ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process

Field	Type	Description
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Create

This event type is supported on Windows, Linux, and macOS operating systems.

File Create event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileDelafterreboot	string	True if file will be deleted after reboot. Specified for delete operation. Specified only for Windows
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed

Field	Type	Description
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the file that was executed
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource

Field	Type	Description
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process.
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file

Field	Type	Description
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Creation flags of grand-parent process
GrandParentProcessDirectory	string	Current working directory of grand-parent process. Specified for Linux and macOS
GrandParentProcessFileLnkName	string	Name without the path of the LNK file that started the grand-parent process
GrandParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the grand-parent process
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS

Field	Type	Description
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process.
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Modify

This event type is supported on Windows, Linux, and macOS operating systems.

File Modify event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileDelafterreboot	string	True if file will be deleted after reboot. Specified for delete operation. Specified only for Windows
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed

Field	Type	Description
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource

Field	Type	Description
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file

Field	Type	Description
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS

Field	Type	Description
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Rename

This event type is supported on Windows, Linux, and macOS operating systems.

File Rename event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileDelafterreboot	string	True if file will be deleted after reboot. Specified for delete operation. Specified only for Windows
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
FileOldName	string	Previous name of the file
FileOldPath	string	Previous path of the file
FileOldFullname	string	Previous full path to the file
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process

Field	Type	Description
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource

Field	Type	Description
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified

Field	Type	Description
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS

Field	Type	Description
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process

Field	Type	Description
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Read

This event type is supported on Windows and Linux operating systems (on Linux only for versions with eBPF integration).

File Read event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base

Field	Type	Description
AgentIndexTimestamp	int	Timestamp of last bases update for all components
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileDelafterreboot	string	True if file will be deleted after reboot. Specified for delete operation. Specified only for Windows
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)

Field	Type	Description
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource

Field	Type	Description
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file

Field	Type	Description
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS

Field	Type	Description
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Delete

This event type is supported on Windows, Linux, and macOS operating systems.

File Delete event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileDelafterreboot	string	True if file will be deleted after reboot. Specified for delete operation. Specified only for Windows
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed

Field	Type	Description
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource

Field	Type	Description
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file

Field	Type	Description
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS

Field	Type	Description
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Attributes Modify

This event type is supported on Windows and Linux operating systems.

File Attributes Modify event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileDelafterreboot	string	True if file will be deleted after reboot. Specified for delete operation. Specified only for Windows
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed

Field	Type	Description
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource

Field	Type	Description
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file

Field	Type	Description
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS

Field	Type	Description
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Creation Time Modify

This event type is supported on Windows operating systems.

File Creation Time Modify event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileDelafterreboot	string	True if file will be deleted after reboot. Specified for delete operation. Specified only for Windows
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level

Field	Type	Description
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process

Field	Type	Description
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags

Field	Type	Description
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Hardlink Created

This event type is supported on Windows operating systems.

File Hardlink Created event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileType	string	Type of the file
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileTargetName	string	Name of the target file
FileTargetPath	string	Path of the target file
FileTargetFullname	string	Full path to the target file
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file

Field	Type	Description
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process

Field	Type	Description
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process

Field	Type	Description
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Symlink Created

This event type is supported on Windows operating systems.

File Symlink Created event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileType	string	Type of the file
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileTargetName	string	Name of the target file
FileTargetPath	string	Path of the target file
FileTargetFullname	string	Full path to the target file
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file

Field	Type	Description
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process

Field	Type	Description
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process

Field	Type	Description
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Module

This event type is supported on Windows and Linux operating systems.

Module event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileAttr	int	The file system attributes
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileSignSubjectname	string	Information about the organization that signed the file
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileType	string	Type of the file
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
FileHijackingpath	string	Path to original DLL
DotnetFileAssemblyName	string	Fully qualified assembly name. Contains certificate hash (used for filtering)
DotnetFileAssemblyFlags	int	.NET assembly flags
DotnetFileModuleFlags	int	.NET assembly module flags
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS

Field	Type	Description
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process

Field	Type	Description
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file

Field	Type	Description
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field

Field	Type	Description
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Registry Create

This event type is supported on Windows operating systems.

Registry Create event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
RegKeyName	string	Full path and name of the registry key which has been affected by the operation
RegValueName	string	Name of registry value
RegValueType	string	Type of registry value
RegValueData	string	Data in the registry value
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process

Field	Type	Description
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id

Field	Type	Description
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Registry Delete

This event type is supported on Windows operating systems.

Registry Delete event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
RegKeyName	string	Full path and name of the registry key which has been affected by the operation
RegValueName	string	Name of registry value
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process

Field	Type	Description
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process

Field	Type	Description
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Registry Modify

This event type is supported on Windows operating systems.

Registry Modify event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
RegKeyName	string	Full path and name of the registry key which has been affected by the operation
RegValueName	string	Name of registry value
RegValueType	string	Type of registry value
RegValueData	string	Data in the registry value
RegOldValueData	string	Previous data in the registry value
RegOldValueMd5	string	The previous MD5 hash value of the file from the RegValueData field
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file

Field	Type	Description
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file

Field	Type	Description
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process

Field	Type	Description
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessLogonType	string	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username who executed process that runs child process.

Registry Rename

This event type is supported on Windows operating systems.

Registry Rename event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	
HostOsmpId	string	
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
RegKeyName	string	Full path and name of the registry key which has been affected by the operation

Field	Type	Description
RegValueName	string	Name of registry value
RegValueType	string	Type of registry value
RegValueData	string	Data in the registry value
RegOldKeyName	string	Previous registry key name
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file

Field	Type	Description
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id

Field	Type	Description
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Registry Query

This event type is supported on Windows operating systems.

Registry Query event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
RegKeyName	string	Full path and name of the registry key which has been affected by the operation
RegValueName	string	Name of registry value
RegValueType	string	Type of registry value
RegValueData	string	Data in the registry value
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file

Field	Type	Description
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id

Field	Type	Description
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Registry Save

This event type is supported on Windows operating systems.

Registry Save event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
RegKeyName	string	Full path and name of the registry key which has been affected by the operation
RegValueName	string	Name of registry value
RegValueType	string	Type of registry value
RegValueData	string	Data in the registry value
FileFullname	string	Full path to the file
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false

Field	Type	Description
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process

Field	Type	Description
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Connection

This event type is supported on Windows, Linux, and macOS operating systems.

Connection event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
NetSrcIp	string	Source ipv4/ipv6 address
NetSrcPort	int	Source port number
NetDstIp	string	Destination ipv4/ipv6 address
NetDstPort	int	Destination port number
NetUrlHostname	string	Remote host name
NetUrlPort	int	Remote host port
NetUri	string	Destination URI for HTTP
NetHttpMethod	string	HTTP method
NetHttpUseragent	string	An identifier of the client program that initiated the request
NetHttpReferrer	string	URI reference to the resource from which the target URI was obtained
NetProtocol	string	IP protocol
NetDirection	string	Direction of network connection (inbound, outbound)
NetHttpHeaderName	string	Name of HTTP header
NetHttpHeaderValue	string	Value of HTTP header
NetRaw	string	Flag whether the raw socket was used
NetTlsVersion	string	TLS version
NetTlsSni	string	TLS Server Name Indication
NetTlsSniEncrypted	string	TLS Encrypted server name indication
NetTlsCertificateMd5	string	MD5 hash of TLS certificate
NetTlsCertificateSha1	string	SHA1 hash of TLS certificate
NetTlsCertificateSubjectname	string	TLS Subject alternative name (SAN)
NetTlsCertificateIssuername	string	Issuer name of TLS certificate
NetTlsCertificateSerialnumber	string	Serial number of TLS certificate
NetTlsCertificateCheckresult	string	Result of TLS certificate verification
NetTlsCertificateValidfrom	int	TLS certificate start-of-validity date
NetTlsCertificateValidto	int	TLS certificate end-of-validity date
NetTlsCiphersuite	int	TLS supported algorithms
NetTlsJa3	string	Ja3 fingerprint of TLS certificate
NetTlsJa3s	string	Ja3s fingerprint of TLS certificate
NetTlsJa3Md5	string	MD5 hash of Ja3 fingerprint of TLS certificate
NetTlsJa3sMd5	string	MD5 hash of Ja3s fingerprint of TLS certificate
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed

Field	Type	Description
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource

Field	Type	Description
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file

Field	Type	Description
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS

Field	Type	Description
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Port Listen

This event type is supported on Windows and Linux operating systems.

Port Listen event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
NetDstIp	string	Source ipv4/ipv6 address
NetDstPort	int	Source port number
NetProtocol	int	IP protocol
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID

Field	Type	Description
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS

Field	Type	Description
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)

Field	Type	Description
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

AMSI Scan

This event type is supported on Windows operating systems.

AMSI Scan event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
AmsiContentType	string	Type of object that was sent to AMSI scan.
AmsiContentData	string	Content of the detected object.
AmsiContentName	string	Name of the object that was sent to AMSI scan.
AmsiContentMd5	string	MD5 of object that was sent to AMSI scan.
AmsiContentSha256	string	SHA256 of object that was sent to AMSI scan.
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed

Field	Type	Description
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process

Field	Type	Description
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Process Console Input

This event type is supported on Windows and Linux operating systems.

Process Console Input event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
InputText	string	Interactive input text
InputType	string	Type of input object
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID

Field	Type	Description
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field

Field	Type	Description
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)

Field	Type	Description
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Driver

This event type is supported on Windows operating systems.

Driver event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows,)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file

Field	Type	Description
FileModificationtime	int	The last time when the file was modified
FileType	string	Type of the file
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment

Process Interpreted File Run

This event type is supported on Windows operating systems.

Process Interpreted File Run event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	The name of the file without path, that will be executed by the interpreter
FilePath	string	Path to the file without its name, that will be executed by the interpreter
FileFullname	string	Full path to the file, that will be executed by the interpreter
FileSize	int	Size (in bytes) of the file, that will be executed by the interpreter
FileCreationtime	int	Creation time of the file, that will be executed by the interpreter
FileModificationtime	int	Time of last modification of the file, that will be executed by the interpreter
FileAttrModificationtime	int	Time of the last change of the file attribute, that will be executed by the interpreter
FileMd5	string	MD5 hash of the file, that will be executed by the interpreter
FileSha256	string	SHA256 hash of the file, that will be executed by the interpreter
FileAttr	int	The list of file system attributes for file, that will be executed by the interpreter
FileType	string	Type of the file, that will be executed by the interpreter
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
FileProductname	string	The name of the application from the VERSIONINFO resource
FileProductvendor	string	Company name value from the VERSIONINFO resource
FileDescription	string	Description from the VERSIONINFO resource
FileOriginalname	string	Original file name from the VERSIONINFO resource
FileSignSubjectname	string	The subject name of the certificate which was used to sing the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded, that will be executed by the interpreter
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment, that will be executed by the interpreter
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file

Field	Type	Description
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed

Field	Type	Description
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file

Field	Type	Description
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field

Field	Type	Description
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

DNS

This event type is supported on Windows and Linux operating systems (on Linux only for external connections).

DNS event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
DnsServerIp	string	DNS server being queried
DnsQueryOptions	string	Options of the performed DNS query
DnsQueryStatus	int	Error code for an operation
DnsResourceName	string	URL being queried
DnsResourceType	string	Type of performed DNS query
DnsAnswer	string	DNS query result
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded

Field	Type	Description
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS

Field	Type	Description
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process

Field	Type	Description
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Pipe Create

This event type is supported on Windows operating systems.

Pipe Create event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
PipeName	string	Name of the named pipe which created or connection have been established with
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource

Field	Type	Description
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file

Field	Type	Description
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Pipe Connect

This event type is supported on Windows operating systems.

Pipe Connect event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
PipeName	string	Name of the named pipe which created or connection have been established with
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource

Field	Type	Description
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file

Field	Type	Description
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

LDAP

This event type is supported on Windows operating systems.

LDAP event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
LdapSearchScope	string	The area or range of the directory tree that should be searched
LdapSearchFilter	string	Conditions or criteria that an LDAP search query will use to match entries in a directory
LdapSearchDn	string	Starting point or base in the directory tree where the search operation will begin
LdapSearchAttr	string	List of specific attributes that are used for filtering or searching by
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file

Field	Type	Description
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process

Field	Type	Description
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

WMI Activity

This event type is supported on Windows operating systems except for Windows XP.

WMI Activity event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
WmiRemote	string	Flag of remote WMI operation
WmiHostName	string	Name of the source host of WMI activity
WmiUserName	string	Name of the user account that performed the WMI operation
WmiNamespacename	string	WMI namespace that was queried
WmiQuery	string	WMI query
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed

Field	Type	Description
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process

Field	Type	Description
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

WMI Consumer Register

This event type is supported on Windows operating systems except for Windows XP.

WMI Consumer Register event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
WmiNamespacename	string	WMI namespace that was queried
WmiFiltername	string	Name of the filter used by the event consumer
WmiConsumerName	string	Name of the created event consumer
WmiConsumerText	string	MOF code of the event consumer
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process

Field	Type	Description
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id

Field	Type	Description
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Code Injection

This event type is supported on Windows and Linux operating systems.

Code Injection event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
TargetProcessUniqueid	int	Target process unique id
TargetProcessId	int	Target process identifier (PID)
TargetProcessCmdline	string	Command line arguments passed into the target process
TargetProcessFileName	string	Name of the executable file of the target process (the process in which the code injection was performed)
TargetProcessFilePath	string	Full path without the file name to the executable file of the target process (the process in which the code injection was performed)
TargetProcessFileFullname	string	Full path to the executable file of the target process (the process in which the code injection was performed)
TargetProcessFileMd5	string	MD5 of the executable file of the target process
TargetProcessFileSha256	string	SHA256 of the executable file of the target process
TargetProcessIntegritylevel	int	Target process integrity level
TargetProcessFileUrl	string	URL from where the target process executable file was downloaded
TargetProcessFileEmailSrcAddress	string	The sender's address from which the target process executable file was received as an attachment
TargetProcessFileAttr	int	The list of file system attributes of the target process
SyscallArgs	string	System call arguments. Specified for Linux
ProcessCalltrace	string	Stack trace of the process
ProcessModifiedcmdline	string	Command line of the process
InjectMethod	string	Injection method
InjectAddress	string	Field contains information about address from which execution starts after injection
InjectImageFileName	string	Only for SET_WINDOWS_HOOK
InjectImageFileFullname	string	Only for SET_WINDOWS_HOOK
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS

Field	Type	Description
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id

Field	Type	Description
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file

Field	Type	Description
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Process Access

This event type is supported on Windows operating systems.

Process Access event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
AccessOperationtype	string	The type of access operation performed on a process handle (by one process on another process).
AccessRights	string	Desired access rights to the process object
ProcessCalltrace	string	Stack trace of the process
TargetProcessFileName	string	Name of the executable file of the target process (the process in which the code injection was performed)
TargetProcessFilePath	string	Full path without the file name to the executable file of the target process (the process in which the code injection was performed)
TargetProcessFileFullname	string	Full path to the executable file of the target process (the process in which the code injection was performed)
TargetProcessFileMd5	string	MD5 of the executable file of the target process
TargetProcessFileSha256	string	SHA256 of the executable file of the target process
TargetProcessFileCreationtime	int	Creation time of the target process executable file
TargetProcessFileModificationtime	int	The last modification time of the target process executable file
TargetProcessFileAttrModificationtime	int	The last time, when the target process executable file attributes were modified
TargetProcessFileSize	int	Target process executable file size in bytes
TargetProcessUniqueid	int	Target process unique id
TargetProcessId	int	Target process identifier (PID)
TargetProcessCmdline	string	Command line arguments passed into the target process
TargetProcessFileUrl	string	URL from where the target process executable file was downloaded
TargetProcessFileEmailSrcAddress	string	The sender's address from which the target process executable file was received as an attachment
TargetProcessFileAttr	int	The list of file system attributes of the target process
HandleProcessSrcFileName	string	Name of the process from which the handle was duplicated
HandleProcessSrcFilePath	string	Full path without the file name of the process from which the handle was duplicated
HandleProcessSrcFileFullname	string	Full path of the process from which the handle was duplicated
HandleProcessSrcFileMd5	string	MD5 of the process from which the handle was duplicated
HandleProcessSrcFileSha256	string	SHA256 of the process from which the handle was duplicated
HandleProcessSrcFileCreationtime	int	Creation time of the process from which the handle was duplicated
HandleProcessSrcFileModificationtime	int	The last modification time of the process from which the handle was duplicated
HandleProcessSrcFileAttrModificationtime	int	The last modification time of attributes of the process from which the handle was duplicated
HandleProcessSrcFileSize	int	Size of the executable file of the process from which the handle was duplicated
HandleProcessSrcUniqueid	int	Unique PID of the process from which the handle was duplicated
HandleProcessSrcId	int	Process identifier (PID) of the process from which the handle was duplicated
HandleProcessSrcIntegritylevel	int	Integrity level of the process from which the handle was duplicated
HandleProcessSrcCmdline	string	Command line options of the process from which the handle was duplicated
HandleProcessSrcFileUrl	string	URL from where the source process was downloaded
HandleProcessSrcFileEmailSrcAddress	string	The sender's address from which the source process executable file was received as an attachment
HandleProcessDstFileName	string	Name of the process to which the handle was duplicated
HandleProcessDstFilePath	string	Full path without the file name of the process to which the handle was duplicated
HandleProcessDstFileFullname	string	Full path of the process to which the handle was duplicated
HandleProcessDstFileMd5	string	MD5 of the process to which the handle was duplicated

Field	Type	Description
HandleProcessDstFileSha256	string	SHA256 of the process to which the handle was duplicated
HandleProcessDstFileCreationtime	int	Creation time of the process to which the handle was duplicated
HandleProcessDstFileModificationtime	int	The last modification time of the process to which the handle was duplicated
HandleProcessDstFileAttrModificationtime	int	The last modification time of attributes of the process to which the handle was duplicated
HandleProcessDstFileSize	int	Size of the executable file of the process to which the handle was duplicated
HandleProcessDstUniqueid	int	Unique PID of the process to which the handle was duplicated
HandleProcessDstId	int	Process identifier (PID) of the process to which the handle was duplicated
HandleProcessDstIntegritylevel	int	Integrity level of the process to which the handle was duplicated
HandleProcessDstCmdline	string	Command line options of the process to which the handle was duplicated
HandleProcessDstFileUrl	string	URL from where the source process was downloaded
HandleProcessDstFileEmailSrcAddress	string	The sender's address from which the source process executable file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment

Field	Type	Description
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file

Field	Type	Description
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Threat Detect

This event type is supported on Windows, Linux, and macOS operating systems.

Threat Detect event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
ThreatObjectFullname	string	Full path to the file
ThreatObjectMd5	string	MD5 hash of the file content
ThreatObjectSha256	string	SHA256 hash of the file content
ThreatObjectType	string	Type of the detected object
ThreatVerdictname	string	Threat verdict name
ThreatRecordid	int	The ID of the record that detected a threat
ThreatDatabaseTimestamp	int	Date and time when the database was last updated
ThreatProcessingmode	int	The processing mode at which the object was detected
ThreatSilent	string	True for silent detects
NetProtocol	int	IP protocol
NetDstIp	string	Local (attacked) ipv4/ipv6 address
NetDstPort	int	Local (attacked) port number
NetSrcIp	string	Remote (attacker's) ipv4/ipv6 address
NetSrcPort	int	Remote (attacker's) port number
ThreatEmailAddress	string	The sender's address from which the detected file was received as an attachment
ThreatEmailDestination	string	The destination address of the detected email
ThreatEmailSubject	string	The subject of the detected email
ThreatEmailMessageid	string	The Message-ID of the detected email
ThreatEmailReceivedtimestamp	string	The received time of the detected email
ThreatDownloaderFileFullname	string	The path to the executable file of the process that downloaded the detected file
AmsiContentType	string	Type of object that was sent to AMSI scan.
AmsiContentData	string	Content of the detected object.
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS

Field	Type	Description
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS

Field	Type	Description
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file

Field	Type	Description
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Threat Detect Processing Result

This event type is supported on Windows, Linux, and macOS operating systems.

Threat Detect Processing Result event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
ThreatObjectFullname	string	Full path to the file
ThreatObjectMd5	string	MD5 hash of the file content
ThreatObjectSha256	string	SHA256 hash of the file content
ThreatObjectType	string	Type of the detected object
ThreatVerdictname	string	Threat verdict name
ThreatRecordid	int	The ID of the record that detected a threat
ThreatDatabaseTimestamp	int	Date and time when the database was last updated
ThreatProcessingmode	int	The processing mode at which the object was detected
NetProtocol	int	IP protocol
NetDstIp	string	Local (attacked) ipv4/ipv6 address
NetDstPort	int	Local (attacked) port number
NetSrcIp	string	Remote (attacker's) ipv4/ipv6 address
NetSrcPort	int	Remote (attacker's) port number
ThreatEmailAddress	string	The sender's address from which the detected file was received as an attachment
ThreatDownloaderFileFullname	string	The path to the executable file of the process that downloaded the detected file
ThreatAction	string	Type of action taken with the object that is detected by exact detect
ThreatActionresult	string	The result of the taken action, specified in the field ThreatAction.
ThreatActionreason	string	In case of successful action, field contains 0. In case of unsuccessful action, this field contains the reason of failure
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS

Field	Type	Description
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process

Field	Type	Description
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file

Field	Type	Description
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified

Field	Type	Description
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Linux Event Log

This event type is supported on Linux operating systems.

Linux Event Log event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
LinuxEventType	string	Type of the event
LinuxEventMessage	string	Message from a log
LinuxOperationResult	string	Operation result—For example, Success or Failed
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID

Field	Type	Description
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS

Field	Type	Description
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)

Field	Type	Description
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Windows Event Log

This event type is supported on Windows operating systems.

Windows Event Log event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
SystemLogEventXml	string	XML from System Event Log
SystemLogEventId	int	Event ID in the system log
SystemLogChannelName	string	Channel name in the system log
SystemLogProviderName	string	Provider name in the system log
WinBinary	string	File attributes of an object being processed
WinData	string	Main data of the Windows Event Log event
WinAccessGranted	string	Security parameters from windows event log events
WinAccessList	string	Access rights for the object being processed
WinAccessMask	string	Access rights for the object being processed
WinAccessReason	string	Reason for moving the file to the category
WinAccessRemoved	string	Access rights that were removed from the object
WinAccountDomain	string	Name of the domain used to authenticate the owner of the logon session
WinAccountExpires	string	Active directory objects parameters
WinAccountName	string	Id of the account under which the controlled process was started
WinAccountSessionIdentifier	string	Authentication session identifier in the Network Policy Server event
WinAction	string	System or security action in the event
WinActionID	string	Identifier of the action performed during the event
WinActionName	string	Name of the action performed during the event
WinActiveProfile	string	Active configuration or network profile
WinAddedCAPs	string	List of added Central Access Policies
WinAdditionalActionsID	string	Identifiers of additional actions related to the event
WinAdditionalActionsString	string	Description or strings of additional actions related to the event
WinAdditionalDetails	string	Query string
WinAdditionalInfo	string	Additional information about the event or object
WinAdditionalInfo2	string	Additional information about the event or object (second field)
WinAdvancedOptions	string	Advanced configuration options
WinAlgorithmName	string	Name of the cryptographic algorithm used
WinAllowedToDelegateTo	string	Id of the account under which the controlled process was started
WinAppCorrelationID	string	Object type code
WinApplication	string	Name of the object being processed
WinAppName	string	Software name
WinAppVersion	string	Version of the software's component
WinAsIsCAPs	string	List of non-modified Central Access Policies
WinAttributeLDAPDisplayName	string	Attributes of executable file being processed
WinAttributes	string	Attributes of the object or event
WinAttributeSyntaxOID	string	File attributes of an object being processed
WinAttributeValue	string	Attributes of executable file being processed
WinAuditPolicyChanges	string	Security parameters from windows event log events
WinAuditSourceName	string	Name of the object being processed
WinAuditStatusCode	string	Event audit status code

Field	Type	Description
WinAuthenticationLevel	string	Authentication level for the request or connection
WinAuthenticationPackageName	string	Name of the object being processed
WinAuthenticationProvider	string	Authentication provider for the event
WinAuthenticationServer	string	Server that performed the authentication
WinAuthenticationService	string	Authentication service used in the event
WinAuthenticationType	string	Authentication type for the event
WinBackupType	string	Backup type
WinBcdCCID	string	Smart card device settings and properties
WinBMaxSlotIndex	string	Smart card device settings and properties
WinBNumClockSupported	string	Smart card device settings and properties
WinBNumDataRateSupported	string	Smart card device settings and properties
WinBootMode	string	User sessions parameters from windows event log events
WinBuildVersion	string	Version of the statistics being sent
WinBVoltageSupport	string	Smart card device settings and properties
WinCalledStationID	string	Called station identifier in authentication
WinCallerProcessId	string	Parent process system id (pid)
WinCallerProcessName	string	Name of the object being processed
WinCallingStationID	string	Calling station identifier in authentication
WinCalloutKey	string	Key of the called function or rule
WinCalloutName	string	Name of the called function or rule
WinCategoryId	string	Operations parameters from windows event log events
WinCategoryName	string	Category of the event or threat
WinCertificateTemplate	string	Certificate template used in the event
WinCertIssuerName	string	Certificate issuer name
WinCertSerialNumber	string	Certificate serial number
WinCertThumbprint	string	Digital certificate thumbprint of the scanned object and hashing algorithm
WinChangeType	string	Type of change made
WinClassId	string	Object type code
WinClassName	string	Name of the object being processed
WinClientAddress	string	Local ip address
WinClientIPAddress	string	Client IP address initiating the event
WinClientName	string	Id of the account under which the controlled process was started
WinClientProcessId	string	Client process identifier
WinClientProcessStartKey	string	The unique key of the process that created the task
WinCommandLine	string	Command line of the launched process
WinCompatibleIds	string	Windows event log events additional parameters
WinComputerAccountChange	string	Operations parameters from windows event log events
WinComputerName	string	Name of the computer where the event occurred
WinConditions	string	Conditions related to the event or filter
WinConfigAccessPolicy	string	Configuration access policy

Field	Type	Description
WinConfiguredNames	string	Configured names of resources or objects
WinContextInfo	string	Tasks parameters recorded in the windows event log events
WinCountOfCredentialsReturned	string	Number of returned credentials
WinCrashOnAuditFailValue	string	Value of crash-on-audit-fail setting
WinCredType	string	Type of credentials
WinCurrentEngineVersion	string	Current version of the security engine
WinCurrentSignatureVersion	string	Current signature version
WinCVEID	string	Windows event log events additional parameters
WinDCDNSName	string	Domain Controller DNS name
WinDCOMorRPC	string	DCOM or RPC protocol used
WinDeletedCAPs	string	List of deleted Central Access Policies
WinDestAddress	string	Destination address for network event
WinDestinationDRA	string	Network connections parameters from windows event log events
WinDestPort	string	Destination port for network event
WinDetectionID	string	Identifier of the detected threat
WinDetectionSource	string	Source of the threat detection
WinDetectionSourceIndex	string	Index of the detection source
WinDetectionTime	string	Time when the threat was detected
WinDetectionType	string	Type of threat detection
WinDetectionTypeIndex	string	Index of the detection type
WinDetectionUser	string	User under whom the threat was detected
WinDeviceClaims	string	Devices involved in authentication
WinDeviceDescription	string	Description of an object being processed as defined in the object properties
WinDeviceId	string	Device id
WinDirection	string	Direction of network traffic
WinDisabledPrivilegeList	string	List of disabled privileges
WinDisableIntegrityChecks	string	Flag to disable integrity checks
WinDisplayName	string	Id of the account under which the controlled process was started
WinDisposition	string	Result of processing event or object
WinDnsHostName	string	User device name
WinDnsName	string	User device name
WinDomain	string	Domain associated with the event or object
WinDomainBehaviorVersion	string	Active directory objects parameters
WinDomainName	string	Name of the domain used to authenticate the owner of the logon session
WinDomainPolicyChanged	string	Active directory objects parameters
WinDomainSid	string	User account security identifier (sid)
WinDSName	string	Name of the object being processed
WinDSType	string	Type of the object detected by the software
WinDummy	string	Windows event log events additional parameters
WinDuration	string	Duration of the event

Field	Type	Description
WinDwDataRate	string	Smart card device settings and properties
WinDwDefaultClock	string	Smart card device settings and properties
WinDwFeatures	string	Smart card device settings and properties
WinDwMaxDataRate	string	Smart card device settings and properties
WinDwMaxIFSD	string	Smart card device settings and properties
WinDwMaximumClock	string	Smart card device settings and properties
WinDwMechanical	string	Smart card device settings and properties
WinDwProtocols	string	Smart card device settings and properties
WinDwSyncProtocols	string	Smart card device settings and properties
WinEAPErrorCode	string	EAP error code
WinEAPReasonCode	string	EAP reason code
WinEapRootCauseString	string	Description of the root cause of the EAP error
WinEAPType	string	Type of EAP authentication
WinEffectiveState	string	Current state of the object or system
WinElevatedToken	string	Security parameters from windows event log events
WinEnabledPrivilegeList	string	List of enabled privileges
WinEndUSN	string	End change identifier in the USN journal
WinEngineVersion	string	Engine version at the time of the event
WinEntryType	string	Type of the object detected by the software
WinErrorCode	string	Operations parameters from windows event log events
WinErrorDescription	string	Description of the error occurred during the event
WinEventCount	string	Number of event repetitions
WinEventCountTotal	string	Total number of related events
WinEventId	string	Event identifier
WinEventIdx	string	Event index in the sequence
WinEventSourceId	string	Object type code
WinExecutionID	string	Identifier of the process that generated the event
WinExecutionName	string	Name of the process that generated the event
WinExecutionStatus	string	Execution status of the action
WinExecutionStatusIndex	string	Index of the execution status
WinExeFileName	string	Name of the object being processed
WinFailureId	string	Failure identifier
WinFailurePoint	string	Point where failure occurred
WinFailureReason	string	Reason for moving the file to the category
WinFileName	string	Name of the object being processed
WinFilterId	string	Filter identifier
WinFilterKey	string	Filter key
WinFilterName	string	Filter name
WinFilterRTID	string	Network connections parameters from windows event log events
WinFilterType	string	Filter type
WinFlags	string	Operations parameters from windows event log events

Field	Type	Description
WinFlightSigning	string	Flag for flight build signing
WinForceLogoff	string	Active directory objects parameters
WinForestRoot	string	Id of the account under which the controlled process was started
WinForestRootSid	string	User account security identifier (sid)
WinFQDN	string	The fully qualified domain name (FQDN) of the host or computer from which the event was initiated
WinFullyQualifiedSubjectMachineName	string	Fully qualified machine name of the subject
WinFullyQualifiedSubjectUserName	string	Fully qualified username of the subject
WinFWLink	string	Link to the page describing the threat
WinGPOList	string	Access rights for the object being processed
WinGroupDomainName	string	Group domain name
WinGroupMembership	string	Group membership
WinGroupName	string	Group name
WinGroupPolicyApplied	string	Applied group policy
WinGroupSid	string	Group SID
WinGroupTypeChange	string	Information about user group
WinHandleId	string	Object type code
WinHangType	string	Type of the object detected by the software
WinHardwareIds	string	Hardware identifiers
WinHomeDirectory	string	Path to the object being processed
WinHomePath	string	Path to the object being processed
WinHypervisorDebug	string	Hypervisor debug flag
WinHypervisorLaunchType	string	Hypervisor launch type
WinHypervisorLoadOptions	string	Hypervisor load options
WinIdentity	string	User or device identifier
WinImagePath	string	Path to the object being processed
WinImpersonationLevel	string	Security parameters from windows event log events
WinInitiatorCookie	string	Initiator operation cookie
WinInterfaceName	string	Network interface name
WinIntfGuid	string	Network interface GUID
WinIpAddress	string	Local ip address
WinIpAddresses	string	IP addresses associated with the object
WinIpPort	string	Port numbers of the source and the destination of the network connection being processed
WinKerberosPolicyChange	string	Security parameters from windows event log events
WinKernelDebug	string	Kernel debug flag
WinKeyFilePath	string	Key file path
WinKeyLength	string	Active directory objects parameters
WinKeyModName	string	Keying module name
WinKeyName	string	Cryptographic key name
WinKeyType	string	Cryptographic key type
WinLayerId	string	Filter layer identifier

Field	Type	Description
WinLayerKey	string	Filter layer key
WinLayerName	string	Network connections parameters from windows event log events
WinLayerRTID	string	Network connections parameters from windows event log events
WinLinkName	string	Name of the object being processed
WinLmPackageName	string	Name of the object being processed
WinLoadOptions	string	Load options
WinLocalAddress	string	Local address in network event
WinLocalKeyModPort	string	Local key module port
WinLocalMac	string	Local MAC address
WinLocalMMPrincipalName	string	Local security principal that was used during the IPsec Main Mode authentication process
WinLocationInformation	string	User sessions parameters from windows event log events
WinLockoutDuration	string	Active directory objects parameters
WinLockoutObservationWindow	string	Active directory objects parameters
WinLockoutThreshold	string	Active directory objects parameters
WinLogDroppedPacketsEnabled	string	Flag indicating whether logging of dropped network packets is enabled
WinLoggingResult	string	Logging result
WinLogonGuid	string	Information about user group
WinLogonHours	string	Active directory objects parameters
WinLogonID	string	User account security identifier (sid)
WinLogonProcessName	string	Object name derived from the windows event log
WinLogonType	string	Logon session type
WinLogSuccessfulConnectionsEnabled	string	Flag indicating whether logging of successful network connections is enabled
WinMachineAccountQuota	string	Active directory objects parameters
WinMachineInventory	string	Machine inventory
WinMajorVersion	string	Version of the statistics being sent
WinMandatoryLabel	string	Mandatory security label of the process
WinMasterKeyId	string	Master key identifier for data encryption
WinMaxPasswordAge	string	Active directory objects parameters
WinMemberName	string	Id of the account under which the controlled process was started
WinMemberSid	string	User account security identifier (sid)
WinMessageNumber	string	Windows event log events additional parameters
WinMessageTotal	string	Windows event log events additional parameters
WinMinorVersion	string	Version of the statistics being sent
WinMinPasswordAge	string	Active directory objects parameters
WinMinPasswordLength	string	Active directory objects parameters
WinMixedDomainMode	string	Active directory objects parameters
WinMMAuthMethod	string	The authentication method used during IPSec main mode negotiation
WinMMFilterID	string	Identifier that Windows assigns to a specific IPSec Main Mode filter
WinMMImpersonationState	string	Field shows whether impersonation was used during the IPSec Main Mode authentication process

Field	Type	Description
WinModifiedCAPs	string	List of modified Central Access Policies
WinModifiedObjectProperties	string	Description of an object being processed as defined in the object properties
WinMulticastFlowsEnabled	string	Multicast flows enabled flag
WinNamingContext	string	Network connections parameters from windows event log events
WinNASIdentifier	string	Network Access Server (NAS) identifier
WinNASIPv4Address	string	Network Access Server (NAS) IPv4 address
WinNASIPv6Address	string	Network Access Server (NAS) IPv6 address
WinNASPort	string	Network Access Server (NAS) port for the connection
WinNASPortType	string	Network Access Server (NAS) port type
WinNetbiosName	string	Name of the object being processed
WinNetworkPolicyName	string	Applied network policy name
WinNewMaxUsers	string	Distributed file system resources properties
WinNewObjectDN	string	Object distinguished name
WinNewProcessId	string	New process ID
WinNewProcessName	string	New process name
WinNewRemark	string	Distributed file system resources properties
WinNewSd	string	Security parameters from windows event log events
WinNewShareFlags	string	Distributed file system resources properties
WinNewState	string	New state of the object or system
WinNewTargetUserName	string	Id of the account under which the controlled process was started
WinNewTime	string	Event time
WinNewUacValue	string	Properties of user account control component
WinNewValue	string	File attributes of an object being processed
WinNewValueType	string	Type of the object detected by the software
WinNotificationPackageName	string	Name of the object being processed
WinObjectClass	string	Bit mask of application categories in the application update component
WinObjectCollectionName	string	Name of the object being processed
WinObjectDN	string	Object distinguished name
WinObjectGUID	string	Information about user group
WinObjectIdentifyingProperties	string	Windows event log events additional parameters
WinObjectName	string	Object name derived from the windows event log
WinObjectProperties	string	Tasks parameters recorded in the windows event log events
WinObjectServer	string	Tasks parameters recorded in the windows event log events
WinObjectType	string	Type of the object detected by the software
WinObjectValueName	string	Name of the object being processed
WinOemInformation	string	Description of an object being processed as defined in the object properties
WinOldMaxUsers	string	Distributed file system resources properties
WinOldObjectDN	string	Object distinguished name
WinOldRemark	string	Distributed file system resources properties
WinOldSd	string	Security parameters from windows event log events

