threat Intelligence Portal (Kaspersky TIP). As a result, the information is updated in the **Status update** column. Requires integration with Kaspersky Threat Intelligence Portal (Premium access).
- **Enrich data from Kaspersky TIP**. Use this button to obtain detailed information about all of the listed observables from Kaspersky TIP. As a result, the information is updated in the **Enrichment** column. Use a link in the **Enrichment** column to open the obtained enrichment details about an observable. Requires integration with Kaspersky Threat Intelligence Portal (Premium access).
- **Select response actions**. To perform response actions, select the check box next to the observable, and, in the **Select response actions** drop-down list, specify the required response actions:
  - **Run**. Use this button to start the application with the specified parameters.
  - **Get file**. Use this button to download the archive with the file to your device.
  - **Block (NGFW)**. Use this button to add an IP address, URL, or domain to the denylist on network devices.
  - **Manage services**. Use this button to remotely start, stop, pause, resume, or remove a service on a device. This button is only available for hash (MD5 or SHA256) observables.
  - **Terminate process**. Use this button to terminate processes associated with the file. This button is only available for hash (MD5 or SHA256) observables.
  - **Delete file**. Use this button to delete files.
  - **Move to quarantine**. Use this button to move the device on which the file is located to quarantine. This button is only available for hash (MD5 or SHA256) observables.
  - **Add prevention rule**. Use this button to add a rule that prevents the file from running. This button is only available for hash (MD5 or SHA256) observables.
  - **Delete prevention rule**. Use this button to delete the rule that prevents the file from running. This button is only available for hash (MD5 or SHA256) observables.

- **Similar closed alerts**

  In the **Similar closed alerts** section you can view the list of closed alerts that have the same affected artifacts as the current alert. The affected artifacts include observables and affected devices. The similar closed alerts can help you investigate the current alert.

  By using the list, you can evaluate the degree of similarity of the current alert and other alerts. The similarity is calculated as follows:

  Similarity = M / T * 100

  Here, 'M' is a number of artifacts that matched in the current and a similar alert, and 'T' is total number of artifacts in the current alert.

  If the similarity is 100%, the current alert has nothing new in comparison with the similar alert. If the similarity is 0%, the current and the similar alert are completely different. Alerts that have a similarity of 0% are not included in the list.

  The calculated value is rounded off to the nearest whole number. If similarity is equal to a value between 0% and 1%, the application does not round such a value down to 0%. In this case, the value is displayed as less than 1%.

  Clicking an alert ID opens the alert details.

Customizing the similar closed alerts list

You can customize the table by using the following options:

- Filter the alerts by selecting the term for which the alerts have been updated. By default, the list contains the alerts that have been updated for the last 30 days.
- Click the **Columns settings** icon ( ), and then select which columns to display and in which order.
- Click the **Filter** icon ( ), and then select and configure the filters that you want to apply. If you select several filters, they are applied simultaneously by logical AND operator.
- Click a column header, and then select the sorting options. You can sort the alerts in ascending or descending order.

- **Similar incidents**

  In the **Similar incidents** section, you can view the list of incidents that have the same affected artifacts as the current alert. The affected artifacts include observables and affected devices. The similar incidents can help you decide if the current alert may be linked to an existing incident.

  By using the list, you can evaluate the degree of similarity of the current alert and the incidents. The similarity is calculated as follows:

  Similarity = M / T * 100

  Here, 'M' is a number of artifacts that matched in the current alert and a similar incident, and 'T' is total number of artifacts in the current alert.

  If the similarity is 100%, the current alert has nothing new in comparison with the similar incident. If the similarity is 0%, the current alert and the similar incident are completely different. Incidents that have similarity of 0% are not included in the list.

The calculated value is rounded off to the nearest whole number. If similarity is equal to a value between 0% and 1%, the application does not round such a value down to 0%. In this case, the value is displayed as less than 1%.

Clicking an incident ID opens the incident details.

Customizing the similar incidents list

You can customize the table by using the following options:

- Filter the incidents by selecting the term for which the incidents have been updated. By default, the list contains the incidents that have been updated for the last 30 days.
- Click the **Columns settings** icon ( ), and then select which columns to display and in which order.
- Click the **Filter** icon ( ), and then select and configure the filters that you want to apply. If you select several filters, they are applied simultaneously by logical AND operator.
- Click a column header, and then select the sorting options. You can sort the incidents in ascending or descending order.

- **Comments**

  In the **Comments** section, you can leave comments related to the alert. For example, you can enter a comment about investigation results or when you change the alert properties, such as the alert assignee or status.

  To save your comment, press **Enter**. To start a new line, press **Shift+Enter**. To edit or delete your comment, use the buttons on the top right.

  You can edit or remove your own comments only within a specified period after the comment was left. The default period is 15 minutes.

  If you want to change it, on the administrator host run the following command:

  ```
  k0s kubectl -n irp set env deploy/comment -c comment
  OSMP_COMMENT_LOCK_AFTER_DURATION=Nx
  ```

  where `N` is a time interval, and `x` is a unit of measurement: `h` (hours) or `m` (minutes).

  The comments of other users cannot be modified or removed. The **Write** permission in the **Alerts and incidents** functional area is required to leave comments.

- **History**

  In the **Alert event log** section, you can track the changes that were made to the alert as a work item:
  - Changing alert status
  - Changing alert assignee
  - Linking alert to an incident
  - Unlinking alert from an incident
  - Uploading a file to the alert
  - Deleting a file from the alert

In the **Response history** section, you can review the log of manual and playbook response actions. The resource table contains the following columns:

- **Time**. The time when the event occurred.
- **Launched by**. Name of the user who launched the response action.
- **Events**. Event description.
- **Response parameters**. Response action parameters that are specified in the response action.
- **Asset**. Number of the assets for which the response action was launched. You can click the link with the number of the assets to view the asset details.
- **Action status**. Execution status of the response action. The following values can be shown in this column:
  - **Awaiting approval**—Response action awaiting approval for launch.
  - **Launched**—Response action is in progress.
  - **Success**—Response action is completed without errors or warnings.
  - **Warning**—Response action is completed with warnings.
  - **Error**—Response action is completed with errors.
  - **Terminated**—Response action is completed because the user interrupted the execution.
  - **Approval time expired**—Response action is completed because the approval time for the launch has expired.
  - **Rejected**—Response action is completed because the user rejected the launch.
- **Playbook**. Name of the playbook in which the response action was launched. You can click the link to view the playbook details.
- **Response action**. Name of the response action that was performed.
- **Asset type** Type of asset for which the response action was launched. Possible values: **Device** or **User**.
- **Asset tenant**. The tenant that is the owner of the asset for which the response action was launched.

Assigning alerts to analysts

As a work item, an alert can be assigned to a SOC analyst or to a user group for inspection and possible investigation. You can assign alerts to a user group if you want to automatically assign alerts to analysts within the selected group. For details, refer to Configuring the automatic assignment of alerts and incidents.

You can change the assignee of an active alert at any time. You cannot change an assignee of a closed alert.

Alerts can be assigned only to analysts and user groups who have the access right to read and modify alerts and incidents.

To assign one or several alerts:

1. In the main menu, go to **Monitoring → Alerts**.
2. Select the check boxes next to the alerts that you want to assign.

   You must select only the alerts detected in the same tenant. Otherwise, the **Assign** button will be disabled.

   Alternatively, you can assign an alert to an analyst or to a user group from the alert details. To open the alert details, click the link with the alert ID you need.
3. Click the **Assign** button.
4. In the **Assign to analyst** window that opens, select whether to assign the alerts to a user or a user group.
5. Start typing the name of an analyst or a user group, and then select the assignee from the list.

   If you want to unassign alerts, select **Not assigned**.

   > You can select **Not assigned** for all alerts, except alerts with the **Closed** status.
6. Click the **Assign** button.

Alerts are assigned.

You also can assign an alert by using playbooks.

Changing an alert status

As a work item, an alert has a status that shows the current state of the alert in its life cycle.

> You can change alert statuses for your own alerts or the alerts of other analysts only if you have the access right to read and modify alerts and incidents.

> If the alert status is changed manually, playbooks will not launch automatically. You can launch a playbook for such an alert manually.

An alert can have one of the following statuses:

- **New**

  When Kaspersky EDR Expert registers a new alert, the alert has the *New* status. You can change the status to *In progress* or *Closed*. When you change the *New* status to *Closed*, and the alert has no assignee, the alert is automatically assigned to you.

- **In progress**

  This status means that an analyst started working on the alert. You can change the *In progress* status to *New* or *Closed*.

- **Closed**

  True positive alerts are to be linked to incidents and be investigated within the incidents. When you close an incident, the linked alerts also gain the *Closed* status. You close an unlinked alert only as false positive or a low-priority alert. When you close an alert, you must select a resolution.

  Status *Closed* can only be changed to *New*. If you want to return a closed alert back to active, change its status as follows: *Closed* → *New* → *In progress*.

  When you close an alert linked to an incident, the alert is automatically unlinked from the incident. If the alert that you are going to close has no assignee, the alert is automatically assigned to the analyst who closes the alert.

- **In incident**

  Alerts gain this status when they are linked to an incident. This status cannot be selected manually. The *Closed* status can only be assigned to a linked alert. To change this status to *New* or *In progress*, you must first unlink the alert from the incident.

To change the status of one or several alerts:

1. In the main menu, go to **Monitoring** → **Alerts**.
2. Do one of the following:
   - Select the check boxes next to the alerts whose status you want to change.
   - Click the link with the ID of the alert whose status you want to change.

     The **Alert details** window opens.
3. Click the **Change status** button.
4. In the **Change status** pane, select the status to set.

   If you select the *Closed* status, you must select a resolution.

   > If you change the alert status to *Closed* and this alert contains uncompleted playbooks or response actions, all related playbooks and response actions will be terminated.

5. Click **Save**.

The status of the selected alerts is changed.

If an alert is added to the investigation graph, you can also change the alert status through the graph.

You also can change the alert status by using playbooks.

Creating alerts manually

You can create an alert manually from a set of events. You can use this functionality to examine a hypothetical incident that has not been detected automatically.

> If the alert is created manually, playbooks will not launch automatically. You can launch a playbook for such an alert manually.

To create an alert manually:

1. In the main menu, go to **Monitoring** → **Threat hunting**.
2. Select the events for which you want to create an alert. The events should belong to the same tenant.
3. Click the **Create alert** button.

   A window shows up that displays the created alert, and you receive a corresponding email notification if notifications templates are configured. The **Severity** field value corresponds to the maximum severity among the selected events.

Manually created alerts have a blank **Rules** value in the **Monitoring** → **Alerts** table.

Linking alerts to incidents

You can link one or multiple alerts to an incident for the following reasons:

- Multiple alerts may be interpreted as indicators of the same issue in an organization's IT infrastructure. If this is the case, the alerts in the incident can be investigated as a single issue. You can link up to 200 alerts to an incident.
- A single alert may be linked to an incident if the alert is defined as true positive.

You can link an alert to an incident if the alert has any status other than *Closed*. When linked to an incident, an alert loses its current status and gains the special status *In incident*. If you link alerts that are currently linked to other incidents, the alerts are unlinked from the current incidents, because an alert can be linked to only one incident.

> Alerts can only be linked to an incident that belongs to the same tenant.

Alerts can be linked to an incident manually or automatically.

Linking alerts manually

To link alerts to an existing or new incident:

1. In the main menu, go to **Monitoring → Alerts**.
2. Select the check boxes next to the alerts that you want to link to an incident.
3. If you want to link alerts to an existing incident:
   a. Click the **Link to incident** button.
   b. Select an incident to link the alerts to.

   Alternatively, click an alert to display its details and click the **Link to incident** button in the toolbar at the top.
4. If you want to link alerts to a new incident:
   a. Click the **Create incident** button.
   b. Fill in the properties of the new incident: name, assignee, priority, and description.

   Alternatively, click an alert to display its details and click the **Create incident** button in the toolbar at the top.
5. Click **Save**.

The selected alerts are linked to an existing or new incident.

Linking alerts automatically

If you want alerts to automatically link to an incident, you have to configure segmentation rules.

Unlinking alerts from incidents

You might need to unlink an alert from an incident, for example, if the alert analysis and investigation showed that the alert is not connected to other alerts in the incident. When you unlink an alert from an incident, Kaspersky EDR Expert performs the following actions:

- Refreshes all of the data related to the incident, to reflect that the alert no longer belongs to the incident. For example, you can view the changes in the incident details.
- Resets the status of the unlinked alerts to *New*.

To unlink an alert from an incident:

1. Open the alert details.
2. Click the **Unlink from incident** button in the toolbar at the top.

   The **Unlink alerts** window opens.
3. If you want to change the assignee, select **Assign the alerts to**, and then specify the new assignee.
4. If you want to add a comment, specify it in the **Comment** section. The comment you specify will be displayed in the **Details** column in the **History** section.

The selected alerts are unlinked from the incident.

Linking events to alerts

If during the investigation you found an event that is related to the alert being investigated, you can link this event to the alert manually.

> You can link an event to an alert that has any status other than **Closed**.

To link an event to an alert:

1. In the main menu, go to the **Monitoring** → **Alerts** section.
2. In the list of alerts, click the link with the ID of the alert to which you want to link the event.

   The **Alert details** window opens.
3. Go to the **Details** section, and then click the **Find in Threat hunting** button.

   The **Threat hunting** section opens. By default, the event table contains events related to the selected alert.

   > The event table contains only events related to tenants that you have access to.
4. In the upper part of the window, open the first drop-down list, and then select **Storage**.
5. Open the third drop-down list, and then specify the time range.

   You can select predefined ranges relative to the current date and time, specify a custom range by using the **Range start** and **Range end** fields, or by selecting dates in the calendar.
6. Click the **Run query** button.
7. In the updated list of events, select an event that you want to link to the alert, and then click **Link to alert**.

The selected events are linked to the alert.

Unlinking events from alerts

You might need to unlink an event from an alert, for example, if the alert analysis and investigation showed that the event is not connected to the alert.

To unlink an event from an alert:

1. In the main menu, go to the **Monitoring** → **Alerts** section.
2. In the list of alerts, click the link with the ID of the alert from which you want to unlink the event.

   The **Alert details** window opens.
3. In the **Details** section, select the events that you want to unlink, and then click the **Unlink from alert** button.

The selected event are unlinked from the alert.

Searching for events related to an imported IOA alert

You can search for events related to an alert that was imported from KEDR 7.1.

> This scenario only works if telemetry was transferred from KEDR 7.1 to OSMP.

To search for events related to an alert:

1. Open the required alert details page.

   The required alert can be identified by its creation date and the absence of any events in the alert body.
2. Remember or save in any convenient way the alert event date range (**First event** and **Last event** fields in the **Summary** section).
3. In the **Summary** section, click the IOA rule name in the **IOA rules** field, and select **Open properties**.

   The **IOA rule** page opens.
4. On the IOA rule page, click the **Find in Threat Hunting** button.