Field	Type	Description
WinOldShareFlags	string	Distributed file system resources properties
WinOldTargetUserName	string	Id of the account under which the controlled process was started
WinOldUacValue	string	Properties of user account control component
WinOldValue	string	File attributes of an object being processed
WinOldValueType	string	Type of the object detected by the software
WinOpCorrelationID	string	Object type code
WinOperation	string	Type of operation performed
WinOperationId	string	Operations parameters from windows event log events
WinOperationMode	string	Operation execution mode
WinOperationType	string	Type of the object detected by the software
WinOptions	string	Operations parameters from windows event log events
WinOriginID	string	Identifier of the object origin
WinOriginName	string	Name of the object origin
WinPackage	string	Name or identifier of the package related to the event
WinPackageFullName	string	Name of the object being processed
WinPackageName	string	Name of the object being processed
WinPackageRelativeAppId	string	Object type code
WinPackageSid	string	Package SID related to the event
WinParam1	string	Query string
WinParam2	string	Query string
WinParam3	string	Query string
WinParam4	string	Query string
WinParam5	string	Query string
WinParentProcessId	string	The ID of the parent process that launched the current process when the task was created
WinParentProcessName	string	Parent process name
WinPasswordHistoryLength	string	Active directory objects parameters
WinPasswordLastSet	string	Active directory objects parameters
WinPasswordProperties	string	Description of an object being processed as defined in the object properties
WinPath	string	Path to the object being processed
WinPathFound	string	Path to the detected file or object
WinPayload	string	File attributes of an object being processed
WinPeerMac	string	Peer device MAC address
WinPostCleanStatus	string	Status after threat remediation
WinPreAuthType	string	Type of the object detected by the software
WinPreExecutionStatus	string	Status before executing the action
WinPreviousEngineVersion	string	Previous version of the security engine
WinPreviousSignatureVersion	string	Previous signature version
WinPreviousTime	string	Event time
WinPrimaryGroupId	string	Information about user group
WinPrivilegeList	string	Access rights for the object being processed

Field	Type	Description
WinProcessCreationTime	string	Process creation time
WinProcessId	string	Process system id (pid)
WinProcessName	string	Name of the object being processed
WinProductName	string	Name of the security product that generated the event
WinProductVersion	string	Version of the security product
WinProfile	string	User or system profile name/ID
WinProfileChanged	string	Operations parameters from windows event log events
WinProfilePath	string	Path to the object being processed
WinProfiles	string	List of applied profiles
WinProfileUsed	string	Profile used in the event
WinProperties	string	Description of an object being processed as defined in the object properties
WinPropertyName	string	Property name of the object
WinProtocol	string	Network connections parameters from windows event log events
WinProviderKey	string	Provider key for filter or operation
WinProviderName	string	Provider name for operation or event
WinProxyPolicyName	string	Proxy policy name
WinPuaCount	string	Windows event log events additional parameters
WinPuaPolicyId	string	Object type code
WinQfeVersion	string	Version of the statistics being sent
WinQuarantineSessionIdentifier	string	Quarantine session identifier
WinQuarantineState	string	Object state in quarantine
WinReadOperation	string	Flag for read operation
WinReason	string	Reason for the event or action
WinReasonCode	string	Reason code for the event
WinReasonForRejection	string	Reason for rejection of the operation
WinReasonText	string	Text description of the reason for the event
WinRecoveryKeyId	string	Recovery key identifier
WinRecoveryReason	string	Reason for using recovery key
WinRecoveryServer	string	Data recovery server
WinRelativeTargetName	string	Name of the object being processed
WinRemediationUser	string	User who initiated the remediation
WinRemoteAddress	string	Remote address of the connection or operation
WinRemoteAdminEnabled	string	Remote administration enabled flag
WinRemoteEventLogging	string	Remote event logging flag
WinRemoteKeyModPort	string	Remote key module port
WinRemoteMachineID	string	Remote machine identifier
WinRemoteMMPrincipalName	string	Remote security principal that was used during the IPsec Main Mode authentication process
WinRemoteUserID	string	Remote user identifier
WinReplicationEvent	string	Replication event flag
WinReportId	string	Object type code

Field	Type	Description
WinRequestClientInfo	string	Client information sending the request
WinRequestCSPProvider	string	Requested CSP provider in the event
WinRequester	string	Requester
WinRequestId	string	Request ID
WinRequestOSVersion	string	OS version of the requesting client
WinResource	string	Resource or object involved in the operation
WinResourceAttributes	string	File attributes of an object being processed
WinResourceManager	string	Resource manager responsible for the object
WinResponderCookie	string	Responder operation cookie
WinRestrictedAdminMode	string	Security parameters from windows event log events
WinRestrictedSidCount	string	Number of restricted SIDs for the operation
WinReturnCode	string	Return code of the operation result
WinRole	string	Role of the subject in the operation
WinRpcCallClientLocality	string	The RPC client locality that initiated the event, indicating whether the call was local or remote
WinRuleAttr	string	Security rule or filter attribute
WinRuleId	string	Object type code
WinRuleName	string	Name of the object being processed
WinRunspaceId	string	PowerShell runspace ID
WinSamAccountName	string	Id of the account under which the controlled process was started
WinScanID	string	Identifier of the scan
WinScanParameters	string	Scan parameters
WinScanParametersIndex	string	Index of the scan parameters
WinScanResources	string	Resources that were scanned
WinScanTimeHours	string	Hours taken for the scan
WinScanTimeMinutes	string	Minutes taken for the scan
WinScanTimeSeconds	string	Seconds taken for the scan
WinScanType	string	Type of scan
WinScanTypeIndex	string	Index of the scan type
WinSchema	string	Schema of the object or event
WinSchemaFriendlyName	string	Friendly name of the schema
WinScriptBlockId	string	Object type code
WinScriptBlockText	string	User sessions parameters from windows event log events
WinScriptPath	string	Path to the object being processed
WinSecurityDescriptor	string	Security descriptor of the object
WinSecurityPackageName	string	Name of the object being processed
WinSerialNumber	string	Serial number of the certificate or security object
WinServerNames	string	List of server names involved in the operation
WinService	string	Name of the service or service component associated with the event
WinServiceAccount	string	Id of the account under which the controlled process was started
WinServiceFileName	string	Name of the object being processed

Field	Type	Description
WinServiceName	string	Object name derived from the windows event log
WinServicePrincipalNames	string	Name of the object being processed
WinServiceSid	string	User account security identifier (sid)
WinServiceStartType	string	Start type of the windows service
WinServiceType	string	Type of the object detected by the software
WinServiceVersion	string	Version of the statistics being sent
WinSessionId	string	Unique id of the logon session
WinSessionName	string	User sessions parameters from windows event log events
WinSettingType	string	Type of the object detected by the software
WinSettingValue	string	File attributes of an object being processed
WinSeverityID	string	Identifier of the threat severity level
WinSeverityName	string	Name of the threat severity level
WinShareLocalPath	string	Path to the object being processed
WinShareName	string	Id of the account under which the controlled process was started
WinSID	string	Security Identifier (SID) related to a user or object
WinSidFilteringEnabled	string	Security parameters from windows event log events
WinSidHistory	string	User account security identifier (sid)
WinSidList	string	User account security identifier (sid)
WinSignatureType	string	Type of threat signature
WinSignatureTypeIndex	string	Index of the signature type
WinSignatureVersion	string	Signature version at the time of the event
WinSourceAddr	string	Network connections parameters from windows event log events
WinSourceAddress	string	Local ip address
WinSourceDRA	string	Network connections parameters from windows event log events
WinSourceHandleId	string	Handle ID of the source object
WinSourceID	string	Identifier of the event or action source
WinSourceName	string	Name of the event or action source
WinSourcePort	string	Port numbers of the source and the destination of the network connection being processed
WinSourceProcessId	string	Source process ID
WinSourceSid	string	SID of the subject that initiated the operation
WinSourceUserName	string	Source username
WinSpnName	string	SPN (Service Principal Name) used for authentication
WinSSID	string	Wireless network identifier (SSID)
WinStagingReason	string	Reason for staging the object for audit
WinStartTime	string	Event time
WinStartType	string	Type of the object detected by the software
WinStartUSN	string	Network connections parameters from windows event log events
WinState	string	State of the object or system at the time of the event
WinStatus	string	Description of an object being processed as defined in the object properties
WinStatusCode	string	Operations parameters from windows event log events

Field	Type	Description
WinStatusDescription	string	Description of the current status of the event or action
WinStopTime	string	Event time
WinSubcategoryGuid	string	Information about user group
WinSubcategoryId	string	Object type code
WinSubject	string	Information about the subject that initiated the action
WinSubjectAlternativeName	string	Certificate SAN (Subject Alternative Name) field containing alternate identities
WinSubjectDomainName	string	Name of the domain used to authenticate the owner of the logon session
WinSubjectKeyIdentifier	string	Certificate Subject Key Identifier
WinSubjectLogonId	string	User account security identifier (sid)
WinSubjectMachineName	string	Name of the machine on whose behalf the action was performed
WinSubjectMachineSID	string	Machine SID for the system that performed the action
WinSubjectUserDomainName	string	Name of the domain used to authenticate the owner of the logon session
WinSubjectUserName	string	Id of the account under which the controlled process was started
WinSubjectUserSid	string	User account security identifier (sid)
WinSubStatus	string	Operations parameters from windows event log events
WinTargetDomainName	string	Name of the domain used to authenticate the owner of the logon session
WinTargetHandleId	string	Handle ID of the target object
WinTargetInfo	string	Description of an object being processed as defined in the object properties
WinTargetLinkedLogonId	string	User account security identifier (sid)
WinTargetLogonGuid	string	Information about user group
WinTargetLogonId	string	User account security identifier (sid)
WinTargetName	string	Name of the target object or resource
WinTargetOutboundDomainName	string	Name of the domain used to authenticate the owner of the logon session
WinTargetOutboundUserName	string	Id of the account under which the controlled process was started
WinTargetProcessId	string	Process system id (pid)
WinTargetProcessName	string	Name of the object being processed
WinTargetServer	string	Target server of the event
WinTargetServerName	string	User device name
WinTargetSid	string	User account security identifier (sid)
WinTargetState	string	State of the target object after the operation
WinTargetUserDomain	string	Domain of the target user
WinTargetUserName	string	Id of the account under which the controlled process was started
WinTargetUserSid	string	User account security identifier (sid)
WinTaskContent	string	Original content of the scheduled task associated with the event
WinTaskContentActionsContext	string	Operating system task scheduler tasks parameters
WinTaskContentActionsExecCommand	string	Command line arguments for the process
WinTaskContentPrincipalsPrincipalid	string	User account security identifier (sid)
WinTaskContentPrincipalsPrincipalLogonType	string	Logon session type

Field	Type	Description
WinTaskContentPrincipalsPrincipalRunLevel	string	Operating system task scheduler tasks parameters
WinTaskContentPrincipalsPrincipalUserId	string	User account security identifier (sid)
WinTaskContentRegistrationInfoAuthor	string	Id of the account under which the controlled process was started
WinTaskContentRegistrationInfoDate	string	Date of event
WinTaskContentSettingsAllowHardTerminate	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsAllowStartOnDemand	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsDisallowStartIfOnBatteries	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsEnabled	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsExecutionTimeLimit	string	Event time
WinTaskContentSettingsHidden	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsIdleSettingsRestartOnIdle	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsIdleSettingsStopOnIdleEnd	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsMultipleInstancesPolicy	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsPriority	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsRunOnlyIfIdle	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsRunOnlyIfNetworkAvailable	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsStartWhenAvailable	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsStopIfGoingOnBatteries	string	Operating system task scheduler tasks parameters
WinTaskContentSettingsWakeToRun	string	Operating system task scheduler tasks parameters
WinTaskContentTriggers	string	Tasks parameters recorded in the windows event log events
WinTaskContentversion	string	Version of the task in its original content
WinTaskContentNew	string	Updated content of the scheduled task
WinTaskContentNewActionsContext	string	Operating system task scheduler tasks parameters
WinTaskContentNewActionsExecCommand	string	Command line arguments for the process
WinTaskContentNewPrincipalsPrincipalid	string	User account security identifier (sid)
WinTaskContentNewPrincipalsPrincipalLogonType	string	Logon session type
WinTaskContentNewPrincipalsPrincipalRunLevel	string	Operating system task scheduler tasks parameters
WinTaskContentNewPrincipalsPrincipalUserId	string	User account security identifier (sid)
WinTaskContentNewRegistrationInfoAuthor	string	Id of the account under which the controlled process was started
WinTaskContentNewRegistrationInfoDate	string	Date of event
WinTaskContentNewSettingsAllowHardTerminate	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsAllowStartOnDemand	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsDisallowStartIfOnBatteries	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsEnabled	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsExecutionTimeLimit	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsHidden	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsIdleSettingsRestartOnIdle	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsIdleSettingsStopOnIdleEnd	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsMultipleInstancesPolicy	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsPriority	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsRunOnlyIfIdle	string	Operating system task scheduler tasks parameters

Field	Type	Description
WinTaskContentNewSettingsRunOnlyIfNetworkAvailable	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsStartWhenAvailable	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsStopIfGoingOnBatteries	string	Operating system task scheduler tasks parameters
WinTaskContentNewSettingsWakeToRun	string	Operating system task scheduler tasks parameters
WinTaskContentNewTriggers	string	Tasks parameters recorded in the windows event log events
WinTaskContentNewversion	string	Version of the task in its updated content
WinTaskName	string	Name of the object being processed
WinTdoAttributes	string	File attributes of an object being processed
WinTdoDirection	string	Network connections parameters from windows event log events
WinTdoType	string	Type of the object detected by the software
WinTemplateContent	string	Content of the certificate template
WinTemplateDSObjectFQDN	string	FQDN of the template object in Active Directory
WinTemplateInternalName	string	Internal name of the certificate template
WinTemplateOID	string	OID (Object Identifier) of the certificate template
WinTemplateSchemaVersion	string	Schema version of the certificate template
WinTemplateVersion	string	Version of the certificate template
WinTerminationTime	string	Event time
WinTestSigning	string	Flag indicating whether Test Signing mode is enabled on the system
WinThreatID	string	Identifier of the threat
WinThreatName	string	Name of the threat
WinTicketEncryptionType	string	Type of the object detected by the software
WinTicketOptions	string	Active directory objects parameters
WinTokenElevationType	string	Security token elevation type
WinTopLevelName	string	Name of the object being processed
WinTransactionId	string	Object type code
WinTransitionsToOn	string	Transition of the object or component to the 'on' state
WinTransmittedServices	string	Operations parameters from windows event log events
WinTreeDelete	string	Windows event log events additional parameters
WinType	string	Type of the event or object
WinTypeID	string	Identifier of the event or threat type
WinTypeName	string	Name of the event or threat type
WinUnused	string	Reserved or unused field
WinUnused2	string	Additional reserved field not used by the event
WinUnused3	string	Additional reserved field not used by the event
WinUnused4	string	Additional reserved field not used by the event
WinUnused5	string	Additional reserved field not used by the event
WinUnused6	string	Additional reserved field not used by the event
WinUpdateType	string	Type of product or signature update
WinUpdateTypeIndex	string	Index of the update type
WinUser	string	Username associated with the event
WinUserAccountControl	string	Properties of user account control component

Field	Type	Description
WinUserClaims	string	List of user claims for new logon session
WinUserData	string	User sessions parameters from windows event log events
WinUserName	string	Username
WinUserParameters	string	Id of the account under which the controlled process was started
WinUserPrincipalName	string	Id of the account under which the controlled process was started
WinUserSid	string	SID of the user associated with the event
WinUserUPN	string	User Principal Name (UPN) of the user
WinUserWorkstations	string	User device name
WinVendorIds	string	User sessions parameters from windows event log events
WinVirtualAccount	string	Id of the account under which the controlled process was started
WinVsmLaunchType	string	Launch type of Virtual Secure Mode (VSM)
WinWakeFromState	string	Power state from which the system was awakened (sleep, hibernation, etc.)
WinWakeRequesterTypeAc	string	Wake requester type when running on AC power
WinWakeRequesterTypeDc	string	Wake requester type when running on DC power
WinWeight	string	Weight or priority associated with the event object
WinWorkstation	string	User device name
WinWorkstationName	string	User device name
WinProcessingErrorDataDataItemName	string	Name of the data item that caused a processing error
WinProcessingErrorDataErrorCode	string	Error code that occurred during event processing
WinProcessingErrorDataEventPayload	string	Original event payload that caused the error
WinSystemChannel	string	Windows Event Log channel from which the event was recorded
WinSystemComputer	string	Name of the computer that generated the event
WinSystemEventID	string	The event identifier that defines the type of event that occurred in the system
WinSystemEventIDQualifiers	string	Additional event qualifiers providing extended information about the event
WinSystemEventRecordID	string	A unique record identifier in the log
WinSystemExecutionProcessID	string	The process identifier (PID) associated with the event execution
WinSystemExecutionThreadID	string	The thread identifier (TID) that triggered the event
WinSystemKeywords	string	Event keywords used for categorizing and filtering events
WinSystemLevel	string	The event level indicating its severity or importance
WinSystemOpcode	string	The event operation code describing the type of action associated with the event
WinSystemProviderEventSourceName	string	The name of the source that generated the event
WinSystemProviderGuid	string	The globally unique identifier of the event provider
WinSystemProviderName	string	The name of the event provider
WinSystemSecurityUserID	string	The identifier of the user associated with the event
WinSystemTask	string	The task identifier associated with the event
WinSystemTimeCreatedSystemTime	string	The timestamp when the event was created
WinSystemVersion	string	The version of the event schema
WinAutoBackupBackupPath	string	The file or folder path where the automatic backup is stored
WinAutoBackupChannel	string	The channel or source used for automatic backup

Field	Type	Description
WinEventProcessingFailureErrorCode	string	Error code encountered during event processing
WinEventProcessingFailureEventID	string	The ID of the event that caused the processing failure
WinEventProcessingFailurePublisherID	string	Identifier for the application or service that was trying to log the event that failed
WinEventXMLAddress	string	Address associated with the event
WinEventXMLParam1	string	Additional event information field
WinEventXMLParam2	string	Additional event information field
WinEventXMLParam3	string	Additional event information field
WinEventXMLSessionID	string	The user session ID associated with the event
WinEventXMLSource	string	The source of the event
WinEventXMLTargetSession	string	The target session related to the event
WinEventXMLUser	string	The user associated with the event
WinFileIsFull	string	An indicator that the log is full and can no longer accept new entries.
WinLogFileClearedSubjectDomainName	string	The domain of the user who cleared the event log
WinLogFileClearedSubjectLogonId	string	The logon ID of the user who cleared the event log
WinLogFileClearedSubjectUserName	string	The username of the user who cleared the event log
WinLogFileClearedSubjectUserSid	string	The SID of the user who cleared the event log
WinOperationClientFailureClientMachine	string	The name of the client machine where the operation failure occurred
WinOperationClientFailureClientProcessId	string	The process ID of the client that caused the operation failure
WinOperationClientFailureComponent	string	The system component where the operation failure occurred
WinOperationClientFailureId	string	The unique identifier of the operation failure
WinOperationClientFailureOperation	string	The name or description of the operation that failed
WinOperationClientFailurePossibleCause	string	The possible cause of the operation failure
WinOperationClientFailureResultCode	string	The result code of the operation indicating success or failure reason
WinOperationClientFailureUser	string	The user who initiated the operation that failed
WinOperationStartedOperationalCode	string	The code of the started operation
WinOperationStartedOperationalHostProcess	string	The host process that initiated the operation
WinOperationStartedOperationalProcessID	string	The process ID associated with the started operation
WinOperationStartedOperationalProviderName	string	The name of the provider or event source
WinOperationStartedOperationalProviderPath	string	The path to the provider or event source
WinServiceShutdown	string	A Windows service has been stopped

Blocked Document

This event type is supported on Windows and Linux operating systems.

Blocked Document event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file

Field	Type	Description
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS

Field	Type	Description
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id

Field	Type	Description
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Applock

This event type is supported on Windows, Linux, and macOS operating systems.

Applock event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessCalltrace	string	Stack trace of the process
ProcessFileLnkName	string	Name of the LNK file that was used for the process execution (without the path)
ProcessFileLnkPath	string	Path to the LNK file that was used for the process execution (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was used for the process execution
ProcessFileLnkCmdline	string	Command line of the LNK file for the process execution
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username

Field	Type	Description
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field

Field	Type	Description
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process

Field	Type	Description
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Process Terminated

This event type is supported on Windows, Linux, and macOS operating systems.

Process Terminated event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessCalltrace	string	Stack trace of the process
ProcessFileLnkName	string	Name of the LNK file that was used for the process execution (without the path)
ProcessFileLnkPath	string	Path to the LNK file that was used for the process execution (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was used for the process execution
ProcessFileLnkCmdline	string	Command line of the LNK file for the process execution
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username

Field	Type	Description
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field

Field	Type	Description
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process

Field	Type	Description
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
ProcessTerminationtime	int	The time the process was completed

Device

This event type is supported on Windows operating systems.

Device event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventVersion	string	Event schema version
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
DeviceId	string	Device id
DeviceName	string	Device name
DevicePath	string	Device path
DeviceOperationtype	string	Device operation type (e.g. 1 - connect)
DeviceType	string	Device type
DeviceSystemflag	string	Flag if device is system

File System Mount

This event type is supported on Windows and Linux operating systems.

File System Mount event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
VolumeName	string	Disk volume name
VolumePath	string	Disk volume mount point
DeviceClass	string	GUID for device class according to official specification
DeviceId	string	Device id
DeviceBustype	string	Bus type used by connected device
DeviceType	string	Device type
DeviceHotpluggable	string	Is device hot pluggable or not (true or false)

Field	Type	Description
DeviceSerialnumber	string	Manufacturer device ID
VolumeFilesystemtype	string	File system type of disk volume
DeviceSpaceTotal	uint	Total disk capacity (in Mb)
DeviceSpaceUsed	uint	Used space on the disk (in Mb)
DeviceSpaceFree	uint	Available free space on the disk (in Mb)

File System Unmount

This event type is supported on Windows and Linux operating systems.

File System Unmount event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
VolumeName	string	Disk volume name
VolumePath	string	Disk volume mount point
DeviceClass	string	GUID for device class according to official specification
DeviceId	string	Device id
DeviceBustype	string	Bus type used by connected device
DeviceType	string	Device type
DeviceHotpluggable	string	Is device hot pluggable or not (true or false)

Field	Type	Description
DeviceSerialnumber	string	Manufacturer device ID
VolumeFilesystemtype	string	File system type of disk volume
DeviceSpaceTotal	uint	Total disk capacity (in Mb)
DeviceSpaceUsed	uint	Used space on the disk (in Mb)
DeviceSpaceFree	uint	Available free space on the disk (in Mb)

Bits Job Create

This event type is supported on Windows operating systems.

Bits Job Create event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
BitsjobId	string	Identifier of job (GUID)
BitsjobName	string	The name of job
BitsjobOwnerUserName	string	Username of job owner
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the file that was executed
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource

Field	Type	Description
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file

Field	Type	Description
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Creation flags of grand-parent process
GrandParentProcessFileLnkName	string	Name without the path of the LNK file that started the grand-parent process
GrandParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the grand-parent process
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Bits Job Complete

This event type is supported on Windows operating systems.

Bits Job Complete event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
BitsjobId	string	Identifier of job (GUID)
BitsjobName	string	The name of job
BitsjobOwnerUserName	string	Username of job owner
BitsjobUserName	string	Username who performs the operation
BitsjobFilestotal	int	Total count of files in job
BitsjobBytestransferred	int	Total count of transferred bytes in job
BitsjobPeerBytestransferred	int	The count of bytes transferred via p2p

Bits Job Start

This event type is supported on Windows operating systems.

Bits Job Start event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
BitsjobId	string	Identifier of job (GUID)
BitsjobName	string	The name of job
BitsjobTransferid	string	Unique identifier of file transferring in job (GUID)
BitsjobRemotename	string	Data source URL
BitsjobDatasourceCreationtime	int	Creation time of data source
BitsjobDatasourceSize	int	Size of data source
BitsjobBytestotal	int	Total count of files in job

Field	Type	Description
BitsjobBytestransferred	int	Total count of transferred bytes in job
BitsjobPeerHostname	int	Hostname of p2p data source
BitsjobPeerBytestransferred	int	The count of bytes transferred via p2p

Bits Job Stop

This event type is supported on Windows operating systems.

Bits Job Stop event fields

Field	Type	Description
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
BitsjobId	string	Identifier of job (GUID)
BitsjobName	string	The name of job
BitsjobTransferid	string	Unique identifier of file transferring in job (GUID)
BitsjobRemotename	string	Data source URL
BitsjobDatasourceCreationtime	int	Creation time of data source
BitsjobDatasourceSize	int	Size of data source

Field	Type	Description
BitsjobBytestotal	int	Total count of files in job
BitsjobBytestransferred	int	Total count of transferred bytes in job
BitsjobResultStatuscode	int	The result of data transferring operation via BITS
BitsjobResultAdditionalinfo	int	Additional information about the result of data transferring via BITS
BitsjobPeerHostname	string	Hostname of p2p data source
BitsjobPeerContextinfo	int	Identifying information of p2p data source
BitsjobPeerProtocolflags	int	Configuration flags that determine if the computer serves content to peers and can download content from peers
BitsjobPeerBytestransferred	int	The count of bytes transferred via p2p
BitsjobProxy	string	Proxy server that was used in transferring data
BitsjobBandwidthLimit	int	The maximum speed that a BITS job can use for downloading or uploading data
BitsjobBandwidthIgnoreonlan	int	The parameter determines whether to ignore speed limits if the source or destination is on a local network

Bits Job Add File

This event type is supported on Windows operating systems.

Bits Job Add File event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
BitsjobId	string	Identifier of job (GUID)
BitsjobName	string	The name of job
BitsjobOwnerUserName	string	Username of job owner
BitsjobUserName	string	Username who performs the operation
BitsjobFilestotal	int	Total count of files in job
BitsjobRemotename	string	Data source URL
BitsjobLocalname	string	Local path to file for saving job data
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file

Field	Type	Description
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified

Field	Type	Description
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Bits Job Error

This event type is supported on Windows operating systems.

Bits Job Error event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
BitsjobErrorid	int	Error Identifier
BitsjobId	string	Identifier of job (GUID)
BitsjobName	string	The name of job
BitsjobTransferid	string	Unique identifier of file transferring in job (GUID)
BitsjobRemotename	string	Data source URL

Field	Type	Description
BitsjobDatasourceCreationtime	int	Creation time of data source
BitsjobDatasourceSize	int	Size of data source
BitsjobBytestotal	int	Total count of bytes in job
BitsjobBytestransferred	int	Total count of transferred bytes in job
BitsjobResultStatuscode	int	The result of data transferring operation via BITS
BitsjobResultAdditionalinfo	int	Additional information about the result of data transferring via BITS
BitsjobPeerHostname	string	Hostname of p2p data source
BitsjobPeerContextinfo	int	Identifying information of p2p data source
BitsjobPeerProtocolflags	int	Configuration flags that determine if the computer serves content to peers and can download content from peers.
BitsjobPeerBytestransferred	int	The count of bytes transferred via p2p
BitsjobProxy	string	Proxy server that was used in transferring data
BitsjobBandwidthLimit	int	The maximum speed that a BITS job can use for downloading or uploading data
BitsjobBandwidthIgnoreonlan	uint	The parameter determines whether to ignore speed limits if the source or destination is on a local network
BitsjobOwnerUserName	string	Username of job owner

Service Create

This event type is supported on Windows and Linux operating systems.

Service Create event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
FileName	string	Name of the file (without the path)

Field	Type	Description
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileType	string	Type of the file
FileAttr	int	The file system attributes
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ServiceTitle	string	Service name, unique identifier of service
ServiceType	string	Service type
ServiceStarttype	string	The type of service start
ServiceCmdline	string	Command line of started service
ServiceLoadordergroup	string	Load order group name of this service
ServiceTagid	uint	Unique tag value for this service in ServiceLoadOrderGroup
ServiceDependencies	string	Load order group names or service names that must start before this service
ServiceStartname	string	The account name from which the service will be launched
ServiceDisplayname	string	Displayed name of service
ServiceDeletedelayed	uint	Flag of delayed deletion. 1 - service will be deleted when it stops; 0 - service is deleted immediately. For "Service Create" event this field is optional.
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessProperties	string	List of properties of the account that runs process
ProcessIntegritylevel	int	Process integrity level
ProcessUserName	string	Domain and username who executed the process
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource

Field	Type	Description
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessUserName	string	Domain and username who executed parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessProperties	string	List of properties of the account which runs parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process

Service Modify

This event type is supported on Windows and Linux operating systems.

Service Modify event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content

Field	Type	Description
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileType	string	Type of the file
FileAttr	int	The file system attributes
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ServiceTitle	string	Service name, unique identifier of service
ServiceType	string	Service type
ServiceStarttype	string	The type of service start
ServiceCmdline	string	Command line of started service
ServiceLoadordergroup	string	Load order group name of this service
ServiceTagid	uint	Unique tag value for this service in ServiceLoadOrderGroup
ServiceDependencies	string	Load order group names or service names that must start before this service
ServiceStartname	string	The account name from which the service will be launched
ServiceDisplayname	string	Displayed name of service
ServiceOldType	string	Service type before modification
ServiceOldStarttype	string	The type of service start before modification
ServiceOldCmdline	string	The path to executable file before service modification
ServiceOldLoadordergroup	string	Load order group name of this service before modification
ServiceOldTagid	uint	Unique tag value for this service in ServiceLoadOrderGroup before modification
ServiceOldDependencies	string	Load order group names or service names that must be started prior to this service (before service modification)
ServiceOldStartname	string	The account name from which the service is launched before service modification
ServiceOldDisplayname	string	Displayed service name before service modification
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessProperties	string	List of properties of the account that runs process
ProcessIntegritylevel	int	Process integrity level
ProcessUserName	string	Domain and username who executed the process
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource

Field	Type	Description
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessUserName	string	Domain and username who executed parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessProperties	string	List of properties of the account which runs parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process

Service Delete

This event type is supported on Windows and Linux operating systems.

Service Delete event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
FileName	string	Name of the file (without the path)

Field	Type	Description
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileType	string	Type of the file
FileAttr	int	The file system attributes
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ServiceTitle	string	Service name, unique identifier of service
ServiceType	string	Service type
ServiceStarttype	string	The type of service start
ServiceCmdline	string	Command line of started service
ServiceLoadordergroup	string	Load order group name of this service
ServiceTagid	uint	Unique tag value for this service in ServiceLoadOrderGroup
ServiceDependencies	string	Load order group names or service names that must start before this service
ServiceStartname	string	The account name from which the service will be launched
ServiceDisplayname	string	Displayed name of service
ServiceDeletedelayed	uint	Flag of delayed deletion. 1 - service will be deleted when it stops; 0 - service is deleted immediately. For "Service Create" event this field is optional.
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessProperties	string	List of properties of the account that runs process
ProcessIntegritylevel	int	Process integrity level
ProcessUserName	string	Domain and username who executed the process
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource

Field	Type	Description
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessUserName	string	Domain and username who executed parent process
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessProperties	string	List of properties of the account which runs parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process

Scheduled Task Create

This event type is supported on Windows and Linux operating systems.

Scheduled Task Create event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
TaskName	string	The name of task, unique identifier of service
TaskAuthorName	string	Username of task author
TaskUserName	string	Username from which the service will be launched
TaskUserId	int	Identifier of user from which the service will be launched. Only for Linux/Mac OS
TaskUserSid	string	SID of user from which the service will be launched. Only for Windows
TaskRunlevel	string	The level of privileges for task running
TaskCreationtime	int	Date and time of task creation
TaskCmdline	string	Actions performed in task
TaskEnabled	string	Flag whether the task is enabled
TaskHidden	string	Flag whether the task is hidden
TaskLocation	string	Path to the task object in the operating system
TaskSchedule	string	Schedule of task running
TaskSource	string	The source of task
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file

Field	Type	Description
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process

Field	Type	Description
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file

Field	Type	Description
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process.
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process.
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment

Field	Type	Description
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Scheduled Task Modify

This event type is supported on Windows (Windows Vista, Windows Server 2008 and later) and Linux operating systems.

Scheduled Task Modify event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base

Field	Type	Description
AgentIndexTimestamp	int	Timestamp of last bases update for all components
TaskName	string	The name of task, unique identifier of service
TaskAuthorName	string	Username of task author
TaskUserName	string	Username from which the service will be launched
TaskUserSid	string	SID of user from which the service will be launched. Only for Windows
TaskRunlevel	string	The level of privileges for task running
TaskCreationtime	int	Date and time of task creation
TaskCmdline	string	Actions performed in task
TaskEnabled	string	Flag whether the task is enabled
TaskHidden	string	Flag whether the task is hidden
TaskLocation	string	Path to the task object in the operating system
TaskSchedule	string	Schedule of task running
TaskSource	string	The source of task
TaskOldUserName	string	Name of previous user from which the service was launched
TaskOldUserSid	string	SID of the previous user under which the task will be run
TaskOldEnabled	string	Previous value of flag whether the task is enabled
TaskOldHidden	string	Previous value of the flag indicating whether the task is hidden
TaskOldRunlevel	string	Previous level of privileges for task running
TaskOldCmdline	string	Previous actions performed in task
TaskOldSchedule	string	Previous task execution schedule
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified

Field	Type	Description
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process

Field	Type	Description
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags

Field	Type	Description
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process

Field	Type	Description
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Scheduled Task Delete

This event type is supported on Windows and Linux operating systems.

Scheduled Task Delete event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
TaskName	string	The name of task, unique identifier of service
TaskAuthorName	string	Username of task author
TaskUserName	string	Username from which the service will be launched
TaskUserId	int	Identifier of user from which the service will be launched. Only for Linux/Mac OS
TaskUserSid	string	SID of user from which the service will be launched. Only for Windows
TaskRunlevel	string	The level of privileges for task running
TaskCreationtime	int	Date and time of task creation
TaskCmdline	string	Actions performed in task
TaskEnabled	string	Flag whether the task is enabled
TaskHidden	string	Flag whether the task is hidden
TaskLocation	string	Path to the task object in the operating system
TaskSchedule	string	Schedule of task running
TaskSource	string	The source of task
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file

Field	Type	Description
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process

Field	Type	Description
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed

Field	Type	Description
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process.
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process.
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded

Field	Type	Description
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File Owner Change

This event type is supported on Windows and Linux operating systems, except for Windows XP x64, Windows Server 2003 x64, and Linux with a kernel version earlier than 4.19.*.

File Owner Change event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base

Field	Type	Description
AgentIndexTimestamp	int	Timestamp of last bases update for all components
FileOldOwnerUserName	string	Domain username of previous file owner
FileOldOwnerGroupName	string	Domain group name of previous file owner
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)

Field	Type	Description
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource

Field	Type	Description
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified

Field	Type	Description
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS

Field	Type	Description
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process.
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process.
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

File ACL Change

This event type is supported on Windows and Linux operating systems, except for Windows XP x64, Windows Server 2003 x64, and Linux with a kernel version earlier than 4.19.*.

File ACL Change event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base

Field	Type	Description
AgentIndexTimestamp	int	Timestamp of last bases update for all components
FileDacl	string	The list of access control entries defined in the DACL of the file
FileOldDacl	string	The previous list of access control entries defined in the DACL of the file
FileModifiedDacl	string	The list of modified entries from the DACL of the file
FileSacl	string	The list of access control entries defined in the SACL of the file
FileOldSacl	string	The previous list of access control entries defined in the SACL of the file
FileModifiedSacl	string	The list of modified entries from the SACL of the file
FileName	string	Name of the file (without the path)
FilePath	string	Full path to the file (without file name)
FileFullname	string	Full path to the file
FileMd5	string	MD5 hash of the file content
FileSha256	string	SHA256 hash of the file content
FileSize	int	Size of the file in bytes
FileCreationtime	int	Creation time of the file
FileModificationtime	int	The last time when the file was modified
FileOwnerUserId	int	File owner user id. Specified for Linux and macOS
FileOwnerUserName	string	File owner username. Specified for Linux and macOS
FileOwnerGroupName	string	File owner group name. Specified for Linux and macOS
FileOwnerGroupId	int	File owner group id. Specified for Linux and macOS
FileType	string	Type of the file
FileCapPermitted	string	Permitted capabilities of the file
FileCapInheritable	string	Inherited capabilities of the file
FileCapEffective	string	Effective capabilities of the file
FileOpenflags	string	Specified open flags (for example O_RDWR | O_APPEND), for create/modify/read operations.
FileAttrModificationtime	int	The last time, when the file attributes were modified
FileAttr	int	The file system attributes
FileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier of the file
FileProductname	string	Product name value from the VERSIONINFO resource of the file
FileProductvendor	string	Company name value from the VERSIONINFO resource of the file
FileDescription	string	Description from the VERSIONINFO resource of the file
FileOriginalname	string	Original file name from the VERSIONINFO resource of the file
FileSignSubjectname	string	Information about the organization that signed the file
FileSignResult	string	The result of the signature verification: passed - true, otherwise - false
FileSignTimestamp	int	Date and time when the file was signed
FileUrl	string	URL from where the file was downloaded
FileEmailSrcAddress	string	The sender's address from which the file was received as an attachment
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags

Field	Type	Description
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file

Field	Type	Description
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)

Field	Type	Description
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process

Field	Type	Description
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process.
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process.
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process

Field	Type	Description
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Registry Owner Change

This event type is supported on Windows operating systems except for Windows XP x64 and Windows Server 2003 x64.