   The **Threat hunting** page opens
5. Specify the event date range from step 2 of this procedure:

   a. Click the time period drop-down list and enter the dates into the **Range from** and **Range to** fields. The date and time format depends on your browser settings.

      You can also select a date in the calendar. In this case, the **Range from** field is automatically populated with 00:00:00.000, and the **Range to** field with 23:59:59.999.

   b. Click **Apply**.
6. Click the **Run query** button.

Events related to an alert will be displayed in the **Events** table.

Working with alerts on the investigation graph

On the investigation graph, you can perform the following actions with alerts:

- Add an alert to the graph.
- Hide an alert from the graph.
- View an alert details by selecting the corresponding item from the context menu of the alert node.
- Change an alert status.
- View events related to an alert.
- View assets related to an alert.
- View observables related to an alert.

Adding alerts to the investigation graph

You can add an alert to the investigation graph in one of the of the following ways:

- From the general table of alerts that opens when you click the **Add alert** button on the investigation graph. You have to select the check boxes next to the alerts that you want to be displayed on the investigation graph, and then click the **Show on graph** button.
- From the table of similar alerts.

To add an alert to the investigation graph from the table of similar alerts:

1. Do one of the following:
   - If on the investigation graph you have an asset, observable, or segmentation rule, click its node, and then in the context menu, click **Find similar alerts**.
   - If on the investigation graph you have an event, click its node, and then in the context menu, click **View details**. In the window that opens, click the **Show on graph** button.
   - If on the investigation graph you have an alert, click its node, and in the context menu, click **Events**. In the table of events, click the event whose details you want to open. If the event details contain an observable, asset, or segmentation rule, click the link in the corresponding field, and then in the context menu, click **Find similar alerts**.
   - On the investigation graph, click the **Threat hunting** button, and then in the general table of events, click the event whose details you want to open. If the event details contain an observable, asset, or segmentation rule, click the link in the corresponding field, and then in the context menu, click **Find similar alerts**.

The table of similar alerts is displayed.

2. Select the check boxes next to the alerts that you want to be displayed on the investigation graph, and then click the **Show on graph** button.

The selected alerts are added to the investigation graph.

Hiding alerts from the investigation graph

You can hide an alert from the investigation graph in one of the following ways:

- By clicking the alert node and selecting **Hide** in the context menu.
- Through the table of alerts.

To hide an alert from the graph through the table of alerts:

1. Do one of the following:
   - In the toolbar at the top of the investigation graph, click the **Add alert** button.
   - If you have observables, assets, or events nodes displayed on the graph, click the node for which you want to add an alert, and then in the context menu, select **Find similar alerts**.

   The alerts table is displayed.

2. Select the check boxes next to the alerts that you want to hide from the investigation graph, and then click the **Show on graph** button.

The selected alerts and their links will be hidden from the investigation graph. The related nodes remain on the investigation graph.

Changing an alert status

To change an alert status:

1. Click the alert node, and in the context menu, select **Change status**.
2. In the **Change status** pane that opens, select the status, and then click **Save**.

   If you select the *Closed* status, you must select a resolution.

The status of the selected alerts is changed.

Viewing the events related to an alert

To view events related to an alert, do one of the following:

- Click the digit next to the alert node for which you want to display the events. The digit shows the number of events related to the alert.
- Click the alert node for which you want to display the events, and then in the context menu, click **Events**.

If you want to add the events from the table to the investigation graph, select the check boxes next to the events, and then click the **Show on graph** button.

If you want to hide the events from the investigation graph, select the check boxes next to the events, and then click the **Hide on graph** button.

Viewing assets related to an alert

To view assets related to an alert, click the alert node.

In the context menu, the digits next to the **Devices** and **Users** items show the number of devices and users related to the alert.

If you want to add devices or users to the investigation graph, click the corresponding menu item.

Viewing observables related to an alert

To view observables related to an alert, click the alert node, and in the context menu, click **Events**.

In the menu that opens, the digits next to the items show the number of observables relate related to the alert.

If you want to add an observable (for example, **Hash**, **Domain**, **IP address**) to the investigation graph, click the corresponding menu item.

Adding an IOA rule to exclusions

If you do not want to generate alerts for events generated as part of asset activity that is normal for your organization, you can add an IOA rule to exclusions.

To add an IOA rule to exclusions from the alert table:

1. In the main menu, go to **Monitoring** → **Alerts**.
2. Click the filter icon.

3. On the **Filters** tab, specify and apply the **Detected** filter criterion for the desired IOA rule.
4. In the alert table, click the ID of an alert.

   The alert details are displayed.
5. In the **Summary** section, click the IOA rule name.
6. In the IOA rule panel, click **Add to exclusions**.

   The **Add to exclusions** panel is invoked.
7. In the **Add to exclusions** panel, select a policy or profile to add the IOA rule to exclusions. Click **Next**.
8. Specify the exclusion rule properties and click **Add**.

   The IOA rule is added to exclusions.

To view and edit the list of IOA exclusions for a policy:

1. In the main menu, go to **Policies**.
2. Click the desired policy.
3. Select the **Application settings** tab. Expand the **General settings** menu on the left and select **Telemetry Settings**.

   In the **EDR Expert (on-premises) telemetry** tab, the **General exclusions** tab shows IOA exclusions.

   - To disable an exclusion rule, turn off its **Status** toggle switch.
   - To delete an exclusion rule, select the check box next to the exclusion rule and click **Delete**.
   - To view exclusion rule details, click the exclusion rule name.

Managing aggregation rules

This section contains general information about aggregation rules and gives instructions on how to create, edit, duplicate, copy to another tenant, and delete aggregation rules.

> To manage aggregation rules, you must have one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator.

Aggregation rules allow you to combine repetitive events of other Kaspersky solutions into Open Single Management Platform alerts. The alerts are either linked to the existing incidents, or form new incidents.

You can create and manage aggregation rules in the **Monitoring → Resources and services → Aggregation rules**. The aggregation rules are displayed in a table. The higher the rule is in the table of aggregation rules, the higher its priority. If you want to change the aggregation rule priority, you have to drag and drop the rule by clicking the drag (⠿) icon.

For inherited rules, you can change the priority from the parent tenant only. In a child tenant, the priority of inherited rules is always higher than the priority of the rules created in the child tenant. Also, inherited rules maintain the same priority order as they had in the parent tenant.

Also, the table contains the predefined aggregation rule created by Kaspersky experts. This rule combines the events for which the same correlation rule was triggered during the default aggregation interval (30 seconds).

You cannot delete the predefined aggregation rule, but you can edit it. By default, the rule is enabled.

By default, predefined rules are created on all tenants, and inheritance is disabled for them. If you enable inheritance for a rule on the parent tenant, the corresponding rule on the child tenant will be overwritten by the parent tenant settings. If you disable inheritance, the parent tenant rule will be deleted. However, since a tenant cannot exist without predefined rules, a new local predefined rule will be automatically created on the child tenant.

The aggregation rules are processed sequentially according to the specified priority. When the condition set in the **Trigger** section is met, the aggregation rule is triggered, and the search for other suitable aggregation rules continues. The search stops only when all the rules in the table are processed.

Limitations related to detection technologies

Depending on detection technology, there are some limitations on alert aggregation:

- YARA, Sandbox and Anti-Malware detection on file:
  - You can aggregate detections by these technologies on the same file.
  - You cannot add IOA detections or the results of IOC or YARA scans.
- IOA detection:
  - You can aggregate into one alert detections triggered by one IOA rule or different IOA rules.
  - You cannot add detections by all other technologies.
- IOC scans:
  - You can aggregate the results of IOC scans (for example, detections by the same IOC rule, different IOC rules, the same or different hosts).
  - You cannot add detections by all other technologies.
- YARA scans:
  - You can aggregate the results of YARA scans (for example, detections by the same YARA rule, different YARA rules, the same or different hosts).
  - You cannot add detections by all other technologies.

Creating aggregation rules

Aggregation rules help you to combine repetitive events of other Kaspersky solutions into Open Single Management Platform alerts.

To create aggregation rules, you must have one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator.

To create an aggregation rule:

1. In the main menu, go to **Monitoring** → **Resources and services** → **Alert aggregation**.

   The table of aggregation rules opens.

2. Click **Create**.

   The **Create aggregation rule** window opens.

3. In the **Status** field, enable the aggregation rule you want to create.

   By default, the rule is disabled.

4. In the **Tenant owner** field, specify a tenant to which the aggregation rule will belong.

5. In the **Name** field, specify the aggregation rule name.

   The rule name must be unique.

6. In the **Max events in alert** field, specify the maximum number of events combined in an alert.

   The value must be between 1 and 100. The default value is 100.

7. In the **Aggregation interval** field, specify the searching interval in minutes or seconds.

   The maximum value is 1500 seconds. The default value is 30.

8. If necessary, in the **Inherited by** field change the inheritance settings.

   By default, rules are inherited from the parent tenant by all child tenants down the hierarchy. You can disable inheritance by selecting the **Current tenant only** option, or specify the tenants which must inherit the rule by clicking **Specific tenants**, and then selecting the tenants from the drop-down list.

   You can only specify the tenants for which you have the following XDR roles: Main administrator, Tenant administrator, SOC administrator.
   Editing the inheritance settings, changing the rule priority, duplicating or deleting the inherited rules are possible from the parent tenant only. The inherited rule status can be changed both from the parent and child tenants.

   In a child tenant, the priority of inherited rules is always higher than the priority of the rules created in the child tenant. Also, inherited rules maintain the same priority order as they had in the parent tenant. When duplicating an inherited rule, it is duplicated with its scope. When copying an inherited rule to another tenant, the rule scope is not copied.

9. In the **Alert name** section, specify the jq expression that defines the template that will be used to create the name of the new alert. This expression is also used to combine events into an alert.

   By default, the following expression is specified: `([.Rules[]?.Name // empty] | sort | join(","))`

   When creating a new alert, the name is generated from the values of the fields specified in the template.

   If necessary, you can copy the jq expression for the **Alert name** section from another aggregation rule. To do that, click the **Copy from another rule** button.

Example of the jq expression for the Alert name section

```
if any(.OriginalEvents[]?.BaseEvents[]?.DestinationUserName // empty; startswith("adm_")) then "Brute force
admin" else "Brute force not admin" end
```

10. In the **Trigger** section, specify the jq expression that defines the condition for creating an alert from an event.

    If necessary, you can copy the jq expression for the **Trigger** section from another aggregation rule. To do that, click the **Copy from another rule** button.

    Example of the jq expression for the Trigger section

    ```
    .AggregationID | startswith("bruteforce_DestinationUserName")
    ```

11. If necessary, in the **Description** field, specify a description of the aggregation rule.

12. Click **Create**.

    The aggregation rule is created.

By default, the aggregation rule is created with the lowest priority. To change the aggregation rule priority, in the table of aggregation rules, drag and drop the rule by clicking its name. The higher the rule is in the table of aggregation rules, the higher its priority.

Editing aggregation rules

You can edit the aggregation rule settings.

> For inherited rules, in the child tenant you can change only the rule status. If you want to edit other settings, you have to do it from the parent tenant, and then the changes will be propagated to the child tenants.

To edit the aggregation rule:

1. In the main menu, go to **Monitoring** → **Resources and services** → **Aggregation rules**.

2. In the table of aggregation rules that opens, click the name of the aggregation rule that you want to edit.

3. In the **Edit aggregation rule** window that opens, edit the aggregation rule properties. For more details on the rule properties that you can edit, refer to Creating aggregation rules.

4. Click the **Apply** button.

5. If you want to change the aggregation rule priority, in the table of aggregation rules, drag and drop the rule by clicking its name.

   The higher the rule is in the table of aggregation rules, the higher its priority.

The properties of the aggregation rule are modified and saved.

Copying aggregation rules to another tenant

You can copy an existing aggregation rule to another tenant.

> If the hierarchy of OSMP instances is built, you can copy rules within an instance only.

To copy aggregation rules:

1. In the main menu, go to **Monitoring** → **Resources and services** → **Aggregation rules**.
2. In the table of aggregation rules, select the rules that you want to copy, and then click **Copy to tenant**.
3. Select one or multiple target tenants, and then click **Copy**.
4. If the target tenant contains an aggregation rule with an identical name, the **Overwrite or rename aggregation rules?** window appears:

   - If you want to delete the previously created rule for the target tenant and replace it with the rule that you want to copy, click **Overwrite**.
   - If you want to preserve the previously created rule and copy the specified rule with (copy) appended to its title, click **Copy and rename**.

   If you copy an inherited rule, and the target tenant already has a rule with the same name, this rule is not overwritten. You have to change the name of the rule that you copying. Also, inherited rules are copied with their status but without the scope.

   > When you click the close (×) button, the window is closed, and the aggregation rules whose names are identical to the ones in the target tenants are not copied. However, if at step 2 you also selected the aggregation rules that are absent in the target tenants, such rules are copied.

   The aggregation rules are copied to another tenant or tenants.

Deleting aggregation rules

You can permanently delete one or multiple aggregation rules at once.

If an aggregation rule was inherited, you can delete it from its parent tenant only.

> You cannot delete the predefined aggregation rule. Since a tenant cannot exist without a predefined rule, after you delete it, a new local predefined rule will be automatically created.

To delete aggregation rules:

1. In the main menu, go to **Monitoring → Resources and services → Aggregation rules**.
2. In the table of aggregation rules, select one or multiple aggregation rules that you want to delete, and then click **Delete**.
3. In the confirmation dialog box, click **Delete**.

The aggregation rule is deleted.

Working with incidents

This section contains general information about incidents, their properties, typical life cycle, and connection with alerts. This section also gives instructions on how to create incidents, analyze the incident table, change incident properties according to the current state in the life cycle, and merge incidents.

The **Incidents** section is displayed in the main menu if the following conditions are met:

- You have a license key for Kaspersky EDR Expert.
- You are connected to the root Administration Server in OSMP Console.
- You have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 1 analyst, Tier 2 analyst, SOC manager, Approver, Auditor, Interaction with child incidents.

About incidents

An *incident* is a container of alerts that normally indicates a true positive issue in the organization's IT infrastructure. An incident may contain a single or several alerts. By using incidents, analysts can investigate multiple alerts as a single issue.

You can create incidents manually or enable the rules for automatic creation of incidents. After an incident is created, you can link alerts to the incident. You can link up to 200 alerts to an incident.

After creation, Kaspersky EDR Expert adds incidents to the incident table as work items that are to be processed by analysts.

Incidents can be assigned only to analysts who have the access right to read and modify alerts and incidents.

You can manage incidents as work items by using the following incident properties:

- **Incident status**

  Possible values: *New*, *In progress*, *On hold*, or *Closed*.

The incident status shows the current state of the incident in its life cycle. You can change the status as you like, with the following exceptions:

- Status *New* cannot be changed to *On hold*.
- Status *Closed* can only be changed to *New*.

- **Incident severity**

  Possible values: **Low**, **Medium**, **High**, or **Critical**.