Registry Owner Change event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
RegKeyName	string	Full path and name of the registry key which has been affected by the operation
RegOwnerUserName	string	Domain username of key registry owner
RegOldOwnerUserName	string	Domain username of previous key registry owner
RegOwnerGroupName	string	Domain group name of key registry owner
RegOldOwnerGroupName	string	Domain group name of previous key registry owner
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file

Field	Type	Description
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file

Field	Type	Description
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified

Field	Type	Description
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Registry ACL Change

This event type is supported on Windows operating systems except for Windows XP x64 and Windows Server 2003 x64.

Registry ACL Change event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base

Field	Type	Description
AgentIndexTimestamp	int	Timestamp of last bases update for all components
RegKeyName	string	Full path and name of the registry key which has been affected by the operation
RegDacl	string	The list of access control entries defined in the DACL of the registry key
RegOldDacl	string	The previous list of access control entries defined in the DACL of the registry key
RegModifiedDacl	string	The list of modified entries from the DACL of the registry key
RegSacl	string	The list of access control entries from SACL registry key
RegOldSacl	string	The previous list of access control entries defined in the SACL of the registry key
RegModifiedSacl	string	The list of modified entries from the SACL of the registry key
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name

Field	Type	Description
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified

Field	Type	Description
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Executable Memory Mapped

This event type is supported on Linux operating systems.

Executable Memory Mapped event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Field	Type	Description
SyscallArgs	string	System call arguments. Specified for Linux
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of LNK file
ProcessFileLnkMd5	string	MD5 hash of the LNK file that was executed
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	File name of executed process (without the path)
ProcessFilePath	string	Full path to the process of executed file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	File size of executed process (in bytes)
ProcessFileCreationtime	int	Creation time of the process executable file
ProcessFileModificationtime	int	The last time, when the executed file of current process was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the file that was executed
ProcessFileSha256	string	SHA256 hash of the process executed file
ProcessFileAttr	int	The list of file system attributes of the executable file from which the process was started
ProcessFileType	string	File type of executed process
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executed file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username

Field	Type	Description
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The name of the entity (person or organization) that issued the certificate
ProcessLogonType	string	Type of logon session of the user who has executed the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	string	The type of account of the user who started the process. Possible values: Unknown, Admin, NotAdmin
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	The fully qualified domain name (FQDN) of the remote host from which the user who started the process logged in
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field

Field	Type	Description
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	string	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process.
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)

Field	Type	Description
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process.
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process.
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file

Field	Type	Description
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	string	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Agent Start

This event type is supported on Windows, Linux, and macOS operating systems.

Agent Start event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
InitiatorId	string	Event initiator identifier
InitiatorName	string	Name of the event initiator
InitiatorType	string	Type of the event initiator
AgentInstanceid	string	Identifier of unique agent run
ProcessId	int	Process id
ProcessUniqueid	int	Process unique id

Agent Stop

This event type is supported on Windows, Linux, and macOS operating systems.

Agent Stop event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
InitiatorId	string	Event initiator identifier
InitiatorName	string	Name of the event initiator
InitiatorType	string	Type of the event initiator
AgentInstanceid	string	Identifier of unique agent run
ProcessId	int	Agent process id
ProcessUniqueid	int	Agent process unique id

Field	Type	Description
AgentStopreason	string	Reason for agent termination
AgentExitcode	int	Agent process exit code

Agent Install

This event type is supported on Windows, Linux, and macOS operating systems.

Agent Install event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
InitiatorId	string	Event initiator identifier
InitiatorName	string	Name of the event initiator
InitiatorType	string	Type of the event initiator

Agent Uninstall

This event type is supported on Windows, Linux, and macOS operating systems.

Agent Uninstall event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
InitiatorId	string	Event initiator identifier
InitiatorName	string	Name of the event initiator
InitiatorType	string	Type of the event initiator

Agent Action

This event type is supported on Windows, Linux, and macOS operating systems.

Agent Action event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
InitiatorId	string	Event initiator identifier

Field	Type	Description
InitiatorName	string	Name of the event initiator
InitiatorType	string	Type of the event initiator
AgentInstanceid	string	Identifier of unique agent run
ProcessId	int	Agent process id
ProcessUniqueid	int	Agent process unique id
AgentActionType	string	The type of action performed in the agent:0 → SelfProtectionDisabled,1 → SelfProtectionEnabled,2 → SelfProtectionTriggered,3 → PasswordProtectionOn,4 → PasswordProtectionOff,5 → CheckedPermission,Otherwise → Unknown
AgentActionDescription	string	Description of the performed action
AgentResultcode	int	The result code of the performed action

System Startup

This event type is supported on Windows, Linux, and macOS operating systems.

System Startup event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

System Shutdown

This event type is supported on Windows, Linux, and macOS operating systems.

System Shutdown event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux, macOS)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname, where the event was generated
HostIp	string	IP address of the host
AgentVersion	string	The version of product that is installed on the computer
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components

Connection Close

Enabling the `Connection Close` event may result in a significant increase in resource usage on protected devices.

This event type is supported on Windows and Linux operating systems.

Connection Close event fields

Field	Type	Description
IoAId	string array	Indicator of attack unique identifier
IoAName	string array	The name of indicator of attack
IoAVersion	integer array	Indicator of attack version
IoAAlert	string array	The attribute of raising alert
IoAConfidence	string array	The level of indicator of attack detection confidence (High, Medium, Low)
IoASeverity	string array	The level of indicator of attack severity (High, Medium, Low)
IoATactics	string array	Tactics of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoATechniques	string array	Techniques of the MITRE ATT&CK® Matrix on which the current Indicator of attack was mapped
IoAEventIds	string array	The list of event identifiers related to the current Indicator of attack
IoAEventCount	integer array	The count of events related to the current Indicator of attack
IoASB	string array	Full path to file which will be send to Sandbox according to Indicator of attack logic
EventType	string	Notification type
EventId	string	Unique event id
EventTimestamp	int	Date and time on the client (originally in UTC)
EventReceivedtimestamp	int	Date and time when notification was received on server
EventSequenceid	int	The sequence number of the sent event
HostId	string	Host unique id
HostKscId	string	Host id for administration via KSC
HostMdrId	string	Protected host ID in the MDR solution
HostOsmpId	string	List of identifiers for OSMP Based XDR solution servers associated with the protected host
HostOsFamily	string	Operation system family (Windows, Linux)
HostOsName	string	Operation system name
HostOsVersion	string	Operation system version
HostName	string	Hostname generated event
HostIp	string	IP address of the host
AgentVersion	string	Product that is installed on the computer

Field	Type	Description
AgentKdbTimestamp	int	Timestamp of component update KDB
AgentSw2Timestamp	int	Timestamp of component update sw2 base
AgentIndexTimestamp	int	Timestamp of last bases update for all components
NetSrcIp	string	Source ipv4/ipv6 address
NetSrcPort	int	Source port number
NetDstIp	string	Destination ipv4/ipv6 address
NetDstPort	int	Destination port number
NetProtocol	string	IP protocol
NetDirection	string	Direction of network connection (inbound, outbound)
NetCreationtime	int	Creation time of the connection
NetBytessent	int	Number of bytes sent during the connection
NetBytesreceived	int	Number of bytes received during the connection
NetDuration	int	Duration of the connection in seconds
ProcessUniqueid	int	Process unique id
ProcessId	int	Process id
ProcessCmdline	string	Command line of the process
ProcessCreationflags	string	List of process creation flags
ProcessDirectory	string	Process initial directory
ProcessEnvironment	string	Environment variables
ProcessProperties	string	List of properties of the account that runs process
ProcessFileLnkName	string	Name of the LNK file that was executed (without the path)
ProcessFileLnkPath	string	Full path to the LNK file that was executed (without file name)
ProcessFileLnkFullname	string	Full path to the LNK file that was executed
ProcessFileLnkCmdline	string	Command line of the executed LNK file
ProcessFileLnkMd5	string	MD5 hash of the executed LNK file
ProcessFileLnkSha256	string	SHA256 hash of the executed LNK file
ProcessIntegritylevel	int	Process integrity level
ProcessType	string	Type of the process
ProcessUserRealid	int	Real user id. Specified for Linux and macOS
ProcessGroupRealid	int	Real user group id. Specified for Linux and macOS
ProcessUserRealname	string	Real Username. Specified for Linux and macOS
ProcessGroupRealname	string	Real group name. Specified for Linux and macOS
ProcessUserEffectiveid	int	Effective user id. Specified for Linux and macOS
ProcessGroupEffectiveid	int	Effective user group id. Specified for Linux and macOS
ProcessUserEffectivename	string	Effective username mapped. Specified for Linux and macOS
ProcessGroupEffectivename	string	Effective group name mapped. Specified for Linux and macOS
ProcessFileName	string	Name of the process executable file (without the path)
ProcessFilePath	string	Full path to the process executable file (without file name)
ProcessFileFullname	string	Full path to the process executable file
ProcessFileSize	int	Process executable file size in bytes
ProcessFileCreationtime	int	Creation time of the process executable file

Field	Type	Description
ProcessFileModificationtime	int	The last time, when the process executable file was modified
ProcessFileAttrModificationtime	int	The last time, when the process executable file attributes were modified
ProcessFileMd5	string	MD5 hash of the process executable file
ProcessFileSha256	string	SHA256 hash of the process executable file
ProcessFileAttr	int	The list of file system attributes for the process executable file
ProcessFileType	string	Type of the process executable file
ProcessFileUrl	string	URL from where the process executable file was downloaded
ProcessFileEmailSrcAddress	string	The sender's address from which the process executable file was received as an attachment
ProcessFileOwnerUserId	int	File owner user ID
ProcessFileOwnerGroupId	int	File owner group ID
ProcessFileOwnerUserName	string	File owner username
ProcessFileOwnerGroupName	string	File owner group name
ProcessFileCapPermitted	string	Permitted capabilities of the process executable file
ProcessFileCapInheritable	string	Inheritable capabilities of the process executable file
ProcessFileCapEffective	string	Effective capabilities of the process executable file
ProcessFileZoneidentifier	int	Zone id given from the alternative stream Zone.Identifier connected with the file
ProcessFileProductname	string	The name of the application from the VERSIONINFO resource
ProcessFileProductversion	string	The application version from the VERSIONINFO resource
ProcessFileOriginalname	string	Original file name from the VERSIONINFO resource
ProcessFileProductvendor	string	Company name value from the VERSIONINFO resource
ProcessFileDescription	string	Description from the VERSIONINFO resource
ProcessFileVersion	string	File version from the VERSIONINFO resource
ProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ProcessFileSignTimestamp	int	Date and time when the file was signed
ProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
ProcessLogonType	string	Type of logon session of the process
ProcessLogonSessionId	int	Logon session ID from the access token of the process
ProcessUserType	int	List of properties of the account which runs the process
ProcessUserName	string	Domain and username who executed the process
ProcessLogonUserId	int	Login user id. Specified for Linux and macOS
ProcessLogonHostName	string	Logon remote host/ip. Specified for Linux and macOS
ParentProcessUniqueid	int	Parent process unique id
ParentProcessId	int	Parent process id
ParentProcessCmdline	string	Command line of the parent process
ParentProcessCreationflags	string	Creation flags of parent process
ParentProcessDirectory	string	Current working directory of parent process. Specified for Linux and macOS
ParentProcessFileLnkName	string	Name without the path of the LNK file that started the parent process
ParentProcessFileLnkPath	string	Full path without the name of the LNK file that started the parent process
ParentProcessFileLnkFullname	string	Full path to the LNK file that started the parent process
ParentProcessFileLnkCmdline	string	Command line for LNK file that started the parent process

Field	Type	Description
ParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the parent process
ParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the parent process
ParentProcessIntegritylevel	int	Integrity level of the parent process
ParentProcessType	string	Type of the parent process
ParentProcessUserRealid	int	Real user id of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealid	int	Real user group id of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserRealname	string	Real username of the user who started the parent process. Specified for Linux and macOS
ParentProcessGroupRealname	string	Real group name of the user who started the parent process. Specified for Linux and macOS
ParentProcessUserEffectiveid	int	Effective user ID of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectiveid	int	Effective group ID of the user who started the parent process. Auditd reference field
ParentProcessUserEffectivename	string	Effective username of the user who started the parent process. Auditd reference field
ParentProcessGroupEffectivename	string	Effective group name of the user who started the parent process. Auditd reference field
ParentProcessFileName	string	Name of the parent process executable file (without the path)
ParentProcessFilePath	string	Full path to the parent process executable file (without file name)
ParentProcessFileFullname	string	Full path to the parent process executable file
ParentProcessFileCreationtime	int	Creation time of the parent process executable file
ParentProcessFileModificationtime	int	The last time, when the parent process executable file was modified
ParentProcessFileAttrModificationtime	int	The last time, when the parent process executable file attributes were modified
ParentProcessFileMd5	string	MD5 hash of the parent process executable file
ParentProcessFileSha256	string	SHA256 hash of the parent process executable file
ParentProcessFileAttr	int	The list of file system attributes for the parent process executable file
ParentProcessFileType	string	Type of the parent process executable file
ParentProcessFileUrl	string	URL from where the parent process executable file was downloaded
ParentProcessFileEmailSrcAddress	string	The sender's address from which the parent process executable file was received as an attachment
ParentProcessFileOwnerUserId	int	User ID of the owner of the parent process executable file
ParentProcessFileOwnerGroupId	int	Group ID of the owner of the parent process executable file
ParentProcessFileOwnerUserName	string	Username of the owner of the parent process executable file
ParentProcessFileOwnerGroupName	string	Group name of the owner of the parent process executable file
ParentProcessFileCapEffective	string	Effective capabilities of the parent process executable file
ParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the parent process executable file
ParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the parent process executable file
ParentProcessFileDescription	string	Description from the VERSIONINFO resource of the parent process executable file
ParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
ParentProcessFileSignTimestamp	int	Date and time when the file was signed
ParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file

Field	Type	Description
ParentProcessLogonType	string	Type of logon session of the parent process
ParentProcessLogonSessionId	int	Logon session ID from the access token of the parent process
ParentProcessProperties	int	List of properties of the account which runs parent process
ParentProcessUserName	string	Domain and username who executed parent process
GrandParentProcessUniqueid	int	Grand-parent process unique id
GrandParentProcessId	int	Grand-parent process id
GrandParentProcessCmdline	string	Command line of the grand-parent process
GrandParentProcessCreationflags	string	Grand-parent process creation flags
GrandParentProcessDirectory	string	Current working dir of grand-parent process. Linux or Macos specific field
GrandParentProcessFileLnkName	string	Name of the LNK file that started the grand-parent process (without the path)
GrandParentProcessFileLnkPath	string	Full path to the LNK file that started the grand-parent process (without file name)
GrandParentProcessFileLnkFullname	string	Full path to the LNK file that started the grand-parent process
GrandParentProcessFileLnkCmdline	string	Command line for LNK file that started the grand-parent process
GrandParentProcessFileLnkMd5	string	MD5 hash of LNK file that started the grand-parent process
GrandParentProcessFileLnkSha256	string	SHA256 hash of LNK file that started the grand-parent process
GrandParentProcessIntegritylevel	int	Integrity level of the grand-parent process
GrandParentProcessType	string	Type of the grand-parent process
GrandParentProcessUserRealid	int	Real user id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealid	int	Real user group id of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserRealname	string	Real username of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessGroupRealname	string	Real group name of the user who started the grand-parent process. Specified for Linux and macOS
GrandParentProcessUserEffectiveid	int	Effective user ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectiveid	int	Effective group ID of the user who started the grand-parent process. Auditd reference field
GrandParentProcessUserEffectivename	string	Effective username of the user who started the grand-parent process. Auditd reference field
GrandParentProcessGroupEffectivename	string	Effective group name of the user who started the grand-parent process. Auditd reference field
GrandParentProcessFileName	string	Name of the grand-parent process executable file (without the path)
GrandParentProcessFilePath	string	Full path to the grand-parent process executable file (without file name)
GrandParentProcessFileFullname	string	Full path to the grand-parent process executable file
GrandParentProcessFileCreationtime	int	Creation time of the grand-parent process executable file
GrandParentProcessFileModificationtime	int	The last time, when the grand-parent process executable file was modified
GrandParentProcessFileAttrModificationtime	int	The last time, when the grand-parent process executable file attributes were modified
GrandParentProcessFileMd5	string	MD5 hash of the grand-parent process executable file
GrandParentProcessFileSha256	string	SHA256 hash of the grand-parent process executable file
GrandParentProcessFileAttr	int	The list of file system attributes for the grand-parent process executable file
GrandParentProcessFileType	string	Type of the grand-parent process executable file
GrandParentProcessFileUrl	string	URL from where the grand-parent process executable file was downloaded

Field	Type	Description
GrandParentProcessFileEmailSrcAddress	string	The sender's address from which the grand-parent process executable file was received as an attachment
GrandParentProcessFileOwnerUserId	int	User ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupId	int	Group ID of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerUserName	string	Username of the owner of the grand-parent process executable file
GrandParentProcessFileOwnerGroupName	string	Group name of the owner of the grand-parent process executable file
GrandParentProcessFileCapEffective	string	Effective capabilities of the grand-parent process executable file
GrandParentProcessFileProductname	string	Product name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileDescription	string	Description from the VERSIONINFO resource of the grand-parent process executable file
GrandParentProcessFileSignResult	string	The result of the signature verification: passed - true, otherwise - false
GrandParentProcessFileSignTimestamp	int	Date and time when the file was signed
GrandParentProcessFileSignSubjectname	string	The subject name of the certificate which was used to sing the file
GrandParentProcessLogonType	string	Type of logon session of the grand-parent process
GrandParentProcessLogonSessionId	int	Logon session ID from the access token of the grand-parent process
GrandParentProcessProperties	int	List of properties of the account which runs grand-parent process
GrandParentProcessUserName	string	Domain and username who executed grand-parent process
CreatorProcessUniqueid	int	Unique ID of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessId	int	Id of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCmdline	string	Command line of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessCreationflags	string	Creation flags of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessDirectory	string	Current working directory of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkName	string	Name of the LNK file (without the path) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkPath	string	Full path to the LNK file (without the name) that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkFullname	string	Full path to the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkCmdline	string	Command line parameters of the LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileLnkMd5	string	MD5 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileLnkSha256	string	SHA256 hash of LNK file that started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessIntegritylevel	int	Integrity level of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessType	string	Type of the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealid	int	Real user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealid	int	Real group ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserRealname	string	Real username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupRealname	string	Real group name of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectiveid	int	Effective user ID of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectiveid	int	Effective group ID of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserEffectivename	string	Effective username of the user who started the process that was real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessGroupEffectivename	string	Effective group name of the user who started the process that was real initiator of the current process was downloaded. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileName	string	Name of the executable file of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFilePath	string	Full path (without file name) to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileFullname	string	Full path to the executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCreationtime	int	Creation time of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileModificationtime	int	Modification time of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttrModificationtime	int	The modification time of the attributes of the executable file whose process is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileMd5	string	MD5 hash of executable file of process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSha256	string	SHA256 hash of executable file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileAttr	int	The list of file system attributes for the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileType	string	Type of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileUrl	string	URL from which the process that is real initiator of the current process was downloaded. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileEmailSrcAddress	string	The sender's address from which the executable file was received as an attachment, which is the actual initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserId	int	Owner's User ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupId	int	Owner's Group ID of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerUserName	string	Owner's Username of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOwnerGroupName	string	Owner's Group name of the process file that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileCapEffective	string	Effective capabilities of the process that is real initiator of the current process. Specified for Linux and macOS. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductname	string	Product name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileOriginalname	string	Original file name from the VERSIONINFO resource of the process file that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileProductvendor	string	Company name value from the VERSIONINFO resource of the process file that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Field	Type	Description
CreatorProcessFileDescription	string	Description from the VERSIONINFO resource of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignResult	string	The result of the signature verification for executable file of the process that is real initiator of the current process: passed - true, otherwise - false. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignTimestamp	int	Date and time when the file (real initiator of the current process) was signed. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessFileSignSubjectname	string	The subject name of the certificate which was used to sign the file of the process that is real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonType	string	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessLogonSessionId	int	Logon session ID from the access token of the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessProperties	int	Logon session type for the user who started the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'. Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields
CreatorProcessUserName	string	Domain and username of the user who strated the process that was real initiator of the current process. Typically, 'ParentProcess' is the same as 'CreatorProcess'.Then the CreatorProcess* fields will be absent in the telemetry and it is necessary to look at the ParentProcess* fields

Working with events

The **Threat hunting** section contains tools that help you search threats and vulnerabilities by analyzing the events.

Granular access to events

In KUMA, users with different rights can have granular access to events. Access to events is controlled at the level of storage spaces.

You can assign spaces to users in the **Spaces permissions** section. After upgrading to the latest version, the 'All spaces' space set is assigned to all existing users, that is, access to all spaces is unrestricted. An event contains a tenant ID and a space ID, therefore the user needs rights to the corresponding tenant and space to have access to the event.

Consider the following features of displaying storages:

- If a storage is not listed in the **Active services** section, the storage and its spaces are not displayed in the list of spaces of the set.
- If the storage service was stopped using the `systemctl stop kuma-<storage ID>` command, the storage and its spaces are not displayed in the list of spaces of the set.
- If the storage was started and then deleted using the `uninstall` command, the storage and its spaces remain in the list of spaces of the set.

In the list of events, you can add the **SpaceID** field to the table, which will display the name of the space. The space of audit events is displayed as KUMA Audit. KUMA Default is the space inside each storage, where all events go if the storage does not have configured spaces or if the event does not match the conditions of the existing spaces.

When you export the list of events to a TSV file, the space ID and name are displayed for spaces.

To differentiate access:

1. Configure the space sets.

   You can create, edit, or delete space sets. These actions result in audit events.

2. Configure access permissions for the space set You can grant or revoke access permissions for selected users.

Creating a space set

To create a space set:

1. In the KUMA web console, go to the **Settings** → **Access** → **Access to spaces** section.
2. In the opened window, click the **Add** button.
3. In the **Create space sets** window, configure the following:

   a. In the **Name** field, specify the space set name. You can use up to 128 Unicode characters.

   b. In the **Spaces** drop-down list, select the spaces that you want to include in the set by selecting the check box next to the space name. To remove a space from the set, clear the check box.

   c. If you want the default space set to be available to all users that do not have any of the sets assigned, select the **Make default** check box.

      This makes the created set the default set. In the list of space sets, it is marked as the default set: in the **Default** column, it has **Yes**.

      There can be only one default set. If you select **Make default** check box in the settings of a different set and save the settings, the default set is reassigned.

4. Click **Create**.

The space set is created and displayed in the list of spaces. After the space set is created, an audit event is generated in KUMA.

Then you need to grant users access rights to the created space set.

Editing a space set

To edit a space set:

1. In the KUMA web console, go to the **Settings** → **Access** → **Access to spaces** section.
2. In the opened window, click a set of spaces.
3. In the **Edit space sets** window, configure the following:
   a. In the **Name** field, specify the space set name. You can use up to 128 Unicode characters.
   b. In the **Spaces** drop-down list, select the spaces that you want to include in the set by selecting the check box next to the space name. To remove a space from the set, clear the check box.
   c. If you want the default space set to be available to all users that do not have any of the sets assigned, select the **Make default** check box.

      This makes the set the default set when you save the changes. In the list of space sets, it is marked as the default set: in the **Default** column, it has **Yes**.

      There can be only one default set. If you select **Make default** check box in the settings of a different set and save the settings, the default set is reassigned.
4. Click **Save**.

The space set is saved and displayed in the list of spaces.

The edited set of spaces is accessible to all users who had access to the original space set. You can control access to the edited space set and grant or revoke access permissions using the **Access control** button.

Deleting a space set

To delete a space set:

1. In the KUMA web console, go to the **Settings** → **Access** → **Access to spaces** section.
2. In the **Access to spaces** window, select the check box next to the relevant space set.

   If you want to delete all space sets, select the **Select all** check box in the upper left part of the list and click **Delete**.

   > You cannot delete the default space set and the 'All spaces' space set.

3. Click **Delete**.

   The space set is deleted and removed from the list of spaces. After the space set is deleted, an audit event is generated in KUMA.

If a user had access only to the deleted space set and did not have access to any other sets, such a user automatically gets access rights to the default space set.

Grant access to a space set

To grant access to a space set

1. In the KUMA web console, go to the **Settings** → **Access** → **Access to spaces** section.
2. Select a set of spaces in the list by selecting the check box next to it, then click the **Access control** button on the toolbar.
3. This opens the **Users** window; in that window, click **Add users**.
4. In the list in the **Add users** window, select users to which you want to grant access to the space set and click **Add**.

   If you want to grant access to the selected space set to all users, select the check box in the upper left corner and select one of the following options: **Select all in page** or **Select all**, then click **Add**.

   This opens a confirmation window.
5. If you want to grant access to the listed users, click **Confirm** in the confirmation window.

The users now have access to the space set.

Revoke access to a space set

To revoke access to a space set

1. In the KUMA web console, go to the **Settings** → **Access to spaces** section.
2. Select a set of spaces in the list by selecting the check box next to it, then click the **Access control** button on the toolbar.
3. This opens the **Users** window; in that window, select users by selecting their check boxes, then click **Delete**.

   If you want to revoke access to the selected space set from all users, select the check box in the upper left corner and select one of the following options: **Select all in page** or **Select all**, then click **Delete**.

   This opens a confirmation window.
4. If you want to revoke access from the listed users, click **Confirm** in the confirmation window.

The users no longer have access to the space set.

If a user does not have access to any other space set, such a user automatically gets access to the default set.

Use cases

Migrating to the latest KUMA version with differentiated access to events

Goal: Update the product.

Action: The administrator updates KUMA to version 4.0.

Result: The accessibility of events does not change for users; all users have access to events in those tenants in which users are allowed to view the list of events. When adding new users, tenants, or spaces, all users see the events of tenants depending on whether they are allowed to view the list of events, with no further restrictions.

Restricting access to spaces for all users

Goal: Some spaces in the installation must be inaccessible to some users. Current and new users must not have access to such spaces.

Action: The administrator creates a new set of spaces that includes the spaces to which all users must have access. Each space is specified as a tuple: clusterID, tenantID, spaceID. In this way, you can assemble a set of spaces from a finite number of spaces. After creating the set, the administrator makes this set the default set.

Result: For all users that do not have this space set explicitly specified, including new users, access to events is additionally restricted in accordance with the default space set. That is, such users have access to events in tenants in which the user has the right to view the list of events, and events in spaces that are included in the default set.

Allowing some users to view all events

Goal: KUMA has a default set in which only a finite number of spaces is explicitly specified. Also some users in KUMA must have unrestricted access to all events. You want to allow these users to view events from spaces that are not specified in the default set.

Action: The administrator goes to the **Access to spaces** section and selects the 'All spaces' set, which gives access to all spaces without restrictions, and grants access to this set to the selected users.

Result: Users that have been explicitly granted access to the 'All spaces' set now have unrestricted access to events in spaces. Their access to events depends only on the right to view the list of events in accordance with their assigned role. When you add new spaces or tenants, these users will have access to the events located in these new spaces and tenants, provided they have the right to view the list of events for the corresponding tenant. Users that have not been explicitly granted access to the 'All spaces' set will have restricted access to events in accordance with the default set of spaces.

Permitting some users to view events from a finite set of spaces

Goal: KUMA has a default set in which only a finite number of spaces is explicitly specified. Some users need to see a different space set, but not all available spaces.

Action: The administrator creates a space set that includes the relevant spaces and grants access to this set to the selected users.

Result: User access to events is restricted in accordance with the available space set. Users that have not been explicitly granted access to the set will have restricted access to events in accordance with the default set of spaces.

Supplementing an explicitly specified space set for a user

Goal: Users u1, u2, u3, u4 have been explicitly granted access to space set 'set1', which includes spaces to which Windows and Linux events go. Users u1 and u2, in addition to Windows and Linux events, need to view Cisco and VMware events that go to the respective spaces.

Action: The administrator creates a set of spaces, 'set2', which includes the spaces of Cisco and VMware events. The administrator assigns set2 to u1 and u2 in addition to set1.

Result: Users u1 and u2 now have access to events from the spaces of all of the sets available to them, that is, events from the set1 and set2: Windows, Linux, Cisco, VMware. Access of users u3 and u4 to events remains unchanged.

Editing a space set

Goal: Some users have access to a space set (access is granted explicitly or the set is the default set). For all of these users, you need to add access to a certain space that is not in the set, or revoke access to a space that is in the set.

Action: The administrator edits the existing set of spaces by adding or removing the relevant spaces.

Result: All users that have access to the set can now view events in accordance with the updated space set.

Deleting a space set

Goal: The space set is no longer relevant, and it needs to be deleted from KUMA.

Action: The administrator deletes an existing space set. The 'All spaces' set cannot be deleted. The default space set cannot be deleted.

Result: The deleted space set is gone from KUMA. All users that have been explicitly granted access to this set of spaces now have access to events in accordance with the space sets that remain available to them. If a user does not have any space sets left to which access has been explicitly granted, such a user's access to events is controlled by the default set.

Viewing the events table

The events table provides you with an overview of all events received by KUMA Core from the data sources. The table displays the list of events filtered according to the executed SQL query.

To view the events table:

1. In the main menu, go to **Monitoring** → **Threat hunting**.
2. If necessary, filter tenants. By default, the tenant filter is disabled and the events table displays the events related to all of the tenants to which you have the **Read** access right. To apply tenant filter:
   a. Click the link next to the **Tenant filter** setting.
      The tenant filter opens.
   b. Select the check boxes next to the required tenants.
      The events table displays only the events related to the selected tenants.

The event table is displayed. For details about the table columns, relate to the normalized event data model.

Searching and filtering events

When performing a search for events, an audit event is generated for queries that are run manually.

Audit events are not generated for queries initiated by dashboards, reports, or data collection and analysis rules. REST API requests for receiving events also do not generate audit events.

When using the GROUP BY option, expanding a group triggers the creation of an audit event, since an additional query is executed at that moment.

When the **Run in background** option is selected, two audit events are generated: Event Read Attempt and Search Query Cancelled.

To search and filter events, modify an SQL query in the search field, and then click the **Run Query** button. You can enter the SQL query manually or generate it by using the query builder.

Data aggregation and grouping is supported in SQL queries.

You can add filter conditions to an already generated SQL query in the window for viewing statistics, the events table, and the event details area.

To change the filtering settings in the Statistics window

1. Follow the steps to open the events table.
2. Open **Statistics on threats** details area by using one of the following methods:
   - Click the ••• button in the top right corner of the events table, and then select **Statistics on threats**.
   - In the events table, click any value, and then select **Statistics on threats** in the context menu that opens.

   The **Statistics on threats** details area appears in the right part of the web interface window.
3. Open the drop-down list of the relevant parameter and hover your mouse cursor over the necessary value.
4. Change the filter settings by doing one of the following:
   - To include only events with the selected value, click the + button.
   - To exclude all events with the selected value, click the − button.

To change the filtering settings in the events table

1. Follow the steps to open the events table.
2. Click an event parameter value in the events table.
3. In the opened menu, select one of the following options:
   - To show only events with the selected value, select **Filter by this value**.
   - To exclude all events with the selected value from the table, select **Exclude from filter**.

To change the filter settings in the event details area

1. Follow the steps to open the events table.
2. Click a relevant event to invoke the event details panel.
3. Change the filter settings by doing one of the following:
   - To include only events with the selected value, click the + button.
   - To exclude all events with the selected value, click the — button.

As a result, the filter settings and the events table are updated, and the new search query is displayed in the upper part of the screen.

> When you switch to the query builder, the parameters of a query entered manually in the search field are not transferred to the builder, so you will need to create your query again. The query created in the builder does not overwrite the query that was entered into the search string until you click the **Apply** button in the builder window.

Click the button to save the current filter.

Manually creating SQL queries

You can use the search string to manually create SQL queries of any complexity to filter events.

Executing an SQL query affects the displayed table columns.

If the SQL query contains the * value, columns specified in the query are added to the table if they were absent. Removing a displayed column from the subsequent queries does not hide the corresponding column.

If the SQL query does not contain the * value, the table only displays columns for the specified fields that conform the normalized event data model. Columns are displayed even if there is no data for them.

To manually generate an SQL query:

1. Follow the steps to open the events table.
2. Enter your SQL query into the input field.

   When you enter a function name in the SQL query field, a list of available functions appears. Selecting a function displays a usage example on the right. For example, the `concatWithSeparator` function is accompanied by the following example:

   ```
   concatWithSeparator('a', '1', '2', '3')
   ```

3. Click the **Run query** button.

   A query may take up to several minutes to complete.

You can also run the query in the background. To do this, click the arrow icon next to the **Run query** button and select **Run in the background**. In this case, the following happens:

- The query is queued for execution in the background, and a task is created in the **Analysis and response** section to run this query.
- Background queries run in parallel at low priority.
- A query containing more than 10,000 events cannot be queued for execution in the background.

The table will display the search results based on the generated SQL query. You can view the result of running the query in the background in the **Analysis and response** section.

If necessary, you can cancel the execution clicking the arrow icon next to the **Run query** button and selecting **Cancel query**. When a query is canceled, an audit event is automatically generated.

If necessary, you can filter events in the table by period.

To display non-printable characters in the SQL query field, press either of the following key combinations:

- **Ctrl+*/Command+***
- **Ctrl+Shift+8/Command+Shift+8**

If you enable the display of non-printable characters in the EDR component, other components (such as KUMA) do not automatically display non-printable characters until you reload the components' browser tabs.

Supported functions and operators

SELECT

Event fields that should be returned.

For **SELECT** fields, the program supports the following functions and operators:

Aggregation functions: **count**, **avg**, **max**, **min**, **sum**.

Arithmetic operators: **+**, **-**, *****, **/**, **<**, **>**, **=**, **!=**, **>=**, **<=**.

You can combine these functions and operators.

If you are using aggregation functions in a query, you cannot customize the events table display, sort events in ascending or descending order, or receive statistics.

FROM

Data source.

WHERE

Conditions for filtering events.

- **AND**, **OR**, **NOT**, **=**, **!=**, **>**, **>=**, **<**, **<=**
- **IN**
- **BETWEEN**
- **LIKE**
- **ILIKE**
- **inSubnet**
- **match** (the re2 syntax of regular expressions is used in queries; special characters must be shielded with "\")

GROUP BY

Event fields or aliases to be used for grouping the returned data.

If you are using data grouping in a query, you cannot customize the events table display, sort events in ascending or descending order, receive statistics, or perform a retrospective scan.

ORDER BY

Columns used as the basis for sorting the returned data.

Possible values:

- **DESC**—descending order.
- **ASC**—ascending order.

OFFSET

Skip the indicated number of lines before printing the query results output.

LIMIT

The number of rows that can be displayed in the table.

The default value is 250.

When switching to the query builder, the query parameters that were manually entered into the search string are not transferred to the builder so you will need to create your query again. Also, the query created in the builder does not overwrite the query that was entered into the search string until you click the Apply button in the builder window.

Aliases must not contain spaces.

Example queries:

- **SELECT * FROM `events` WHERE Type IN ('Base', 'Audit') ORDER BY Timestamp DESC LIMIT 250**

  In the events table, all events with the **Base** and **Audit** type are sorted by the **Timestamp** column in descending order. The number of strings that can be displayed in the table is 250.

- **SELECT * FROM `events` WHERE BytesIn BETWEEN 1000 AND 2000 ORDER BY Timestamp ASC LIMIT 250**

  All events of the events table for which the **BytesIn** field contains a value of received traffic in the range from 1,000 to 2,000 bytes are sorted by the **Timestamp** column in ascending order. The number of strings that can be displayed in the table is 250.

- **SELECT * FROM `events` WHERE Message LIKE '%ssh:%' ORDER BY Timestamp DESC LIMIT 250**

  In the events table, all events whose **Message** field contains data corresponding to the defined %ssh:% template in lowercase are sorted by the **Timestamp** column in descending order. The number of strings that can be displayed in the table is 250.

- **SELECT * FROM `events` WHERE inSubnet(DeviceAddress, '00.0.0.0/00') ORDER BY Timestamp DESC LIMIT 250**

  In the events table, all events for the hosts that are in the 00.0.0.0/00 subnet are sorted by the **Timestamp** column in descending order. The number of strings that can be displayed in the table is 250.