  The incident severity shows the impact this incident may have on computer security or corporate LAN security, based on Kaspersky experience. An incident's severity corresponds to the highest severity of the linked alerts and cannot be changed manually.

- **Incident priority**

  Possible values: **Low**, **Medium**, **High**, or **Critical**.

  Incident priority defines the order in which the incidents must be investigated by analysts. Incidents with the **Critical** priority are the most urgent ones and must be investigated first. You can change the incident priority manually.

- **Incident assignee**

  This is an incident owner, the analyst who is responsible for the incident investigation and process. You can change an incident assignee at any time if the **Status** parameter is not set to **Closed**.

Two or more incidents may be interpreted as indicators of the same issue in an organization's IT infrastructure. If this is the case, you can merge the incidents to investigate them as a single issue.

Each incident has *incident details* that provide all of the information related to the incident. You can use this information to investigate the incident or merge incidents.

For each incident, you can create child incidents. Child incidents allow you to investigate and respond to incidents across different tenants. You can also create a child incident of another child incident. A parent incident can have no more than 200 child incidents.

Incident data model

The structure of an incident is represented by fields that contain values (see the table below). Some fields are objects or arrays of objects with their own set of fields (for example, the `Assignee` and `Alerts` fields).

Incident

Field	Value type	Required	Description
`InternalID`	String	Yes	Internal incident ID, in the UUID format.
`ID`	Integer	Yes	Short internal incident ID.
`TenantID`	String	Yes	ID of the tenant that the incident is associated with, in the UUID format.
`IncidentType`	`IncidentType` object	Yes	Incident type
`Name`	String	Yes	A name of an incident.

`WorkflowName`	String	Yes	Name of the incident workflow.
`WorkflowUUID`	String	Yes	Unique identifier of the incident workflow, in the UUID format.
`Description`	String	No	Incident description.
`CreatedAt`	String	Yes	Date and time of the incident creation, in the RFC 3339 format.
`UpdatedAt`	String	Yes	Date and time of the last incident change, in the RFC 3339 format.
`StatusChangedAt`	String	No	Date and time of the incident status change, in the RFC 3339 format.
`Severity`	String	No	Severity of the incident. Possible values: • `critical` • `high` • `medium` • `low`
`Priority`	String	Yes	Incident priority Possible values: • `critical` • `high` • `medium` • `low`
`Assignee`	`Assignee` object	No	Operator to whom the incident is assigned.
`FirstEventTime`	String	No	Date and time of the first telemetry event of the alert related to the incident, in the RFC 3339 format.
`LastEventTime`	String	No	Date and time of the last telemetry event of the alert related to the incident, in the RFC 3339 format.
`State`	String	Yes	Incident status Possible values: • `open` • `inProgress` • `hold` • `closed`
`StatusUUID`	String	Yes	Incident status ID, in the UUID format.
`StatusResolution`	String	No	Resolution of the incident status. Possible values: • `truePositive` • `falsePositive` • `lowPriority` • `merged`
`DetectSources`	Array of strings	No	Components that detect and generate the incident.
`DetectionTechnologies`	Array of strings	No	Triggered detection technology.
`Alerts`	Array of `Alert` objects	No	Alerts included in the incident.
`AdditionalData`	Object	No	Additional information about the alert, in the JSON format. This information can be filled in by a user or a playbook.
`ExternalRef`	String	Yes	Link to an entity in an external system (for example, a link to a Jira ticket).
`SignOfCreation`	String	Yes	Method of creating an incident.
`IsCII`	Boolean	Yes	Indicator that the affected asset (a device or an account) is an object of critical information infrastructure.
`Attachments`	Array of `UnkeyedAttachment` objects	No	Attachments related to the incident.

IncidentType

Field	Value type	Required	Description
`ID`	String	Yes	Incident type ID, in the UUID format.
`Name`	String	Yes	Name of the incident type.
`Description`	String	Yes	Incident type description.

Assignee

Field	Value type	Required	Description
`ID`	String	Yes	User account ID of the operator to whom the incident is assigned.
`Name`	String	Yes	Name of the operator to whom the incident is assigned.

UnkeyedAttachment

Field	Value type	Required	Description
`AttachmentID`	String	Yes	Attachment ID, in the UUID format.
`Name`	String	Yes	Attachment name.
`CreatedAt`	String	Yes	Date and time of the attachment creation, in the UTC format.
`UpdatedAt`	String	Yes	Date and time of the last attachment change, in the UTC format.
`CreatedBy`	String	Yes	Indicator that the affected asset (a device or an account) is a victim.
`Size`	Integer	Yes	Attachment size, specified in bytes.
`State`	String	Yes	Attachment status that indicates whether the attachment upload is in progress, completed, or aborted with an error. Possible values: • `completed` • `error` • `uploading`
`Description`	String	No	Attachment description.
`StatusCode`	String	No	Text of the status that is displayed to a user (for example, an error message that is displayed when the attachment upload fails).

Creating incidents

You can create incidents manually or enable the rules for automatic creation of incidents. This topic describes how to create incidents manually.

To be able to create incidents, you must have the access right to read and modify alerts and incidents.

If the incident is created manually, playbooks will not launch automatically. You can launch a playbook for such an incident manually.

You can create incidents by using the incident table or the alert table.

Creating incidents by using the incident table

To create an incident:

1. In the main menu, go to **Monitoring** → **Incidents**. Click the **Create incident** button.
2. On the **General settings** step, specify the following settings:
   - A name of an incident.
   - **Tenant**

     A tenant that the incident is associated with. Alerts can only be linked to an incident that belongs to the same tenant. You cannot change the incident's tenant later.
   - **Assignee**

     This is an incident owner, the analyst who is responsible for the incident investigation and process. You can change an incident assignee at any time if the **Status** parameter is not set to **Closed**.
   - **Priority**

     Possible values: **Low**, **Medium**, **High**, or **Critical**.

     Incident priority defines the order in which the incidents must be investigated by analysts. Incidents with the **Critical** priority are the most urgent ones and must be investigated first. You can change the incident priority manually.
   - **Description**

     In this field, you can leave a description of the incident. For example, you can describe the issue or provide investigation results of the linked alerts. The description is added to the **Description** section of the incident details.

     This field is optional.
3. Click **OK**.

   The incident has been created.

Creating incidents by using the alert table

You create an incident by selecting the alerts to link to the new incident. Refer to linking alerts to incidents.

Creating child incidents

Child incidents allow you to monitor the investigation progress and respond to incidents across different tenants. You can also create a child incident of another child incident. A parent incident can have up to 200 child incidents.

> You must have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 1 analyst, Tier 2 analyst, SOC manager, Approver, Interaction with child incidents.

To create a child incident:

1. In the main menu, go to the **Monitoring** → **Incidents** section.
2. In the incident table, click the ID of the required incident.

   The **Incident details** window opens.
3. In the **Child incidents** section, click the **Create** button.

   The **Create child incident** window opens.
4. If necessary, in the **Name** field, change the name of the child incident.

   By default, the child incident name includes the [Child] tag and the parent incident name.
5. In the **Tenant** drop-down list, select the tenant to assign the child incident to.
6. In the **Analyst** drop-down list, start typing the analyst's name, and then select the analyst from the list.

   You can also select the **Not assigned** option.
7. If necessary, in the **Priority** drop-down list, change the incident priority.

   By default, the child incident inherits the priority from the parent incident.
8. If necessary, in the **Description** field, specify a description of the child incident.
9. If you want to copy all the information from the parent incident, select the **Copy information from the parent incident** check box.

   If this check box is selected, all information, including observables, assets, and linked alerts, will be copied from the parent incident. The copied alerts will be assigned to the tenant of the child incident.

If this check box is cleared, the child incident will not contain information about assets, observables, and linked alerts from the parent incident.

10. Click **Create**.

The child incident is created and linked to the parent incident. You can find the child incident in the **Child incidents** section of the Incident details window.

If a child incident is assigned to a tenant that does not have the incident type that the parent incident belongs to, the child incident is assigned the default incident type and the default incident workflow. If necessary, you can change the incident type.

Viewing the incident table

The incident table is displayed in the **Monitoring** → **Incidents** section and provides an overview of all created incidents. By default, the table displays the incidents related to all of the tenants to which you have access rights. If necessary, you can configure the incident table.

To configure the incident table, do any of the following:

- Apply tenant filter:

  a. Click the link next to the **Tenant filter** setting.

  The tenant filter opens.

  b. Select the check boxes next to the required tenants.

- Filter the data of the alerts table:

  a. Click the filter ( ) icon.

  b. On the **Filters** tab, specify and apply the filter criterion in the invoked menu.

- If you want to hide or display a column, click the settings ( ) icon, and then select the necessary column.

The incident table is configured and displays the data you need.

The incident table has the following columns:

- **Created**. Date and time when the incident was created.
- **Threat duration**. Time between the earliest and the most recent events among all of the alerts linked to the incident.
- **Updated**. Date and time of the last change, from the incident history.
- **Incident ID**. A unique identifier of an incident.
- **Status**. Current status of the incident.
- **Time to triage**. The time limit to accept the incident, in days, hours and minutes.

- **Time spent to respond**. The time limit for initial response to the incident, in days, hours and minutes.
- **Time to resolve**. The time limit to resolve the incident, in days, hours and minutes.
- **Status changed**. The date and time when the incident status has been changed.
- **Severity.** Severity of the incident.
- **Priority**. Priority of the incident.
- **Linked alerts**. How many alerts are included in the incident.
- **Name**. A name of an incident.
- **Rules**. The rules that were triggered to create the incident.
- **Affected assets**. Devices and users that were affected by the incident. If the number of assets affected by or involved in the incident is greater than or equal to three, the number of affected devices is displayed.
- **Tenant**. The name of the tenant in which the incident was detected.
- **External reference**. The incident number in an external system.
- **Assignee**. Current assignee of the incident.
- **Has parent incident**. Displays whether the incident has a parent incident. If the **Yes** value is displayed, then the incident is a child incident.
- **Status of child incidents**. Resulting status of first-level child incidents. Possible values: **Closed**, **In progress**, **No child incidents**.
- **Creation method**. How the incident was created—manually or automatically.
- **Observables**. Number of the detection artifacts, for example, IP addresses or MD5 hashes of files. If the number of observables is greater than or equal to three, the number of observables is displayed.

If necessary, you can export information about all incidents displayed in the incident table to a JSON file.

Viewing incident details

Incident details are a page in the interface that contains all of the information related to the incident, including the incident properties.

To view incident details:

1. In the main menu, go to the **Monitoring** → **Incidents** section.
2. In the incident table, click the ID of the required incident.

   The window with incident details is displayed.

If necessary, you can refresh the information in the incident details by clicking the refresh (↻) icon next to the incident name.

The toolbar in the upper part of the incident details allows you to perform the following actions:

- Edit the **Name**, **Description** and **External reference** field values
- View the incident on the investigation graph
- Change the incident status
- Change the incident priority
- Assign the incident to an analyst
- Select a playbook
- Link alerts to the incident
- Merge the incident with other incidents

Incident details contain the following sections:

- **Summary**

  The summary section contains the following incident properties:

  - **Type**. Incident type
  - **Analyst**. Current assignee of the incident.
  - **Creation method**. How the incident was created—manually or automatically.
  - **Name**. Name specified at the incident creation. You can click the **Edit** button at the top to change the incident name.
  - **Tenant**. The name of the tenant in which the incident was detected.
  - **Assets**. Number of users and devices that were affected by the incident.
  - **Registered**. Date and time when the incident was created.
  - **Updated**. Date and time of the last change, from the incident history.
  - **First event**. A date and time of the first event related to the incident. This is the earliest event in the Details section of the alert details among all of the alerts linked to the incident.
  - **Last event.** A date and time of the most recent event related to the incident. This is the most recent event in the Details section of the alert details among all of the alerts linked to the incident.
  - **Description.** Incident description. You can click the **Edit** button at the top to specify the description.
  - **External reference.** Link to an entity in an external system. You can click the **Edit** button at the top to specify the external reference.
  - **Priority**. Possible values: **Low**, **Medium**, **High**, or **Critical**. Incident priority defines the order in which the incidents can be investigated. Incidents with the **Critical** priority are the most urgent ones and can be investigated first. You can change the priority by clicking the current priority value.

- **Severity**. Possible values: **Low**, **Medium**, **High**, or **Critical**. The incident severity shows the impact this incident may have on computer security or corporate LAN security, based on Kaspersky experience.
- **Time to triage**—The time limit to accept the incident, in days, hours and minutes.
- **Time to respond**—The time limit for initial response to the incident, in days, hours and minutes.
- **Time to resolve**—The time limit to resolve the incident, in days, hours and minutes.
- **Correlation rules**. The rules that were triggered to detect the linked alerts. By clicking the ellipsis icon next to the rule name, you can open the context menu. Use this menu to learn more details about the rule, find alerts or incidents that were detected by the same rule, or search the rule-triggering events in **Threat hunting** for the period between the first and the last event of the incident. The title of the **Threat Hunting** section displays the ID and name of the incident from which you drilled down here.

  When you click **Go to Threat hunting** in the menu, the **Threat hunting** section opens in the same tab. If you want to open the **Threat hunting** section in a new browser tab, click and hold the `Ctrl` key, and then click **Go to Threat hunting** in the menu.

- **IOA rules**. The IOA rules that were triggered to detect a threat and create the related alert. You can open the context menu by clicking an IOA rule name. By using the context menu, you can do the following:
  - View detailed information about that IOA rule by clicking the **Open properties** button.
  - View related events by clicking the **Go to Threat hunting** button.

    You will be redirected to the **Threat hunting** section that displays only the events tracked by this IOA rule. The default time interval from which to display the events is 24 hours. The section title displays the ID and name of the incident from which you drilled down here.
  - Find similar incidents.
  - View detailed information about an IOA rule in Kaspersky TIP by clicking the **Find in Kaspersky TIP** button.
  - Copy the IOA rule name.
- **MITRE tactic**. A tactic or several tactics detected in the alerts linked to the incident. You can open the context menu by clicking a MITRE tactic name. By using the context menu, you can do the following:
  - View detailed information about a MITRE tactic in Kaspersky TIP by clicking the **Find in Kaspersky TIP** button.
  - View detailed information about a MITRE tactic in the MITRE ATT&CK knowledge base by clicking the **Find in MITRE ATTCK** button.
  - Copy the MITRE tactic name.

- **MITRE technique**. A technique or several techniques detected in the alerts linked to the incident. You can open the context menu by clicking a MITRE technique name. By using the context menu, you can do the following:

  - View detailed information about a MITRE technique in Kaspersky TIP by clicking the **Find in Kaspersky TIP** button.

  - View detailed information about a MITRE technique in the MITRE ATT&CK knowledge base by clicking the **Find in MITRE ATTCK** button.

  - Copy the MITRE technique name.

- **Additional data**. Additional information on the incident. You can edit a value in this field only by using a playbook. The field is displayed if you added a value.

- **Detailed information**

  In the **Details** section, you can track the telemetry events related to the incident.

  To view the events related to the incident, click the **Find in Threat hunting** button. The opened table displays alert events related to the incident. The **Threat Hunting** section title displays the ID and name of the incident from which you drilled down here.

  The toolbar of the event table allows you to perform the following actions:

  - **Download events**. Click this button to download information about related events into a TSV file.

  - **Unlink from incident**. You can select an event or several events in the table, and then click this button to unlink the selected events from the alert related to the incident.

  You can go back to the incident details by clicking **Incident investigation** or by clicking the back button in your browser.

- **Similar incidents**

  In the **Similar incidents** section, you can view the list of incidents that have the same affected artifacts as the current incident. The affected artifacts include both observables and affected devices of the alerts linked to an incident. The list contains incidents in any status.

  By using the list, you can evaluate the degree of similarity of the current incident and other incidents. The similarity is calculated as follows:

  Similarity = M / T * 100

  Here, M is a number of artifacts that matched in the current and a similar incident, and T is total number of artifacts in the current incident.

  If the similarity is 100%, the current incident has nothing new in comparison with the similar incident. If the similarity is 0%, the current and the similar incident are completely different. Incidents that have similarity of 0% are not included in the list.

  The calculated value is rounded off to the nearest whole number. If similarity is equal to a value between 0% and 1%, the application does not round such a value down to 0%. In this case, the value is displayed as less than 1%.

  Clicking an incident ID opens the incident details.

Customizing the similar incidents list

You can customize the table by using the following options:

- Filter the incidents by selecting the term for which the incidents have been updated. By default, the list contains the incidents that have been updated for the last 30 days.
- Click the **Columns settings** icon ( ), and then select which columns to display and in which order.
- Click the **Filter** icon ( ), and then select and configure the filters that you want to apply. If you select several filters, they are applied simultaneously by logical AND operator.
- Click a column header, and then select the sorting options. You can sort the incidents in ascending or descending order.

- **Alerts**

  In the **Alerts** section, you can view the list of the alerts linked to the current incident.

  By clicking an alert ID, you can open the alert details. You can also use the toolbar buttons to unlink alerts from the incident.

- **Assets**

  In the **Assets** section, you can do the following:

  - View the devices and users affected by or involved in the alert.
  - Perform response actions. To do this, select the check box next to the asset, and then in the **Select response action** drop-down list, select the required response action.
  - Export information about affected assets to a CSV file by clicking the **Export to CSV** button.
  - Connect to the asset by using the remote terminal. To do this, click the **Open remote terminal** button.

  The asset table contains the following columns:

  - **Asset type**

    Possible values: device or user.

  - **Asset name**
  - **Asset ID**
  - **Authorization status**

    This parameter is only applied to device asset type. A device authorization status is defined by KICS for Networks. You can change the authorization status by applying the corresponding response action to a device.

  - **Has signs of**

    Possible values: attacker or victim.

- **Administration Server**

  The Administration Server that manages the device.

- **Categories**

  Asset categories which include the asset.

- **Archived**

  Archival status of the asset. Possible values: Yes or No.

- **Count**

  The number of devices and users affected by or involved in the incident that have the same ID, type, and name.

- **Administration Group**

  The administration group to which the device belongs.

By clicking a user name or a device name, you can:

- View the user or the device properties.

  > To view the list of alerts or incidents related to the device, in the device properties window, click the **Show related** button and select either **Alerts** or **Incidents**, depending on what you want to view.

- Copy the user name or the device name in the clipboard.
- Search the user name or the device ID in other alerts.
- Search the user name or the device ID in other incidents.
- Search the user name or the device ID in **Threat hunting** for the period between the first and the last event of the incident.

  > When after clicking a user name or a device name you select **Go to Threat hunting** in the menu, the **Threat hunting** section opens in the same tab. If you want to open the **Threat hunting** section in a new browser tab, click and hold the `Ctrl` key, and then click **Go to Threat hunting** in the menu.

By clicking a user ID or a device ID, you can:

- View the user or the device properties.

  > To view the list of alerts or incidents related to the device, in the device properties window, click the **Show related** button and select either **Alerts** or **Incidents**, depending on what you want to view.

- Copy the user ID or the device ID in the clipboard.
- Search the user ID or the device ID in other alerts.
- Search the user ID or the device ID in other incidents.

- Search the user ID or the device ID in **Threat hunting** for the period between the first and the last event of the incident.

  When after clicking a user ID or a device ID you select **Go to Threat hunting** in the menu, the **Threat hunting** section opens in the same tab. If you want to open the **Threat hunting** section in a new browser tab, click and hold the `Ctrl` key, and then click **Go to Threat hunting** in the menu.

- **Child incidents**

  In the **Child incidents** section, you can view the list of incidents that are child incidents of the incident you are viewing.

- **Files**

  The **Files** section contains files obtained through response actions or manually added to this incident. You can upload, download, delete files related to the incident, or edit the files' description.

  You can upload files of any extension. Duplicate file names are allowed. The maximum number of files that you can attach to the incident and the maximum total file size you can specify in the configuration file.

  Default limitations:

  - The number of files cannot exceed 100 per incident.
  - Total file size cannot exceed 25 MB per incident.

  To upload files, click the **Upload** button and select one or multiple files. If you attempt to upload files exceeding the limitations, the **Uploading files** panel displaying a warning message will open. In this panel, you can remove files from the upload queue until the warning message disappears and click the **Upload** button to upload files. If you click the **Upload** button ignoring the warning message, upload will fail and the file list will include files that could not be uploaded with a warning icon next to the file names.

  After you click the **Upload** button, the pane is closed, and the uploaded file is displayed in the table of files both in the incident details and in the **Files** section of the main menu. When uploading a large file or multiple files, you have to refresh the table so it displays the new files. If the file uploading is in progress, the **Name or full path** column displays the loading spinner, and the **Size** column shows how much of the total file size is already uploaded.

  Click a file to open the **Edit file** panel that displays file details. In this panel, you can edit file description.

  Use check boxes to select a file or multiple files. Select one or more files and click the **Download** button to download them as an archive in the ZIP format. The archive is protected with the password *infected*. Select a file or multiple files and click the **Delete** button to delete the selected files.

  The **Write** permission in the **Alerts and incidents** functional area is required to upload and delete files and edit file descriptions. The **Read** permission in the **Alerts and incidents** functional area is required to download files.

- **Observables**

  In the **Observables** section, you can:

  - View observables that belong to alerts linked to the current Incident.
  - Export information about the related observables to a CSV file by clicking the **Export to CSV** button.
  - Search the table of observables by data from the **Value** column.

    To do this, start entering the data of the desired observable in the search field. If there are no matches with values of observables from the **Value** column, an empty table is displayed.

The observables may include:

- MD5 hash
- URL
- Domain name
- SHA256
- UserName
- HostName
- IP address

> The following private IP addresses are not included in the observables that relate to the alerts linked to the current incident:
> From 10.0.0.0 to 10.255.255.255 with the subnet mask 255.0.0.0 or /8
> From 172.16.0.0 to 172.31.255.255 with the subnet mask 255.240.0.0 or /12
> From 192.168.0.0 to 192.168.255.255 with the subnet mask 255.255.0.0 or /16
> From 100.64.0.0 to 100.127.255.255 with the subnet mask 255.192.0.0 or /10

> To include private IP addresses in the observables, run the following commands on the administrator host:

```
k0s kubectl -n irp set env deploy/transformer -c transformer
OSMP_TRANSFORMER_FILTER_PRIVATE_IPS_DISABLED=true
```

```
k0s kubectl -n irp set env deploy/incident -c incident
OSMP_FILTER_PRIVATE_IPS_DISABLED=true
```

By clicking a link in the **Value** column, you can:

- Search for the observable value in **Threat hunting** for the period between the first and the last event of the incident.

  > When after clicking a link in the **Value** column you select **Go to Threat hunting** in the menu, the **Threat hunting** section opens on the same tab. The section title displays the ID and name of the incident from which you drilled down here. If you want to open the **Threat Hunting** section in a new browser tab, press and hold the `Ctrl` key and in the menu, click the **Go to Threat hunting** section.

- Search the observable value in other alerts.
- Search the observable value in other incidents.
- Copy the observable value in the clipboard.

The toolbar of this section contains the following buttons:

- **Request status from Kaspersky TIP**. Use this button to obtain detailed information about the selected observable from Kaspersky Threat Intelligence Portal (Kaspersky TIP). As a result, the information is updated in the **Status update** column. Requires integration with Kaspersky Threat Intelligence Portal (Premium access).
- **Enrich data from Kaspersky TIP**. Use this button to obtain detailed information about all of the listed observables from Kaspersky TIP. As a result, the information is updated in the **Enrichment** column. Use a link in the **Enrichment** column to open the obtained enrichment details about an observable. Requires integration with Kaspersky Threat Intelligence Portal (Premium access).
- **Move to quarantine**. Use this button to move the device on which the file is located to quarantine. This button is only available for hash (MD5 or SHA256) observables.
- **Add prevention rule**. Use this button to add a rule that prevents the file from running. This button is only available for hash (MD5 or SHA256) observables.
- **Delete prevention rule**. Use this button to delete the rule that prevents the file from running. This button is only available for hash (MD5 or SHA256) observables.
- **Terminate process**. Use this button to terminate processes associated with the file. This button is only available for hash (MD5 or SHA256) observables.

- **History**

  In the **Incident log** section, you can track the changes that were made to the incident as a work item:
  - Changing incident status
  - Changing incident assignee
  - Linking an alert to the incident
  - Unlinking an alert from the incident
  - Creating a child incident
  - Merging the incident with other incidents
  - Uploading a file to the incident
  - Deleting a file from the incident

  In the **Response history** section, you can review the log of manual and playbook response actions. The resource table contains the following columns:
  - **Time**. The time when the event occurred.
  - **Launched by**. Name of the user who launched the response action.
  - **Events**. Event description.
  - **Response parameters**. Response action parameters that are specified in the response action.
  - **Asset**. Number of the assets for which the response action was launched. You can click the link with the number of the assets to view the asset details.

- **Action status**. Execution status of the response action. The following values can be shown in this column:
  - **Awaiting approval**—Response action awaiting approval for launch.
  - **Launched**—Response action is in progress.
  - **Success**—Response action is completed without errors or warnings.
  - **Warning**—Response action is completed with warnings.
  - **Error**—Response action is completed with errors.
  - **Terminated**—Response action is completed because the user interrupted the execution.
  - **Approval time expired**—Response action is completed because the approval time for the launch has expired.
  - **Rejected**—Response action is completed because the user rejected the launch.
- **Playbook**. Name of the playbook in which the response action was launched. You can click the link to view the playbook details.
- **Response action**. Name of the response action that was performed.
- **Asset type** Type of asset for which the response action was launched. Possible values: **Device** or **User**.
- **Asset tenant**. The tenant that is the owner of the asset for which the response action was launched.

- **Effort log**

  In the **Effort log** section, you can view the effort that analysts spent on incident-related work.

  In this section, you manage your effort. You cannot modify or delete effort added by other analysts.

  By clicking a link in the **Data** column, you can view and edit your effort.

- **Comments**

  In the **Comments** section, you can leave comments related to the incident. For example, you can enter a comment about investigation results or when you change the incident properties, such as the incident assignee or status.

  To save your comment, press **Enter**. To start a new line, press **Shift+Enter**. To edit or delete your comment, use the buttons on the top right.

  You can edit or remove your own comments only within a specified period after the comment was left. The default period is 15 minutes.

  If you want to change it, on the administrator host run the following command:

  ```
  k0s kubectl -n irp set env deploy/comment -c comment
  OSMP_COMMENT_LOCK_AFTER_DURATION=Nx
  ```

  where `N` is a time interval, and `x` is a unit of measurement: `h` (hours) or `m` (minutes).

  The comments of other users cannot be modified or removed. The **Write** permission in the **Alerts and incidents** functional area is required to leave comments.

Assigning incidents to analysts

As a work item, an incident must be assigned to a SOC analyst or to a user group for inspection and possible investigation. You can assign incidents to a user group if you want to automatically assign incidents to analysts within the selected group. For details, refer to Configuring the automatic assignment of alerts and incidents.

You can change the assignee of an incident at any time.

> Incidents can be assigned only to analysts and user groups who have the access right to read and modify alerts and incidents.

To assign one or several incidents:

1. In the main menu, go to **Monitoring** → **Incidents**.
2. Select the check boxes next to the incidents that you want to assign.

   You must select only the incidents detected in the same tenant. Otherwise, the **Assign to me** and **Assign** buttons will be disabled.

   Alternatively, you can assign an incident to an analyst or to a user group from the incident details. To open the incident details, click the link with the incident ID.
3. Do one of the following:

   - To assign the incidents to you, click the **Assign to me** button.
   - To assign the incidents to other analyst or user group:

     a. Click the **Assign** button.

     b. In the **Assign** window that opens, select whether to assign the incidents to a user or a user group.

     c. Start typing the name of an analyst or a user group, and then select the assignee from the list.

     d. Click the **Assign** button.

   If you want to unassign incidents, select **Not assigned**.

Incidents are assigned.

You also can assign an incident to an analyst by using playbooks.

Changing an incident status

As a work item, an incident has a status that shows the current state of the incident in its life cycle.

You can change the status of your own incidents or the incidents of other analysts only if you have the access right to read and modify alerts and incidents.

When you change the incident status, the incident and any unassigned linked alerts are automatically assigned to you.

If the incident status is changed manually, playbooks will not launch automatically. You can launch a playbook for such an incident manually.

An incident can have one of the following statuses:

- **New**

  When you create an incident or it is created automatically, the incident has the *New* status. You can change the status to *In progress* or *Closed*. When you change the *New* status to *Closed* and the incident has no assignee, the incident is automatically assigned to you.

- **In progress**

  This status means that an analyst started working on the incident or resumed the work by changing the *On hold* status. You can change the *In progress* status to any other status.

- **On hold**

  This status means that an analyst suspended work on the incident. Normally, you change the *On hold* status to *In progress* when the work is resumed, but you can change the *On hold* status to other statuses as well.

- **Closed**

  You close incidents when no additional work on the incident is expected. You can close an incident with one of the following resolutions:

  - True positive
  - False positive.
  - Low priority.

  When you close an incident, the linked alerts also gain the *Closed* status and inherit the resolution from the incident. If the incident has no assignee, the closed incident is automatically assigned to you. If the closed incident has unassigned linked alerts, those alerts are automatically assigned to you.

  Status *Closed* can only be changed to *New*. If you want to return a closed incident back to active, change its status as follows: *Closed* → *New* → *In progress*.

To change status of one or several incidents:

1. In the main menu, go to **Monitoring** → **Incidents**.
2. Do one of the following:
   - Select the check boxes next to the incidents whose status you want to change.
   - Click the link with the ID of the incident whose status you want to change.

     The **Incident details** window opens.
3. Click the **Change status** button.
4. In the **Change status** pane, select the status to set.

   When you select the *Closed* status, you must select a resolution.