- **SELECT * FROM `events` WHERE match(Message, 'ssh.*') ORDER BY Timestamp DESC LIMIT 250**

  In the events table, all events whose **Message** field contains text corresponding to the ssh.* template are sorted by the **Timestamp** column in descending order. The number of strings that can be displayed in the table is 250.

- **SELECT max(BytesOut) / 1024 FROM `events`**

  Maximum amount of outbound traffic (KB) for the selected time period.

- **SELECT count(ID) AS "Count", SourcePort AS "Port" FROM `events` GROUP BY SourcePort ORDER BY Port ASC LIMIT 250**

  Number of events and port number. Events are grouped by port number and sorted by the **Port** column in ascending order. The number of strings that can be displayed in the table is 250.

  The **ID** column in the events table is named Count, and the **SourcePort** column is named Port.

- **SELECT * FROM `events` WHERE match(Message, 'ssh:\'connection.*') ORDER BY Timestamp DESC LIMIT 250**

  If you want to use a special character in a query, you need to escape this character by placing a backslash (\) character in front of it.

  In the events table, all events whose **Message** field contains text corresponding to the ssh: 'connection' template are sorted by the **Timestamp** column in descending order. The number of strings that can be displayed in the table is 250.

Generating an SQL query using a builder

You can use the query builder to generate an SQL query for filtering events.

Executing an SQL query affects the displayed table columns.

If the SQL query contains the * value, columns specified in the query are added to the table if they were absent. Removing a displayed column from the subsequent queries does not hide the corresponding column.

If the SQL query does not contain the * value, the table only displays columns for the specified fields that conform the normalized event data model. Columns are displayed even if there is no data for them.

To generate an SQL query using a builder:

1. Follow the steps to open the events table.

2. Click the button to open the query builder.

   Generate a search query by providing data in the following parameter blocks:

   - **SELECT**

     Event fields that should be returned. The * value is selected by default, which means that all available event fields must be returned. To adjust the displayed fields, select the desired fields in the drop-down list. Note that Select * increases the duration of the request execution, but eliminates the need to specify the fields in the request.

     When selecting an event field, you can use the field on the right of the drop-down list to specify an alias for the column of displayed data, and you can use the right-most drop-down list to select the operation to perform on the data: **count**, **max**, **min**, **avg**, **sum**.

   - **FROM**

     Data source. Select the **events** value.

   - **WHERE**

     Conditions for filtering events.

     To add conditions and groups, click the **Add condition** and **Add group** buttons. The **AND** operator value is selected by default in a group of conditions. Click the operator value to change it. Available values: **AND**, **OR**, **NOT**.

     To change the structure of conditions and condition groups, use the icon to drag and drop expressions.

     To add filter conditions:

     a. In the drop-down list on the left, select the event field that you want to use for filtering.

     b. Select the necessary operator from the middle drop-down list. The available operators depend on the type of value of the selected event field.

     c. Enter the value of the condition. Depending on the selected type of field, you may have to manually enter the value, select it from the drop-down list, or select it on the calendar.

     To delete filter conditions, click the **X** button. To delete group conditions, click the **Delete group** button.

   - **GROUP BY**

     Event fields or aliases to be used for grouping the returned data.

     If you are using data grouping in a query, you cannot customize the events table display, sort events in ascending or descending order, receive statistics, or perform a retrospective scan.

- **ORDER BY**

  Columns used as the basis for sorting the returned data. In the drop-down list on the right, you can select the necessary order: **DESC**—descending, **ASC**—ascending.

- **LIMIT**

  The number of rows that can be displayed in the table.

  The default value is 250.

  If you are filtering events by a user-defined period and the number of strings in the search results exceeds the defined value, you can click the **Show next records** button to display additional strings in the table. This button is not displayed when filtering events by the standard period.

3. Click **Apply**.

   The current SQL query will be overwritten. The generated SQL query is displayed in the search field.

   To reset the builder settings, click the **Default query** button.

   To close the builder without overwriting the existing query, click the button.

4. Click the **Run query** button to display the data in the table.

   A query may take up to several minutes to complete.

   You can also run the query in the background. To do this, click the arrow icon next to the **Run query** button and select **Run in the background**. In this case, the following happens:

   - The query is queued for execution in the background, and a task is created in the **Analysis and response** section to run this query.
   - Background queries run in parallel at low priority.
   - A query containing more than 10,000 events cannot be queued for execution in the background.

The table will display the search results based on the generated SQL query. You can view the result of running the query in the background in the **Analysis and response** section.

If necessary, you can cancel the execution clicking the arrow icon next to the **Run query** button and selecting **Cancel query**. When a query is canceled, an audit event is automatically generated.

When switching to another section of the web interface, the query generated in the builder is not preserved. If you return to the Events section from another section, the builder will display the default query.

Generating an SQL query using KUMA SQL functions

KUMA's SQL functions allow using the attributes of assets and accounts in search queries to filter events, generate reports and widgets (graph type: **Table**). You can enrich events with data from dictionaries, tables, assets, and accounts using the following sets of functions:

- The enrich function set. Allows enriching query results with fields of the asset or account, values from a dictionary of the **Dictionary** type or a dictionary of the **Table** type. The `enrich` function set includes the following functions:
  - `enrich_assets`;
  - `enrich_accounts`;
  - `enrich_table`;
  - `enrich_dictionary`.
- The lookup function set. Allows adding conditions for assets and accounts to the search query. The `lookup` function set includes the following functions:
  - `lookup_assets`;
  - `lookup_accounts`;
  - `lookup_assets_category`.

> The maximum number of events per query is 10,000.

Using the 'enrich' function set in SQL queries

The `enrich` function set (see the table below) is used in the `SELECT` clause of an SQL query to enrich the results.

When using this set of functions, you cannot group events by enriched fields.

Widgets and reports enriched by the functions must be owned by no more than one tenant.

> The values of asset fields that are specified in SQL queries are case-sensitive.

Description of the 'enrich' set of functions

Function	Event field	Asset field	Description
enrich_assets	DeviceAssetID DestinationAssetID SourceAssetID	name os osBuild ipAddress macAddress fqdn source software cii ramSize kscLastAvBasesUpdate kscLastInfoUpdate kscLastUpdate kscLastSystemStart kscStatusMask kscRtProtectionState kscEncryptionState kscAntiSpamStatus kscEmailAvStatus kscDlpStatus kscStatusID kscEdrStatus lastVisible aistatus aiscore	Enriches the query result with asset fields based on the ID specified passed to the function. Example `enrich_assets(DeviceAssetID, name)`
enrich_accounts	SourceAccountID DestinationAccountID	name guid domain cn dn employee_id email mail_nickname mobile sid sam_name telephone_number principal_name sn type title division department manager location company street_address physical_delivery_office_name uac	Enriches the query result with account fields based on the ID specified passed to the function. Example `enrich_account(SourceAccountID, name)` This function is available only for tenants that have LDAP enrichment enabled.

Function	Event field	Asset field	Description

`enrich_table`	Any	–	Enriches the query result with values from a dictionary of the **Table** type based on event fields in the response from the ClickHouse cluster.
			
			Example
			`enrich_table('Main/some-table', [DeviceProduct], 'value')`
			
			Only one column of the table can be the key, but the record key can be a compound key.
			
			Example
			`enrich_table('Main/Dictionary', [BytesOut|BytesIn], 'value2')`
			
			The `enrich_table` function returns only one column of the table. If you need to call more columns, call the function again specifying the relevant fields.

`enrich_dictionary`	Any	–	Enriches the query result with values from a dictionary of the **Dictionary** type based on event fields in the response from the ClickHouse cluster.
			
			Example 1
			`enrich_dictionary('Main/some-dict', [SourceAddress]`
			
			Example 2
			`enrich_dictionary('Main/some-dict', [SourceAddress, DeviceAddress])`
			
			You can view the path to the dictionary in the **Resources** → **Dictionaries** section.

You can specify an `enrich` function when manually creating SQL queries.

Example queries with an `enrich` function

All events of the `events` table with the `Name` and `Message` fields, as well as the `macAddress` and `osBuild` asset fields to enrich the result with asset data. The number of rows that can be displayed in the table is 250.

```
SELECT Name,
Message,
 enrich_assets(DeviceAssetID, macAddress),
 enrich_assets(DeviceAssetID, osBuild)
FROM `events`
WHERE DeviceAssetID != ''
LIMIT 250
```

All events of the `events` table with event fields `SourceUserName` and `SourceAddress`, as well as values of the `mobile` field to enrich the result with account data. The number of rows that can be displayed in the table is 10.

```
SELECT SourceUserName,
SourceAddress,
 enrich_accounts(SourceAccountID, mobile) as mobile
FROM `events`
WHERE SourceAccountID != ''
LIMIT 10
```

All events in the `events` table with `DeviceProduct` event fields with values from the **Main/[OOTB] Linux. Auditd record types**. Sorted by **Timestamp** in descending order. The number of rows that can be displayed in the table is 1000.

```
SELECT DeviceProduct,
 enrich_table('Main/[OOTB] Linux. Auditd record types', [DeviceProduct], 'Description') as HTTP
FROM `events` WHERE Type!=4
LIMIT 1000
```

All events in the `events` table with `DeviceAction` event fields with values from the **Main/[OOTB] KEDR** dictionary. The number of rows that can be displayed in the table is 255.

```
SELECT DeviceAction,
 enrich_dictionary('Main/[OOTB] KEDR. AccountType', [BytesOut]) as accountType
FROM `events` WHERE Type!=4
LIMIT 255
```

Using the 'lookup' function set in SQL queries

The `lookup` function set (see the table below) is used in the `WHERE` clause of an SQL query to add conditions for assets and accounts to the search query.

In queries containing a `lookup` function, KUMA automatically adds the `*ID` field to the `SELECT` clause, which field is used in the `lookup` function in the query. For example, in a query containing the `lookup_assets(DeviceAssetID, osBuild, '=', '19045.000000')` function a `DeviceAssetID` field is added to the `SELECT` clause.

In queries containing the `lookup` function, we recommend specifying the list of fields to be returned in the `SELECT` clause. We do not recommend using * in the `SELECT` clause. This returns all available fields, which can make the query take significantly longer to be processed.

Description of the 'lookup' set of functions

Function type	Event field	Asset field	Operator	Description
lookup_assets	DeviceAssetID SourceAssetID DestinationAssetID	name os osBuild source cii ramSize kscRtProtectionState kscEncryptionState kscAntiSpamStatus kscEmailAvStatus kscDlpStatus kscStatusID kscEdrStatus aistatus aiscore	=	Allows you to add conditions t result for assets whose field v value specified in the query. For values that are number, yo string with the required numbe For example: lookup_assets(DeviceAss '=', '19045.000000') lookup_assets(DeviceAss '=', '3241234234')
		kscLastAvBasesUpdate kscLastInfoUpdate kscLastUpdate kscLastSystemStart lastVisible ramSize aiscore	< > <= >=	Allows you to add conditions f field values that are: • Less than the value speci • Greater than the value sp query • Less than or equal to the the query • Greater than or equal to t specified in the query For values that are number, yo string with the required numbe For example: lookup_assets(DeviceAss '>', '50') Date values can be specified i formats: • Number of seconds: lookup_assets(Device lastVisible, '>', '1 • Number of milliseconds: lookup_assets(Device lastVisible, '<', '1725971837834') • Number of days: lookup_assets(Device lastVisible, '<', 'n
		name os osBuild fqdn software	like	Allows you to add conditions t result for assets whose field v 'like' expression specified in th For more information about th please refer to the SQL Langu Expressions reference. lookup_assets(Destinati name, 'like','test.compa
		ipAddress macAddress fqdn software kscStatusMask	in	Allows you to add to the result whose values match the value query. For example: lookup_assets(DeviceAss 'in', ['test_fqdn1.compa 'test_fqdn2.company.ru'

Function type	Event field	Asset field	Operator	Description
		`ipAddress`	`insubnet`	Allows you to add conditions f addresses in the specified sub address is specified in CIDR fo For example: `lookup_assets(DeviceAss ipAddress, 'insubnet',`
		`ipAddress`	`inrange`	Allows you to add conditions f addresses in the specified ran The first IP address specified i start IP address, and the seco address. For example: `lookup_assets(DeviceAss ipAddress, 'inrange', [ '192.168.1.184'])` The query filters assets with IP range from 192.168.1.1 to 192.168

Function type	Event field	Asset field	Operator	Description
lookup_accounts	SourceAccountID DestinationAccountID	name guid domain cn dn employee_id email mail_nickname mobile sid sam_name telephone_number principal_name sn title division department manager location company street_address physical_delivery_office_name uac	=	Allows you to add conditions t result for accounts whose fiel the value specified in the quer For values that are number, yo string with the required numbe For example: lookup_accounts(SourceA employee_id, '=', '1545
		name guid domain cn dn employee_id email mail_nickname mobile sid sam_name telephone_number principal_name sn type title division department manager location company street_address physical_delivery_office_name	like	Allows you to add conditions t result for accounts whose fiel the 'like' expression specified i For more information about th please refer to the SQL Langu Expressions reference. lookup_accounts(Destina name, 'like', '_ccount1

Function type	Event field	Asset field	Operator	Description

`lookup_assets_category`	`DeviceAssetID`
	`SourceAssetID`
	`DestinationAssetID`
		–	–	Finds all events that have assc the specified folder.
				For example:
				`lookup_assets_category( ['Main/Business Impact']`
				where `Main` is the name of th `Business Impact` is the nar

Example SQL queries with a lookup function

You can specify a `lookup` function when manually creating SQL queries. Example queries with a `lookup` function

- All events of the 'events' table with the `TenantID` and `DeviceProduct` event fields, as well as the `fqdn` asset field, whose value contains the win10 substring. The number of rows that can be displayed in the table is 250.

```
SELECT TenantID, DeviceProduct
FROM `events`
WHERE DeviceAssetID != ''
AND lookup_assets(DeviceAssetID, fqdn, 'match', 'win10')
LIMIT 250
```

- All events in the 'events' table, with the `TenantID` and `DeviceProduct` event fields, and with values of `the EmployeeID` field, whose value is `15452.` The number of rows that can be displayed in the table is 10.

```
SELECT TenantID, DeviceProduct
FROM `events`
WHERE SourceAccountID != ''
AND lookup_accounts(SourceAccountID, employee_id, '=', '15452')
LIMIT 10
```

- All events of the 'events' table with the `TenantID` and `DeviceProduct` event fields, with the folder in which the asset is located. The number of rows that can be displayed in the table is 100.

```
SELECT TenantID, DeviceProduct
FROM `events`
WHERE DeviceAssetID != ''
AND lookup_assets_category(DeviceAssetID, ['Main/Business Impact'])
LIMIT 100
```

Viewing event details

To open the event details panel, select an event in the events table in the **Threat hunting** section or in an alert details page.

The **Event details** panel appears in the right part of the web interface window and contains a list of the event parameters with values. In this area you can:

- Include the selected field in the search or exclude it from the search by clicking + or − next to a parameter's value.
- Find similar events and add or delete a prevention rule by clicking the **FileHash** and **DeviceCustomString** values.
- When integrated with Kaspersky CyberTrace and Kaspersky Threat Intelligence Portal, you can add to Internal TI of CyberTrace and show info from Threat Lookup by clicking the **FileHash** and **DeviceCustomString** values.
- View the settings of the service that registered the event by clicking the **Service** value.
- View the list of alerts or incidents related to the device by clicking the **DeviceAssetID** value and selecting **Asset details**. In the **Device details** window that opens, click the **Show related** button and select either **Alerts** or **Incidents**, depending on what you want to view.
- View the list of IOA rules that were triggered when the event was created; view the detailed information about those IOA rules by clicking their names.

  The IOA rule pane that opens displays the detailed information.

In the IOA rule details that open, you can do the following:

- View the IOA rule name, ID, severity, and confidence level.
- Add the IOA rule to exclusions.
- View information about hunts by clicking the **Find in Kaspersky TIP** button.
- View the alerts and incidents created when the IOA rule was triggered by clicking the **View in** button.
- View the related events by clicking the **Find in Threat hunting** button.

  The default time interval from which to display the events is 24 hours.

You can also view the detailed information about an IOA rule in Kaspersky TIP. To do this, in the IOA rule details window, click the **Find in Kaspersky TIP** button.

- Enable or disable the compact display mode for `*Label` fields by clicking the ⚙ icon and moving the toggle switch to the required position. By default, the toggle switch is set to the **Full view** position. When the **Compact view** mode is selected for `DeviceCustom*` and `Flex*` fields, the value of the corresponding `*Label` field is displayed as the field name, and the `*Label` field itself is hidden from the event field list. If the `*Label` field value is missing, the original field name is displayed. The selected display mode is retained after refreshing the page and leaving the **Threat hunting** section.

In the **Event details** panel, the name of the described object is shown instead of its ID in the values of the following settings. If you change the filter settings from the **Event details** panel, the object's ID, and not its name, is added to the SQL query:

- TenantID
- SeriviceID
- DeviceAssetID
- SourceAssetID
- DestinationAssetID
- SourceAccountID
- DestinationAccountID

Saving and selecting events filter configuration

You can save the current filter configuration, including the time-based filter, query builder, and the events table settings, for future use. Saved filter configurations are available to you and other users that have corresponding access rights.

To save the current settings of the filter, query, and period

1. Follow the steps to open the events table.
2. Click the icon next to the search query and select **Save current filter**.
3. In the **New filter** window that opens, enter the name of the filter configuration in the **Name** field. The name must contain 128 Unicode characters or less.
4. In the **Tenant** drop-down list, select the tenant for which to save the created filter.
5. Click **Save**.

   The filter configuration is now saved.

To select a previously saved filter configuration

1. Follow the steps to open the events table.
2. Click the icon next to the search query and select the desired filter.

To save the current settings of the filter, query, and the events table settings

1. Follow the steps to open the events table.
2. Click the gear icon in the panel above the events table.
3. Click **Save current preset**.
4. In the **New preset** window that opens, enter the name of the preset in the **Name** field. The name must contain 128 Unicode characters or less.
5. In the **Tenant** drop-down list, select the tenant for which to save the created preset.
6. Click **Save**.

   The preset configuration is now saved.

To select a previously saved preset

1. Follow the steps to open the events table.
2. Click the gear icon in the panel above the events table. Select the **Presets** tab.
3. Select the desired preset.

To delete a previously saved filter configuration for all users

1. Follow the steps to open the events table.
2. Click the icon next to the search query.
3. Click the icon next to the configuration that you need to delete.
4. Click **OK**.

Filtering events by time range

You can specify the period to display events from.

To filter events by period:

1. Follow the steps to open the events table.
2. Open the second drop-down list in the upper part of the window.
3. Specify the time range. You can select predefined ranges relative to the current date and time or specify a custom range by using the **Range start** and **Range end** fields or by selecting dates in the calendar.
4. Click the **Apply** button.

Exporting events

You can export information about events to a TSV file. The selection of events that will be exported to a TSV file depends on filter settings. The information is exported from the columns that are displayed in the events table. The columns in the exported file are populated with the available data even if they did not display in the events table in the **Threat hunting** section due to the special features of the SQL query.

To export information about events:

1. Follow the steps to open the events table.
2. Click the ••• button in the top right corner of the events table and select **Export TSV**.

   The new export TSV file task is created in the KUMA **Task Manager** section.
3. In the KUMA section, find the task you created in the **Task Manager** section.
4. Click the task type name and select **Upload** from the drop-down list.

   The TSV file will be downloaded using your browser's settings. By default, the file name is event-export-<date>_<time>.tsv.

The file is saved based on your web browser's settings.

Viewing audit events and configuring notifications

Audit is a process of monitoring, registering, and analyzing of user actions and system operations aimed to ensure security and traceability of changes.

Kaspersky EDR Expert collects audit events from the solution components automatically, no additional configuration is required. During the solution deployment, Kaspersky EDR Expert creates a predefined collector **[OOTB] Kaspersky OSMP** in the Root tenant. This collector has a linked predefined connector **[OOTB] Kaspersky OSMP** and a linked predefined normalizer **[OOTB] Kaspersky OSMP audit**. The collector sends the audit events to storage space **KUMA Audit**. This storage space is created automatically.

> Kaspersky EDR Expert collects audit events only if you specified a valid license key for the SIEM component in the `license` parameter during a single-node deployment, a multi-node deployment, or in the solution interface.

If necessary, you can configure the storage settings for the audit events when you create a resource set for a storage.

For detailed information about parameters and acton types of audit events, refer to the article: Audit events.

How to view and export audit events to a file

The audit events are available in **Monitoring** → **Threat hunting**.

If you want the evens table to display audit events only, do one of the following:

- In the events table, in the **EventType** field, set the `Audit` value.
- Differentiate access to the space with audit events.

  To do this, go to **Settings** → **KUMA** → **Open KUMA settings** → **Access to spaces**, and then configure the access rights of the KUMA Audit space. Only the users granted with the access rights to the space will be able to view the audit events in the **Threat hunting** section.

After filtering the audit events in the events table, you can export the events to a file.

How to configure email notification about audit events

As soon as an event occurs, for example, a user performs more than five unsuccessful attempts to log in to OSMP Console, a predefined correlation rule is triggered, and an alert is generated.

If you want to receive email notifications about the alerts, you must create a notification template. In the **Create email template** pane, specify the following parameters:

- In the **Event type** drop-down list, select the **Creating a new alert** notification template type.
- In the **Correlation rules** drop-down list, select the predefined correlation rule.

Audit events

Audit events are displayed in the **Threat hunting** section and may include the action types listed in the table below.

Action type	Action name	Parameters and description
Component operation	`Service start`	
	`Service stop`	`reason` Reason for the service interruption, if available.
Operations with alerts	`Alert assigning`	• `alert_id` ID of the alert on which the action is performed. • `group_name` Name of the group to which the alert assigned. • `group_id` ID of the group to which the alert is assigned.
	`Changing alert status`	• `alert_id` ID of the alert on which the action is performed. • `alert_status` Previous status of the alert. • `new_alert_status` New status of the alert.
	`Alert auto assigning`	• `alert_id` ID of the alert on which the action is performed. • `account_name` Name of the user to whom the alert is assigned. • `account_id` ID of the user to whom the alert is assigned.

Operations with incidents	`Creating incident`	`incident_id` ID of the incident on which the action is performed.
	`Incident assigning`	• `incident_id` ID of the incident on which the action is performed. • `group_name` Name of the group to which the incident is assigned. • `group_id` ID of the group to which the incident is assigned.
	`Changing incident status`	• `incident_id` ID of the incident on which the action is performed. • `incident_status` Previous status of the incident. • `new_incident_status` New status of the incident.
	`Merge incidents`	`incident_id` ID of the target incident after the merge.
	`Incident auto assigning`	• `incident_id` ID of the incident on which the action is performed. • `account_name` Name of the user to whom the incident is assigned. • `account_id` ID of the user to whom the incident is assigned.
Operations with segmentation rules	`Creating segmentation rule`	`rule_name` Name of the segmentation rule.
	`Changing segmentation rule`	
	`Enabling segmentation rule`	
	`Disabling segmentation rule`	
	`Deleting segmentation rule`	
Operations with aggregation rules	`Creating aggregation rule`	`rule_name` Name of the aggregation rule.
	`Changing aggregation rule`	
	`Enabling aggregation rule`	
	`Disabling aggregation rule`	
	`Deleting aggregation rule`	
Email notifications	`Creating e-mail templates`	`subject` Subject of the email notification template on which the action is performed.
	`Enabling e-mail templates`	
	`Disabling e-mail template`	
	`Changing e-mail templates`	
	`Deleting e-mail templates`	

Settings	Enabling auto send to SB by IOA trigger	tenant_name Name of the tenant on which the action is performed.
	Disabling auto send to SB by IOA trigger	
	Turning on the Assign "Untrusted" status to alerts toggle switch	
	Turning off the Assign "Untrusted" status to alerts toggle switch	
	Enabling the use of KSN	
	Disabling the use of KSN	
	Enabling the use of KPSN	
	Disabling the use of KPSN	
	Enabling the use of MDR	
	Disabling the use of MDR	
	Configuring the connection of OSMP to a local reputation database of KPSN	
	Enabling auto send to SB	
	Disabling auto send to SB	
	Enabling manual send to SB	
	Disabling manual send to SB	
	Selecting a database update source	
	Updating database manually	version_of_updated_databases Version of the anti-virus databases.
	Auto updating database	
	Changing passwords for archives	
	Enabling the required password change	
	Disabling the required password change	
	Enabling user password change	period Number of days after which the password must be changed.
Tenant management	Creating tenant	tenant_name Name of the tenant.
	Changing tenant	
	Bind Administration Server	
	Changing integration KATA/KEDR	integration_parameters Integration settings.
	Changing integration TIP	
	Changing custom integration	
	Changing integration	
Repository	Uploading file to storage	• file_name Name of the file. • alert_id ID of the incident on which the action is performed. • incident_id ID of the incident on which the action is performed.
	Downloading file from storage	
	Deleting file from storage	
	Auto deleting file from storage	

Setting	`Configuring an IOC scan schedule`	
Prevention rules	`Uploading prevention rules from file`	• `file_name` File name. • `count` Number of prevention rules created after importing a file.
	`Creating a prevention rule`	`file_name` File name.
	`Modifying a prevention rule`	
	`Enabling the use of a prevention rule`	
	`Disabling the use of a prevention rule`	
	`Removing a prevention rule`	
Playbooks	`Creating a playbook`	`playbook_name` Name of the playbook.
	`Removing a playbook`	
	`Changing the operation mode`	
YARA	`Uploading a YARA file`	`file_name` File name.
	`Downloading a YARA rule`	`rule_name` The YARA rule name.
	`Changing YARA rule`	
	`Enabling the automatic use of YARA rules`	
	`Disabling the automatic use of YARA rules`	
	`Deleting a YARA rule`	
IOC	`Uploading an IOC file`	`file_name` File name.
	`Downloading an IOC rule`	`rule_name` Name of the IOC rule.
	`Changing IOC rule`	
	`Enabling the automatic use of IOC rules`	
	`Disabling the automatic use of IOC rules`	
	`Deleting an IOC rule`	
Operation with TLS certificates	`Generating a TLS certificate for the Endpoint Agent component`	
	`Uploading a TLS certificate for the Endpoint Agent component`	
	`Deleting a TLS certificate for the Endpoint Agent component`	
	`Downloading the TLS certificate of the server`	

Sandbox settings	`OS set of virtual machines changed`	`sb_name` Sandbox name.
	`Creating a request for connection to the server with the Sandbox component`	
	`Enabling a connection with the Sandbox component`	
	`Disabling a connection with the Sandbox component`	
	`Deleting a connection with the Sandbox component`	
	`Renaming the Sandbox server`	• `new_sb_name` New Sandbox name. • `sb_ip` IP address of Sandbox.
Sandbox rules	`Creating a file scanning rule in custom images`	`virtual_machine_name` Name of the virtual machine.
	`Enabling a file scanning rule in custom images`	
	`Disabling a file scanning rule in custom images`	
	`Deleting a file scanning rule in custom images`	
	`Editing a file scanning rule in custom images`	• `virtual_machine_name` Name of the virtual machine. • `new_virtual_machine_name` New name of the virtual machine, if it was changed.
	`Export a file scanning rule in custom images`	`file_name` File name.
	`Import a file scanning rule in custom images`	`file_name` File name.
Distributed solution	`Assigning the PCN OSMP role`	`tenant_name` Name of the tenant.
	`Assigning the SCN OSMP role`	
	`Creating a request for connection of the SCN OSMP to the PCN OSMP`	
	`Accepting a request for connection of the SCN OSMP to the PCN OSMP`	
	`Rejecting a request for connection of the SCN OSMP to the PCN OSMP`	
	`Confirming the assign PCN role to CN`	
	`Disconnecting an SCN from PCN`	
Operations with accounts	`Creating a user account`	• `account_name` User name. • `account_id` User ID. • `account_authorization` Date and time of the last login for the account on which the action is performed. • `password_verification` Password verification status for the account on which the action is performed. • `account_expiration_date` Expiration date of the account on which the action is performed. The value is always `01.01.2222`. • `account_status` Status of the account on which the action is performed. • `account_type` Type of the account on which the action is performed.

	`Disabling account`	
	`Deleting an account`	

User authentication and authorization	Successful login	`administrator_rights` Indicates whether the user has administrator privileges.
	Login denied because the user is not registered	
	Login denied because the user is blocked	
	Login denied because the password is incorrect	
	Login denied because the password attempt limit was exceeded	
	Login denied because the password has expired	
	Log off	

Retroscan

You can use retrospective scan to refine the correlation rule resources or analyze historical data.

You can also choose to create alerts based on a retrospective scan.

To use retrospective scan:

1. In the main menu, go to **Monitoring** → **Threat hunting**.
2. Click the ••• button in the top right corner of the events table, and then select **Retroscan**.
   The **Retroscan** panel opens.
3. In the **Correlator** drop-down list, select the Correlator to feed selected events to.
4. In the **Correlation rules** drop-down list, select the Correlation rules that must be used when processing events.
5. To execute responses during event processing, turn on the **Execute responses** toggle switch.
6. To generate alerts during event processing, turn on the **Create alerts** toggle switch.
7. Click the **Create task** button.
   The retrospective scan task is created in the KUMA **Task Manager** section.

Getting events table statistics

You can get statistics for the current events selection displayed in the events table. The selected events depend on the filter settings.

To obtain statistics:

1. Follow the steps to open the events table.
2. Do one of the following:
   - In the upper-right corner of the events table, select **Statistics** from the ••• drop-down list.
   - In the events table, click on any value and select **Statistics** from the opened context menu.

The **Statistics** details area appears with the list of parameters from the current event selection. The numbers near each parameter indicate the number of events with that parameter in the selection. If a parameter is expanded, five most frequently occurring values are displayed. Type a parameter name in **Search fields** to filter displayed data.

The **Statistics** window allows you to modify the events filter.

> When using SQL queries with data grouping and aggregation for filtering events, statistics are not available.

Threat response

To perform response actions, view the result of an enrichment that you performed from the playbook, and launch playbooks manually, you have to go to the **Alerts** or **Incidents** sections.

The **Alerts** and **Incidents** sections are displayed in the main menu if the following conditions are met:

- You have a license key for Kaspersky EDR Expert.
- You are connected to the root Administration Server in OSMP Console.
- You have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst, SOC manager, Approver, Auditor.

After you perform a response action, you can view the response history.

Response actions

The response actions can be launched in one of the following ways:

- Manually, as described in this section.

  For the devices on which Kaspersky Endpoint Security with a built-in agent is not installed, you cannot perform the following response actions: Managing services, Deleting a file, YARA scan, IOC scan, Getting file from quarantine, and the response actions described in the Getting files for further analysis section.

  When responding from the alert or incident details or from the table of assets, you cannot select archived devices.

- Within a playbook.

  In this case, when creating or editing a playbook you can configure the response action to run automatically, or to request the user's manual approval before launching within the playbook. By default, manual approval of response actions is disabled.

  If a device becomes archived while performing a response action, the playbook result displays the **Error** message. If a playbook is triggered for an alert that includes archived devices, the playbook result displays the Warning message and the description that the device is archived.

Terminating processes

The *Terminate process* response action allows you to remotely terminate processes on devices. You can run the Terminate process response action for observables or assets.

You can run the Terminate process response action in one of the following ways:

- From the alert or incident details
- From a device details

- From a telemetry event

  You can open the event details from alert or incident details or from the **Threat hunting** section.

- From an investigation graph

  > The option is available if the investigation graph is built.

- From the table of assets

- From the **Response history** section

You can also configure the response action to run automatically when creating or editing a playbook.

> To run the Terminate process response action, you must have one of the following EDR roles: Main administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

> It might take up to 15 minutes to launch a response action due to the synchronization interval between the managed device and Administration Server.

Responding from the alert or incident details

To terminate process from the alert or incident details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the link with the alert ID you need.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the link with the incident ID you need.

2. In the window that opens, go to the **Assets** tab.

   > You can also go to the **Observables** tab, and select one or several observables for which you want to terminate the process. The observables may include MD5 or SHA256 hashes.

3. In the list of assets, select one or several devices.

4. In the **Select response actions** drop-down list, select **Terminate process**.

5. In the right pane that opens, do the following:

   a. In the **Full path** field, specify the full path to the process file.

   b. In the **Assets** drop-down list, select the devices for which you want to terminate the process.

If at step 2 you selected the **Assets** tab, the names of the devices whose check boxes you selected are specified in the **Assets** field by default. You can either change them or select the **All assets** option in the **Scope** drop-down list to terminate process on all the devices that belong to the alert or incident tenant and its child tenants.

> Only the assets on which you can perform the response action are available for selection.
> The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

c. If necessary, configure the following settings in the corresponding fields:

- Specify either the SHA256 or MD5 hash of the process file.

  If at step 2 you selected the **Observables** tab, the hashes that you selected are specified by default. You can change them.

- Write a description or a comment to the response action.

6. Click the **Terminate** button.

The process is terminated. If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the device details

To terminate process from the device details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device on which the file to be moved to quarantine is located.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device on which the file to be moved to quarantine is located.

2. In the window that opens, go to the **Assets** tab.

3. Click the name of the required device, and then in the drop-down list, select **View properties**.

4. Perform the same actions as described at steps 4–6 in the *Responding from the alert or incident details* procedure.

The process is terminated. If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from a telemetry event

To terminate process from the telemetry event when opening it from the alert or incident details:

1. In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device on which the file to be moved to quarantine is located.
2. In the window that opens, go to the **Details** tab, and do one of the following:
   - Click the name of the required event and select the device.
   - Click the **Find in Threat hunting** button to go to the **Threat hunting** section and select the required device.

     You can also go to the **Observables** tab, and select one or several observables for which you want to terminate the process. The observables may include MD5 or SHA256 hashes.
3. In the **Select response actions** drop-down list, select **Terminate process**.
4. Perform the same actions as described at steps 4–6 in the *Responding from the alert or incident details* procedure.

The process is terminated. If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

To respond from a telemetry event when opening it from the Threat hunting section:

1. In the main menu, go to **Monitoring** → **Threat hunting.**

   The table of events opens.
2. Click the name of the event whose details you want to open.
3. In the event details window that opens, click the device name, and then from the drop-down list that opens, select **Terminate process**.
4. In the right pane that opens, configure the response action settings as described at steps 5–6 in *Responding from the alert or incident details*.

The process is terminated. If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from an investigation graph

The option is available if the investigation graph is built.

To terminate process from an investigation graph:

1. In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the link with the incident ID you need.
2. In the **Incident details** window that opens, click the **View on graph** button.

   The **Investigation graph** window opens.
3. Click the name of the required device, and then in the drop-down list, select **View details**.
4. Perform the same actions as described at steps 4–6 in the *Responding from the alert or incident details* procedure.

The process is terminated. If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the table of assets

To respond from the table of assets:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.

   This opens the table of assets.
2. Select the check box next to the device for which you want to perform the response action.

   You can select several devices.

   > Archived devices cannot be selected.
3. In the **Select response actions** drop-down list, select **Terminate process**.
4. In the right pane that opens, configure the response action settings as described at steps 5–6 in *Responding from the alert or incident details*.

The process is terminated. If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the Response history section

To perform a response action from the Response history section:

1. In the main menu, go to **Monitoring** → **Response history**.

   The table that contains the response history for all alerts and incidents opens.

2. In the **Response** drop-down list, select **Terminate process**.

3. In the right pane that opens, configure the response action settings as described at steps 5–6 in *Responding from the alert or incident details*.

The process is terminated. If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Viewing the response action result

You can view the result of the response actions in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message is displayed. Otherwise, an Error message and the information about the reason of the error are displayed.

If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Moving files to quarantine

To prevent a threat distribution, you can move an infected file to quarantine in one of the following ways:

- From the alert or incident details
- From a device details
- From a telemetry event

  You can open the event details from alert or incident details or from the **Threat hunting** section.
- From an investigation graph
- From the table of assets
- From the **Response history** section

You can also configure the response action to run automatically when creating or editing a playbook.

To move the file to quarantine, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

It might take up to 15 minutes to launch a response action due to the synchronization interval between the managed device and Administration Server.

Responding from the alert or incident details

To move a file to quarantine from the alert or incident details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device on which the file to be moved to quarantine is located.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device on which the file to be moved to quarantine is located.

2. In the window that opens, go to the **Assets** tab.

   > You can also go to the **Observables** tab, select check box next to the file that you want to move to quarantine, and then click the **Move to quarantine** button.

3. Select check box next to the device on which the file to be moved to quarantine is located.

   You can select several devices, if necessary.

4. In the **Select response actions** drop-down list, select **Move to quarantine**.

5. In the right pane that opens, do the following:

   a. In the **Full path** field, specify the full path to the file that you want to move to quarantine.

   b. In the **Assets** field, select the devices on which the file to be moved to quarantine is located.

      If at step 2 you selected the **Assets** tab, the names of the devices whose check boxes you selected are specified in the **Assets** field by default. You can change them and specify the devices that are not related to the alert or incident, but belong to the alert or incident tenant and its child tenants.

      > Only the assets on which you can perform the response action are available for selection.
      > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

c. If necessary, configure the following settings in the corresponding fields:

- Specify either the SHA256 or MD5 hash of the file.