   If at least one SLA metric was breached for an incident, the **SLA breach reasons** field appears when you close the incident. In this field, you need to specify the reason for the SLA breach.

   > If you have selected the **Allow users with certain permissions only to close this incident** check box when editing the *Closed* status in the incident workflow, you must have either Main Administrator or Approver EDR role to close the incident.

   > If you change the incident status to *Closed* and this incident contains uncompleted playbooks or response actions, all related playbooks and response actions will be terminated.
5. Click **Save**.

The status of the selected incidents is changed.

You also can change an incident status by using playbooks.

Changing an incident priority

As a work item, an incident has a priority that defines the order in which the incident must be investigated by analysts. You can change the incident priority manually.

> If you have the right to read and modify alerts and incidents, you can change the priority of incidents for your own or other analysts' incidents.

An incident can have one of the following priorities:

- **Low**
- **Medium** (default value)
- **High**
- **Critical**

Incidents with the **Critical** priority are the most urgent ones and must be investigated first. The **Low** priority usually means that the incident is placed in the backlog. You can define your own criteria as to which priority should be set to which incident.

To change an incident priority:

1. In the main menu, go to **Monitoring** → **Incidents**.
2. Do one of the following:
   - Select the check boxes next to the incidents whose priority you want to change.
   - Click the incident ID to open the details of the incident whose priority you want to change.
3. Click the **Change priority** button.
4. In the **Change priority** window, select the priority to set.
5. Click **Save**.

   The priority of the selected incidents is changed.

You also can change an incident priority by using playbooks.

For an incident with the **New** status (either just-created or switched to this status from any other):

- You can edit the priority, but it is automatically reevaluated when an alert is added or removed from this incident.

  The priority is set to the **Incident severity** value.
- If you manually change the priority of an incident that does not have any linked alerts (the incident was created without alerts, or all alerts were removed from the incident), then the **incident severity** is set to the priority value.
- When reevaluating the incident priority, the incident SLA is also automatically reevaluated.

Merging incidents

Two or more incidents may be interpreted as indicators of the same issue in an organization's IT infrastructure. If this is the case, you can merge the incidents to investigate them as a single issue.

When you merge incidents, you need to select a target incident among them. After the incident consolidation, the issue is to be investigated within the target incident. The target incident must have a status other than *Closed*. Other incidents are merged into the target one and, after consolidation, gain the *Closed* status and the **Merged** resolution.

All of the alerts linked to the merged incidents are automatically linked to the target incident. Because an incident can have no more than 1000 linked alerts, the application counts the alerts linked to the incidents that you want to merge. If the total number of linked alerts exceeds 1000, the selected incidents cannot be merged. When you select the target incident, a total number of alerts after merging is displayed.

You cannot merge child incidents or incidents that have child incidents.

To merge incidents from the incident table:

1. In the main menu, go to the **Monitoring** → **Incidents** section.
2. Select the check boxes next to the incidents that you want to merge into a target incident. You will select the target incident on the first step of the Wizard.
3. Click the **Merge into incident** button.
4. The **Merge incidents** Wizard opens.
5. Select the target incident.
6. Click the **Merge** button.

The incidents are merged.

To merge incidents by using incident details:

1. In the main menu, go to the **Monitoring** → **Incidents** section.
2. Click an incident ID to open the incident details. This incident will be merged into a target incident. You will select the target incident on the first step of the Wizard.
3. Click the **Merge into incident** button.

   The **Merge incidents** Wizard opens.
4. Select the target incident.
5. Click the **Merge** button.

The incidents are merged.

Exporting incidents to a file

You can export incidents to a PDF or JSON file.

To export an incident to a PDF file:

1. In the main menu, go to **Monitoring** → **Incidents**. to invoke the incident table.
2. Click the ID of an incident you want to export.
3. Click the **Export to PDF** button in the window with incident details.

   A **Print** window opens.
4. In the **Print** window, expand the **Printer** list and select **Save as PDF**.
5. Click the **Save** button to save the incident as a PDF file.

   If you sort the incident table by **Type** or **Name** fields, the exported PDF file also uses this sorting.

To export all incidents to a JSON file:

1. In the main menu, go to **Monitoring** → **Incidents**. to invoke the incident table.
2. Click the **Export** button in the panel above the table.
3. Specify the file name and select the folder to which to export incidents.
4. Click **Save** to save all incidents as a JSON file.

Creating Managed Detection and Response incidents from EDR incidents

You can create a Managed Detection and Response incident from an EDR incident if Managed Detection and Response integration is enabled in OSMP and the incident's alerts meet the following conditions:

- The detection source is endpoint.
- The selected incident must have at least one alert that has a related asset.
- The detection technology is any of the following:
  - IOA rules
  - IOC
  - YARA
  - SB (Sandbox)
  - AM (Anti-Malware Engine)

Refer to the following article for information on how to enable Managed Detection and Response integration in OSMP: Integration with Kaspersky applications and solutions.

To export an incident to Managed Detection and Response:

1. In the main menu, go to **Monitoring** → **Incidents**.
2. In the incident table, click the ID of the required incident. The window with incident details is displayed.
3. Click the three-dots icon on the toolbar and select **Create MDR incident**.
4. In the **Create MDR incident** panel, specify the incident name and description and click **Create**.

If the incident is created successfully, an appropriate message is displayed. You can now access the incident in the MDR Web Console. The link to the incident is available in the Summary section of the EDR incident.

Segmentation rules

Segmentation rules allow you to automatically split related alerts into different incidents based on the conditions that you specify when creating the rules.

Use segmentation rules to create different incidents based on related alerts. For example, you can combine several alerts with an important distinguishing feature into a separate incident.

Alerts can only be attached to an incident that belongs to the same tenant.

The segmentation rules are triggered according to the specified priority. The higher the rule is in the list of segmentation rules, the higher its priority. If you want to change the segmentation rule priority, drag and drop the rule by clicking its name.

We recommend that you use segmentation rules together with aggregation rules to define more precise rules for creating incidents.

To create a segmentation rule:

1. In the main menu, go to **Monitoring** → **Resources and services** → **Segmentation rules**.

   The list of segmentation rules opens.

2. Click **Create**.

   A **Create segmentation rule** window appears.

3. Specify the segmentation rule settings:

   - **State**

     Enable or disable the rule. By default, the rule is disabled.

   - **Rule**

     A unique name for the rule.

   - **Max alerts in incident**

     Maximum number of alerts in a single incident. The value must be between 1 and 200, and also must be greater than or equal to **Min alerts in incident**. The default value is 200. If the number of alerts exceeds the specified value, another incident is created.

   - **Min alerts in incident**

     Minimum number of alerts in a single incident. The minimum and default value is 1. The value must be less then or equal to **Max alerts in incident**. If the number of alerts does not reach the specified value, an incident is not created.

   - **Search interval**

     A time interval from which to select alerts and incidents. You can specify the value in days or in hours. The default value is 30 days.

   - **Description**

     Optional. Rule description.

- **Groups**

  A jq expression that defines the array of string identifiers by which to assign alerts to incidents.

  If necessary, you can copy the jq expression for **Groups** section from another segmentation rule. To do that, click the **Copy from another rule** button.

  Example: `if any(.Observables[]? | select(.Type | ascii_downcase == "username") | .Value; startswith("adm_")) then ["Brute force admin"] else ["Brute force not admin"] end`

- **Incident name**

  A jq expression that defines the template for naming the incidents created according to this segmentation rule. By default, the following expression is specified: `"\(.Rules[]?.Name), \(.SourceCreatedAt)"`

  If necessary, you can copy the jq expression for **Incident name** section from another segmentation rule. To do that, click the **Copy from another rule** button.

  Example: `if any(.Observables[]? | select(.Type | ascii_downcase == "username") | .Value; startswith("adm_")) then "Brute force admin" else "Brute force not admin" end`

- **Trigger**

  A jq expression that defines the condition for including alerts in the incident.

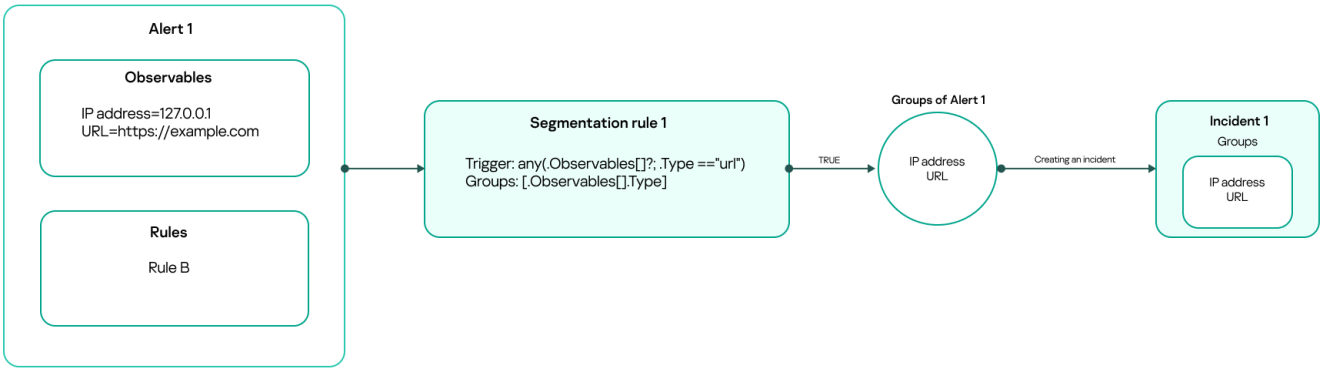
  If necessary, you can copy the jq expression for **Trigger** section from another segmentation rule. To do that, click the **Copy from another rule** button.

  Example: `any(.Rules[]?; .ID == "123")`

4. Click the **Save** button.

The segmentation rule is saved and displayed in the table of segmentation rules. If necessary, you can edit the rule setting by clicking its name in the table.

You can use the `inSubnet` logical operator in jq expressions to test if the left operand (IP address) is in the subnet of the right operand (subnet).



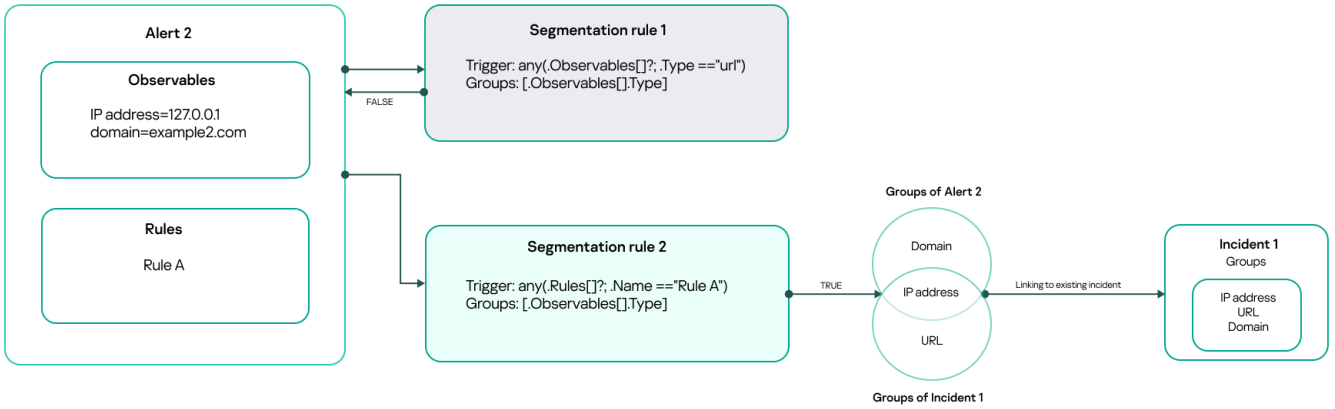
Example: `any(.Observables[]? | select(.Type == "ip") | .Value // empty; inSubnet("11.11.11.1/11"))`

The following predefined segmentation rules are available:

- Links to existing incident: Same MD5 file hash
- Links to existing incident: Same host asset
- Links to existing incident: Same IOA, IOC or Yara rule
- Create incident: Same MD5 file hash
- Create incident: Same host asset
- Create incident: Same IOA, IOC or Yara rule

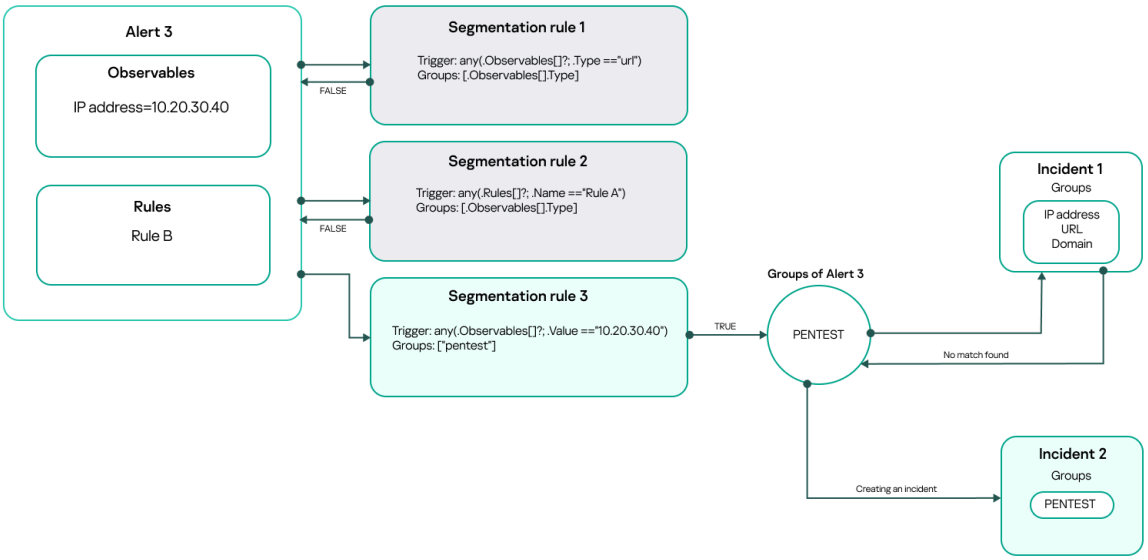
The predefined rules are automatically applied to tenants.

When an alert is created, it is checked by all active segmentation rules in accordance with their priority. After the first rule is triggered, an array of string identifiers is formed for the alert, and the search starts for the incident to which the alert will be linked.



Creating a new incident after the first segmentation rule is triggered

A rule is triggered if the jq expression that you have specified in the **Trigger section** returns `true`.



Alerts cannot be linked to incidents created manually.

An incident also has an array of string identifiers, which include the arrays of the alerts already linked to this incident. If the alert for which the segmentation rule was triggered has at least one element in its array that matches with any of those in the incident's array, the alert is linked to the incident. As a result, the array of this alert is added to the incident's array.

Linking an alert to an existing incident after detecting matching elements

If there are several incidents meeting the condition, the alert is linked to the one with the most recent update. If there are no incidents with matching elements in arrays, a new incident is created.

Creating a new incident after no matching elements are found based on the first two segmentation rules

When an incident is new, its array is empty. A new incident takes the array of string identifiers from an alert after the alert is linked.

Segmentation rule. Example

Configure the aggregation rules from the Aggregation rules. Example section in this topic.

The table below illustrates how to combine all penetration testing alerts in a single incident.

Segmentation rule

Attribute	Value
Trigger	.AggregationID == "Pentest"
Groups	["Pentest"]
Incident Name	"Pentest incident"

Aggregation and segmentation rules. Example

The table below illustrates how to combine alerts that have the same rule id in two incidents based on the user name prefix.

Aggregation rule

Attribute	Value	Description
Trigger	any(.Rules[]?; .ID == "123")	Searches alerts with the rule id set to "123".

Aggregation ID	if any(.OriginalEvents[]?.BaseEvents[]?.DestinationUserName // empty; startswith("adm_")) then "rule123_DestinationUserName_adm" else "rule123_DestinationUserName_not_adm" end	Searches for user names with the "adm_" prefix.
Alert Name	if any(.OriginalEvents[]?.BaseEvents[]?.DestinationUserName // empty; startswith("adm_")) then "Rule123 admin" else "Rule123 not admin" end	Sets the alert name depending on the user name prefix.

Segmentation rule

Attribute	Value
Trigger	.AggregationID | startswith("rule123_DestinationUserName")
Groups	[.AggregationID]
Incident Name	.Name

Copying segmentation rules to another tenant

You can copy an existing segmentation rule to another tenant.

If the hierarchy of OSMP instances is built, you can copy rules within an instance only.

To copy segmentation rules:

1. In the main menu, go to **Monitoring → Resources and services → Segmentation rules**.

   The table of segmentation rules opens.

2. Select the segmentation rules you want to copy, and then click **Copy to tenant**.

3. Select one or multiple target tenants and click **Copy**.

4. If the target tenant contains a segmentation rule with an identical name, an **Overwrite or rename segmentation rules?** window appears.

   Click **Overwrite** to delete the previously created rule for the target tenant and replace it with the rule that you want to copy.

   Click **Copy and rename** to preserve the previously created rule and copy the specified rule with `(copy)` appended to its title.

   If you copy an inherited rule, and the target tenant already has a rule with the same name, this rule is not overwritten. You have to change the name of the rule that you copying. Also, inherited rules are copied with their status but without the scope.

   When you click the close (×) button, the window is closed, and the segmentation rules whose names are identical to the ones in the target tenants are not copied. However, if at step 2 you also selected the segmentation rules which are absent in the target tenants, such rules are copied.

The segmentation rules are copied to another tenant or tenants.

Managing Service Level Agreement (SLA)

Kaspersky EDR Expert allows you to configure Service Level Agreement (SLA) entries that define the time limits to process incidents.

You can define an SLA entry for a combination of incident workflow and priority.

The **Incidents** table and incident details show the remaining time for SLA entries.

You can configure an email notification template with the **Incident SLA expiring** and **Incident SLA changed** types.

Restarting calculation of SLA metrics when the incident status is reverted

When an incident is considered responded, SLA metrics for this incident stop being calculated. Reverting the incident status restarts the SLA metric by default.

To prevent restarting SLA metrics when the incident status is reverted:

1. Ensure that the kubectl utility is installed on the administrator host.
2. Execute the following command:

   ```
   kubectl -n irp set env deploy/incident
   OSMP_INCIDENT_SLA_DISABLE_RESTART_CALCULATION_ON_START_TRIGGER=true
   ```

3. Restart the incident service.

Creating Service Level Agreement (SLA) entries

Creating SLA entryies requires one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator.

To create an SLA entry:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Click the **Settings** tab, and then click **Incident management**.
4. Select the **SLA** tab, and then click the **Create** button.
5. In the **Create SLA** pane that opens, configure the following settings:

   - **SLA name**—The display name of the entry.
   - **Priority**—The incident priority to which to apply the entry.
   - **Workflow**—The incident workflow to which to apply the entry.

     You can only assign a single entry to a combination of **Workflow** and **Priority**. You cannot select the incident workflow that are used in other SLAs with the same priority.

- **Time to triage**—The time limit to accept the incident, in days, hours and minutes. The incident is considered accepted when its status changes from one status to another.

  To define this transition, select the **From status** and the **To status** values.

- **Time to respond**—The time limit for initial response to the incident, in days, hours and minutes.

  Select stop condition:

  - If you want the incident to be considered responded after the response action is applied, select **On first response action**. After that, select one or multiple values in the **From status** field.

  - If you want the incident to be considered responded after its status changes to another one, select **When status changes to**. After that, select one or multiple values in the **From status** and the **To status** fields.

- **Time to resolve**—The time limit to resolve the incident, in days, hours and minutes. The incident is considered resolved when its status changes from one status to another.

  To define this transition, select the **From status** and the **To status** values.

6. Click the **Create** button.

   The created SLA entry is displayed in the table.

Deleting Service Level Agreement (SLA) entries

Deleting SLA entries requires one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator.

To delete an SLA entry:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Click the **Settings** tab, and then click **Incident management**.

4. Select the **Delete** tab.

5. Select the check box next to the SLA entry that you want to delete.

6. Click the **Delete** button.

7. In the confirmation window that opens, click **Delete**.

When you delete an SLA entry, time limits for incidents with the entry's **Incident type** and **Priority** are no longer calculated.

Managing incident types

Kaspersky EDR Expert allows you to manage incidents and customize the incident handling process by using incident types.

An incident type is a set of attributes, for which you can configure different processes, for example, assign a workflow to the incident type, configure a trigger, or configure a playbook algorithm.

You can create an incident type or use predefined incident types that you can customize.

Incident types can be active or inactive. If the incident type is active, you will be able to select this type in the incident details window.

The incident type marked as a default type is assigned to all new incidents automatically. You cannot switch a default incident type to inactive.

The **Common** incident type is set as default. You can edit this setting.

You can create only one default incident type in a tenant.

Viewing the incident types table

To view the incident types table:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.
   This opens the tenant properties window.
3. On the **Settings** tab, click **Incident management**.
   The **Types** tab is displayed with the incident types table.
4. If you want to configure the incident types table, do any of the following:
   - Click the filter icon ( ), and then specify and apply filter criterion in the invoked menu.
   - To hide or display a column, click the settings icon ( ), and then select the necessary column.

The incident types table contains the following information:

- **Name**. Name of the custom or predefined incident type.

The table contains the following predefined incident types:

- Common

  > By default, this type has the **Yes** value in the **Default** column.

- Information gathering
- Compromise
- Unauthorized access
- Malware attack
- Phishing
- Availability
- Insider threat
- Data breaches
- Configuration error
- Supply chain attack
- Web application attack
- Vulnerability exploitation

- **Active type**. If the incident type is active, you will be able to select this type in the incident details window.
- **Default**. When you create an incident, the default type is automatically assigned to it. Possible values:
  - **True**
  - **False**
- **Workflow**. Incident workflow.
- **Tenant**. Name of the tenant to which the incident type belongs.
- **Creation type**. Way the incident type was created. Possible values:
  - **Custom**
  - **Predefined**
- **ID**. Unique identifier of the custom or predefined incident type. By default, this column is hidden.
- **Description**. Incident type description. By default, this column is hidden.

If necessary, you can create new incident types, as well as edit and delete predefined and custom incident types.

Creating incident types

To create an incident type:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.
   This opens the tenant properties window.
3. On the **Settings** tab, click **Incident management**, and then select the **Types** tab.
4. Click the **Create** button.
   The **Create incident type** window opens.
5. If you want the new incident type to be active, enable the **Active type** toggle switch.
6. In the **Name** field, enter the name of the new incident type.
7. If you want all new incidents to be assigned this type by default, select the **Set as default** check box.

   > There can be only one default incident type in a tenant. It means that if the tenant already has a default incident type, this type will no longer be default after you select this check box.

8. In the **Workflow** field, select the incident workflow.
9. If necessary, in the **Description** field, enter an incident type description or a comment.
10. Click **Create**.

The new incident type is displayed in the incident types table.

Editing incident types

If necessary, you can edit incident types.

To edit an incident type:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.
   This opens the tenant properties window.
3. On the **Settings** tab, click **Incident management**.
   The **Types** tab is displayed with the incident types table.

4. Click the name of the incident type that you want to edit.

   The **Edit incident type** window opens.

5. Make your edits, and then click **Save**. For more details on the incident types properties that you can edit, refer to Creating incident types.

The incident type properties are edited and saved.

Deleting incident types

If you want to delete an incident type that is used in a playbook, you have to delete this incident type from the playbook trigger and/or algorithm to avoid errors.

You cannot delete an incident type in the following cases:

- An incident type is set as default in the tenant where this incident type was created.

  When trying to delete this incident type, you are prompted to set a new default incident type. In the window that opens, you have to select the incident type from the list.

- An incident type is set as default in a child tenant.

- The current tenant or a child tenant contains an incident with the type that you want to delete.

  Before deleting such a type, you have to assign another type to the incident.

- A Service Level Agreement (SLA) rule is defined for the incident type.

To delete the incident type:

1. In the main application window, go to the **Settings** → **Tenants** section.

2. Click the name of the required tenant.

   This opens the tenant properties window.

3. On the **Settings** tab, click **Incident management**.

   The **Types** tab is displayed with the incident types table.

4. Do one of the following:

   - Select the incident type that you want to delete, and then click **Delete**.

   - Click the name of the incident type that you want to delete, and then in the **Edit incident type** window, click **Delete**.

5. In the confirmation dialog box, click **Delete**.

The incident type is deleted.

Managing incident workflows

Kaspersky EDR Expert allows you to configure a flexible incident workflow. Kaspersky EDR Expert also visualizes the workflow in the visual editor.

The incident workflow is a set of statuses and transitions that an incident goes through during its lifecycle. *Status* is a step in the incident handling process. *Transition* helps the incident to move between different statuses. A transition is a link that allows you to configure transitions from one incident status to another and back. If necessary, you can use a transition as a one-way link.

You can create an incident workflow or use a predefined workflow that you can customize.

You also can assign a workflow to the incident types. This will help you manage the incident lifecycle in the most convenient way.

Viewing incident workflows table

To view the incident workflows table:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Incident management**, and then select the **Workflows** tab.

   To hide or display a column, click the settings icon (⚙), and then select the necessary column.

The incident workflows table is displayed.

The incident workflows table contains the following information:

- **Name**. Name of the custom or predefined incident workflow.
- **Linked types**. Number of linked incident types.
- **Tenant name**. Name of the tenant to which the incident workflow belongs.
- **Creation type**. Way the incident workflow was created. Possible values:
  - **Custom**.
  - **Predefined**.
- **Workflow ID**. Unique identifier of the incident workflow. By default, this column is hidden.
- **Description**. Incident workflow description By default, this column is hidden.

Predefined incident workflows

Kaspersky EDR Expert allows you to manage incidents by using the predefined incident workflow. In the incident workflows table, such workflow is named **Standard**. In the **Creation type** column, these workflows are marked as **Predefined**.

If necessary, you can edit the predefined workflow to customize it.

The table below shows the statuses of the predefined workflow, and the reasons why incidents switch to these statuses.

State	Reasons
New	• A new incident has been created (manually or automatically). • The incident status has been changed to **New** from one of the following statuses: **In progress**, **On hold**, or **Closed**.
In progress	The user manually changed the incident status from **New** or **On hold** to **In progress**.
On hold	The user manually changed the incident status from **In progress** to **On hold**.
Closed	• The user closed the incident. • The user linked the incident to another similar incident that has not been closed yet.

Creating incident workflows

The incident workflow allows you to manage incident lifecycle.

To create an incident workflow:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Incident management**, and then select the **Workflows** tab.
4. Click **Create**.

   This opens the **Create workflow** window.

   By default, each incident workflow contains predefined statuses **New** and **Closed**. You cannot delete or edit these statuses.
5. In the **Name** field, enter the name of the new workflow.
6. If necessary, in the **Description** field, enter a workflow description or a comment.
7. To add new statuses, in the **Workflow** section, click **Add status**.

8. In the window that opens, specify the following settings:

   a. In the **Status name** field, enter a name for the new status.

   b. In the **Category** field, select one of the following status categories:

      - **New**
      - **In progress**
      - **Resolved**
      - **Closed**

      The category determines the color of the status icon.

   c. In the **Incoming transition** field, select one or several incoming statuses.

      If you want to configure the transition from all statuses to incoming statuses, select the **Allow all statuses to transition to this one** option.

   d. In the **Outgoing transition** field, select one or several outgoing statuses.

      If you want to configure the transition from outgoing statuses to all statuses, select the **Allow this status to transition to all statuses** option

   e. Click **Add**.

      The visualized workflow is displayed in the **Create workflow** window

      If necessary, repeat steps 7-8e to add new statuses.

9. In the **Create workflow** window, click the **Save** button.

The new incident workflow is displayed in the table.

Editing incident workflows and statuses

You can edit workflow properties, as well as workflow' statuses and transitions.

To edit the incident workflow:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Incident management**, and then select the **Workflows** tab.
4. Click the name of the workflow that you want to edit.

   This opens the **Edit workflow** window.
5. Edit the workflow properties. For more details on the workflow properties that you can edit, see Creating incident workflows.

The workflow's properties are modified and saved.

To edit statuses of the incident workflow:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Incident management**, and then select the **Workflows** tab.
4. Click the name of the workflow that you want to edit.

   This opens the **Edit workflow** window.
5. Click the name of the status that you want to edit.

   The **Edit status** window opens.
6. Edit the status and transition settings. For more details on the status settings that you can edit, see Creating incident workflows.

   If necessary, you can delete the status by clicking the **Delete** button.

   > You cannot edit the name and the category of the following predefined statuses: **New** and **Closed** statuses. You also cannot delete these predefined statuses.

   > You cannot delete a status if it is assigned to an incident.
7. Click the **Save** button.

The workflow statuses are modified and saved.

Deleting incident workflows

> You cannot delete the incident workflow if there are linked incident types that belong to the parent or child tenant. In this case, you need to assign a different workflow to the linked incident types, and then try to delete incident workflow again.

> If you want to delete a workflow that is used in a playbook, before deleting, edit the playbook's trigger and/or algorithm to avoid errors.

To delete an incident workflow:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Incident management**, and then select the **Workflows** tab.

4. In the list of workflows, select the workflow that you want to delete, and then click **Delete**.
5. In the confirmation dialog box, click **Delete**.

   The incident workflow is deleted.

Managing incident effort

Kaspersky EDR Expert allows you to track effort for incident-related work. This helps calculate the time spent by an analyst on incident analysis and response, evaluate analysts' workload, and allocate labor resources efficiently.

Analysts can manually add details of their effort on incident-related work, including time spent and, if necessary, effort category.

Effort categories can be viewed, added, edited or deleted through the API. To manage effort categories, you must have one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator.

To manage incident effort, you must have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 1 analyst, Tier 2 analyst, SOC manager, Approver.