  If at step 2 you selected the **Observables** tab, the hash is specified. You can change the value.

- Write a description or a comment to the response action.

6. Click the **Move** button.

If the operation is completed successfully, an appropriate message is displayed on the screen. The file is deleted from the directory of the device where it is located and moved to the quarantine directory on the same device. Otherwise, an error message is displayed.

Responding from the device details

To move a file to quarantine from the device details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device on which the file to be moved to quarantine is located.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device on which the file to be moved to quarantine is located.

2. In the window that opens, go to the **Assets** tab.

3. Click the name of the required device, and then in the drop-down list, select **View properties**.

4. Perform the same actions as described at steps 4–6 in the *Responding from the alert or incident details* procedure.

If the operation is completed successfully, an appropriate message is displayed on the screen. The file is deleted from the directory of the device where it is located and moved to the quarantine directory on the same device. Otherwise, an error message is displayed.

Responding from a telemetry event

To move a file to quarantine from a telemetry event when opening it from the alert or incident details:

1. In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device on which the file to be moved to quarantine is located.
2. In the window that opens, go to the **Details** tab, and do one of the following:
   - Click the name of the required event and select the device.
   - Click the **Find in Threat Hunting** button to go to the **Threat hunting** section and select the required device.

     You can also go to the **Observables** tab, select check box next to the file that you want to move to quarantine, and then click the **Move to quarantine** button.
3. In the **Select response actions** drop-down list, select **Move to quarantine**.
4. Perform the same actions as described at steps 4–6 in the *Responding from the alert or incident details* procedure.

If the operation is completed successfully, an appropriate message is displayed on the screen. The file is deleted from the directory of the device where it is located and moved to the quarantine directory on the same device. Otherwise, an error message is displayed.

To respond from a telemetry event when opening it from the Threat hunting section:

1. In the main menu, go to **Monitoring** → **Threat hunting.**

   The table of events opens.
2. Click the name of the event whose details you want to open.
3. In the event details window that opens, click the device name, and then from the drop-down list that opens, select **Move to quarantine**.
4. Perform the same actions as described at steps 5–6 in *Responding from the alert or incident details* procedure.

If the operation is completed successfully, an appropriate message is displayed on the screen. The file is deleted from the directory of the device where it is located and moved to the quarantine directory on the same device. Otherwise, an error message is displayed.

Responding from an investigation graph

This option is available if the investigation graph is built.

To move a file to quarantine from an investigation graph:

1. In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device on which the file to be moved to quarantine is located.
2. In the window that opens, click the **View on graph** button.

   The investigation graph opens.
3. Click the device name to open the device details.
4. In the **Select response actions** drop-down list, select **Move to quarantine**.
5. Perform the same actions as described at steps 4–6 in the *Responding from the alert or incident details* procedure.

If the operation is completed successfully, an appropriate message is displayed on the screen. The file is deleted from the directory of the device where it is located and moved to the quarantine directory on the same device. Otherwise, an error message is displayed.

Responding from the table of assets

To respond from the table of assets:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.

   This opens the table of assets.
2. Select the check box next to the device for which you want to perform the response action.

   You can select several devices.

   > Archived devices cannot be selected.
3. In the **Select response actions** drop-down list, select **Move to quarantine**.
4. In the right pane that opens, configure the response action settings as described at steps 5–6 in *Responding from the alert or incident details*.

If the operation is completed successfully, an appropriate message is displayed on the screen. The file is deleted from the directory of the device where it is located and moved to the quarantine directory on the same device. Otherwise, an error message is displayed.

Responding from the Response history section

To perform a response action from the Response history section:

1. In the main menu, go to **Monitoring** → **Response history**.

   The table that contains the response history for all alerts and incidents opens.

2. In the **Response** drop-down list, select **Move to quarantine**.

3. In the right pane that opens, configure the response action settings as described at steps 5–6 in *Responding from the alert or incident details*.

   If the operation is completed successfully, an appropriate message is displayed on the screen. The file is deleted from the directory of the device where it is located and moved to the quarantine directory on the same device. Otherwise, an error message is displayed.

Viewing the response action result

You can view the result of the response actions in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message is displayed. Otherwise, an **Error** message and information about the error are displayed.

If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Performing the Add prevention rule and Delete prevention rule response actions

Prevention rules enable you to prevent files or processes that you consider insecure from running on the devices. Kaspersky EDR Expert identifies files based on their hash by using the MD5 or SHA256 hashing algorithms.

You can configure the **Add prevention rule** and **Delete prevention rule** response actions to add and delete a prevention rule for a device or a file hash in one of the following ways:

- From the alert or incident details
- From a device details
- From an investigation graph
- From the table of assets
- From the **Response history** section
- From the event details

  This option is available for the **Add prevention rule** response action. You can open the event details from alert or incident details or from the **Threat hunting** section.

- From the file details

You can also configure the response action to run automatically when creating or editing a playbook.

To perform the response actions, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

Performing response actions from alert or incident details

To respond from the alert or incident details:

1. Do one of the following:
   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **Alert ID** column, click the ID of the alert that includes the required device.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **Incident ID** column, click the ID of the incident that includes the required device.
2. In the window that opens, go to the **Assets** tab.
3. Select the select check box next to the required device.

   You can select several devices, if necessary.
4. In the **Select response actions** drop-down list, select **Manage prevention rules**, and then in the context menu, select the response action that you want to perform:
   - **Add prevention rule**
   - **Delete prevention rule**
5. In the window that opens, set the necessary parameters for the response action you selected at step 4:
   - **For adding prevention rule**

     In the right pane that opens, configure the following settings:

     1. In the **MD5 or SHA256** field, specify a hash of the file that you want to block.

        If you want to specify more than one hash, click the **Add hash** button.
     2. If necessary, configure the following settings:
        - Change the scope of the response action.

          By default, in the **Scope** of settings, the **Specific assets** option is selected, and the **Assets** drop-down list contains the names of the devices whose check box you previously selected.

          You can either change the devices for which the prevention rule is to be added, or select the **All assets** option in the **Scope** group of settings to add the prevention rule for all the devices that belong to the alert or incident tenant and its child tenants.

Only the assets on which you can perform the response action are available for selection. The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

- Enable the **Notify user about blocking file execution** toggle switch.
- In the **Description** field, write a description or a comment to the response action.

3. Click **Add**.

The window is closed.

- **For deleting prevention rule**

In the right pane that opens, configure the following settings:

1. Select what you want to delete.

   By default, in the **Rules** group of settings the **Specific rules** option is selected. If you want to delete a prevention rule by file hash, in the **MD5 or SHA256** field specify a hash of the file to be deleted. If you want to specify more than one hash, click the **Add hash** button.

   If you want to delete all prevention rules, select **All rules** option.

2. If necessary, configure the following settings:

   - Change the scope of the response action.

     By default, in the **Scope** of settings, the **Specific assets** option is selected, and the **Assets** drop-down list contains the names of the devices whose check box you previously selected.

     You can either change the devices for which the prevention rule is to be deleted, or select the **All assets** option in the **Scope** group of settings to delete prevention rules for all the devices that belong to the alert or incident tenant and its child tenants.

     Only the assets on which you can perform the response action are available for selection. The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

   - In the **Description** field, write a description or a comment to the response action.

3. Next, click the **Delete** button.

The window is closed.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing response actions from the device details

To respond from the device details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **Alert ID** column, click the ID of the alert that includes the required device.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **Incident ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, go to the **Assets** tab.

3. Click the name of the required device, and then in the drop-down list, select **View properties**.

4. Perform the same actions as described at steps 4-5 in *Performing response actions from the device details*.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing response actions from an investigation graph

This option is available if the investigation graph is built.

To respond from an investigation graph:

1. In the main menu, go to the **Monitoring** → **Incidents** section. In the **Incident ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, click the **View on graph** button.

   The investigation graph opens.

3. Click the device name to open the device details.

4. Perform the same actions as described at steps 4-5 in *Performing response actions from the device details*.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing a response action from the table of assets

To respond from the table of assets:

1. In the main menu, go to **Asset management** → **Assets (Devices).**

   This opens the table of assets.

2. Select the check box next to the device for which you want to perform the response action.

   You can select several devices.

   > Archived devices cannot be selected.

3. In the **Response** drop-down list, select **Manage prevention rules**, and then in the context menu, select the response action that you want to perform.

4. In the right pane that opens, configure the response action settings as described at step 5 in *Performing a response action from the alert or incident details*.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing a response action from the Response history section

To perform a response action from the Response history section:

1. In the main menu, go to **Monitoring** → **Response history**.

   The table that contains the response history for all alerts and incidents opens.

2. In the **Response** drop-down list, select either **Add prevention rule** or **Delete prevention rule**.

3. In the right pane that opens, configure the response action settings as described at step 5 in *Performing a response action from the alert or incident details*.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing a response action from the event details

> This option is available for the **Add prevention rule** response action.

To perform a response action from the event details:

1. In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the required device.
2. In the window that opens, go to the **Details** tab, and select the required file hash.
3. Click the **Add prevention rule** button, and then select the device for which you want to add the prevention rule.

   You can also go to the **Observables** tab, and select check box next to the file hash that you want to block. In the **Select response actions** drop-down list, click **Manage prevention rules**, and then select either **Add prevention rule** or **Delete prevention rule**.

4. Perform the same actions as described at step 5 in *Performing response actions from the device details*.

   If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

In the event details window that opens, in the Host name field, click the device name, and then from the drop-down list that opens, select Add prevention rule.

Perform the same actions as described at step 5 in Performing response actions from the device details.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Viewing the response action result

You can view the result of the response action in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message and the **View asset** button are displayed. You can click the button, and then in the window that opens, go to the **Prevention rules** tab to view the status of the prevention rule on the device.

Otherwise, the Error message and the information about the reason of the error are displayed.

If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

If you have not yet installed Kaspersky Endpoint Security with a built-in agent on your device, and encounter a failure when running the response actions, you have to make sure that the device name in Kaspersky EDR Expert is the same as in Kaspersky Anti Targeted Attack Platform version earlier than 8.0.

Managing a service

You can remotely start, stop, pause, resume, or remove a service on a device.

To perform the **Manage services** response action, you must have:

- One of the following XDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.
- Kaspersky Endpoint Security with a built-in agent installed on your devices

You can perform the response actions in one of the following ways:

- From the alert or incident details
- From a device details
- From a telemetry event

  You can open the event details from alert or incident details or from the **Threat hunting** section.
- From an investigation graph

  > This option is available if the investigation graph is built.
- From the table of assets
- From the **Response history** section

You can also configure the response action to run automatically when creating or editing a playbook.

Responding from the alert or incident details

To respond from the alert or incident details:

1. Do one of the following:
   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the required device.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.
2. In the window that opens, go to the **Assets** tab.

   > You can also go to the **Observables** tab, select the check box next to the alert for which you want to perform the response action, and then click **Manage services**.

3. Select the check box next to the device for which you want to perform the response action.

   You can select several devices.

4. In the **Select response actions** drop-down list, select **Manage services**.

5. In the right pane that opens, configure the following settings in the corresponding fields:

   a. The devices on which you want to manage the service.

      By default, in the **Scope** of settings, the **Specific assets** option is selected, and the **Assets** drop-down list contains the names of the devices whose check box you selected at step 3.

      You can either change the devices or select the **All assets** option in the **Scope** group of settings to manage service on all the devices that belong to the alert or incident tenant and its child tenants.

      > Only the assets on which you can perform the response action are available for selection.
      > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

   b. Service name.

   c. The action to be performed on the service: **Modify startup type**, **Start**, **Stop**, **Pause**, **Resume**, or **Delete**.

      If you select the **Modify startup type** action, you have to select the value in the **New startup type** drop-down list.

      > Stopping, pausing, deleting services, or changing the start type of services that affect the functioning on the host is strongly not recommended.
      > **List of services for which management is not recommended**

      - AVP*
      - BFE
      - CertPropSvc
      - CoreMessagingRegistrar
      - CryptSvc
      - DcomLaunch
      - Dhcp
      - DispBrokerDesktopSvc
      - EventLog
      - EventSystem
      - LanmanServer
      - LanmanWorkstation

- LSM
- mpssvc
- Netlogon
- Netman
- PlugPlay
- PolicyAgent
- Power
- ProfSvc
- RasMan
- RpcEptMapper
- RpcSs
- SamSs
- SCardSvr
- SecurityHealthService
- SessionEnv
- Spooler
- SstpSvc
- TermService
- UmRdpService
- UserManager
- UsoSvc
- VaultSvc
- W32Time
- WebClient
- Winmgmt
- WlanSvc
- wscsvc

d. If necessary, configure the following settings:

- Specify either the SHA256 or MD5 hash of the file.

  If at step 2 you selected the **Observables** tab, the hash is specified. You can change the value.

- Write a description or a comment to the response action.

6. Click the **Launch** button.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the device details

To respond from the device details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the required device.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, go to the **Assets** tab.

3. Click the name of the required device, and then in the drop-down list, select **View properties**.

   The device details pane opens.

4. Perform the same actions as described at steps 4–6 in the *Responding from the alert or incident details* procedure.

The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from a telemetry event

To respond from a telemetry event when opening it from the alert or incident details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the required device.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, go to the **Details** tab, and do one of the following:

   - Click the name of the required event and select the device.
   - Click the **Find in Threat hunting** button to go to the **Threat hunting** section, and then select the required device.

3. Perform the same actions as described at steps 4–6 in the *Responding from the alert or incident details* procedure.

The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

To respond from a telemetry event when opening it from the Threat hunting section:

1. In the main menu, go to **Monitoring → Threat hunting.**

   The table of events opens.

2. Click the name of the event whose details you want to open.

3. In the event details pane that opens, click the device name, and then from the drop-down list, select **Manage services**.

4. In the right pane that opens, configure the response action settings as described at step 5 in the *Responding from the alert or incident details* procedure, and then launch the response action.

The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from an investigation graph

To respond from an investigation graph:

1. In the main menu, go to the **Monitoring → Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. Click the **View on graph** button.

3. In the investigation graph that opens, click the device name, and then in the drop-down list, select **View properties**.

4. In the device details pane that open, perform the same actions as described at steps 4–6 in *Responding from the alert or incident details* procedure.

The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the table of assets

To respond from the table of assets:

1. In the main menu, go to **Asset management → Assets (Devices).**

   This opens the table of assets.

2. Select the check box next to the device for which you want to perform the response action.

   You can select several devices.

   > Archived devices cannot be selected.

3. In the **Select response actions** drop-down list, select **Manage services**.

4. In the right pane that opens, configure the response action settings as described at steps 5–6 in the *Responding from the alert or incident details* procedure.

The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the Response history section

To perform a response action from the Response history section:

1. In the main menu, go to **Monitoring → Response history**.

   The table that contains the response history for all alerts and incidents opens.

2. In the **Response** drop-down list, select **Manage services**.

3. In the right pane that opens, configure the response action settings as described at step 5 in *Responding from the alert or incident details* procedure, and then launch the response action.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Viewing the response action result

You can view the result of the response action in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message is displayed. Otherwise, an **Error** message and information about the error are displayed.

If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Getting files for further analysis

This section contains response actions aimed to obtain the evidence of a security breach, for further investigation. You can get:

- File
- Registry key
- NTFS metafiles
- Forensics
- Disk image
- Memory dump
- Process memory dump

To perform the response actions, you must have:

- One of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst
- Kaspersky Endpoint Security with a built-in agent installed on your devices

You can perform the response actions in one of the following ways:

- From the alert or incident details
- From the device details
- From a telemetry event

  You can open the event details from alert or incident details or from the **Threat hunting** section.
- From an investigation graph

  > This option is available if the investigation graph is built.
- From the table of assets
- From the **Response history** section

You can also configure the response action to run automatically when creating or editing a playbook.

Responding from the alert or incident details

To respond from the alert or incident details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the link with the alert ID you need.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the link with the incident ID you need.

2. In the window that opens, go to the **Assets** tab.

3. Select the check box next to the device for which you want to perform the response action.

   If you want to perform the **Registry key** or **Forensics** response action, you can select several devices.

4. In the **Select response actions** drop-down list, click **Get**.

5. In the context menu that opens, select the required response action.

Responding from the device details

To respond from the device details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the link with the alert ID you need.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the link with the incident ID you need.

2. In the window that opens, go to the **Assets** tab.

3. Click the name of the required device, and then in the drop-down list, select **View properties**.

   The device details window opens.

4. In the **Select response actions** drop-down list, click **Get**.

5. In the context menu that opens, select the required response action.

Responding from a telemetry event

To perform a response action from a telemetry event when opening it from the alert or incident details:

1. Do one of the following:
   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the link with the alert ID you need.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the link with the incident ID you need.
2. In the window that opens, go to the **Details** tab, and do one of the following:
   - Click the name of the required event and select the device.
   - Click the **Find in Threat hunting** button to go to the **Threat hunting** section, and then select the required device.
3. In the **Select response actions** drop-down list, click **Get**.
4. In the context menu that opens, select the required response action.

To respond from a telemetry event when opening it from the Threat hunting section:

1. In the main menu, go to **Monitoring** → **Threat hunting.**

   The table of events opens.
2. Click the name of the event whose details you want to open.
3. In the event details window that opens, click the device name, and then from the drop-down list that opens, select the required response action.

Responding from an investigation graph

To respond from an investigation graph:

1. In the main menu, go to the **Monitoring** → **Incidents** section. In the ID column, click the ID of the incident that includes the device for which you want to perform a response action.
2. In the window that opens, click the **View on graph** button.

   The investigation graph opens.
3. Click the name of the required device, and then in the drop-down list, select **View properties**.

   The device details window opens.
4. In the **Select response actions** drop-down list, click **Get**.
5. In the context menu that opens, select the required response action.

Responding from the table of assets

To respond from the table of assets:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.
   This opens the table of assets.
2. Select the check box next to the device for which you want to perform the response action.
   If you want to perform the Forensics or Registry key response actions, you can select several devices.

   > Archived devices cannot be selected.

3. In the **Select response actions** drop-down list, select the required response action.

Responding from the Response history section

To perform a response action from the Response history section:

1. In the main menu, go to **Monitoring** → **Response history**.
   The table that contains the response history for all alerts and incidents opens.
2. In the **Response** drop-down list, select the required response action.

Getting a file

To get a file:

1. Select the File response action.
   The **Get file** pane opens.
2. In the **Full path** field, specify the path to the file that you want to obtain.
3. If necessary, configure the following settings:
   - In the **Assets** drop-down list, change the device from which you want to obtain a file.
   - By default, the field contains the name of the device whose check box you previously selected. You can select devices that are not related to the alert or incident, but belong to the alert or incident tenant and its child tenants.

     > Only the assets on which you can perform the response action are available for selection.
     > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

- In the **MD5 or SHA256** field, specify the hash of the file that you want to obtain.
- If you do not want to scan the file, disable the **Scan file** option.

  By default, this option is enabled. This means that after a file is obtained, it is checked for threats.

  > When launching the response action within a playbook, you have to add this option manually if you want to scan the obtained file.

- In the **Description** field, write a description or a comment to the response action.

4. Click the **Get** button.

   The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

As a result of the response action, the file is saved to a ZIP archive. The password is *infected*.

Viewing the response action result

You can view and download the archive in one of the following ways:

- From the Response history section in the main menu or from the History tab in the alert or incident details
- From the **Files** section of the main menu or from the **Files** tab in the alert or incident details.

If at step 2 you did not disable the **Scan file** option, the result of the file scan is also displayed. After you click the link in the **Action status** column, the file details open with the **Result** tab selected, where you can view the scan results and download the file to your computer, if necessary.

Getting a registry key

To get a registry key:

1. Select the Registry key response action.

   The **Get registry key** pane opens.

2. In the **Relative path to the registry key** field, specify the path to the registry key that you want to obtain in one of the following formats:

   - Relative to the root key, for example:

     \REGISTRY\MACHINE\SOFTWARE\Microsoft\WindowsUpdate\Orchestrator
   - Relative with the full name of the root key, for example:

     HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\WindowsUpdate\Orchestrator
   - Relative with an abbreviation instead of the full name of the root key, for example:

     HKLM\SOFTWARE\Microsoft\WindowsUpdate\Orchestrator

3. If necessary, configure the following settings:

   - In the **Assets** drop-down list, change the devices from which you want to get registry keys.

     By default, the field contains the names of the devices whose check boxes you previously selected. You can select devices that are not related to the alert or incident, but belong to the alert or incident tenant and its child tenants.

     > Only the assets on which you can perform the response action are available for selection.
     > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

4. In the **Description** field, write a description or a comment to the response action.

5. Click the **Get** button.

   The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

As a result of the response action, an REG file is generated. This file contains the list of registry keys and their values, located at the path that you specified.

Viewing the response action results

You can view and download the file in one of the following ways:

- From the **Files** section of the main menu or from the **Files** tab in the alert or incident details.
- From the Response history section in the main menu or from the History tab in the alert or incident details

  After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, a **Success** message and the generated file are displayed. Otherwise, an **Error** message and the information about the reason of the error are displayed.

  If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Getting NTFS metafiles

> The **Get NTFS metafiles** task retrieves only the default data stream of a file. Alternate (named) data streams are not supported.

To get NTFS metafiles:

1. Select the NTFS metafiles response action.

   The **Get NTFS metafiles** pane opens.

2. In the **Metafiles** field, select the check boxes next to the metafiles that you want to get:
   - $MFT
   - $LogFile
   - $Boot
   - $Secure
   - $Extend/$UsnJrnl
3. In the **Volume** field, specify the name of the disk from which you want to get metafiles.

   By default, the *%SystemDrive%* value is specified.
4. If necessary, configure the following settings:
   - In the **Assets** drop-down list, select the device from which you want to get metafiles.

     By default, the field contains the name of the device whose check box you previously selected. You can select a device that is not related to the alert or incident, but belongs to the alert, or incident tenant and its child tenants.

     > Only the assets on which you can perform the response action are available for selection.
     > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

   - In the **Description** field, you can write a description or a comment to the response action.
5. Click the **Get** button.

The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

As a result of the response action, the NTFS metafiles are saved to a ZIP archive.

Viewing the response action result

You can view and download the archive in one of the following ways:

- From the **Files** section of the main menu or from the **Files** tab in the alert or incident details.
- From the Response history section in the main menu or from the History tab in the alert or incident details

  After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message and the obtained files are displayed. Otherwise, an **Error** message and the information about the reason of the error are displayed.

  If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Getting forensics

To get forensics:

1. Select the Forensics response action.

   The **Get forensics** pane opens.

2. In the **Information type** section, select the check boxes next to the type of data that you want to obtain:

   - **Processes list**. For a list of processes running on the device.
   - **Autorun points list**. For a list of autorun points.

     The list includes information about applications added to the startup folder or registered in the Run registry keys, as well as applications that are automatically run when the specified device is started and a user logs in to the operating system on the device.

     List of supported autorun points

     The following types of autorun points are supported:

     - Logon
     - Shell
     - Office
     - Browsers
     - Scheduler
     - Services
     - Drivers
     - Cryptography
     - Debuggers
     - COM
     - SessionManager
     - Network
     - LSA
     - Applications
     - WMI
     - GroupPolicy
     - DriverLog

- BootLog
- Process
- OsUpdate
- Printer
- Unspecified
- OsLoader
- EfiLoader

- **File list**. For a list of files and folders stored on the disk.

> The maximum number of files displayed in the list is 20,000.

3. If you selected the **File list** check box, do the following:

   a. Specify the scope of the files search by selecting one of the following group of settings:

   - **All local disks**. The list will include the files stored in all folders on local disks.
   - **Folder**, and then in the **Initial folder** field, specify the path to the folder from which the file search must start.

     The list will include the files stored in the specified folder and its subfolders.

   b. If necessary, specify the following search criteria for files in folders:

   - The mask of files to be included in the list of files.
   - The **Alternate data streams** option to record information about alternate data streams in the file list.

     The toggle switch is turned on by default.
   - Maximum nesting level of folders in which the application searches for files.
   - In the **Exclusions** field, specify the path to the folder in which you want to prohibit the search for information about files.

4. If necessary, configure the following settings:

   - In the **Assets** drop-down list, select the devices from which you want to get forensics.

     By default, the field contains the names of the devices whose check boxes you previously selected. You can select devices that are not related to the alert or incident, but belong to the alert, or incident tenant and its child tenants.

Only the assets on which you can perform the response action are available for selection.
The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

- In the **Description** field, write a description or a comment to the response action.

5. Click the **Get** button.

   The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

As a result of the response action, the selected data are saved to a password-protected ZIP archive. The password is *infected*.

Viewing the response action result

You can view and download the archive in one of the following ways:

- From the **Files** section of the main menu or from the **Files** tab in the alert or incident details.
- From the Response history section in the main menu or from the History tab in the alert or incident details

  After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message and the obtained file are displayed. Otherwise, an **Error** message and the information about the reason of the error are displayed.

  If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Getting a disk image

To get a disk image:

1. Select the Disk image response action.

   The **Get disk image** pane opens.

2. In the **Path to a shared network resource** field, specify the path to the shared network resource, in the UNC format.

3. In the **User name** field, select the user name of the account to be used for accessing the shared network resource.

   You have to configure the credentials for accessing the shared network resource in advance in the tenant settings.

4. In the **Disk type** group of settings, select one of the following:

   - **Logical**, and then in the **Volume** field, specify the drive letter without the colon and slash, for example, E or C.

     The default value is %SystemDrive%.

   - **Physical**, and then in the **Physical drive** field, specify the path to the disk in the following format:

     - For a device with Kaspersky Endpoint Security for Windows: \\.\PHYSICALDRIVE0, \\.\PHYSICALDRIVE1, \\.\PHYSICALDRIVE2

     - For a device with Kaspersky Endpoint Security for Linux: /dev/sda

5. If you want to divide the disk image file into several parts, turn on the **Split file into parts** option, and then specify the minimum size of one part of the saved file in GB.

6. If necessary, configure the following settings:

   - In the **Assets** drop-down list, change the device from which you want to get a disk image.

     By default, the field contains the name of the device whose check box you previously selected. You can select devices that are not related to the alert or incident, but belong to the alert, or incident tenant and its child tenants.

     > Only the assets on which you can perform the response action are available for selection.
     > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

   - In the **Description** field, write a description or a comment to the response action.

7. Click the **Get** button.

The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

As a result of the response action, the disk image is saved to an EWF file.

> The files cannot be overwritten: if the destination folder already includes a file with the name, the name of your EWF file will contain a postfix, for example, Filename-1.

Viewing the response action result

You can view the result of the response actions in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message and the path to the file with the memory disk image located in the shared network resource are displayed. You can copy the path.

Otherwise, an **Error** message and the information about the reason of the error are displayed.

If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

> You cannot move to the shared network resource directly from the response action result.

Getting a memory dump

To get a memory dump:

1. Select the selected the Memory dump response action.

   The **Get memory dump** pane opens.

2. In the **Path to a shared network resource** field, specify the path to the shared network resource, in the UNC format.

3. In the **User name** field, select the user name of the account to be used for accessing the shared network resource.

   > You have to configure the credentials for accessing the shared network resource in advance in the tenant settings.

4. If necessary, configure the following settings:

   - In the **Assets** drop-down list, select the device from which you want to obtain the memory dump.

     By default, the field contains the name of the device whose check box you previously selected. You can select devices that are not related to the alert or incident, but belong to the alert, or incident tenant and its child tenants.

     > Only the assets on which you can perform the response action are available for selection.
     > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

   - In the **Description** field, write a description or a comment to the response action.

5. Click the **Get** button.

The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

As a result of the response action, the disk image is saved to a RAW file.

> The files cannot be overwritten: if the destination folder already includes a file with the name, the name of your RAW file will contain a postfix, for example, Filename-1.

Viewing the response action result

You can view the result of the response actions in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message and the path to the file with the memory dump located in the shared network resource are displayed. You can copy the path.

Otherwise, an **Error** message and the information about the reason of the error are displayed.

If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

> You cannot move to the shared network resource directly from the response action result.

Getting a process memory dump

To get a process memory dump:

1. Select the Process memory dump response action.

   The **Get process memory dump** pane opens.

2. In the **Process ID** field, specify the ID of the process for which you want to get a memory dump.

3. If necessary, configure the following settings:

   - In the **Assets** drop-down list, change the device from which you want to obtain the process memory dump.

     By default, the field contains the name of the device whose check box you previously selected. You can select devices that are not related to the alert or incident, but belong to the alert, or incident tenant and its child tenants.

     > Only the assets on which you can perform the response action are available for selection.
     > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

- In the **MD5 or SHA256** field, specify the hash of the file for whose process you want to get a memory dump.
- In the **Description** field, write a description or a comment to the response action.

4. Click the **Get** button.

   The pane is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

As a result of the response action, the memory dump of the process is saved to a ZIP archive.

Viewing the response action result

You can view and download the archive in one of the following ways:

- From the **Files** section of the main menu or from the **Files** tab in the alert or incident details.
- From the Response history section in the main menu or from the History tab in the alert or incident details

  After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message and a password-protected ZIP archive with the scan result are displayed. You can download the archive to your computer. The password is the following: infected.

  Otherwise, an Error message and the information about the reason of the error are displayed.

  If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Getting a file from quarantine

To perform the response action, you must have:

- One of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst
- Kaspersky Endpoint Security with a built-in agent installed on your devices

The quarantined file located on a device can be obtained from the quarantine directory for further analysis. The obtained file will be displayed in the **Files** section of OSMP Console.

You can perform this response action in one of the following ways:

- From the **Quarantine** section of the main menu.
- From the results of the **Move to quarantine** response action.

You can also configure the response action to run automatically when creating or editing a playbook.

Responding from the Quarantine section

To respond from the Quarantine section:

1. In the main menu, go to **Repositories** → **Quarantine**.
2. Do one of the following:
   - Select the file that you want to get from quarantine.
   - Click the name of the file that you want to get from quarantine.

   The file details open.
3. Click the **Get file** button, and then confirm the operation.

   If you want the file to be checked for threats after it is obtained, click the **Get & scan** button.

If the operation is completed successfully, an appropriate message is displayed on the screen, and the quarantined file is obtained from the device. Otherwise, an error message is displayed.

Responding from the results of the Move to quarantine response action

To respond from the results of the Move to quarantine response action:

1. Open the result of the **Move to quarantine** response action in one of the following ways:
   - In the main menu, go to **Monitoring** → **Response history**.
   - In the main menu, go to **Monitoring**, and then select the **Alerts** or **Incidents** section. In the **ID** column, click the ID of the alert or incident that includes the asset or observable for which you performed the **Move to quarantine** response action. In the alert or incident details that open, move to the **History** tab.
2. For the result of the **Move to quarantine** response action, in the **Action status** column, click the **Success** link.
3. In the details window that opens, click the **Get file** button, and then confirm the operation.

   If you want the file to be checked for threats after it is obtained, click the **Get & scan** button.

Viewing the response action result

The result of the response action is displayed:

- In the **Files** section of the main menu.
- In the **Response history** section of the main menu.

  After you click the link in the **Action status** column, the file details open with the **Result** tab selected, where you can view and download a password-protected ZIP archive with the file to your computer, if necessary. The password is *infected*.

  If the response action was unsuccessful, an **Error** message and information about the reason of the error are displayed.

  If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Scanning devices for threats

To prevent a threat distribution on an infected device, you can scan the device for threats by performing one of the following response actions:

- Malware scan
- YARA scan
- IOC scan

To perform the response actions, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

You can perform the response actions in one of the following ways:

- From the alert or incident details
- From the device details
- From a telemetry event

  You can open the event details from alert or incident details or from the **Threat hunting** section.
- From an investigation graph

  This option is available if the investigation graph is built.
- From the table of assets
- From the **Response history** section

- From the list of YARA rules or IOC rules

  This option is available for YARA scan and IOC scan response actions.

You can also configure the response action to run automatically when creating or editing a playbook.

Running a scan from the alert or incident details

To scan a device from the alert or incident details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device to be scanned.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device to be scanned.

2. In the window that opens, go to the **Assets** tab.
3. Select the check box next to the device to be scanned.

   You can select several devices, if necessary.

4. In the **Select response actions** drop-down list, click **Scan**.
5. In the context menu that opens, select the required response action.

Running a scan from the device details

To scan a device from the device details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device to be scanned.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device to be scanned.

2. In the window that opens, go to the **Assets** tab.
3. Click the name of the required device, and then in the drop-down list, select **View properties**.
4. In the **Select response actions** drop-down list, click **Scan**.
5. In the context menu that opens, select the required response action.

Running a scan from an investigation graph

To scan a device from an investigation graph:

1. In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device to be scanned.
2. Click the **View on graph** button.
3. In the investigation graph that opens, click the device name to open the device details.
4. In the **Select response actions** drop-down list, click **Scan**.
5. In the context menu that opens, select the required response action.

Running a scan from a telemetry event

To scan a device from a telemetry event when opening it from the alert or incident details:

1. Do one of the following:
   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the link with the alert ID you need.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the link with the incident ID you need.
2. In the window that opens, go to the **Details** tab, and do one of the following:
   - Click the name of the required event and select the device.
   - Click the Find in Threat hunting button to go to the **Threat hunting** section, and then select the required device.
3. In the **Select response actions** drop-down list, click **Scan**.
4. In the context menu that opens, select the required response action.

To scan a device from a telemetry event when opening it from Threat hunting section:

1. In the main menu, go to **Monitoring** → **Threat hunting.**

   The table of events opens.
2. Click the name of the event whose details you want to open.
3. In the event details window that opens, click the device name, and then from the drop-down list that opens, select the required response action.

Running a scan from the table of assets

To run a scan from the table of assets:

1. In the main menu, go to **Asset management** → **Assets (Devices).**
   This opens the table of assets.
2. Select the check box next to the device for which you want to perform the response action.
   You can select several devices.

   > Archived devices cannot be selected.

3. In the **Select response actions** drop-down list, select the required response action.

Running a scan from the Response history section

To run a scan from the Response history section:

1. In the main menu, go to **Monitoring** → **Response history**.
   The table that contains the response history for all alerts and incidents opens.
2. In the **Response** drop-down list, select the required response action.

Running a scan from the list of YARA rules or IOC rules

To scan a device from the list of YARA rules or IOC rules:

1. In the main menu, go to **Rules and services**, and then select either **YARA rules** or **IOC rules**.
   The list of rules is displayed.
2. Select the check box next to one or several devices for which you want to run the scan.
3. In the toolbar, click the button:
   - **Run YARA scan** if at step 1 you selected **YARA rules**.
   - **Run IOC scan** if at step 1 you selected **IOC rules**.
4. In the right pane that opens, configure the scan settings.

YARA scan

A YARA scan is a search for malicious activity signatures on devices, by using YARA files, manually downloaded via OSMP Console.

To perform a YARA scan, you must have:

- Kaspersky Endpoint Security with a built-in agent installed on your devices
- At least one rule in the list of YARA rules

To perform a YARA scan:

1. Select the YARA scan response action.

   The **Run YARA scan** pane opens.

2. In the **Rules** drop-down list, select one or more YARA rules.

   You can enter the name of the rule or a sequence of characters from the name of the rule.

   > The maximum number of rules you can specify is 200.

3. In the **Scan scope** do the following:

   a. Select the option and specify its mandatory parameters:

   - **RAM** to scan processes that are running at the time of the response action execution.

     This option is selected by default, and in the **Scan** group of settings the **All processes** option is selected.

     If you want to scan specific processes, in the **Scan** group of settings, select the **Specific processes** option, and then enter the name of one or more processes to be scanned. Otherwise, all processes will be scanned.

     > The application does not scan processes with a low priority.

   - **Autorun points** scan autorun points obtained from the **Forensics** response action.

     Then, specify the scan type:

     - **Quick scan**. All autorun points are scanned, except COM objects.
     - **Full scan**. All autorun points are scanned, as well as files involved with them.

     List of supported autorun points

     The following types of autorun points are supported:

     - Logon
     - Shell

- Office
- Browsers
- Scheduler
- Services
- Drivers
- Cryptography
- Debuggers
- COM
- SessionManager
- Network
- LSA
- Applications
- WMI
- GroupPolicy
- DriverLog
- BootLog
- Process
- OsUpdate
- Printer
- Unspecified
- OsLoader
- EfiLoader

- **All local disks** to scan files stored in all folders on local disks.

  > Scanning all local disks can cause high load on the device.

- **Specified directories** to scan files that are located in a specified directory and all its nested folders.

  You have to specify the full path to the directory in the corresponding field, appending the mask `*` at the end to include subdirectories, for example, `C:\Users\Administrator\Desktop\*`.

b. If necessary, in the corresponding fields, specify the following parameters for the selected option:

- **Maximum scan duration (hours)**

  The default value is 23. After the specified time elapses, the scan is stopped even if some rules were not applied to scan the devices. The response action result contains data that is up-to-date at the moment when the scan was stopped.

- **Exclusions**

  Specify short names of processes or a mask of files that you want to exclude from scanning. If multiple processes with identical names are running on the device, the application excludes all such processes from scanning.