Kaspersky EDR Expert also allows you to generate and export an effort report by analysts or groups for further analysis.

Adding effort for incidents

You can add the effort spent on incident-related work to the **Effort log** section of the incident details. This helps analyze the time analysts spend on handling incidents, plan their workload, and calculate payroll costs.

To add effort for an incident:

1. In the main menu, go to the **Monitoring** → **Incidents** section.
2. In the incident table, click the ID of the required incident.

   The window with incident details is displayed.
3. Go to the **Effort log** tab, and then click the **Add** button.

   The **Add effort** pane opens.
4. If necessary, in the **Category** drop-down list, select the effort category.

5. In **Hours** and **Minutes** fields, specify the time you spent on incident-related work.

   > Maximum value for the **Minutes** field is 59.

6. Click **Add**.

The effort you spent on incident-related work is added.

Editing effort for incidents

You can edit previously added efforts.

> You cannot edit effort added by other analysts.

To edit effort for an incident:

1. In the main menu, go to the **Monitoring** → **Incidents** section.
2. In the incident table, click the ID of the required incident.
   The window with incident details is displayed.
3. Go to the **Effort log** tab.
4. In the **Date** column, click the link with the date and time for the effort that you want to edit.
   The **Edit effort** pane opens.
5. Edit the effort properties, and then click the **Save** button.

The effort properties are modified and saved.

Deleting effort for incidents

You can delete previously added efforts.

> You cannot delete effort added by other analysts.

To delete effort for an incident:

1. In the main menu, go to the **Monitoring** → **Incidents** section.
2. In the incident table, click the ID of the required incident.
   The window with incident details is displayed.

3. Go to the **Effort log** tab.

4. In the list of efforts, select the check box next to the effort that you want to delete, and then click the **Delete** button.

The effort is deleted.

Generating and exporting incident reports

You can generate and export the reports on analysts' effort spent to work with incidents and on the incident compliance to SLA metrics. The reports are saved in the CSV format.

To generate a report for an incident, you must have:

- Access to the tenant to which the incident belongs.
- One of the following XDR roles: Main administrator, SOC administrator, Tenant administrator, Junior analyst, Tier 1 analyst, Tier 2 analyst, SOC manager, Interaction with NCIRCC, Approver, Auditor.

To generate and export a report:

1. In the main menu, go to the **Monitoring** → **Incidents** section.
2. In the toolbar, click the **Export** button, and then, in the drop-down menu, select one of the following:
   - **Effort report** to export a report on the effort spent by analysts when working with an incident.
   - **Incident metrics report** to export a report on the incident compliance to SLA metrics.
3. In the right pane that opens, specify the period for which you want to display the data in the report. To do this, select the date and time in the **From** and **To** fields.

   By default, in the **From** field the first day of the current month is selected, and the time is set to 00:00. In the **To** field, the current date is selected, and the time is set to 23:59.
4. If necessary, specify the other settings, depending on the type of report that you selected at step 3:
   - For the **Effort report**:
     - Select analysts or user groups if you want the report to include the incidents that required the efforts of the users that you specify.
     - Enable the **Include incident ID and effort category details** toggle switch if you want the effort report to contain these details.

       The toggle switch is turned off by default.

- For the **Incident metrics report**:
  - Select the priorities of the incidents to be included in the report. Possible values: **Low**, **Medium**, **High**, **Critical**.
  - Enable the **Export only incidents with SLA breaches** toggle switch if you want to include in the report only the incidents with SLA breaches.

    An incident is included in the report if it has at least one expired SLA entry. The SLA entry is considered expired when at least one of its lime limits (**Time to triage**, **Time spent to respond**, or **Time to resolve**) is less than 0.

5. Click the **Export** button.

The pane closes, and the report is generated and downloaded to your computer.

Configuring the retention period of alerts and incidents

Kaspersky EDR Expert allows you to reduce or increase the retention periods of alerts and incidents, depending on your needs. By default, the retention period of alerts and incidents is 360 days.

The child tenant copies the retention period of alerts and incidents from the parent tenant. If necessary, you can edit the retention period for the child tenant.

To configure the alert or incident retention period:

1. In the main menu, go to **Settings** → **Tenants**.
2. Click the name of the required tenant.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Alerts & incidents**.
4. In the **Retention period** section, specify the new retention period in one or both of the following fields:
   - **Alert retention period (days)**
   - **Incident retention period (days)**

   The minimum value is `1`.
5. Click the **Save** button.

The new retention period is configured.

Regardless of the configured retention period, if the expired alert is linked to an unexpired incident, the alert will be deleted only after the retention period of the linked incident expires. If the expired incident has unexpired linked alerts, the incident will be deleted only after the retention period of the linked alerts expires.

If the expired parent incident has the unexpired child incidents, the parent incident will be deleted only after the retention period of the last child incident expires.

Viewing asset details

Asset details are a window that contains all information related to the asset.

You can view asset details in one of the following ways:

- From alert details
- From incident details
- From event details (if the event contains assets)
- From an investigation graph

To view asset details:

1. In the main menu, go to **Monitoring**, and then do one of the following:
   - If you want to view asset details from alert details, click **Alerts**, and then in the **ID** column, click the ID of the alert that includes the asset whose details you want to view. In the window that opens, go to the **Assets** tab.
   - If you want to view asset details from incident details, click **Incidents**, and then in the **ID** column, click the ID of the incident that includes the asset whose details you want to view. In the window that opens, go to the **Assets** tab.
   - If you want to view asset details from event details, click **Threat hunting**, and then click the event that contains the asset whose details you want to view.
   - If you want to view asset details from an investigation graph, click **Incidents**, and then in the **ID** column, click the ID of the incident that includes the asset whose details you want to view. In the window that opens, click the **View on graph** button. Click the alert node, and then in the context menu, select **Devices** or **Users**.
2. Do one of the following:
   - Click the name of the required asset, and then in the drop-down list, select **View properties**.
   - On the investigation graph, click the asset node, and then in the context menu, select **View details**.

   The asset details window is displayed.

In the asset details window, you can switch between the **General** and **Prevention rules** tabs.

General tab

The **General** tab contains the following sections:

- **Asset properties**—Information about the asset, for example, asset name, ID, and tenant to which the asset belongs.

  If the current license in KUMA includes the AI module, the **AI score** field is displayed and shows the asset score. This field shows the degree of atypical activity on the asset and may take the values in the range from 0 to1, where 0 is expected behavior, and 1 is completely unexpected behavior for the asset within the infrastructure. If Kaspersky Endpoint Security with a built-in agent is installed on the asset (device), the **Isolation status** field is displayed. You can view and change the device's network isolation status by clicking the **Settings** link next to the status.

- **Categories**—Information about the categories associated with the asset.

- **Custom fields**—Asset fields that you created in KUMA Console.

- **Installed software**—Information about software installed on the asset.

  You can use the **Search** field to quickly find a required application. It is displayed after you can start entering any of the information: the application name, version, vendor, or installation date.

- **KSC: vulnerabilities**—Vulnerabilities of the asset, if provided. This information is available for the assets imported from Kaspersky Security Center.

- **Kaspersky applications**—Information about the Kaspersky applications installed on the asset.

- **Device protection status**—Status of the asset; the following values are possible: *OK*, *Critical*, *Warning*. This information is available for the assets imported from Kaspersky Security Center.

- **KICS for Networks: asset properties**—Information about the asset. This information is imported from KICS for Networks.

- **KICS for Networks: vulnerabilities**—Vulnerabilities of the asset, if provided. This information is available for the assets imported from KICS for Networks.

You can expand the sections by clicking the chevron icons (>) next to their names.

From the toolbar, you can perform the following actions:

- Edit the asset details by clicking the **Edit** button.

- Run a response action by clicking the **Response** button, and then selecting a response action from the drop-down list.

- Assign a category to the asset by clicking the **Link to category** button.

- Move to the **Response history** section, the **Threat hunting** section, the list of related alerts, or the list of related incidents by clicking the **View in** button, and then from the drop-down list, selecting where you want to move.

  The **Response history** section, the events in the **Threat hunting** section, the alerts or incident will be filtered by the asset from whose details you moved.

- Connect to the asset by using the remote terminal. To do this, click the **Open remote terminal** button.
- Export information about the asset to a CSV file by clicking the **Export to CSV** button.

Prevention rules tab

The tab contains the table of prevention rules applied to the device.

The table is displayed with one of the following statuses of the rules progress: **Applied, Applying**, or **Error**.

> To view the prevention rules list you must have one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator, SOC manager, Tier 1 analyst, Tier 2 analyst, Junior analyst, Approver, Auditor.

The table has the same columns as the one that you open from the Resources and servicess section.

You can view and edit the prevention rule settings. To do this, open the prevention rule details by clicking the link with the rule name in the **Name** column. The **Edit prevention rule** pane opens with the **Details** tab selected. You can edit the prevention rule settings.

Also, you can click the **Go to Threat hunting** button to view the events obtained when a prevention rule was triggered. On the **Change log** tab, you can view all the changes applied to the prevention rule.

> To open the prevention rule details, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.
> If the prevention rule belongs to a parent tenant to which you have no rights, you cannot edit the prevention rule.

Investigating and responding via remote terminal

Kaspersky EDR Expert allows you to connect to an asset by using the remote terminal. Once connected, you can interact with the operating system shell in real time to investigate alerts and incidents, perform diagnostics, and respond to threats.

Through the remote terminal, you can manage the asset by using the commands supported by the operating system installed on the asset.

By using the remote terminal, you can connect to multiple assets simultaneously. In this case, a separate remote terminal window is opened for each asset in OSMP Console.

You can connect to the asset by using the remote terminal if the following conditions are met:

- You have activated the application under the Kaspersky EDR Expert license.
- You have one of the following EDR roles: Main administrator, Tier 1 analyst, Tier 2 analyst.
- Kaspersky Endpoint Security for Linux or Kaspersky Endpoint Security for Windows is installed on the asset.

You cannot use the remote terminal to connect to the asset from which you access the OSMP Console.

If an asset is compromised, managing this asset through the remote terminal can lead to unintended execution of malicious code. Use the remote terminal only to connect to devices you trust.

Managing remote terminal connections

You can use the remote terminal to investigate threats and respond to them on the assets in real time.

You can access the remote terminal in one of the following ways:

- From the incident details.
- From the alert details.
- From the asset details.
- From the asset table (**Analysis and response** tab).

Connecting to assets by using the remote terminal

To connect to assets:

1. In the main menu, do one of the following:
   - To access the remote terminal from the incident details, go to **Monitoring** → **Incidents**. In the incident table, click the ID of the required incident, and then, in the window that opens, go to the **Assets** tab.
   - To access the remote terminal from the alert details, go to **Monitoring** → **Alerts**. In the alert table, click the ID of the required alert, and then, in the window that opens, go to the **Assets** tab.
   - To access the remote terminal from the asset details, go to **Asset management** → **Assets (Devices)**. Select the **Analysis and response** tab, and then, in the asset table, click the name of the required asset. In the context menu, click **Details**. In the asset details pane that opens, click the ellipsis (⋮) icon.
   - To access the remote terminal from the asset table, go to **Asset management** → **Assets (Devices)**. Select the **Analysis and response** tab, and then, in the asset table, select the required asset.
2. Click the **Open remote terminal** button.

3. If you want to perform response actions on the asset, perform the following steps:

   a. In the **Remote terminal** window that opens, run one of the following:

   - For devices running Windows:

     ```
     response.exe
     ```

   - For devices running Linux:

     ```
     responser
     ```

   b. Press **`Enter`**.

   c. Copy the password by clicking the **Copy password** link, and then paste the password into the remote terminal.

After the remote session with the asset has been established, you can investigate threats and perform response actions if needed.

All actions performed in the remote terminal are logged.

If there is no activity for more than 10 minutes, the connection to the asset is terminated.

Viewing active connections in the remote terminal

With the remote terminal, you can connect to and work with multiple assets at the same time. If you have not manually ended a session with an asset, or it has not expired due to inactivity, the session remains active even if you navigate to another section of OSMP Console.

To view to the active remote terminal sessions,

in the upper-right corner of OSMP Console, click the **N connections**.

The **Remote terminal** window opens.

Disconnecting from assets by using the remote terminal

To disconnect from assets,

in the **Remote terminal** window, click the cross (✕) icon to disconnect from the asset.

Alternatively, if you want to disconnect from more than one asset, click the **Disconnect all** button.

The asset is disconnected from the remote terminal.

Performing response actions via remote terminal

After you connected to the asset via the remote terminal, you can investigate threats and respond to them by using command line interface.

To run commands, use the following syntax:

```
<common> <parameter> <argument> [--option=value] [--flag]
```

Note that `--flag` is boolean flag. If specified, it is set to `true`. You can also set it explicitly to `true` or `false`. If not specified, it is set to `false`. The `--case-sensitive` flag is an exception to this rule, and its behavior is described in more detail below on this page.

Common command line parameters

Setting	Type	Description
help	string	Open online help.
task-timeout	integer	Task execution time limit (seconds).
storage-path	string	Path to the file share for storing response action results.

Response action parameters

You can use the following parameters depending on the response action you want to perform on the asset:

Delete file

To delete a file from the device, use the following response action parameters:

Parameter	Arguments	Possible values	Type	Description
`delete-file`	[filePath]	`md5`	string	MD5 file hash. Used with the file path. Can be specified with or without SHA256.
		`sha256`	string	SHA256 file hash. Used with the file path. Can be specified with or without MD5.
		`skip`	array of enum	Conditions for skipping the response action. Possible values: • `self-defence` • `sco` • `kl-signed` • `kl-by-trusted-app`
		`with-subfolders`	flag	Perform a recursive search if `filePath` specifies a directory.
		`case-sensitive`	flag	Specifies whether the path is case-sensitive. If the `--case-sensitive` flag is not specified, the task uses the case-sensitivity behavior of the operating system and runs as case-sensitive. To run the task as case-insensitive, specify `--case-sensitive=false`.

Example

```
delete-file "C:/file path.txt" --md5=12345 --case-sensitive --skip=self-defence --skip=sco --skip=kl-signed --
skip=kl-by-trusted-app
```

Managing a service

This response action is only available on Windows devices.

To manage a service on the device, use the following response action parameters:

Setting	Arguments	Possible values	Type	Description
`change-service`	[operationType] Possible values: • `start` • `stop` • `pause` • `resume` • `delete` • `change-startup-type`	`startup-type`	enum	Specifies the startup type for the `change-startup-type` operation. This parameter is ignored for other operations. Possible values: • `Boot` • `System` • `Automatic` • `Manual` • `Disabled`
		`service-name`	string	Service name. Masks are supported.
		`md5`	string	MD5 file hash. Can be specified with or without SHA256.
		`sha256`	string	SHA256 file hash. Can be specified with or without MD5.

Example

```
change-service change-startup-type --startup-type=auto --service-name=ServiceName --md5=12345
```

Move file to quarantine

To prevent a threat distribution, you can move an infected file to quarantine. To do that, use the following response action parameters:

Parameter	Arguments	Possible values	Type	Description
`quarantine-file`	[filePath]	`skip`	array of enum	Conditions for skipping the response action. Possible values: • `self-defence` • `sco` • `kl-signed` • `kl-by-trusted-app`
		`legacy-file-id`	flag	When specified, returns legacy 64-bit quarantine IDs instead of GUIDs.
		`case-sensitive`	flag	Specifies whether the path is case-sensitive. If the `--case-sensitive` flag is not specified, the task uses the case-sensitivity behavior of the operating system and runs as case-sensitive. To run the task as case-insensitive, specify `--case-sensitive=false`.
		`delete`	flag	Deletes the file after quarantining it.
		`md5`	string	MD5 file hash. Used with the file path. Can be specified with or without SHA256.
		`sha256`	string	SHA256 file hash. Used with the file path. Can be specified with or without MD5.

Example

```
quarantine-file C:/filePath --skip=self-defence --skip=sco --skip=kl-signed --skip=kl-by-trusted-app
```

Delete file from quarantine

To delete an infected file from the quarantine directory on the device, use the following response action parameters:

Setting	Possible values	Type	Description
`delete-quarantined-file`	`file-id`	string	ID of the quarantined file.
	`legacy-file-id`	integer	Legacy quarantine ID.

Example

```
delete-quarantined-file --file-id=453C4D2A-1B45-49C9-A954-1C086E4347F0
```

Restore file from quarantine

If you have reasons to believe that the file in the quarantine is safe, you can restore the file on the device. To do that, use the following response action parameters:

Setting	Possible values	Type	Description
`restore-quarantined-file`	`file-id`	string	ID of the quarantined file.
	`legacy-file-id`	integer	Legacy quarantine ID
	`replace`	flag	Replaces the existing file.
	`remove`	flag	Removes the file from quarantine after restoration.
	`destination`	string	Specifies the destination path used to restore the object from backup. If not specified, the object is restored to the original path.
	`fallback-destination`	string	Specifies a fallback destination path. Used only if restoring to the original path fails because the path does not exist or access is denied.

Example

```
restore-quarantined-file --file-id=453C4D2A-1B45-49C9-A954-1C086E4347F0 --replace --fallback-destination="C:/path"
```

Get file from quarantine

The quarantined file located on a device can be obtained from the quarantine directory for further analysis. To get a file from quarantine, use the following response action parameters:

Setting	Possible values	Type	Description
`get-quarantined-file`	`file-id`	string	ID of the quarantined file.
	`legacy-file-id`	integer	Legacy quarantine ID
	`stream-index`	integer	Index of the file stream to retrieve.

After the response action is completed, the obtained file is displayed in the **Files** section of the OSMP Console.

Example

```
get-quarantined-file --file-id=453C4D2A-1B45-49C9-A954-1C086E4347F0 --stream-index=0
```

Terminate process

To terminate processes on the device, use the following response action parameters:

Setting	Possible values	Type	Description
`terminate-process`	`path`	string	Path to the process executable.
	`pid`	integer	System process ID.
	`unique-pid`	integer	Process ID.
	`md5`	string	MD5 file hash. Used with the file path. Can be specified with or without SHA256.
	`sha256`	string	SHA256 file hash. Used with the file path. Can be specified with or without MD5.
	`case-sensitive`	flag	Specifies whether the path is case-sensitive. If the `--case-sensitive` flag is not specified, the task uses the case-sensitivity behavior of the operating system and runs as case-sensitive. To run the task as case-insensitive, specify `--case-sensitive=false`.
	`expand-env`	flag	Expands environment variables in paths.
	`skip`	array of enum	Conditions for skipping the response action. Possible values: • `self-defence` • `sco` • `kl-signed` • `kl-by-trusted-app`
	`limit`	integer	Maximum number of process termination attempts. If not specified, the number of attempts is unlimited.

Example

```
terminate-process --pid=1234 --limit=100
```

Get file

To get a file from the device, use the following response action parameters:

Parameter	Arguments	Possible values	Type	Description
`get-file`	[filePath]	`md5`	string	MD5 file hash. Used with the file path. Can be specified with or without SHA256.
		`sha256`	string	SHA256 file hash. Used with the file path. Can be specified with or without MD5.
		`max-size`	integer	Maximum file size in bytes. The response action fails if the file exceeds this size. By default, the size is unlimited.
		`case-sensitive`	flag	Specifies whether the path is case-sensitive. If the `--case-sensitive` flag is not specified, the task uses the case-sensitivity behavior of the operating system and runs as case-sensitive. To run the task as case-insensitive, specify `--case-sensitive=false`.

After the response action is completed, the file is saved to a password-protected ZIP archive. The password is *infected*.

Example

```
get-file C:/file --md5=1234567890 --max-size=1000 --case-sensitive
```

Enable network isolation

To enable network isolation for the device, use the following response action parameters:

Parameter	Possible values	Type	Description
`start-network-isolation`	`timeout`	integer	Duration of network isolation. When the timeout expires, isolation is disabled automatically. By default, the duration is unlimited.
	`expand-env`	flag	Expands environment variables in paths.
	`no-notify-user`	flag	Disables user notification about the network isolation operation.
	`exclude`		Network exclusion rule. This option cannot be used independently. To configure exclusions, specify one or more child options: • `process` • `direction` • `remote-ip-v4` • `remote-ip-v6` • `local-port-from` • `local-port-to` • `remote-port-from` • `remote-port-to` • `protocol`
	`process`	string	Specifies an optional receiving or transmitting process. The value must be the full path to the executable. Masks are not supported. Environment variables are supported on Windows only.
	`direction`	enum	Specifies the connection direction for connection-based protocols (for example, TCP) or the packet direction for datagram-based protocols (for example, UDP). If not specified, both directions are used. Possible values: • `inbound` • `outbound` • `both`
	`remote-ip-v4`	string	Remote IPv4 address in the xxx.xxx.xxx.xxx format. Subnet prefixes are supported. If neither IPv4 nor IPv6 is specified, any IP address is matched.
	`remote-ip-v6`	string	Remote IPv6 address in the xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx format. Subnet prefixes are supported. If neither IPv4 nor IPv6 is specified, any IP address is matched.
	`local-port-from`	integer	Lower bound of the local port range. If not specified, any port is matched. If the port is not applicable to the packet protocol, the rule is inactive.
	`local-port-to`	integer	Upper bound of the local port range. If not specified, any port is matched. If the port is not applicable to the packet protocol, the rule is inactive.
	`remote-port-from`	integer	Lower bound of the remote port range. If not specified, any port is matched. If the port is not applicable to the packet protocol, the rule is inactive.
	`remote-port-to`	integer	Upper bound of the remote port range. If not specified, any port is matched. If the port is not applicable to the packet protocol, the rule is inactive.
	`protocol`	integer	IANA protocol identifier (for example, TCP = 6). If not specified, any protocol is matched.

Example

```
start-network-isolation --timeout=300 exclude --process="C:/process.exe" exclude --local-port-from=1 --local-port-to=10 --direction=inbound --no-notifyuser
```

Disable network isolation

To disable network isolation for a device, use the following response action parameters:

Setting	Possible values	Type	Description
`stop-network-isolation`	`no-notify-user`	flag	Disables network isolation for a device. By default, the user receives a notification when network isolation is disabled. If the `--no-notify-user` option is specified, the user is not notified. The `--no-notify-user` option is available only on devices running Windows.

Example

```
stop-network-isolation --no-notify-user
```

Getting a file list

To get a list of files and folders stored on the disk, use the following response action parameters.

Parameter	Possible values	Type	Description
`get-forensic files`	`case-sensitive`	flag	Indicates whether the path is case-sensitive. Available only on devices running Windows. If the `--case-sensitive` flag is not specified, the task uses the case-sensitivity behavior of the operating system and runs as case-sensitive. To run the task as case-insensitive, specify `--case-sensitive=false`.
	`with-data-streams`	flag	Specifies whether Alternate Data Streams are included in the forensic report.
	`max-depth`	integer	Maximum search depth. 0 means unlimited depth. 1 searches only the specified directory.
	`max-files`	integer	Maximum number of files or Alternate Data Streams to find. The search stops when the limit is reached.
	`include-dir`	array of strings	Directories to include in the scan. Directory paths can contain environment variables (for example, %TMP% or %TEMP%). If not specified, all local directories are included.
	`exclude-dir`	array of strings	Directories to exclude from the scan. Directory paths can contain environment variables (for example, %TMP% or %TEMP%).
	`include-files`	array of strings	File name masks to include in the search (for example, *.ps1). If not specified, all files are included.
	`exclude-files`	array of strings	File name masks to exclude from the search (for example, *.ps1). If not specified and `exclude-dir` is specified, all files are excluded.

Example

```
get-forensic files --max-depth=3 --max-files=1000 --include-dir="C:/include1" --include-dir=D:/include2
```

Getting a processes list

To get a list of processes running on the device, run the following command:

```
get-forensic processes
```

Getting a list of autorun points

To get a list of autorun points, run the following command:

```
get-forensic autoruns
```

Getting a process memory dump

To get a process memory dump, use the following response action parameters:

Parameter	Possible values	Type	Description
`get-forensic process-dump`	`pid`	integer	System process ID.
	`unique-pid`	integer	Unique process ID.
	`md5`	string	MD5 file hash. Used with the file path.
	`sha256`	string	SHA256 file hash. Used with the file path.

Example

```
get-forensic process-dump --pid=123 --md5=abcdef123456
```

Getting a file dump

To get a file dump, use the following response action parameters:

Parameter	Possible values	Type	Description
`get-forensic files-dump`	`case-sensitive`	flag	Indicates whether the path is case-sensitive. By default, this is determined by the file system. Available only on devices running Windows. If the `--case-sensitive` flag is not specified, the task uses the case-sensitivity behavior of the operating system and runs as case-sensitive. To run the task as case-insensitive, specify `--case-sensitive=false`.
	`path`	array of string	Full paths of files to dump. Generic and metadata files (for example, $Mft, $Boot) are supported. Masks are not supported.
	`with-data-streams`	flag	Specifies whether Alternate Data Streams are included in the forensic report.
	`sha256`	string	SHA256 file hash. Used with the file path.

Example

```
get-forensic files-dump --path="C:/path1"--path="D:/path2" --with-data-streams
```

Getting a registry key

Available only on devices running Windows.

To get a registry key, use the following response action parameters:

Parameter	Possible values	Type	Description
`get-forensic registry-dump`	`path`	array of string	Full paths of registry keys to dump. Masks are not supported.

Example

```
get-forensic registry-dump --path="C:/path1" --path="D:/path2"
```

Getting system information

To get system information of the device, run the following command:

```
get-forensic system-info
```

Getting environment variables

Available only on devices running Windows.

To get environment variables, run the following command:

```
get-forensic environment-variables
```

Getting a memory dump

To get a memory dump, use the following response action parameters:

Setting	Possible values	Type	Description
`get-forensic memory-dump`	`compress`	flag	Specifies whether the dump is compressed using gzip with a fast compression level.
	`segment-size`	integer	Specifies the size of dump segments in bytes. The dump is split into segments of the specified size. If the value is 0 or not specified, the dump is not split.

Example

```
get-forensic memory-dump --compress --segment-size=1000
```

Getting a disk image

To get a disk image, use the following response action parameters:

Parameter	Possible values	Type	Description
`get-forensic disk-dump`	`logical`	string	Logical drive name in the OS-specific format (for example, C:, D:, E: on Windows).
	`physical`	string	Physical drive name in the OS-specific format (for example, \\.\PHYSICALDRIVE0 on Windows).
	`compress`	flag	Specifies whether the dump is compressed using gzip with a fast compression level.
	`segment-size`	integer	Specifies the size of dump segments in bytes. The dump is split into segments of the specified size. If the value is 0 or not specified, the dump is not split.

Example

```
get-forensic disk-dump --logical="C:" --segment-size=1000 --compress
```

Threat hunting

The **Threat hunting** page contains tools that help you analyze events to search threats and vulnerabilities that have not been detected automatically. To create an alert from a set of events, select the events, and then click the **Create alert** button.

You can open the **Threat hunting** page in any of the following ways:

- In the main menu, go to **Monitoring → Threat hunting.**
- In the Alert or Incident details, invoke the context menu for an attribute, and then select **Search in Threat Hunting**.
- In the Incident details, click the **View on graph** button. In the investigation graph that opens, click the **Threat hunting** button.

The **Threat hunting** page displays events. You can filter out events:

- By editing the SQL query
- By changing the time range
- By selecting the tenants to which the events belong

Event data model

Endpoint Agents send information about the following events to OSMP:

- Process
- File Create
- File Modify
- File Rename
- File Read
- File Delete
- File Attributes Modify
- File Creation Time Modify
- File Hardlink Created
- File Symlink Created
- Module
- Registry Create

- Registry Delete
- Registry Modify
- Registry Rename
- Registry Query
- Registry Save
- Connection
- Port Listen
- AMSI Scan
- Process Console Input
- Driver
- Process Interpreted File Run
- DNS
- Pipe Create
- Pipe Connect
- LDAP
- WMI Activity
- WMI Consumer Register
- Code Injection
- Process Access
- Threat Detect
- Threat Detect Processing Result
- Linux Event Log
- Windows Event Log
- Blocked Document
- Applock
- Process Terminated
- Device
- File System Mount

- File System Unmount
- Bits Job Create (new in version 8.0)
- Bits Job Complete (new in version 8.0)
- Bits Job Start (new in version 8.0)
- Bits Job Stop (new in version 8.0)
- Bits Job Add File (new in version 8.0)
- Bits Job Error (new in version 8.0)
- Service Create (new in version 8.0)
- Service Modify (new in version 8.0)
- Service Delete (new in version 8.0)
- Scheduled Task Create (new in version 8.0)
- Scheduled Task Modify (new in version 8.0)
- Scheduled Task Delete (new in version 8.0)
- File Owner Change (new in version 8.0)
- File ACL Change (new in version 8.0)
- Registry Owner Change (new in version 8.0)
- Registry ACL Change (new in version 8.0)
- Executable Memory Mapped (new in version 8.0)
- Agent Start (new in version 8.0)
- Agent Stop (new in version 8.0)
- Agent Install (new in version 8.0)
- Agent Uninstall (new in version 8.0)
- Agent Action (new in version 8.0)
- System Startup (new in version 8.0)
- System Shutdown (new in version 8.0)
- Connection Close (new in version 8.0)

Enabling the `Connection Close` event may result in a significant increase in resource usage on protected devices.

Process

This event type is supported on Windows, Linux, and macOS operating systems.

Process event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessCalltrace	string	Stack trace of the process
ProcessFileLnkName	string	Name of the LNK file that was used for the process execution (without the path)
ProcessFileLnkPath	string	Path to the LNK file that was used for the process execution (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was used for the process execution
ProcessFileLnkCmdline	string	Command line of the LNK file for the process execution
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username

Field	Type	Description
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field

Field	Type	Description
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