4. If necessary, configure the following settings:

- Specify the tenant.

  If you ran the response action from the list of YARA rules and selected rules that belong to different tenants, the **Tenant** field is empty. You have to specify the tenant manually for whose devices you want to perform a YARA scan.

- Change the scope of the response action.

  By default, in the **Scope** of settings, the **Specific assets** option is selected, and the **Assets** drop-down list contains the names of the devices whose check box you previously selected. The YARA scan will be performed on these devices.

  You can either change the devices to be scanned or select the **All assets** option in the **Scope** group of settings to scan all the devices that belong to the alert or incident tenant and its child tenants.

  > Only the assets on which you can perform the response action are available for selection.
  > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

- In the **Description** field, write a description or a comment to the response action.

5. Click the **Run** button.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Viewing the response action result

You can view the result of the response action in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

In the **Assets** column, you have to click the link with the number of assets for which the YARA scan was launched. In the window opens with the **Result** tab selected, you can view the scan status for every YARA rule. If the scan detects a threat, a corresponding alert is created. You can move to the alert from the response action result.

If the response action was unsuccessful, an **Error** message and information about the reason of the error are displayed.

IOC scan

An IOC scan searches for signs of targeted attacks, as well as infected and probably infected objects on devices, by using IOC files (indicators of compromise files) manually downloaded via OSMP Console.

To perform an IOC scan, you must have:

- Kaspersky Endpoint Security with a built-in agent installed on your devices
- At least one rule in the list of IOC rules

To perform an IOC scan:

1. Select the IOC scan response action.

   The **Run IOC scan** pane opens.

2. In the **Rules** drop-down list, select one or several IOC rules.

3. If necessary, configure the following settings:

   - Specify the tenant.

     If you ran the response action from the list of IOC rules and selected rules that belong to different tenants, the **Tenant** field is empty. You have to specify the tenant manually for whose devices you want to perform an IOC scan.

   - Change the scope of the response action.

     By default, in the **Scope** of settings, the **Specific assets** option is selected, and the **Assets** drop-down list contains the names of the devices whose check box you previously selected. This means the IOC scan will be performed on these devices.

     You can either change the devices to be scanned or select the **All assets** option in the **Scope** group of settings to scan all the devices that belong to the alert or incident tenant and its child tenants.

     > Only the assets on which you can perform the response action are available for selection.
     > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

   - In the **Maximum scan duration (hours)** field, specify the maximum scan duration.

     The default value is 23. After the specified time elapses, the scan is stopped even if some rules were not applied to scan the devices. The response action result contains data that is up-to-date at the moment when the scan was stopped.

   - In the **Description** field, write a description or a comment to the response action.

4. Click the **Run** button.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Viewing the response action result

You can view the result of the response action in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

In the **Assets** column, you have to click the link with the number of assets for which the IOC scan was launched. In the window that opens with the **Result** tab selected, you can view the scan status for every IOC rule. If the scan detects a threat, a corresponding alert is created. You can move to the alert from the response action result.

If the response action was unsuccessful, an Error message and information about the reason of the error are displayed.

Deleting a file

To perform the **Delete file** response action, you must have:

- One of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst
- Kaspersky Endpoint Security with a built-in agent installed on your devices

You can perform the response actions in one of the following ways:

- From the alert or incident details
- From the device details
- From a telemetry event

  You can open the event details from alert or incident details or from the **Threat hunting** section.
- From an investigation graph

  > This option is available if the investigation graph is built.
- From the table of assets
- From the **Response history** section

You can also configure the response action to run automatically when creating or editing a playbook.

Responding from the alert or incident details

To respond from the alert or incident details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device with the file to be deleted.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device with the file to be deleted.

2. In the window that opens, go to the **Assets** tab.

   > You can also go to the **Observables** tab, select the check box next to the file that you want to delete, and then click **Delete file**.

3. Select the check box next to the device on which the file to be deleted is located.

   You can select several devices.

4. In the **Select response actions** drop-down list, select **Delete file**.

5. In the right pane that opens, do the following:

   - In the **Full path** field, specify the full path to the file that you want to delete.

   - In the **Assets** drop-down list, select the devices on which the file is located.

     If at step 2 you selected the **Assets** tab, the names of the devices whose check boxes you selected are specified in the **Assets** field by default.

     You can either change the devices or select the **All assets** option in the **Scope** group of settings to perform the response action for all the devices that belong to the alert or incident tenant and its child tenants.

     > Only the assets on which you can perform the response action are available for selection.
     > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

- If necessary, configure the following settings in the corresponding fields:
  - Specify either the SHA256 or MD5 hash of the file.

    > If at step 2 you selected the **Observables** tab, the hash is specified. You can change the value.

  - Write a description or a comment to the response action.

6. Click the **Delete** button.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the device details

To respond from the device details:

1. Do one of the following:
   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device with the file to be deleted.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device with the file to be deleted.
2. In the window that opens, go to the **Assets** tab.
3. Click the name of the required device, and then in the drop-down list, select **View properties**.
4. Perform the same actions as described at steps 4–6 in *Responding from the alert or incident details*.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from a telemetry event

To respond from a telemetry event when opening it from the alert or incident details:

1. Do one of the following:
   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the device with the file to be deleted.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the device with the file to be deleted.

2. In the window that opens, go to the **Details** tab, and do one of the following:

   - Click the name of the required event and select the device.
   - Click the **Find in Threat hunting** button to go to the **Threat hunting** section, and then select the required device.

3. Perform the same actions as described at steps 4–6 in *Responding from the alert or incident details*.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

To respond from a telemetry event when opening it from the Threat hunting section:

1. In the main menu, go to **Monitoring → Threat hunting.**

   The table of events opens.

2. Click the name of the event whose details you want to open.

3. In the event details pane that opens, click the device name, and then from the drop-down list, select **Delete file**.

4. In the right pane that opens, configure the response action settings as described at steps 5–6 in *Responding from the alert or incident details*.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from an investigation graph

To scan a device from an investigation graph:

1. In the main menu, go to the **Monitoring → Incidents** section. In the **ID** column, click the ID of the incident that includes the device with the file to be deleted.

2. Click the **View on graph** button.

3. In the investigation graph that opens, click the device name to open the device details.

4. In the **Select response actions** drop-down list, select **Delete file**.

5. Perform the same actions as described at steps 5–6 in *Responding from the alert or incident details*.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the table of assets

To respond from the table of assets:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.

   This opens the table of assets.

2. Select the check box next to the device for which you want to perform the response action.

   You can select several devices.

   > Archived devices cannot be selected.

3. In the **Select response actions** drop-down list, select **Delete file**.

4. In the right pane that opens, configure the response action settings as described at steps 5–6 in *Responding from the alert or incident details*.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Responding from the Response history section

To perform a response action from the Response history section:

1. In the main menu, go to **Monitoring** → **Response history**.

   The table that contains the response history for all alerts and incidents opens.

2. In the **Response** drop-down list, select **Delete file**.

3. In the right pane that opens, configure the response action settings as described at steps 5–6 in *Responding from the alert or incident details*.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Viewing the response action result

You can view the result of the response actions in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message is displayed. Otherwise, the Error message and the information about the reason of the error are displayed.

If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

If the file has been blocked by another process, the result is displayed with the **Success** status but the file will be deleted only after the device is restarted. It is recommended to check whether the file is successfully deleted after the device is restarted.

Responding through Active Directory

You can integrate Kaspersky EDR Expert with the Active Directory services that are used in your organization. Active Directory is considered to be integrated with Kaspersky EDR Expert after the integration between Active Directory and KUMA is configured.

The process of configuring integration between Kaspersky EDR Expert and Active Directory consists of configuring connections to LDAP. You must configure connections to LDAP separately for each tenant.

As a result, if an alert or an incident occurs, you will be able to perform response actions in relation to the associated users of that tenant.

You can perform a response action through Active Directory in one of the following ways:

- From the alert or incident details
- From a telemetry event (if you open it from alert details).
- From an investigation graph

  This option is available if the investigation graph is built.

You can also configure a response action to run automatically when creating or editing a playbook.

To perform a response action through Active Directory, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

To perform a response action through Active Directory:

1. In the main menu, go to **Monitoring**, and then select the **Alerts** or **Incidents** section.

   If you want to respond from the telemetry event, select the **Alerts** section.

   If you respond from an investigation graph, select the **Incidents** section.

2. Click the ID of the required alert or incident.

3. In the window that opens, do one of the following:

   - If you want to respond through the alert or incident details, go to the **Assets** tab, and then click the name of the user.
   - If you want to respond through a telemetry event, go to the **Details** tab, and either click the name of the required event, and then select the user; or click the **Find in Threat hunting** button to go to the **Threat Hunting** section, and then select the required user.
   - If you want to respond through an investigation graph, click the **View on graph** button. In the investigation graph that opens, click the name of the user.

   The **Account details** window opens on the right side of the screen.

4. In the **Response through Active Directory** drop-down list, select an action that you want to perform:

   - **Lock account**

     If the user account is locked in response to the related alert or incident, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

   - **Reset password**

     If the user account password is reset in response to the related alert or incident, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

   - **Add user to security group**

     In the window that opens, in the mandatory field **Security group DN**, specify a full path to the security group to which you want to add the user. CN = Team, OU = Groups, OU = ExchangeObjects, DC = example, DC = com. Then click the **Add** button. Only one group can be specified within one operation.

     If the user is added to the security group in response to the related alert or incident, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

   - **Delete user from security group**

     In the window that opens, in the mandatory field **Security group DN**, specify a full path to the security group from which you want to delete the user. For example, CN = Team, OU = Groups, OU = ExchangeObjects, DC = example, DC = com. Click the **Delete** button. Only one group can be specified within one operation.

     If the user is deleted from the security group in response to the related alert or incident, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Enabling and disabling network isolation

You can enable and disable network isolation on a device in one of the following ways:

- From the alert or incident details
- From the device details
- From an investigation graph
- From the table of assets

- From the event details

  The option is only available to enable network isolation.

You can also configure the response action to run automatically when creating or editing a playbook.

> To perform the response actions, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

For the devices with Kaspersky Endpoint Security with a built-in agent installed, the network isolation status is displayed in the device details.

The device may have one of the following statuses: *Isolated*, *Isolating*, *Error applying isolation*, *Not isolated*.

Also, the network isolation status is displayed in the table of assets when you open it from the **Assets** tab in the alert or incident details or from **Asset management** → **Assets (Devices).** You can filter the values in the **Isolation status** column of the table to display the devices with the required status of network isolation.

Performing response actions from alert or incident details

To respond from the alert or incident details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the required device.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, go to the **Assets** tab.

3. Select the select check box next to the required device.

   You can select several devices, if necessary.

4. In the **Select response actions** drop-down list, select **Network isolation**, and then in the context menu, select the response action that you want to perform:

   - **Enable**

     If you select this response action for a device on which network isolation is already enabled, the parameters are overwritten with new values.

     > Before enabling network isolation, ensure that the assets are imported from Kaspersky Security Center: in **Tasks** → **Analysis and response** the **KSC assets import** task is displayed with the Completed status.

   - **Disable**

     After you select this response action, in the confirmation dialog box, click **Disable**.

     You can select this response action for devices on which network isolation is enabled.

5. If you selected **Enable**, in the right pane that opens, configure the following settings:

   a. In the **Assets** drop-down list, specify the devices to be isolated.

      By default, the devices whose check boxes you previously selected are displayed. If necessary, you can change the devices. You cannot select the devices that have the following statuses: **Isolated**, **Isolating**, **Error applying isolation**.

      > Only the devices on which you can perform the response action are available for selection.
      > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

   b. Specify the period of the device isolation and the units.

   c. In the **Description** field, write a description or a comment to the response action.

   d. If you want to add an exception from the network isolation rule, click the **Add exclusion** button, and in the **Network traffic direction** drop-down list, select one of the following values:

      - **Inbound**, and then in the corresponding fields specify the IP address of the device to be excluded from the network traffic blocking and a local ports range.
      - **Outbound**, and then in the corresponding fields specify the IP address of the device to be excluded from the network traffic blocking and the remote ports range.
      - **Inbound/Outbound**, and then specify the IP address of the device to be excluded from the network isolation.

6. Click the **Enable** button.

The pane closes. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing response actions from the device details

To respond from the device details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the required device.
   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, go to the **Assets** tab.

3. Click the name of the required device, and then in the drop-down list, select **View properties**.

4. Perform the same actions as described at steps 4–6 in *Performing response actions from the device details*.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing response actions from an investigation graph

This option is available if the investigation graph is built.

To respond from an investigation graph:

1. In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, click the **View on graph** button.

   The investigation graph opens.

3. Click the device name to open the device details.

4. Perform the same actions as described at steps 4–6 in *Performing response actions from the device details*.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing the response actions from the table of assets

To respond from the table of assets:

1. In the main menu, go to **Asset management** → **Assets (Devices).**

   This opens the table of assets.

2. Select the check box next to the device for which you want to perform the response action.

   You can select several devices.

   Archived devices cannot be selected.

3. In the **Select response actions** drop-down list, select one of the following:

   - **Enable network isolation**, and then in the right pane that opens, configure the response action settings.
   - **Disable network isolation**, and then in the confirmation dialog box, click **Disable**.

Enabling network isolation from the event details

To enable network isolation from the event details:

1. In the main menu, go to **Monitoring** → **Threat hunting**.

   The table of events opens.

2. Click the name of the event whose details you want to open.

3. In the event details window that opens, click the device name, and then from the drop-down list that opens, select **Enable network isolation**.

4. In the right pane that opens, configure the response action settings.

If you have not yet installed Kaspersky Endpoint Security with a built-in agent on your device, and encounter a failure when running the response actions, you have to make sure that the device name in Kaspersky EDR Expert is the same as in Kaspersky Anti Targeted Attack Platform version earlier than 8.0.

Running a program

You can run the response action in one of the following ways:

- From the alert or incident details
- From the device details
- From an investigation graph
- From the table of assets
- From the **Response history** section
- From the event details

You can also configure the response action to run automatically when creating or editing a playbook.

To perform the response actions, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

Performing the response action from alert or incident details

To respond from the alert or incident details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the required device.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, go to the **Assets** tab.

3. Select the select check box next to the required device.

   You can select several devices, if necessary.

4. In the **Select response actions** drop-down list, select **Run**, and then in the context menu, click **Program**.

5. In the right pane that opens, do the following:

   a. In the **Full path** field, specify the full path to the executable file to be run.

   b. If necessary, configure the following settings:

   - Change the scope of the response action.

     By default, in the **Scope** drop-down list the **Specific assets** option is selected, and the **Assets** drop-down list contains the names of the devices whose check box you previously selected. It means, the executable file is to be run on these devices.

     You can either change the devices or select the **All assets** option in the **Scope** drop-down list to run executable file on all the devices that belong to the alert or incident tenant (and its child tenants).

   > Only the assets on which you can perform the response action are available for selection.
   > The devices are displayed as follows: devices belonging to the alert or incident are placed in the beginning of the **Assets** drop-down list, and then the devices belonging to the alert or incident tenant and child tenants are displayed alphabetically.

   - In the **Command line parameters** field, specify additional options for running the executable file, for example: `/all argument`.

   - In the **Working directory** field, specify the working directory.

   - In the **Description** field, write a description or a comment to the response action.

6. Click the **Run** button.

The pane closes. The window is closed. If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing the response action from the device details

To respond from the device details:

1. Do one of the following:

   - In the main menu, go to the **Monitoring** → **Alerts** section. In the **ID** column, click the ID of the alert that includes the required device.

   - In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, go to the **Assets** tab.

3. Click the name of the required device, and then in the drop-down list, select **View properties**.

4. Perform the same actions as described at steps 4–6 in *Performing a response action from the device details* procedure.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing the response action from an investigation graph

This option is available if the investigation graph is built.

To respond from an investigation graph:

1. In the main menu, go to the **Monitoring** → **Incidents** section. In the **ID** column, click the ID of the incident that includes the required device.

2. In the window that opens, click the **View on graph** button.

   The investigation graph opens.

3. Click the device name to open the device details.

4. Perform the same actions as described at steps 4–6 in *Performing response actions from the device details* procedure.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

If you have not yet installed Kaspersky Endpoint Security with a built-in agent on your device, and encounter a failure when running the response actions, you have to make sure that the device name in Kaspersky EDR Expert is the same as in Kaspersky Anti Targeted Attack Platform version earlier than 8.0.

Performing the response actions from the table of assets

To respond from the table of assets:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.

   This opens the table of assets.

2. Select the check box next to the device for which you want to perform the response action.

   You can select several devices.

   > Archived devices cannot be selected.

3. In the **Select response actions** drop-down list, select **Program**.

4. In the right pane that opens, configure the response action settings as described at steps 4–6 in *Performing a response action from the device details* procedure.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing a response action from the Response history section

To perform a response action from the Response history section:

1. In the main menu, go to **Monitoring** → **Response history**.

   The table that contains the response history for all alerts and incidents opens.

2. In the **Response** drop-down list, select **Program**.

3. In the right pane that opens, configure the response action settings as described at steps 4–6 in *Performing a response action from the device details* procedure.

If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Performing the response action from the event details

To perform the response action from the event details:

1. In the main menu, go to **Monitoring** → **Threat hunting.**

   The table of events opens.

2. Click the name of the event whose details you want to open.

3. In the event details window that opens, click the device name, and then from the drop-down list that opens, select **Program**.

4. In the right pane that opens, configure the response action settings as described at steps 4–6 in *Performing a response action from the device details* procedure.

   If the response action is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

Viewing the response action result

You can view the result of the response actions in one of the following ways:

- From the Response history section in the main menu
- From the History tab in the alert or incident details

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the response action completed successfully, the **Success** message is displayed. Otherwise, an Error message and the information about the reason of the error are displayed.

If you want to view the Launch ID and the JSON with the response action result, move to the **Debug data** tab.

Viewing response history from alert or incident details

After you perform a response action, you can view the response history in one of the following ways:

- From the alert or incident details.
- From the Response history section.
- From a playbook details.
- From Quarantine section.

  When you select a check box next to the required file, and then click the **View file in response history** button, you move to the **Response history** section. You can view the response action as a result of which the file was moved to **Quarantine**.

To view the response action history from the alert or incident details:

1. In the main menu, go to the **Monitoring** section.
2. Open the **Alerts** or **Incidents** section, and then click the ID of the alert or incident for which the response action was performed.
3. In the window that opens, go to the **History** tab, and then select the **Response history** tab.

The table of events is displayed and contains the following columns:

- **Time**. The time when the event occurred.
- **Launched by**. Name of the user who launched the response action.
- **Events**. Event description.
- **Response parameters**. Response action parameters that are specified in the response action.
- **Asset**. Number of the assets for which the response action was launched. You can click the link with the number of the assets to view the asset details.
- **Action status**. Execution status of the response action. The following values can be shown in this column:
  - **Awaiting approval**—Response action awaiting approval for launch.
  - **Launched**—Response action is in progress.
  - **Success**—Response action is completed without errors or warnings.
  - **Warning**—Response action is completed with warnings.
  - **Error**—Response action is completed with errors.
  - **Terminated**—Response action is completed because the user interrupted the execution.
  - **Approval time expired**—Response action is completed because the approval time for the launch has expired.
  - **Rejected**—Response action is completed because the user rejected the launch.
- **Playbook**. Name of the playbook in which the response action was launched. You can click the link to view the playbook details.
- **Response action**. Name of the response action that was performed.
- **Asset type** Type of asset for which the response action was launched. Possible values: **Device** or **User**.
- **Asset tenant**. The tenant that is the owner of the asset for which the response action was launched.

4. If necessary, click the settings icon (⚙), and then select the columns to be displayed in the table.

5. If necessary, click the filter icon ( ), and then in the window that opens, specify and apply the filter criterion:

- Add a new filter by clicking the **Add filter** button.
- Edit a filter by selecting necessary values in the following fields:
  - **Property**
  - **Condition**
  - **Value**

- Delete a filter.
- Delete all filters by clicking the **Reset all** button.

Working with files obtained as a result of response actions

To view the **Files** section, you must have one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator, SOC manager, Tier 1 analyst, Tier 2 analyst, Junior analyst, Approver, Auditor.

The **Files** section displays the files that you download manually and obtain as a result of performing the following response actions: File, Forensics, Registry key, NTFS metafiles, Process memory dump, Get file from quarantine.

We recommend that you enable automatic rotation of files so the oldest files are deleted from the **Files** repository, and you can upload new files. Files for which a threat was detected are not deleted. Such files are linked to the alerts created as a result of threat detection.
You will not get notifications about the deletion of the oldest files.

Viewing the table of files

To open the table of files, in the main menu, go to **Repositories** → **Files**. The table displays the files that are stored in the tenants to which you have access rights.

In the upper right part of the toolbar, you can group, filter, and search the data in the table as follows:

- Click the settings icon (⚙), and then select the columns to be displayed in the table.
- Click the filter icon ( ), and then specify and apply the filter criterion in the invoked menu.
- Click the search icon (🔍), in the **Search** field that displays, write what you want to find, and then press **ENTER**.

The resource table contains the following columns:

- **Name or full path**. If you downloaded the file manually, the file name is displayed in the column. If the file is obtained as a result of a response action, the full path to the file is displayed.
- **Size**. File size.
- **MD5**. The MD5 hash of the file, if any.
- **SHA256**. The SHA256 hash of the file, if any.
- **Uploaded on**. The date when the file was added to the **Files** repository.
- **Updated on**. The date when the file was updated in the **Files** repository.

- **Tenant**. The tenant to which the file belongs.

  In a hierarchy of OSMP instances, if a tenant was created on a child instance, the value in the **Tenant** filed is displayed with the child instance icon (⛓).

- **Source**. The name of the user who added the file to the **Files** repository or the name of the device from which the file was obtained as a result of a response action.

- **Adding method**. The way used to add the file to the **Files** repository.

  If the file was uploaded by a user, the **Uploaded by user** value is displayed in the column. If the file was obtained as a result of a response action, the response action name is displayed.

- **Scan status**. The result of the last performed scan of the file. The following values can be shown in this column:

  - **Not scanned**
  - **Scanning**
  - **Not detected**
  - **Detected**
  - **Error**

- **Description**. The column contains the information (if any) that you wrote in the **Description** field when configuring a response action parameters or uploading a file manually.

You can filter data in the **Adding method** and **Scan status** columns by clicking the column header and selecting the required method or status from the drop-down list.

Performing actions in the table of files

In the upper left part of the toolbar, you can perform the following actions:

- Click the **Refresh** button to update the data in the table.

- Upload a file from your computer to the **Files** repository by clicking the **Upload** button.

  This opens a sidebar on the right. In the **Tenant** field, specify the tenant that you want to own the file. Then click the **Upload files** link and select the file on your computer. If necessary, you can also add a comment or a description in the **Description** field, and enable the **Scan files after uploading** toggle switch if you want to scan the files for threats.

  After you click the **Upload** button, the pane is closed, and the uploaded file is displayed in the table. When uploading a large file or multiple files, you have to refresh the table so it displays the new files. If the file uploading is in progress, the **Name or full path** column displays the loading spinner, and the **Size** column shows how much of the total file size is already uploaded.

- Save files to your computer. To do this, select the check box next to one or several files in the table, and then click the **Download** button.

- Scan the selected files for threats using the following technologies: YARA, Sandbox, and Anti-Malware Engine. To do this, select the check box next to one or several files in the table, and then click the **Scan** button.

- Delete files. To do this, select the check box next to one or several files in the table, and then click the **Delete** button.
- Go to the list of the alerts to which the files are related. To do this, select the check box next to one or several files in the table, and then click the **Find alerts** button. The alerts created as a result of threat detect and the alerts from whose details you ran the response action (if a file was placed to the **Files** repository as a result of a response action) are displayed.

The **Scan** option is not available and the file hash is not calculated for files obtained as a result if the following response actions: Forensics, Registry key, NTFS metafiles, Process memory dump.

Viewing the file details

You can open a file details by clicking the link in the **Name or full path** column in the table.

In the right pane that opens, the file metadata (for example, the file name or path, size, hash), the scan status, the scan result are displayed:

- If an archive was sent for scan, the file details display information for those files in the archive for which the threat was detected, as well as the hashes of such files and the status from each of the technology: Anti-Malware, Sandbox, YARA.
- If the file was not scanned, the corresponding information is displayed.
- If the scan is not available for the file, the file details display the metadata only.

If a file was manually uploaded and scanned for threats, in the file details, you can also view the report on scan by clicking the **Download report** link in the **Scan status** field.

In the file details, you can do the following:

- Perform the following actions by clicking the corresponding buttons in the toolbar: scan, download, delete files, find linked alerts, edit the file description, move to the response history.

  The **Show in response history** option is not available for the manually uploaded files. For a file obtained as a result of a response action, after you click **Show in response history**, you move to the **Response history** section where the table of events will be filtered by the file.

- Click the link with the MD5 or SHA256 hash, and then in the drop-down list select the action that you want to perform:
  - **Create prevention rule** for the file in which a threat was detected. After you select the option, the **Add prevention rule** pane opens where you can Working with the table of prevention rules.
  - **Find on Kaspersky TIP** to check the file hash at Kaspersky Threat Intelligence Portal.
  - **View Sandbox report**. The option is available for files manually uploaded to the **Files** repository and scanned with the Sandbox technology.

- **Find linked alerts**. The linked alerts are the ones created as a result of threat detect and the alerts from whose details you ran the response action (if a file was placed to the **Files** repository as a result of a response action).

- **Find linked events** to move to the **Threat hunting** section where the events table is filtered by the hash of your file.

In a hierarchy of OSMP instances, files downloaded and obtained as a result of response actions performed on a child instance are displayed in the table of files on the parent instance with the following icon in the **Tenant** field: (⛓).

Working with the table of prevention rules

Prevention rules enable you to prevent files or processes that you consider insecure from running on the devices. Kaspersky EDR Expert identifies files based on their hash by using the MD5 or SHA256 hashing algorithms.

You can manage prevention rules in the following ways:

- Manually create, import, edit, and delete prevention rules from the table of prevention rules, as described in this article

- Create and delete prevention rules by performing corresponding response actions

- Configure the response actions to run automatically when creating or editing a playbook

To open the table of prevention rules, you must have one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator, SOC manager, Tier 1 analyst, Tier 2 analyst, Junior analyst, Approver, Auditor. To create or import prevention rules, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

To open the table of prevention rules, in the main menu, go to **Monitoring** → **Resources and services** → **Prevention rules**.

The resource table contains the following columns:

- **Name**. For manually created prevention rules, the column displays the name that you specified in the **Create prevention rule** pane. For imported prevention rules, the file hash is displayed in the column.

- **Hash**. The MD5 or SHA256 hash of the file to be blocked.

- **Tenant owner**. The tenant to which the prevention rule belongs.

  In the distributed solution mode, if a tenant was created on a secondary node, the value in the **Tenant** filed is displayed with the secondary node icon (⛓).

- **Assets**. The devices for which the prevention rule is applied. The column either displays the number of devices or the **All assets of tenant** value.

- **Created on**. The date and time of the prevention rule creation or import.

- **Created by**. The user who created or imported the prevention rule.

- **Updated on**. The date and time when the prevention rule settings were last edited.
- **Updated by**. The user who last edited the prevention rule settings.
- **Rule status**. If the prevention rule is enabled, the column displays the **Enabled** value for the rule. Otherwise, the **Disabled** value is displayed.
- **Notify on file block**. If when creating or editing the prevention rule you disabled notification about blocking a file, the column displays the **No** value. Otherwise, the **Yes** value is displayed.

In the table you can perform the following actions:

- Create or import a prevention rule.
- Delete a prevention rule by selecting a check box next to the required rule name, and then clicking the **Delete** button in the toolbar. You can also delete all rules at once.
- Enable and disable a prevention rule by selecting a check box next to the name of the required rule, clicking the **Change status** button, and then selecting **Enable** or **Disable**. You can also enable and disable all rules at once.
- View and edit the prevention rule details by clicking the rule name in the table.

  The **Edit prevention rule** pane opens with the **Details** tab selected. You can edit the prevention rule settings. The settings are the same as when you create a prevention rule from the table of rules. Also, you can click the **Go to Threat hunting** button to view the events obtained when a prevention rule was triggered.

  On the **Change log** tab, you can view all the changes applied to the prevention rule: manually from the table of prevention rules, by performing response actions, or by launching a playbook.

To apply an action to all rules at once:

1. Select the check box next to the **Name** column.
2. In the drop-down list click one of the items:
   - **Select all** if you want to perform an action for all rules in the table.
   - **Select all on current page** if you want to perform an action for all rules on current page.
3. If necessary, you can exclude one or several rules from the scope by removing the check boxes next to the names of the rules.
4. In the toolbar, click the required button depending on the action you want to perform: **Delete** or **Change status** (enable or disable the rules).

The action will be applied to all the rules that you selected.

Creating a prevention rule

To create a prevention rule:

1. In the main menu, go to **Monitoring** → **Resources and services** → **Prevention rules**.

   The table of prevention rules is displayed.
2. In the toolbar, click the **New** button.

3. In the **Create prevention rule** pane that opens, configure the settings:

   a. In the **Tenant owner** field, specify a tenant to which the prevention rule will belong.

   > After you save the prevention rule settings, you cannot edit the value in the **Tenant owner** field. If you want to change the tenant, you have to delete the prevention rule, create a new one, and specify the required value in the **Tenant owner** field.

   b. In the **MD5 or SHA256** field, specify a hash of the file that you want to block.

   If you want to specify more than one hash, click the **Add hash** button.

   > The application checks, if the hash is present in the tenant in the list of file hashes to be blocked. You cannot specify such hashes when creating a new prevention rule.

   c. If necessary, configure the following settings:

   - Change the scope of the prevention rule.

     By default, in the **Apply rule to** group of settings, the **All assets** option is selected. This means the prevention rule is applied to all devices. You can select the **Specific assets** option, and then in the **Assets** field that displays, specify one or several devices to which you want to apply the prevention rule.

     > If you set the devices for which you want to apply the prevention rule, and then a device is deleted, such device will be deleted from the prevention rule as well, and a corresponding information will be displayed in the **Change log** tab of the prevention rule details.

   - In the **Rule name** field, specify the name of the prevention rule. If you do not specify the name, the field is displayed empty.

   - In the **Notify user about blocking file execution** field, disable the toggle switch if you do not want to get notifications on file block.

     By default, this option is enabled.

   - In the **State** field, disable the toggle switch if you do not want the prevention rule to be applied.

     If you want to create a prevention rule with the **Disabled** state, you have to configure the other settings first. Otherwise, you will not be able to save the rule.

   d. Click the **Create** button.

The pane is closed, and the prevention rule is displayed in the list of rules.

Importing a prevention rule

To import a prevention rule:

1. In the main menu, go to **Monitoring** → **Resources and services** → **Prevention rules**.

   The table of prevention rules is displayed.

2. In the toolbar, click the **Import** button.

   Prevention rules imported from a file will be applied to the assets that belong to the tenant including the child tenants.

3. In the **Import prevention rules** pane that opens, configure the necessary settings:

   a. Select a CSV file from your computer.

      You can add only one CSV file that contains hashes. The number of hashes equals the number of prevention rules to be created. The maximum file size must not exceed 15 MB

   b. In the drop-down list, select the tenant to which the prevention rules are to be applied.

      By default, the tenant to which you have access rights is selected. If necessary, you can change the value.

      If you have access rights to several tenants, the value is empty, and you must specify the required tenant.

   c. Click the **Import** button.

The pane is closed, and the imported prevention rule is displayed in the table of rules.

Working with the table of IOC rules

Kaspersky EDR Expert scans devices for indicators of compromise (IOCs). Multiple IOCs are combined into a structured description in an IOC file. When you import an IOC rule, Kaspersky EDR Expert extracts the structured description from an IOC file and creates a rule based on the description. After an IOC rule is triggered, IOC alert is generated.

Viewing the table of IOC rules

To view the table of IOC rules, you must have one of the following XDR roles: Main administrator, Tenant administrator, SOC administrator, SOC manager, Tier 1 analyst, Tier 2 analyst, Junior analyst, Approver, Auditor.

To open the table of IOC rules, in the main menu, go to **Monitoring** → **Resources and services** → **IOC rules**. The table displays the IOC rules that are stored in the tenants to which you have access rights.

You can group, filter, and search the data in the table as follows:

- Click the settings icon (⚙), and then select the columns to be displayed in the table.
- Click the filter icon ( ), and then specify and apply the filter criterion in the invoked menu.
- Click the search icon (🔍), in the **Search** field that displays, write what you want to find, and then press **ENTER**.

The resource table contains the following columns:

- **Name**. The IOC rule name.
- **Created on**. Date and time the IOC rule was created.
- **Created by**. The user who created the IOC rule.
- **Updated on**. Date when the IOC rule was updated.
- **Updated by**. The user who last edited the IOC rule settings
- **Importance**. The level of the IOC rule importance: **Low**, **Medium**, or **High**.
- **Tenant owner**. The tenant to which the IOC rule belongs.

  In the distributed solution mode, if a tenant was created on a child instance, the value in the **Tenant** filed is displayed with the child instance icon (🖧).
- **Scheduled scan**. The status of scheduled scan: **Enabled** or **Disabled**. You can change the status by moving the toggle switch to the **Enabled** or **Disabled** position.

Performing actions in the table of IOC rules

In the upper left part of the toolbar, you can perform the following actions:

- Click the **Refresh** button to update the data in the table.
- Import IOC rules from files containing IOC rules by clicking the **Import** button.

  To import IOC rules, you must have one of the following XDR roles: Main administrator, Tenant administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst.
- Save IOC rules to your computer. To do this, select the check box next to one or several rules in the table, and then click the **Export** button.
- Delete IOC rules. To do this, select the check box next to one or several rules in the table, and then click the **Delete** button. You can also delete all rules at once.
- Perform the IOC scan response action. To do this, select the check box next to one or several rules in the table, and then click the **Run IOC scan** button. You can also perform the response action for all rules at once.

  To run the scan, you must have one of the following XDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.
- Turn on or turn off scheduled scanning for the selected IOC rules. To do this, select the check box next to one or several rules in the table, click the **Scheduled scan** button, and then in the drop-down menu select one of the options: **Enable** or **Disable**. You can also enable and disable scan for all rules at once.

  The scanning on schedule must be configured.

To apply an action to all rules at once:

1. Select the check box next to the **Name** column.
2. In the drop-down list click one of the items:
   - **Select all** if you want to perform an action for all rules in the table.
   - **Select all on current page** if you want to perform an action for all rules on current page.
3. If necessary, you can exclude one or several rules from the scope by removing the check boxes next to the names of the rules.
4. In the toolbar, click the required button depending of the action you want to perform: **Delete**, enable or disable **Scheduled scan**.

   The action will be applied to all the rules that you selected.

In the hierarchy of OSMP instances, if you are enabling, disabling, or deleting all rules at once in a child instance, and the selection includes some rules of the parent instance, the action is not applied to such rules.
If you click **Select all** → **Scheduled scan** or **Select all** → **Delete**, the action is applied only to the rules of the child instance.
If you click **Select all on current page**, the **Scheduled scan** and **Delete** buttons are disabled.

Viewing the IOC rule details

You can open an IOC rule details by clicking the link in the **Name** column in the table.

In the right pane that opens, the information about the IOC rule is displayed in the corresponding fields: the rule name, the tenant to which the rule belongs, the importance of the rule, the scheduled scan status (enabled or disabled), and the condition under which the rule is triggered.

In the details pane, you can do the following:

- Save the IOC rule to your computer by clicking the **Export** button.
- Perform the IOC scan response action by clicking the **Run IOC scan** button.
- Go to the list of the alerts to which the IOC rule is related by clicking the **Find alerts** button.

  The alerts in which the IOC rule was triggered are displayed. If there are no such alerts, then all IOC alerts are displayed.

Working with the table of YARA rules

YARA rules are the descriptions of signatures for targeted attacks and intrusions into the organization's IT infrastructure. Kaspersky EDR Expert scans scans the objects according to these rules.

Viewing the table of YARA rules

To view the table of YARA rules, you must have one of the following XDR roles: Main administrator, Tenant administrator, SOC administrator, SOC manager, Tier 1 analyst, Tier 2 analyst, Junior analyst, Approver, Auditor.

To open the table of YARA rules, in the main menu, go to **Monitoring → Resources and services → YARA rules.**

The table displays the YARA rules that are stored in the tenants to which you have access rights.

You can group, filter, and search the data in the table as follows:

- Click the settings icon (⚙), and then select the columns to be displayed in the table.
- Click the filter icon ( ), and then specify and apply the filter criterion in the invoked menu.
- Click the search icon (🔍), in the **Search** field that displays, write what you want to find, and then press **ENTER**.

The resource table contains the following columns:

- **Name**. The YARA rule name.
- **Created on**. Date and time the YARA rule was created.
- **Created by**. The user who created the YARA rule.
- **Updated on**. Date when the YARA rule was updated.
- **Updated by**. The user who last edited the YARA rule settings
- **Importance**. The level of the YARA rule importance: **Low**, **Medium**, or **High**.
- **Tenant owner**. The tenant to which the YARA rule belongs.

  In the distributed solution mode, if a tenant was created on a child instance, the value in the **Tenant** filed is displayed with the child instance icon (🖧).
- **File scanning**. The status of YARA scan: **Enabled** or **Disabled**. You can change the status by moving the toggle switch to the **Enabled** or **Disabled** position.
- **Description**. A description or a comment to the YARA rule.

Performing actions in the table of YARA rules

In the upper left part of the toolbar, you can perform the following actions:

- Click the **Refresh** button to update the data in the table.
- Import YARA rules from files containing YARA rules by clicking the **Import** button.

  To import YARA rules, you must have one of the following XDR roles: Main administrator, Tenant administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst.
- Save YARA rules to your computer. To do this, select the check box next to one or several rules in the table, and then click the **Export** button.
- Delete YARA rules. To do this, select the check box next to one or several rules in the table, and then click the **Delete** button. You can also delete all rules at once.
- Perform the YARA scan response action. To do this, select the check box next to one or several rules in the table, and then click the **Run YARA scan** button. You can also perform the response action for all rules at once.

  To run the scan, you must have one of the following XDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.
- Turn on or turn off scheduled scanning for the selected YARA rules. To do this, select the check box next to one or several rules in the table, click the **File scanning** button, and then in the drop-down menu select one of the options: **Enable** or **Disable**. You can also enable and disable scan for all rules at once.

To apply an action to all rules at once:

1. Select the check box next to the **Name** column.
2. In the drop-down list click one of the items:
   - **Select all** if you want to perform an action for all rules in the table.
   - **Select all on current page** if you want to perform an action for all rules on current page.
3. If necessary, you can exclude one or several rules from the scope by removing the check boxes next to the names of the rules.
4. In the toolbar, click the required button depending on the action you want to perform: **Delete**, enable or disable **File scanning**.

   The action will be applied to all the rules that you selected.

If you want to enable or disable all rules at once, and the selection contains rules belonging to subtenants:

- When clicking **Select all**, only the rules that belong to the Root tenant will change their status.
- When clicking **Select all on current page**, the **File scanning** button is grayed out.

In a hierarchy of OSMP instances, applying an action to all rules at once involves specific considerations.

Click here to view

Enabling and disabling all rules at once

On the parent instance

- If you click **Select all**, and the selection contains rules belonging to the subtenants of the parent or child instances, the action will not be applied to these rules.

  For both the instances, only the rules belonging to the Root tenant will be enabled or disabled.

- If you click **Select all on current page**, and the selection contains rules belonging to the subtenants of the parent or child instances, the **File scanning** button is grayed out.

On the child instance

- If you click **Select all**, and the selection contains rules belonging to subtenants or any rules of the parent instance, the action will be applied only to the child instance rules belonging to the Root tenant.

- If you click **Select all on current page**, and the selection contains rules belonging to subtenants or any rules of the parent instance, the **File scanning** button is grayed out.

Deleting all rules at once

On the parent instance,

you can delete any rules belonging to any tenants of the parent and child instances.

On the child instance:

- If you click **Select all**, and the selection contains parent instance rules, these rules will not be deleted.

- If you **Select all on current page**, and the selection contains parent instance rules, the **Delete** button is grayed out.

Viewing the YARA rule details

You can open a YARA rule details by clicking the link in the **Name** column in the table.

In the right pane that opens, the information about the YARA rule is displayed in the corresponding fields: the rule name, the tenant to which the rule belongs, the importance of the rule, the scan status (enabled or disabled), the rule description, and the condition under which the rule is triggered.

In the details pane, you can do the following:

- Save the YARA rule to your computer by clicking the **Export** button.

- Perform the YARA scan response action by clicking the **Run YARA scan** button.

- Go to the list of the alerts to which the YARA rule is related by clicking the **Find alerts** button.

  The alerts in which the YARA rule was triggered are displayed. If there are no such alerts, then all YARA alerts are displayed.

Playbooks

Kaspersky EDR Expert uses playbooks that allow you to automate workflows and reduce the time it takes to process alerts and incidents.

Playbooks respond to alerts or incidents according to the specified *algorithm*. Playbook launches an algorithm that includes a sequence of response actions that help analyze and handle alerts or incidents. You can launch the playbook manually or configure the automatic launch of the playbook you need.

The automatic launch of playbooks is performed according to the *trigger* that you configure when creating a playbook. A trigger defines the conditions that an alert or incident must meet to launch this playbook automatically.

One playbook scope is limited to only alerts or only incidents.

Playbooks cannot be launched automatically for child incidents. For child incidents, you can only launch the playbook manually. Before launching, you need to select the assets and observables for which the playbook must be launched. Note that the playbook can only be launched for objects that belong to the alert or incident tenant.

Note that the playbook can only belong to one tenant and it is automatically inherited by all child tenants of the parent tenant, including child tenants that will be added after the playbook is created. You can disable playbook inheritance by child tenants when creating or editing a playbook.

In Kaspersky EDR Expert, there are two types of playbooks:

- Predefined playbooks

  Predefined playbooks are created by Kaspersky experts. These playbooks are marked with the [KL] prefix in the name and cannot be edited or deleted.

  By default, predefined playbooks operate in the **Training** operation mode. For more information, refer to the Predefined playbooks section.

- Custom playbooks

  You can create and configure playbooks yourself. When creating a custom playbook, you need to specify a playbook scope (alert or incident), a trigger for launching the playbook automatically, and an algorithm for responding to threats. For details about creating a playbook, see Creating playbooks.

You can use XDR REST API to import and export playbooks for a specific tenant.

Operation modes

You can configure both automatic and manual launch of playbooks. The way to launch the playbook depends on the selected operation mode.

These are the following types of operation modes:

- **Auto**. A playbook in this operation mode automatically launches when corresponding alerts or incidents are detected.
- **Training**. When corresponding alerts or incidents are detected, a playbook in this operation mode requests the user's approval to launch.
- **Manual**. A playbook in this operation mode can only be launched manually.

User role

You grant user rights to manage playbooks by assigning user roles to the users.

The table below shows access rights for managing playbooks and performing the user actions.

User role	User roles rights				
	Read	Write	Delete	Execute	Response confirmation
Main administrator	✓	✓	✓	✓	✓
SOC administrator	✓	✓	✓	—	—
Junior analyst	✓	—	—	—	—
Tier 1 analyst	✓	—	—	✓	—
Tier 2 analyst	✓	✓	✓	✓	—
SOC manager	✓	—	—	—	—
Approver	✓	—	—	—	✓
Auditor	✓	—	—	—	—
Tenant administrator	✓	✓	✓	✓	✓

Response actions available in playbooks

In Kaspersky EDR Expert, you can include the following response actions in a playbook:

- Get file
- Get forensics
- Get registry key
- Get NTFS metafiles

- Get process memory dump
- Get disk image
- Get RAM dump
- Terminate process
- Start YARA scan
- Manage services
- Run application
- Delete file
- Quarantine file
- Delete file from quarantine
- Restore file from quarantine
- Isolate host
- Create prevention rule
- Delete prevention rule
- Start IOC scan

Viewing the playbooks table

The playbooks table is displayed in the **Monitoring** → **Playbooks** section. By default, the table displays the playbooks related to all of the tenants to which you have access rights.

> The playbooks table displays all existing playbooks, except for playbooks in the **Deleted** status.

To configure the playbooks table, do any of the following:

- Apply tenant filter:

  a. Click the link next to the **Tenant filter** setting.

  b. The tenant filter opens.

  c. Select the check boxes next to the required tenants.

- Filter the data of the playbooks table:

  a. Click the filter ( ) icon.

  b. On the **Filters** tab, specify and apply the filter criterion in the invoked menu.

- If you want to hide or display a column, click the settings ( ) icon, and then select the necessary column.

The playbooks table is configured and displays the data you need.

The playbooks table contains the following information:

- **Name**. Name of the custom or predefined playbooks.

  > The predefined playbooks are marked with the [KL] prefix in the name and cannot be edited or deleted.

- **Status**. Playbook status. Possible values:

  - **Active**. Playbook is created and ready to use (all necessary web plug-ins are installed).
  - **Draft**. Playbook is created and saved as a draft. The playbook cannot be launched but is available for viewing, editing, customizing, and deleting in the tenant to which the playbook belongs.
  - **Deleted**. Playbook was deleted. By default, playbooks in this status are not displayed in the table. If you want to view them, click the **Status** column, and then in the drop-down list, select **Deleted**.

    > Only active and unavailable playbooks have the **Deleted** status after deletion. Playbooks in the **Draft** status are deleted permanently and not displayed in the playbooks table.

  - **Unavailable**. Playbook algorithm uses an unavailable web plug-in or contains response actions that are not allowed by your license.

- **Operation mode**. Playbook operation mode that defines the way to launch the playbook. For more details on operation modes, see the Playbooks section.
- **Tags**. Tags that are assigned to a playbook. You can filter playbooks by using the assigned tags.
- **Actions**. Actions that are launched within playbooks.
- **Launches**. Total number of playbook launches.
- **Modified**. Date and time of the last edit of the playbook.
- **Created**. Date and time the playbook was created.
- **Parent tenant**. Name of the tenant to which the playbook belongs.
- **Description.** Playbook description or a comment. By default, this column is hidden.
- **Scope**. Playbook scope. Possible values: **Alert** or **Incident**.

- **Created by**. Name of the user who created the playbook. By default, this column is hidden.
- **Updated by**. Name of the user who edited the playbook. By default, this column is hidden.

Creating playbooks

You can create a playbook to automate threat analysis and threat response.

To create a playbook, you must have one of the following roles: Main administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

Kaspersky EDR Expert also allows you to create a new playbook that will meet your needs, based on an existing one. For more details, refer to Customizing playbooks.

To create a new playbook:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. Click the **Create** button.

   The **Create playbook** window opens with the visual editor work area on the left and the **Playbook settings** pane on the right. The visual editor allows you to build and visualize the playbook execution flow, and the relationship between the steps involved in playbook creation.

   Based on the actions that you perform in the visual editor, the DSL schema of the playbook algorithm is generated. The changes you make in the visual editor working area are displayed in code, and vice versa. If necessary, you can open the code editor by clicking the **Show code** button in the toolbar.

3. In the **Playbook settings** pane, specify the following settings:

   - In the **Tenant and inheritance** field, select a parent tenant and child tenants for which the playbook should be launched.

     All child tenants of the selected parent tenant will automatically inherit this playbook. To disable playbook inheritance, clear the check box next to a required child tenant. Playbook inheritance will be disabled for this tenant as well as for its subtenants, if any.
     If you select a child tenant, its subtenants will be selected automatically.

   - In the **Name** field, enter the playbook name.

     Note that the playbook name must be unique within a tenant and cannot be more than 255 characters long.

   - In the **Scope** list, select one of the following options:

     - **Alert**. The playbook will be launched only for alerts. This option is selected by default.
     - **Incident**. The playbook will be launched only for incidents.

- In the **Operation mode** list, select one of the following options:
  - **Auto**. A playbook in this operation mode automatically launches when corresponding alerts or incidents are detected.
  - **Training**. When corresponding alerts or incidents are detected, a playbook in this operation mode requests the user's approval to launch.
  - **Manual**. A playbook in this operation mode can only be launched manually.
- If necessary, in the **Tags** field, specify up to 30 tags. You can filter playbooks by using the assigned tags.

  Note that the maximum tag length is 50 characters.
- If necessary, in the **Description** field, enter a playbook description or a comment.
- In the **When launching several playbook instances at the same time** drop-down list, choose an action to perform if two or more playbook instances are launching at the same time:
  - **Add new playbook instances to the queue**. The new playbook instance will be launched after the current one is completed. By default, this action is selected.
  - **Terminate current execution and launch a new instance**. The execution of the current playbook instance will be terminated. After that, a new playbook instance is launched.
  - **Do not launch new playbook instances**. A new playbook instance will not be launched. The execution of the current playbook instance will continue.

  > The **When launching several playbook instances at the same time** list is displayed only if the **Auto** operation mode is selected.
- By default, the playbook will only be launched for new alerts or incidents that match the trigger.

  If you want to launch a new playbook for existing alerts or incidents that match the trigger, select the **Launch the playbook for all matching alerts or incidents. Note that the system may be overloaded** check box.
- If necessary, in the **Additional settings** section, specify the following playbook parameters:
  - **Playbook timeout**—The maximum execution time of the playbook. By default, the value is 24h. The maximum value is 48h.

    If you want to create policies to be further applied in response actions, enable the **Use timeout policies for the response action** toggle switch, and then add the policies.

    > After you disable the toggle switch, the added policies are deleted.
  - **Input**—A jq expression to modify incoming data of the playbook before execution.
  - **Output**—A jq expression to modify the output data of the playbook after execution.
  - **Change method**—How to change the output data. Select whether to merge current and new data or overwrite current data with new data by selecting the **Merge** or **Overwrite** option.

The other additional settings are predefined and cannot be changed:

- **Playbook version**—Version of the playbook. May be required to identify the playbook in telemetry more accurately.
- **DSL version**—DSL schema version.
- **Action version**—Response actions schema version with the description of the response function input parameters.

4. In the visual editor work area, configure the playbook trigger and algorithm. Click the **Trigger** step, and then in the trigger settings pane that opens, specify the condition for the automatic launch of the playbook.

   If you select the **Manual** operation mode, trigger settings are unavailable.

   To describe the trigger condition, use jq expressions. For more information about jq expressions, refer to jq Manual.

   Depending on the option you select in the **Scope** list when creating or editing a playbook, alert data model or incident data model is used.

   For example, to filter alerts or incidents by critical severity, specify the following expression:

   ```
   .Severity == "critical"
   ```

   You can also specify complex expressions to filter alerts or incidents.

   For example, to filter critical alerts or incidents by rule name, specify the following expression:

   ```
   (.Severity == "critical") and (.Rules[] |.Name | contains("Rule_1"))
   ```

   where `Rules[] |.Name` defines the name of the triggered rule.

   Validation of jq expressions is configured. If you specify an incorrect expression when configuring the playbook trigger, the error is marked in red. If you want to view the details, hover the mouse cursor over the error.

5. If you want to view alerts or incidents that match the playbook trigger, in the **Trigger matching** section, click the **Find** button. By default, the last 10 modified alerts and incidents are displayed. If you want to change the value, open the drop-down list, and then select the required value.

   You can also request a full list of alerts or incidents. To do this, in the **Trigger** section, enter `true`, and then click the **Find** button.

   The full list of alerts or incidents is displayed.

6. Specify the playbook algorithm steps.

   You can copy an algorithm from another playbook. To do this, in the toolbar, click the **Copy algorithm** button, then in the window that opens, select a playbook from which to copy the algorithm, and then click **OK**.

   Validation of jq expressions and JSON syntax is configured. If you specify an incorrect expression when configuring the playbook algorithm, the error is marked in red. If you want to view the details, hover the mouse cursor over the error.

To add an algorithm step, do the following:

a. Hover the mouse cursor over the step from which a relation with the new step is to be built.

   If you are adding a step for the first time, you can hover the mouse cursor over the **Trigger** step only.

b. Click and hold the white dot sign (○) that displays, and then start drawing an arrow.

c. Release the mouse cursor, and then in the menu that opens, select the step.

   The selected step is displayed in the visual editor.

d. Click the step to configure its settings. For more details, refer to Configuring playbook execution steps in visual editor.

Alternately, you can right-click any part of the visual editor work area to invoke the menu, and then select the step you want to add. In this case, after adding the step, you have to build the relationships by drawing arrows between the required steps. If no relationships are built, you can only save the playbook as a draft.

> If algorithm steps are not added, you can save the playbook only as a draft.

7. Save the playbook in one of the following ways:

   - By clicking the **Publish** button. The saved playbook is ready to use and displayed in the playbooks table, with the **Active** status.

   - By clicking the **Create as draft** button. This allows you to create a playbook, by specifying only its name and the tenant to which it belongs. The playbook is displayed in the list of playbooks with the **Draft** status. You can open it and continue editing.

     > When you save the playbook as a draft, it is checked; errors are highlighted but ignored.
     > You can only save the playbook as a draft if no links are built between the execution steps and the trigger, the required parameters are not configured, or invalid parameters are specified.

A new playbook is created and displayed in the list of playbooks.

Configuring playbook execution steps in visual editor

After you add a playbook execution step when creating or editing a playbook, you have to configure its settings. To do this, click the block with the step, and then in the right pane, specify the required parameters by using jq expressions.

In visual editor, you can add and configure the following types of playbook execution steps:

- Action

  - In the **Action type** list, select the type of response action. The other settings vary based on the selected type.

    The types of response actions can be conventionally divided **into groups**

KATA/KEDR response actions:

- **Add prevention rule**

  Specify the assets to which the action should be applied, and the SHA256 or MD5 hashes of the files that you want to block.

- **Delete prevention rule**

  Specify the assets on which the prevention rule was applied, and the file hashes to be deleted.

- **Reset prevention rules**

  Specify the assets on which the prevention rules are to be reset.

- **Run program**

  Specify the assets and the executable file parameters: the full path to the file in the **Full path** field, and the parameters with which you want to start the file in the **Command line parameters** field. In the **Working directory** file, you can specify the path to the directory in which you want to save the results of the command or file execution.

- **Enable network isolation**

  Specify the assets for which you want to enable isolation, and the period of isolation. If you want to add an exception from the network isolation rule, click the **Add exclusion** button, and then specify the required parameters.

- **Disable network isolation**

  Specify the assets on which the network isolation was applied.

Active Directory response actions:

- **Lock account**

  Specify the users whose account you want to block.

- **Reset password**

  Specify the users whose password is to be reset.

- **Add user to security group**

  Specify the users and the group to which you want to add the users.

- **Delete user from security group**

  Specify the users and the group from which you want to remove the users.

KES for Windows response actions:

- **Run malware scan**

  Specify the assets and the scan type:

  - **Critical areas scan**.
  - **Custom scan**. Then specify the path to the file that you want to scan.
  - **Full scan**. If necessary, include network devices into the scan by enabling the **Scan network drives** toggle switch.

If you want the next response action to be launched only after the malware scan, enable the **Wait for the response action to complete** toggle switch.

- **Update databases**

  Specify the devices on which you want to update databases. If you want the next response action to be launched only after the databases update, enable the **Wait for the response action to complete** toggle switch.

- **Terminate process**

  Specify the devices on which you want to terminate a process. Then, select one of the parameters and specify the jq expression with the required information: **Hash and path** to the process file, **Full path** to the file, or the **PID** (process ID).

  > When Kaspersky Endpoint Security with a built-in agent operates in EDR Expert mode, terminating processes by system PID is not supported.

- **Move to quarantine**

  Specify the devices on which the file to be moved is located. Then, select one of the parameters and specify the jq expression with the required information: **Full path** to the file you want to quarantine, or **Hash and path** to the file.

Kaspersky Security Center response action:

- **Move to group**

  Specify the devices and path to the group to which you want to move the devices.

Kaspersky Threat Intelligence Portal response action:

- **Enrich data**

  Select the number of objects to enrich: all objects or the top 100 objects from the source. Specify a jq expression with an array of observables to enrich. You can enrich the following types of observables: MD5, SHA256, URL, domain, or IP address.

Editing alerts or incidents by using a playbook:

- **Assign to user or group**

  Select the users or groups to whom you want to assign an alert or an incident.

- **Change external reference attribute**

  Specify a jq expression with the alert or incident external reference attribute, and then select whether to overwrite the current output data or merge the current and new data.

- **Change additional data**

  Select whether to overwrite the current output data, or merge the current and new data.

- **Change status**

  Select the status of the alert or incident: **New**, **In progress**, or **Closed**. If the playbook scope is incidents, you also have to select the incident type.

- **Change type**

  Select the type for the incident.

This action type is available only if you selected **Incident** in the **Scope** drop-down list when creating or editing a playbook.

- **Change description**

  Specify a jq expression with the incident description, and then select whether to overwrite the current output data, or merge the new and the current data.

  This action type is available only if you selected **Incident** in the **Scope** drop-down list when creating or editing a playbook.

- **Change priority**

  Select the priority for the incident: **Critical**, **High**, **Medium**, or **Low**.

  This action type is available only if you selected **Incident** in the **Scope** drop-down list when creating or editing a playbook.

- **Add a comment**

  Specify a jq expression with a comment to the alert or incident.

- If necessary, in the **Additional settings** section, click the chevron icon (›) and **specify additional settings**

  - Click the **Terminate** or **Continue** button to select whether to terminate or continue the execution of the playbook if an error occurs.

  - Configure the response action timeout. You can either select the **Policy** option, and then specify the required timeout policy; or select the **Custom** option, and then specify the timeout in hours.

  - Modify the playbook outgoing data by enabling the **Output data** toggle switch. In the **Output** field, specify the jq expressions to replace the data returned by the response action, and then select the **Merge** or **Overwrite** replace method.

  - Manually approve the response function call by enabling the **Manual approve** toggle switch, and then specifying the approval timeout in minutes. The default value is 60 minutes.

    If you want to enable email notification, select the **Notify by email** check box, and then specify the delay before sending the email notification. The minimum value is 5 minutes, the maximum value is 30 minutes. Also, make sure that the SMTP server connection is configured and the email address is specified in the user's properties.

- Loop

  After you select this type of step, the **Loop** and **End loop** blocks are added to the visual editor.

  - Click the **Loop** block, specify a jq expression to form an array of incoming data, and then select the **Parallel** or **Sequence** mode for processing the elements.

  - If necessary, in the **Additional settings** section, click the chevron icon (›) and **specify additional settings**

    - Click the **Terminate** or **Continue** button to select whether to terminate or continue the execution of the playbook if an error occurs.

    - In the **Maximum batch size** field, specify the number of elements that a playbook can take as an input.

    - Set the rules for aggregating the results of the playbook execution over the elements of the incoming array. After you enable the **Aggregate results** toggle switch, in the **Expression** field, specify the jq expression to use the outgoing data as an input data for the next execution steps.

- Modify the outgoing data by specifying the jq expression in the **Output** field.
- Click the **Merge** or **Overwrite** button to select whether to overwrite the current output data, or merge the new and the current data.

- Parallel

  After you select this type of step, the **Parallel** and **End of Parallel** blocks are added to the visual editor.

  - Click the **Parallel** block, specify a jq expression to form an array of incoming data, and then enter the names of the branches.

    You can add new branches by clicking the **Add branch** button.

  - If necessary, in the **Additional settings** section, click the chevron icon (›) and **specify additional settings**
    - Click the **Terminate** or **Continue** button to select whether to terminate or continue the execution of the playbook if an error occurs.
    - Set the rules for aggregating the results of the playbook execution over the elements of the incoming array. After you enable the **Aggregate results** toggle switch, in the **Expression** field, specify the jq expression to use the outgoing data for the next execution steps.
    - Modify the outgoing data by specifying the jq expression in the **Output** field.
    - Click the **Merge** or **Overwrite** button to select whether to overwrite the current output data, or merge the new and the current data.

- Decision

  After you select this type of step, the **Decision** and **End of Decision** blocks are added to the visual editor. Click the **Decision** block, specify a jq expression with a condition, and the condition name.

  If necessary, add new conditions by clicking the **Add condition** button.

- Update data

  Specify the jq expressions in the **Output** field, and then select whether to overwrite the current output data or merge the new and the current data.

You can perform the following actions with playbook execution steps:

- Editing by clicking the execution step block, and then in the properties window that opens, changing the required parameters.

  > For parameters that imply entering jq expressions, syntax is highlighted and suggestions are displayed when you start typing.

- Moving through the visual editor work area by clicking and dragging the execution step block.
- Deleting by clicking the execution step block, and then pressing **`Backspace`** or **`Delete`**.

From the toolbar, you can perform the following actions:

- Opening the **Playbook settings** pane by clicking the **Settings** button.
- Opening the code editor with the DSL schema by clicking the **Show code** button.

  You can expand the code panel by clicking the (⌃) icon, and close the panel by clicking the (×) icon.

- Copying an algorithm from another playbook by clicking the **Copy algorithm** button.
- Opening the playbook response history by clicking the **View response history** button.
- Emulate the playbook launch without actually performing response actions, by clicking the **Launch in test mode** button.
- Undoing any action in visual editor by clicking the **Undo** button.
- Reverting a previously undone action by clicking the **Redo** button.
- Automatically aligning the elements by clicking the **Arrange** button.

Editing playbooks

To edit a playbook, you must have one of the following roles: Main administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

For predefined playbooks, you can only change the playbook mode and launching rule. You can also view alerts or incidents that match the predefined playbook.

You can edit a playbook only if you have permission to change the tenant to which the playbook belongs.

To edit a playbook:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. Click the name of the playbook that you want to edit.
3. In the window that opens, edit the playbook's properties. For more details on the playbook's properties that you can edit, refer to Creating playbooks.
4. If you changed the operation mode to **Auto**, in the **When launching several playbook instances at the same time** drop-down list, select one of the following actions:
   - **Add new playbook instances to the queue**. The new playbook instance will be launched after the current one is completed. By default, this action is selected.
   - **Terminate current execution and launch a new instance**. The execution of the current playbook instance will be terminated. After that, a new playbook instance is launched.
   - **Do not launch new playbook instances**. A new playbook instance will not be launched. The execution of the current playbook instance will continue.

5. If you changed the operation mode to **Manual**, in the **Action on launched playbook instances** drop-down list, select an action to apply to launching playbook instances:

   - **Terminate instances that are in progress or awaiting approval**.
   - **Terminate only the instances that are awaiting approval**.
   - **Execute all instances that are in progress or awaiting approval**.

6. Save the changes by clicking the **Save** button.

   You can also click the **Save with comment** button if you want to add a comment to the playbook before saving.

The playbook's properties are modified and saved.

Customizing playbooks

You can customize any playbook to your needs.

To customize playbooks:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. Open the playbook for editing by selecting the playbook from the list, and then clicking the **Duplicate and edit** button.
3. In the window that opens, configure the playbook's properties according to your needs.

   For more details on the playbook's properties that you can edit, refer to Creating playbooks.

   If you want to customize the playbook algorithm parameters, refer to Playbook algorithm.

   > The name of the customized playbook must be unique.

4. Click the **Save** button.

The customized playbook is modified and saved.

Viewing playbook properties

Playbooks allow you to automate workflows and reduce the time it takes to process alerts and incidents.

> To view a playbook, you must have one of the following roles: Main administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst, SOC manager, Approver, Auditor, Tenant administrator.

To view a playbook's properties:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. In the list of playbooks, click the name of the playbook that you want to view.

   The window that opens contains information about the playbook.

In the **Playbook settings** pane on the right, the following general information is displayed:

- **Tenant and inheritance**. Name of the tenant to which the playbook belongs.
- **Name**. Name of the playbook.
- **Scope**. Playbook scope. Possible values: **Alert** or **Incident**.
- **Operation mode**. Playbook operation mode. Possible values: **Auto**, **Training**, **Manual**.

  If the playbook operation mode is set to **Auto**, the **When launching several playbook instances at the same time** filed is displayed. Possible values: **Do not launch new playbook instances**, **Terminate current execution and launch a new instance**, **Add new playbook instances to the queue**.
- **Tags**. Tags assigned to the playbook.
- **Description**. Playbook description.
- **Additional settings**. Optional settings specified when creating the playbook.

In the visual editor work area on the left, the playbook trigger and algorithm (playbook execution steps) are displayed.

> You can edit the playbook's properties if you have one of the following roles: Main administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

You can view the playbook response history by clicking the **View response history** button in the toolbar. The list of all playbooks or response actions launched within the playbook opens. You can terminate any launched playbooks or response actions by clicking the **Terminate** button.

If necessary, you can group and filter the data in the table as follows:

- Click the settings icon (⚙), and then select the columns to be displayed in the table.
- Click the filter icon (▽), and then specify and apply the filter criterion in the invoked menu.

  > When you apply the filter criterion for the **Status** column, the table displays the manually launched responses whose status contains the selected value and the playbooks that include response actions whose status contains the selected value. It means that only the response actions of the playbook that meet the filter criterion will be displayed.

  The filtered table of playbooks is displayed.

The resource table contains the following columns:

- **Actions**. Response action name.
- **Response parameters**. Response action parameters that are specified in the playbook algorithm.
- **Start**. Date and time the playbook or response action was launched.
- **End**. Date and time the playbook or response action was completed.
- **Alert or incident ID**. ID that contains a link to the alert or incident details.
- **Launched by**. Name of the user who launched the playbook or response action.
- **Approver**. Name of the user who approved the launch of the playbook or response action.

  By default, this column is hidden. To display the column, click the settings icon (⚙), and then select the **Approver** column.
- **Approval time**. Date and time when the user confirmed or rejected the launch of the playbook or response action.

  By default, this column is hidden. To display the column, click the settings icon (⚙), and then select the **Approval time** column.
- **Status**. Execution status of the playbook. The following values can be shown in this column:
  - **Awaiting approval**—Playbook awaiting approval for launch.
  - **In progress**—Playbook is in progress.
  - **Success**—Playbook is completed without errors or warnings.
  - **Warning**—Playbook is completed with warnings.
  - **Error**—Playbook is completed with errors.
  - **Terminated**—Playbook is completed because the user interrupted the execution.
  - **Approval time expired**—Playbook is completed because the approval time for the launch has expired.
  - **Rejected**—Playbook is completed because the user rejected the launch.

  You can click the **Status** value to open the window with the result of the playbook launch. The Launch ID can be used by Technical Support to download the data necessary for analysis in case of the execution errors. By default, the data is stored for 72 hours.
  If the status is **In progress**, you can view the Launch ID by hovering the mouse cursor over the icon next to the status.
- **Assets**. Number of the assets for which the playbook or response action is launched. You can click the link with the number of the assets to view the asset details. The field is empty, if the playbook or response action does not involve assets.

You can also view response history from the **Response history** section or from alert or incident details.

Terminating playbooks

You can forcibly terminate the launched playbook. In this case, the uncompleted response actions will be terminated. The completed response actions will not be canceled after the termination of the playbook.

To terminate a playbook, you must have one of the following roles: Main administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

To terminate a playbook:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. In the list of playbooks, do one of the following:
   - Select the required playbook, and then in the toolbar click the **View history** button.
   - Click the name of the required playbook, and then, in the window that opens, click the **View history** button.
3. Select **View response history**.
   The pane with the list of the launched playbook instances opens.
4. Select one or several instances that you want to terminate, and then click the **Terminate** button, and confirm your selection.

The playbook is terminated.

Deleting playbooks

Predefined playbooks cannot be deleted.

To delete a custom playbook, you must have one of the following roles: Main administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

To delete a custom playbook:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. Select the playbook from the list, and then click the **Delete** button.
3. In the confirmation dialog box, click **Delete**.

   The playbook cannot be deleted if there are launched playbook instances. In this case, terminate all launched instances before deleting the playbook.

If you deleted a playbook in the **Active** or **Unavailable** status, the playbook is displayed in the playbooks table with the **Deleted** status and is only available for viewing and copying.

Playbooks in the **Deleted** status are deleted permanently.

Managing playbook versions

Kaspersky EDR Expert stores a version history of playbooks. A new version is created automatically when you create a playbook or save changes to an existing one. You can manage versions of playbooks only after they are published. Version management does not apply to playbook drafts.

A newly published playbook is assigned version `1`. Each time you save changes, the version number increases by one. The latest saved version is marked as `Current` in the version list.

If you upgrade from Kaspersky EDR Expert version 2.0, a playbook version will be assigned to the existing playbook after you edit it for the first time. The previous version of the existing playbook will also be saved and available for comparison with the latest version.

Comparing playbook versions

Kaspersky EDR Expert allows you to compare different versions of a playbook to track changes and restore previous versions.

To do this, you must have one of the following XDR roles: Main administrator, Tenant administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst, SOC manager, Approver, Auditor.

To compare playbook versions:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. In the list of playbooks, select the playbook for which you want to compare versions.
3. Click the **View history** button, and then select **View version history**.

   The **Playbook version history** window opens.
4. In the playbook versions list, select two versions to compare, and then click the **Compare** button.

   A window that displays the differences between playbook versions appears. Note that you cannot edit the playbook in this window.

   If necessary, in the window that opens, you can choose different playbook versions to compare.

Playbook versions are compared.

Restoring playbook versions

You can restore a previous version of a playbook at any time.

To do this, you must have one of the following XDR roles: Main administrator, Tenant administrator, SOC administrator, Tier 1 analyst, Tier 2 analyst.

To restore a playbook version:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. In the list of playbooks, select the playbook for which you want to restore a previous version.

   Alternatively, you can click the playbook name.
3. Click the **View history** button, and then select **View version history**.

   The **Playbook version history** window opens.
4. In the playbook versions list, find the version that you want to restore.

   If you want to view the details of the selected playbook version, click the version name.
5. In the **Action** column, click the **Restore** button.
6. In the confirmation dialog box that opens, click **Restore**.

   If necessary, you can add a comment. If you do not add one, a comment is added automatically indicating the version from which the playbook was restored.

A previous version of the playbook is restored.

Launching playbooks in test mode

You can launch playbooks in test mode to debug them or validate the result. During a test run, the playbook processes selected alerts and incidents but does not perform any actions on assets.

Launching in test mode is available for playbooks with any status.

To launch a playbook in test mode, you must have one of the following roles: Main administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

To launch a playbook in test mode:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. Do one of the following:
   - Click the name of the playbook that you want to edit. In the **Playbook details** window that opens, click the **Launch in test mode**.
   - Select the playbook from the list, and then click the **Launch in test mode** button.

     Depending on the playbook's scope, either a **Select incident** or a **Select alert** is invoked.
3. Select the incident or the alert in the invoked panel.

   If the playbook requires selecting observables and assets, enable the **Select target objects before launching the playbook** option.
4. Click **Launch**.

   If you enabled the **Select target objects before launching the playbook** option, the **Target objects** is invoked. Select the objects from the **Observables** and **Assets** tabs for which you want to launch the playbook, and then click the **Apply and launch** button.
5. The **Playbook launched in test mode** popup appears. When the test run finishes, the **Playbook is completed in test mode** popup is shown. Click the **View results** link in this popup to display the panel that shows the result. If the test run succeeded, the **Playbook success** panel is invoked. If the test run failed, the **Playbook Error** panel is invoked.

   Test run results are saved in the **Response history** section of the playbook. Test run results are not shown in the general Response history section.

Launching playbooks and response actions

Launching playbooks

Depending on your needs, you can configure the way to launch the playbook. You can select one of the following operation modes during the playbook creation:

- **Auto**. Select this operation mode if you want to automate the launch of playbook and response actions.

  Playbooks in this mode help automate threat response, and also reduce the time it takes to analyze alerts and incidents.
- **Training**. Select this operation mode if you want to check if the playbook is configured correctly.

  Playbooks in this mode will not be launched automatically when a corresponding alert or incident is detected. Instead, the playbook requests the user's approval to launch.
- **Manual**. Select this operation mode if you want to launch the playbook manually only.

  Playbooks in this mode have no trigger, so you can launch such playbooks for any alert or incident, depending on the selected playbook scope. For more details, see Launching playbooks manually.

You can also change the operation mode of the existing playbook. For more details, see Editing playbooks.

Launching response actions

Response actions can be launched manually, automatically within a playbook, or can be configured to request the user's approval before launching within the playbook. By default, manual approval of the response action is disabled.

For more details on how to configure the manual approval of a response action launched within the playbook, see Configuring manual approval of response actions.

Launching playbooks manually

Kaspersky EDR Expert allows you to manually launch any playbook that matches alerts or incidents you want to respond to.

To launch a playbook manually, you must have one of the following roles: Main administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

You can also launch a playbook for observables and assets if you have specified these objects when creating the playbook and when launching it.

Launching a playbook for an alert

To launch a playbook manually for an alert:

1. In the main menu, go to the **Monitoring** → **Alerts** section.
2. In the table of alerts, click the link with the ID of the alert for which you want to launch the playbook.
3. In the **Alert details** window that opens, click the **Select playbook** button.

   The **Select playbook** window opens.
4. In the list of playbooks that match the alert, select the playbook you want to launch, and then click the **Launch** button.

   If the selected playbook is already running for this alert, in the **Monitoring** window that appears, do one of the following:

   - If you want to wait until the current playbook instance is completed, click the **Wait and launch** button.

     The new playbook instance will be launched after the current one is completed.
   - If you want to launch a new playbook instance immediately, click the **Terminate and launch a new one** button.

     The current playbook instance will be terminated and the new one will be launched.
   - If you want to cancel the new playbook launch, click the **Close** button (✕).

If the selected playbook already has the status **Awaiting approval**, after manual launch, the playbook status will change to **Launched**.

The playbook is launched for the selected alert. After the playbook is completed, you will receive a notification.

Launching a playbook for an incident

To launch a playbook manually for an incident:

1. In the main menu, go to **Monitoring** → **Incidents**, and then select the **XDR incidents** tab.
2. In the table of incidents, click the link with the ID of the incident for which you want to launch the playbook.
3. In the **Incident details** window that opens, click the **Select playbook** button.

   The **Select playbook** window opens.
4. In the list of playbooks that match the incident, select the playbook you want to launch, and then click the **Launch** button.

   If the selected playbook is already running for this incident, in the **Monitoring** window that appears, do one of the following:

   - If you want to wait until the current playbook instance is completed, click the **Wait and launch** button.

     The new playbook instance will be launched after the current one is completed.
   - If you want to launch a new playbook instance immediately, click the **Terminate and launch a new one** button.

     The current playbook instance will be terminated and the new one will be launched.
   - If you want to cancel the new playbook launch, click the **Close** button (✕).

If the selected playbook already has the status **Awaiting approval**, after manual launch, the playbook status will change to **Launched**.

The playbook is launched for the selected incident. After the playbook is completed, you will receive a notification.

Launching playbooks for objects specified by users

You can specify observables and assets for which a playbook must run. You have to create a playbook with the following settings:

- In the **Scope** list, select **Alert** or **Incident**.
- In the **Operation mode** list, select **Manual**.
- In the workspace of the visual editor, when Configuring playbook execution steps in visual editor, use jq expressions to specify the objects (observables or assets) for which you want to start the playbook. These objects will be the input to the playbook when it is launched.

If you do not specify the objects in the playbook algorithm and only select them before launching the playbook, these objects will be ignored.

After the playbook is created, you can launch it for the selected objects.

To do this, you must have one of the following EDR roles: Main administrator, Tier 1 analyst, Tier 2 analyst, or Tenant administrator.

To launch a playbook for the selected objects:

1. In the main menu, go to the **Monitoring** section, and then in the **Alerts** or **Incidents** section, click the ID of the alert or incident from which you want to launch the playbook.
2. In the details window that opens, click the **Select playbook** button.

   The **Select playbook** window opens.
3. Select the **Select target objects before launching the playbook** option, and then click the **Launch** button.
4. In the **Target objects** window that opens, select the objects from the **Observables** and **Assets** tabs for which you want to launch the playbook, and then click the **Apply and launch** button.

   The playbook is launched for the objects you selected.

You can view the result of the playbook from the **History** tab in the alert or incident details, from the playbook details or playbooks table by clicking the **View history** button, and from the Response history section.

For example, you write a script that is called during the executeCustomScript response action. When creating a playbook, in the visual editor work area, you add the **Run custom script** execution step with the playbook input data. Then, you have to run the script for an observable with an IP type that you select when launching the playbook. The script uses the IP address that you selected as a parameter:

```
{
 "dslSpecVersion": "1.1.0",
 "version": "1",
 "actionSpecVersion": "1",
 "executionFlow": [
 {
 "action": {
 "function": {
```

```
 "type": "executeCustomScript",
 "params": {
 "commandLine": "./script.py",
 "commandLineParameters": "${ \"-ip \" + ([.input.observables[] | select(.type == \"ip\")] | map(.value) |
join(\",\")) }",
 "workingDirectory": "/folder/with/script"
 }
 },
 "onError": "stop"
 }
 },
 {
 "action": {
 "function": {
 "type": "updateBases",
 "params": {
 "wait": false
 },
 "assets": "${ [.input.assets[] | select(.Type == \"host\") | .ID] }"
 }
 }
 }
 ]
}
```

Several objects will be an input to the playbook, and the list of IP addresses separated with commas must be an input to the script:

```
{
 "input": {
 "observables": [
 {
 "type": "ip",
 "value": "127.0.0.1"
 },
 {
 "type": "ip",
 "value": "127.0.0.2"
 },
 {
 "type": "md5",
 "value": "29f975b01f762f1a6d2fe1b33b8e3e6e"
 }
 ],
 "assets":[
 {
 "AttackerOrVictim": "unknown",
 "ID": "c13a6983-0c40-4986-ab30-e85e49f98114",
 "InternalID": "6d831b04-00c2-44f4-b9e3-f7a720643fb7",
 "KSCServer": "E5DE6B73D962B18E849DC0BF5A2BA72D",
 "Name": "VIM-W10-64-01",
 "Type": "host"
 }
 ]
}
```

After jq expressions perform calculations on the playbook operational data, the following information is passed as command line parameters:

```
-ip 127.0.0.1,127.0.0.2
```

For a playbook expecting input data, if you specified different types of objects when creating the playbook and when launching it, or if you did not select the **Select target objects before launching the playbook** option, the playbook will finish with one of the following results:

- An error will occur because the playbook did not receive input data.
- The action will not be performed because the playbook contains a condition or a loop that is based on the input data.
- The result will depend on the response of the application, or service, or script that performs the action.

Launching playbooks in the Training operation mode

The **Training** operation mode allows you to check if the playbook is configured correctly. This can be helpful if you are planning to change the playbook operation mode to **Auto**.

All playbooks in the **Training** operation mode request the user's approval to launch.

> To launch a playbook in the **Training** operation mode, you must have one of the following roles: Main administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

In the **Training** operation mode, the playbook is triggered by alerts or incidents, but requires manual approval before launch. You can test launching the playbook in the **Training** operation mode in one of the following ways:

- Create an alert or incident that matches the playbook trigger.
- Edit an alert or incident that matches the playbook trigger. The alert or incident must be in a status other than **Closed**.

  > Editing an alert or incident triggers the playbook only if the trigger is set to respond to manual changes. By default, manual changes to an alert or incident are ignored. To make the playbook respond to manual changes, the trigger must use the `event.manual` function. For details, refer to Playbook trigger.

When one of the above actions is completed, the playbook requests the user's approval to launch. For more information on how to approve the playbook, see Approving playbooks or response actions.

> The manual approval for launching the playbook is limited to 60 minutes.

Configuring manual approval of response actions

Kaspersky EDR Expert allows you to configure manual approval of a response action launched within a custom playbook. By default, manual approval of the response action is disabled.

Before configuring manual approval, make sure that email notifications for tenants are configured and the email address of the approver is specified.

We recommend that you configure manual approval of the following response actions: moving devices to another administration group, moving files to quarantine, enabling and disabling network isolation, responding on accounts through Active Directory, and data enrichment.

To configure manual approval of a response action:

1. In the main menu, go to **Monitoring** → **Playbooks**.
2. Open the playbook for editing by doing one of the following:
   - Click the name of the playbook that you want to edit. In the **Playbook details** window that opens, click the **Edit** button.
   - Select the playbook from the list, and then click the **Edit** button.

     If you select more than one playbook, the **Edit** button will be disabled.

   The **Edit playbook** window opens.
3. In the **Algorithm** section, specify one of the following parameters for the response action for which you want to enable the manual approval:
   - To enable the manual approval of a response action with the default approval time, specify the following parameter:

     ```
     "manualApprove": true
     ```

     By default, the approval time is 60 minutes.

- To enable the manual approval of a response action with an adjustable approval time, specify the following parameter:

  ```
  "manualApprove": {"timeout": "period"}
  ```

  where `"period"` is an adjustable approval time.

  You can configure the approval time in hours (h) and/or minutes (m), for example:

  ```
  "manualApprove": {"timeout": "20h"}
  "manualApprove": {"timeout": "2h30m"}
  ```

- To enable the manual approval of a response action with notifications sent to the email address of the approver, specify the following parameter:

  ```
  "emailNotifications": {
   "enabled":true
  }
  ```

- To enable the manual approval of a response action with a notification that is sent to the email address of the approver after a certain period, specify the following parameter:

  ```
  "manualApprove": {
   "emailNotifications": {
   "enabled": true,
   "delay": "period"
   }
  ```

  where `"period"` is an adjustable sending time.

  You can configure the sending time in minutes (m), for example:

  ```
  "delay": "20m"
  ```

4. Click the **Save** button.

Manual approval of a response action is configured. Email notifications with a request to approve the response action will be sent to the email specified in the user account properties.

You can view requests for approval of response actions in the **Approval requests** section.

Approving playbooks or response actions

All playbooks in the **Training** operation mode require a user's approval. You can also configure manual approval of response actions launched within the playbook.

To approve or reject a playbook launch, you must have one of the following roles: Main administrator, Tier 1 analyst, Tier 2 analyst, Tenant administrator.

To approve or reject a response action launch, you must have one of the following roles: Main administrator, Approver, Tenant administrator.

If any playbooks or responses are awaiting a user's approval, a notification is displayed in the upper part of the OSMP Console. Additionally, if the user's approval is required for the response action launch, an email notification is sent to the email address within the time period specified in the algorithm of the playbook.

Viewing the list of playbooks and response actions

To view the list of playbooks and response actions that are awaiting approval, do one of the following:

- Click the **View approval requests** link in the upper part of the OSMP Console.
- Follow the link in the notification that is sent to your email address.

The **Approval requests** pane with the table that contains the full list of approval requests opens.

The **Approval requests** table contains the following columns:

- **Time**. Date and time when a playbook or a response action requested a user's approval.
- **Approval due date**. Date and time by which the user must approve or reject the playbook or the response action. If the user has not approved the playbook or the response action by this time, the launch is canceled.
- **Playbook**. Name of a custom or predefined playbook that requests a user's approval.
- **Response action**. Actions that are launched within playbooks.
- **Assets**. Number of the assets for which the playbook or response action is launched. You can view the list of assets for which the user's approval is requested by clicking the link with the number of the assets.
- **Response parameters**. Response action parameters that are specified in the response action or playbook algorithm.
- **Alert or incident ID**. ID that contains a link to the alert or incident details.

Approving and rejecting playbooks

To approve or reject playbooks:

1. In the notification at the top of the OSMP Console, click the **View approval requests** link.

   A notification with the **View approval requests** link is displayed only if there is a playbook that is waiting for a user's approval.

2. In the **Approval requests** pane that opens, select one or more playbooks, and then do one of the following:

   - To approve the launching of a playbook, click the **Approve** button.

     After that, the playbook is launched. The action status in the **Response history** sections changes to **In progress**.

   - To decline the launching of a playbook, click the **Reject** button.

     After that, the launching of the playbook is canceled. The action status in the **Response history** sections changes to **Rejected**.

3. Click the **Close** button (×) to close the **Approval requests** pane.

After approving or rejecting playbooks, you can view their statuses in the **Response history** section.

Approving and rejecting response actions

To approve or reject response actions:

1. In the notification at the top of the OSMP Console, click the **View approval requests** link.

   A notification with the **View approval requests** link is displayed only if there is a response action that is waiting for a user's approval.

   The **Approval requests** pane opens.

2. In the **Approval requests** pane that opens, in the **Assets** column, click the link with the number of assets.

   The **Assets to approve** pane that contains the full list of assets opens.

3. Check the list of assets for which the manual approval is required, and then do one of the following:

   - To approve the launch of a response action for assets, select one or more assets you need, and then click the **Approve** button. After that, the response action for the selected assets is launched.

   - To decline the launch of a response action for assets, select one or more assets you need, and then click the **Reject** button. After that, the launch of the response action for the selected assets is canceled.

4. Click the **Close** button (×) to close the **Assets to approve** pane.

5. Click the **Close** button (×) to close the **Approval requests** pane.

After approving or rejecting response actions, you can view their statuses in the **Response history** section.

Enrichment from playbook

After you configure integration between Kaspersky EDR Expert and Kaspersky TIP, you can obtain information about the reputation of observables related to an alert or incident from Kaspersky TIP or Kaspersky OpenTIP, and then enrich the obtained data.

> You can obtain information only for observables with the following types: domain, URL, IP, MD5, SHA256.

You can configure data enrichment to run automatically. To do this, when creating or editing a playbook, in the visual editor work area you must add the Configuring playbook execution steps in visual editor, and specify the following:

1. Limit for data returned by Kaspersky TIP or Kaspersky OpenTIP, if necessary.

   You can specify one of the following values:

   - All records
   - Top100

     > This value is set by default.

2. Observable for which the playbook requests data from Kaspersky TIP or Kaspersky OpenTIP.

   > Data enrichment is performed by using the service specified in the integration with Kaspersky Threat Intelligence Portal.

In the playbook algorithm, you can use the output enrichment parameters that are displayed in the fields that Kaspersky TIP returns.

You can view the enrichment result for all observables related to an alert or incident in one of the following ways:

- From the alert or incident details
- From a response history
- From a playbook

To view an enrichment result:

1. In the main menu, go to **Monitoring**, and then do one of the following:

   - If you want to view the result from an alert or incident details, go to the **Alerts** or **Incidents** section, and then click the ID of the alert or incident for which the enrichment was performed. In the window that opens, go to the **History** tab, and then select the **Response history** tab.

   - If you want to view the result from a response history, go to the **Response history** section.

   - If you want to view the result from the playbooks table, go to the **Playbooks** section, and do one of the following:

     - Select the playbook for which the enrichment was performed. In the toolbar, click the **View history** button, and then select **View response history**.

     - Click the name of the playbook for which the enrichment was performed. In the window that opens, click the **View history** button, and then select **View response history**.

2. In the **Action status** column, click the status of the playbook for which you want to view the enrichment result.

You can also obtain the information from Kaspersky TIP, and then enrich data manually on the **Observables** tab in alert or incident details.

Viewing response history

The **Response history** section allows you to view the detailed response history for all detected alerts and incidents. Note that if an alert or incident is deleted, the response history for this alert or incident is not displayed.

> To view a response history, you must have one of the following roles: Main administrator, Tier 1 analyst, Tier 2 analyst, SOC manager, Junior analyst, Approver, Auditor, Tenant administrator.

To view a response history, in the main menu, go to **Monitoring** → **Response history**. The table that contains the response history for all alerts and incidents opens.

By default, the table is sorted according to the time the playbook or response action was launched. The response actions in the playbooks are sorted according to their order in the playbook algorithm.

The toolbar in the upper part of the table allows you group and filter the data in the table as follows:

- Click the settings icon (⚙), and then select the columns to be displayed in the table.

- Click the filter icon (▽), and then specify and apply the filter criterion in the invoked menu.

  > When you apply the filter criterion for the **Action status** column, the table displays the manually launched responses whose status contains the selected value and the playbooks that include the response actions whose status contains the selected value. It means that only the response actions of the playbook that meet the filter criterion will be displayed.

Table search is available for all columns except **Action status** and **Playbook status**. To filter data in these columns, click the column header and select the required status from the drop-down list.

The resource table contains the following columns:

- **Actions**. Response action or playbook name.
- **Response parameters**. Response action parameters that are specified in the response action or playbook algorithm.
- **Start**. Date and time the playbook or response action was launched.
- **End**. Date and time the playbook or response action was completed.
- **Alert or incident ID**. ID that contains a link to the alert or incident details.
- **Launched by**. Name of the user who launched the playbook or response action.
- **Action status**. Execution status of the response action. The following values can be shown in this column:
  - **Awaiting approval**—Response action awaiting approval for launch.
  - **In progress**—Response action is in progress.
  - **Success**—Response action is completed without errors or warnings.
  - **Warning**—Response action is completed with warnings.
  - **Error**—Response action is completed with errors.
  - **Terminated**—Response action is completed because the user interrupted the execution.
  - **Approval time expired**—Response action is completed because the approval time for the launch has expired.
  - **Rejected**—Response action is completed because the user rejected the launch.

  Devices on which network isolation has been enabled may receive a **Success** status before the isolation process is complete.

- **Playbook status**. Execution status of the playbook. The following values can be shown in this column:
  - **Awaiting approval**—Playbook awaiting approval for launch.
  - **In progress**—Playbook is in progress.
  - **Success**—Playbook is completed without errors or warnings.
  - **Warning**—Playbook is completed with warnings.
  - **Error**—Playbook is completed with errors.
  - **Terminated**—Playbook is completed because the user interrupted the execution.
  - **Approval time expired**—Playbook is completed because the approval time for the launch has expired.
  - **Rejected**—Playbook is completed because the user rejected the launch.

You can click the **Playbook status** value or the **Action status** value to open the window with the result of the playbook or the response action launch. The Launch ID displayed on the **Debug data** tab can be used by Technical Support to download the data necessary for analysis in case of the execution errors. By default, the data is stored for 72 hours.
If the status is **In progress**, you can view the Launch ID by hovering the mouse cursor over the icon next to the status.

- **Assets**. Number of the assets for which the playbook or response action is launched. You can click the link with the number of the assets to view the asset details. The field is empty, if the playbook or response action does not involve assets.
- **Tenant**. Name of the tenant to which the playbook belongs.
- **Approver**. Name of the user who approved or rejected the playbook or response action launch.

  By default, this column is hidden. To display the column, click the settings icon (⚙), and then select the **Approver** column.
- **Approval time**. Date and time the playbook or response action launch was approved or rejected. This column is not displayed by default.

  By default, this column is hidden. To display the column, click the settings icon (⚙), and then select the **Approval time** column.

Predefined playbooks

Kaspersky EDR Expert provides ready-to-use predefined playbooks that are created by Kaspersky experts. Predefined playbooks are based on KUMA correlation rules. For more information on the KUMA correlation rules included in the distribution kit, see Correlation rules.

You can find predefined playbooks in the **Playbooks** section. Such playbooks are marked with the tag **Predefined** and the [KL] prefix in the name.

Note that you cannot edit the parameters of a predefined playbook, except for the **Operation mode** and the **Action on launched playbook instances** fields. If you want to edit other parameters of a predefined playbook, you need to duplicate the playbook, and then use it as a template to create a custom playbook. For details, refer to Customizing playbooks.

Before using the predefines playbooks, you must do the following in KUMA:

- Configure the enrichment rule settings for the event enrichment with the **Event** type selected as the **Source kind** setting. Specify the **VictimUserID** and **AttackerUserID** values in the **Target field**.
- Configure enrichment in KUMA to get Windows Event Log.

Predefined playbooks cannot be deleted.

Predefined playbooks belong to the parent tenant and are inherited by all child tenants.

[KL] P001 "Creation of executable files by office applications"

This playbook is not available under the EDR license.

This playbook contains the Responding through KASAP response action, and can be used only as a template. If you want to launch the playbook, click the **Duplicate and edit** button. In the window that opens, in the **Assign KASAP group** action, specify the KASAP group ID.

Before using the playbook, you must configure enrichment in KUMA to get Windows Event Log.

By default, the playbook launches the response actions for all users in the alert. If you want the playbook to launch the response actions only for the victim account, you can do the following:

1. In KUMA, configure the enrichment rule settings. For the event enrichment that has the **Event** type selected as the **Source kind** setting, specify the **VictimUserID** value in the **Target field**.

2. In the **Assign KASAP group** action, specify `and .IsVictim` in the **Assets** field, as shown below:

   ```
   [ alert.Assets[] | select(.Type == \"user\" and .IsVictim) | .ID]
   ```

The **[KL] P001 "Creation of executable files by office applications"** predefined playbook allows you to prevent an attacker from using office applications, for example, to perform a phishing attack when a user opens an infected document, and then the document creates an executable file and executes it.

The alert that triggers the playbook is created according to the *Creation of executable files by office applications* correlation rule. This rule helps to detect the creation of files with suspicious extensions such as scripts and executable files on behalf of office applications.

The playbook trigger contains the following expression:

```
[.OriginalEvents[] | .ExternalID == "R350"] | any
```

During execution, this playbook launches the following response actions:

1. Responding through Active Directory, and then resetting the passwords of both the attacker and the victim accounts.

   If an error occurs during the execution of the response action, the playbook is terminated.

2. Responding through KASAP, and then assigning an information security course to the account.

   If an error occurs during the execution of the response action, the execution of the playbook will continue.

The playbook algorithm contains the following sequence of response actions:

```
{
```

```
 "dslSpecVersion": "1.1.0",
 "version": "1",
 "actionSpecVersion": "1",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "resetLDAPPassword",
 "assets": "${[ alert.Assets[] | select(.Type == \"user\") | .ID]}"
 },
 "onError": "stop"
 }
 },
 {
 "action": {
 "function": {
 "type": "assignKasapGroup",
 "assets": "${[ alert.Assets[] | select(.Type == \"user\") | .ID]}",
 "params": {
 "groupId": "SET KASAP GROUP ID"
 }
 },
 "onError": "continue"
 }
 }
 ]
}
```

[KL] P002 "Windows Event Log was cleared"

By default, this playbook operates in the **Manual** operation mode. We do not recommend switching this playbook to the **Auto** or the **Training** operation mode.

Before using the playbook, you must do the following in KUMA:

- Configure the enrichment rule settings for the event enrichment that has the Event type selected as the Source kind setting. Specify the **AttackerUserID** value in the **Target field**.
- Configure enrichment in KUMA to get Windows Event Log.

The **[KL] P002 "Windows Event Log was cleared"** predefined playbook allows you to prevent an attacker from clearing the Windows Event Log, because the log contains sufficient telemetry for an investigation of the attacker's malicious activity.

The incident that triggers the playbook contains one or several alerts created according to the *Windows Event Log was cleared* correlation rule. This rule helps to detect when Windows logs are cleared or deleted by using the wevutil utility, the user interface, or PowerShell commands. To enable the creation of the incident, you have to configure segmentation rules.

The playbook trigger contains the following expression:

```
[.Alerts[] | .OriginalEvents[] | .ExternalID == "R050"] | any
```

During execution, this playbook launches the Responding through Active Directory response action, and then blocks the account of the attacker.

If an error occurs during the execution of the response action, the playbook is terminated.

If one or several alerts in the incident are generated by another correlation rule, the playbook does not apply to those alerts.

The playbook algorithm contains the following sequence of response actions:

```
{
 "dslSpecVersion": "1.1.0",
 "version": "1",
 "actionSpecVersion": "1",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "blockLDAPAccount",
 "assets": "${[ incident.Alerts[] | select(.OriginalEvents[] | .ExternalID == \"R050\") | .Assets[] | select(.Type
== \"user\" and .IsAttacker) | .ID]}"
 },
 "onError": "stop"
 }
 }
 ]
}
```

[KL] P003 "Suspicious child process from wmiprvse.exe"

Before using the playbook, you must do the following in KUMA:

- Configure the enrichment rule settings for the event enrichment that has the Event type selected as the Source kind setting. Specify the **AttackerUserID** value in the **Target field**.
- Configure enrichment in KUMA to get Windows Event Log.

The **[KL] P003 "Suspicious child process from wmiprvse.exe"** predefined playbook allows you detect pairs of parent and child processes that deviate from the norm and must be viewed as suspicious.

The alert that triggers the playbook is created according to the *R297_Suspicious child process from wmiprvse.exe* correlation rule. This rule helps to detect the launch of suspicious processes on behalf of wmiprvse.exe.

The playbook trigger contains the following expression:

```
[.OriginalEvents[] | .ExternalID == "R297"] | any
```

During execution, this playbook launches the following response actions:

1. Responding through Active Directory, and then blocks the account of the attacker.
2. Terminating the process on the device that is registered in the alert.

3. Running a malware scan, and then a full scan is performed on the device where the alert is detected.

> By default, network drives are not scanned, to avoid overloading the system. If you want to scan the network drives, you have to duplicate this playbook, and then in the **Run malware scan** action, enable the **Scan network drives** toggle switch or set the `allowScanNetworkDrives` parameter to `true` in the code editor.

The playbook algorithm contains the following sequence of response actions:

```
{
 "dslSpecVersion": "1.1.0",
 "version": "1",
 "actionSpecVersion": "1",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "blockLDAPAccount",
 "assets": "${[ alert.Assets[] | select(.Type == \"user\" and .IsAttacker) | .ID]}"
 },
 "onError": "stop"
 }
 },
 {
 "loop": {
 "input": "${ [alert.OriginalEvents[] | [select(.DestinationProcessName != null and .DestinationProcessName !=
\"\")][] | .DestinationProcessName] }",
 "onError": "stop",
 "steps": [
 {
 "action": {
 "function": {
 "type": "killProcess",
 "params": {
 "path": "${ .[0] }"
 },
 "assets": "${[ alert.Assets[] | select(.Type == \"host\") | .ID]}"
 }
 }
 }
 ]
 }
 },
 {
 "action": {
 "function": {
 "type": "avScan",
 "params": {
 "scope": {
 "area": "full",
 "allowScanNetworkDrives": false
 },
 "wait": false
 },
 "assets": "${[ alert.Assets[] | select(.Type == \"host\") | .ID]}"
 },
 "onError": "stop"
 }
 }
 ]
}
```

If an error occurs during the execution of any response action, the playbook is terminated.

[KL] P004 "Sandbox Medium Detect"

The **[KL] P004 "Sandbox Medium Detect"** predefined playbook creates a rule to block execution of files assigned **Medium** alert severity by the Sandbox component during analysis.

The playbook trigger contains the following expression:

```
"event.new and .Severity == \"medium\" and any(.DetectionTechnologies[] == \"SB\"; .)"
```

ResponseFunction used by the playbook: `addFilePreventionRules`.

During execution, this playbook uses the Add Prevention Rule response action.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "addFilePreventionRules",
 "assets":[
 "selector": "execution-tenant"
 },
 "params": {
 "files": "${[alert.ScannedFiles[] | select(any(.DetectionTechnologies[] == \"SB\"; .)) | .Hashes | map(.Value)] |
flatten}",
 "notify": true
 }
 },
 "onError": "stop"
 }
 }
 ]
}
```

[KL] P005 "Sandbox High Detect"

The **[KL] P005 "Sandbox High Detect"** predefined playbook creates a rule to block execution of files assigned **High** alert severity by the Sandbox component during analysis.

The playbook trigger contains the following expression:

```
"event.new and .Severity == \"high\" and any(.DetectionTechnologies[] == \"SB\"; .)"
```

ResponseFunction used by the playbook: `addFilePreventionRules`.

During execution, this playbook uses the Add Prevention Rule response action.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
```

```
 "actionsSpecVersion": "1",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "addFilePreventionRules",
 "assets":[
 "selector": "execution-tenant"
 },
 "params": {
 "files": "${[alert.ScannedFiles[] | select(any(.DetectionTechnologies[] == \"SB\"; .)) | .Hashes | map(.Value)] |
flatten}",
 "notify": true
 }
 },
 "onError": "stop"
 }
 }
 ]
}
```

[KL] "Playbook for checking external IP addresses"

The **[KL] "Playbook for checking external IP addresses"** predefined playbook is triggered upon detecting a connection to an external IP address, and it initiates the Kaspersky TIP enrichment process. If the enrichment results indicate a threat score higher than 80, forensics data (a list of processes) is requested for assets of the "host" type, and network isolation is enabled.

Additional information about the playbook:

- Kaspersky TIP integration must be configured for the playbook to function correctly.
- Integration with Active Directory is required to perform account lockout actions.
- If the enrichment result indicates a threat score below 80, the playbook terminates.
- Playbook execution will stop if an error occurs during any of the steps.
- The "Enable network isolation" action requires manual approval during playbook execution.

The playbook trigger contains the following expression:

```
"event.new and ([ .Alerts[] | .Observables[] | select(.Value | test("^(10\\.|172\\.(1[6-
9]|2[0-9]|3[01])\\.|192\\.168\\.|127\\.)") | not) | .Value ] | length > 0)"
```

ResponseFunction used by the playbook: `iocsEnrichment, getForensics, netIsolateOn`.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "iocsEnrichment",
 "params": {
 "fullEnrichment": true,
 "observables": "${[ incident.Alerts[] | .Observables[] | {\"type\": .Type, \"value\": .Value } |
select(.type==\"ip\" and (.value | test(\"^(10\\\\.|172\\\\.(1[6-9]|2[0-
9]|3[01])\\\\.|192\\\\.168\\\\.|127\\\\.)\") | not)) ] | unique_by(.value)}"
```

```
}
},
"onError": "stop",
"timeout": {
"scheduleToCloseTimeout": "24h"
},
"output": {
"filter": "${.}",
"action": "overwrite"
}
}
},
{
"decision": {
"conditions": [
{
"condition": "${\"${([.details.observableData[] | select(.status == \\\"ok\\\" and
.ipObservableData.ipGeneralInfo.threatScore > 80)] | length > 0)}\"}",
"name": "Condition 1",
"steps": [
{
"decision": {
"conditions": [
{
"condition": "${incident.Alerts | map(.Assets) | flatten | map(select(.Type == \"host\")) | length > 0}",
"name": "alert has host(s)",
"steps": [
{
"action": {
"function": {
"type": "getForensics",
"assets": "${incident.Alerts | map(.Assets) | flatten | map(select(.Type == \"host\")) | map(.ID)}",
"params": {
"processes": {
"collect": true
},
"autoruns": {
"collect": false
}
}
},
"onError": "stop",
"timeout": {
"scheduleToCloseTimeout": "24h"
}
}
},
{
"action": {
"function": {

}
},
"onError": "stop",
"timeout": {
"scheduleToCloseTimeout": "24h"
},
"manualApprove": {
"timeout": "60m",
"emailNotifications": {
"enabled": true,
"delay": "10m"
}
}
}
}
]
}
]
}
}
]
}
]
}
}
```

```
  ]
}
```

[KL] "Playbook for isolating a device where an infected file is detected"

The **[KL] "Playbook for isolating a device where an infected file is detected"** predefined playbook isolates a device after an infected file is detected.

The playbook does not contain a trigger. The playbook must be started manually, and it requires a user to select the context. To execute this playbook, you must select the **Select target objects before launching the playbook** box, and then choose the incident assets and observables for which the playbook will be executed.

The following actions are performed for each selected hash-type observable:

1. Retrieving the file from the selected asset.
2. Sending the retrieved file for scanning.
   - If an error occurs during the scan, the playbook terminates.
   - If the scan is completed and no threat is detected, the playbook terminates.
   - If the scan is completed and a threat is detected:
     - Network isolation is enabled on all selected devices.
     - A hash-based prevention rule is added to all devices within the tenant.

Additional information about the playbook:

- If an error occurs during the steps for adding prevention rules of enabling network isolation, playbook execution will stop; in all other cases, it will continue.
- The "Enable network isolation" and "Add prevention rule" actions require manual approval during playbook execution.

ResponseFunction used by the playbook: `getFile`, `serverScan`, `addCommentToIncident`, `addFilePreventionRules`, `netIsolateOn`.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "decision": {
 "conditions": [
 {
 "condition": "${((.input.assets // []) | length) > 0 and ([.input.observables[] | select(.type == \"md5\" or
.type == \"sha256\" and .value != null and .value != \"\")] | length) > 0}",
 "name": "has input data",
 "steps": [
 {
 "loop": {
 "input": "${[(.input.observables | map(select(.type == \"md5\" or .type == \"sha256\") | select(.value != null
and .value != \"\") | .value))[] as $hash | [incident.Alerts[] | .Observables[]? | select((.Type == \"md5\" or
```

```
.Type == \"sha256\") and .Value == $hash and .Details != \"\")][0] | {\"path\": .Details,\"hash\":.Value}]}",
 "steps": [
 {
 "decision": {
 "conditions": [
 {

[KL] "Playbook for isolating a device where an infected file is detected"

The **[KL] "Playbook for isolating a device where an infected file is detected"** predefined playbook isolates a device after an infected file is detected.

The playbook does not contain a trigger. The playbook must be started manually, and it requires a user to select the context. To execute this playbook, you must select the **Select target objects before launching the playbook** box, and then choose the incident assets and observables for which the playbook will be executed.

The following actions are performed for each selected hash-type observable:

1. Retrieving the file from the selected asset.
2. Sending the retrieved file for scanning.
    - If an error occurs during the scan, the playbook terminates.
    - If the scan is completed and no threat is detected, the playbook terminates.
    - If the scan is completed and a threat is detected:
        - Network isolation is enabled on all selected devices.
        - A hash-based prevention rule is added to all devices within the tenant.

Additional information about the playbook:

- If an error occurs during the steps for adding prevention rules of enabling network isolation, playbook execution will stop; in all other cases, it will continue.
- The "Enable network isolation" and "Add prevention rule" actions require manual approval during playbook execution.

ResponseFunction used by the playbook: `getFile`, `serverScan`, `addCommentToIncident`, `addFilePreventionRules`, `netIsolateOn`.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "decision": {

[KL][EDR] "Delete malicious files transferred to the host from alert"

The **[KL][EDR] Delete malicious files transferred to the host from alert** predefined playbook is designed for automatic response to the detection of malicious files that are used to deliver additional malware to the device. When it detects activity related to technique T1105 (Ingress Tool Transfer), the playbook deletes such a file from the device to prevent its further use.

The scope of the playbook is alerts.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "alertChangedOriginalEvents"))) and ([.OriginalEvents //
[] | select(any(.S.KL_EventType == "File Modify" and (.FileFullname // "") != "" and ([.SA.KL_IoAAlert,
.SA.KL_IoATechniques] | transpose | any(.[0] and .[1] == "t1105"))))] | any)"
```

ResponseFunction used by the playbook `deleteFile`.

At runtime, the playbook uses the **Delete file** response.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "loop": {
 "input": "${ [ alert.OriginalEvents[] | select(.S.KL_EventType == \"File Modify\" and (.FileFullname // \"\") !=
\"\" and ([.SA.KL_IoAAlert, .SA.KL_IoATechniques] | transpose | any(.[0] and .[1] == \"t1105\"))) ] }",
 "steps": [
 {
 "action": {
 "function": {
 "type": "deleteFile",
 "assets": "${ [ .[0].AffectedAssets.assets[] | .OsmpID ] }",
 "params": {
 "path": "${ .[0].FileFullname }"
 }
 },
 "onError": "continue",
 "timeout": {
 "scheduleToCloseTimeout": "24h"
 }
 }
 }
 ],
 "onError": "continue",
 "batchSize": 1
 }
 }
 ]
}
```

[KL][EDR] "Delete malicious files transferred to the host from incident"

The **[KL][EDR] Delete malicious files transferred to the host from incident** predefined playbook is designed for automatic response to the detection of malicious files that are used to deliver additional malware to the device. The playbook processes alerts linked to the incident and when it detects activity related to technique T1105 (Ingress Tool Transfer), the playbook deletes such a file from the device to prevent its further use.

The scope of the playbook is incidents.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "incidentLinkedWithAlertsBySystem" or . ==
"incidentLinkedWithAlertsByUser"))) and ([ .Alerts[]? | .OriginalEvents // [] | select(any(.S.KL_EventType ==
"File Modify" and (.FileFullname // "") != "" and ([.SA.KL_IoAAlert, .SA.KL_IoATechniques] | transpose | any(.[0]
and .[1] == "t1105")))) ] | any)"
```

ResponseFunction used by the playbook `deleteFile`.

At runtime, the playbook uses the **Delete file** response.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "loop": {
 "input": "${ [ incident.Alerts[] | .OriginalEvents[] | select(.S.KL_EventType == \"File Modify\" and
(.FileFullname // \"\") != \"\" and ([.SA.KL_IoAAlert, .SA.KL_IoATechniques] | transpose | any(.[0] and .[1] ==
\"t1105\"))) ] }",
 "steps": [
 {
 "action": {
 "function": {
 "type": "deleteFile",
 "assets": "${ [ .[0].AffectedAssets.assets[] | .OsmpID ] }",
 "params": {
 "path": "${ .[0].FileFullname }"
 }
 },
 "onError": "continue",
 "timeout": {
 "scheduleToCloseTimeout": "24h"
 }
 }
 }
 ],
 "onError": "continue",
 "batchSize": 1
 }
 }
 ]
}
```

[KL][EDR] "Isolate host when Discovery activity is detected from alert"

The **[KL][EDR] Isolate host when Discovery activity is detected from alert** predefined playbook is designed to automatically respond to activity involving the collection of information about the device and its environment. If such activity is detected, the playbook turns on network isolation for the device to prevent further activity of the attacker while the investigation is ongoing.

The scope of the playbook is alerts.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "alertChangedOriginalEvents"))) and ([.Rules // [] |
select(any(.Name == "Discovery_activity_on_the_host"))] | any)"
```

ResponseFunction used by the playbook `netIsolateOn`.

At run time, the playbook uses the **Enable network isolation** response. This response enables network isolation of the device for 8 hours. User confirmation is required to enable network isolation.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "netIsolateOn",
 "assets": "${ [ alert.Assets[] | select(.Type == \"host\") | .ID] }",
 "params": {
 "exclusions": [],
 "exclusionsConflictBehavior": "replace",
 "isolationTimeoutSec": 28800
 }
 },
 "manualApprove": true,
 "timeout": {
 "scheduleToCloseTimeout": "24h"
 }
 }
 }
 ]
}
```

[KL][EDR] "Isolate host when Discovery activity is detected from incident"

The **[KL][EDR] Isolate host when Discovery activity is detected from incident** predefined playbook is designed to automatically respond to activity involving the collection of information about the device and its environment. The playbook processes alerts linked to the incident, and if such activity is detected, it turns on network isolation for the device to prevent further activity of the attacker while the investigation is ongoing.

The scope of the playbook is incidents.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "incidentLinkedWithAlertsBySystem" or . ==
"incidentLinkedWithAlertsByUser"))) and ([ .Alerts[]? | .Rules // [] | select(any(.Name ==
"Discovery_activity_on_the_host")) ] | any)"
```

ResponseFunction used by the playbook `netIsolateOn`.

At run time, the playbook uses the **Enable network isolation** response. This response enables network isolation of the device for 8 hours. User confirmation is required to enable network isolation.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "netIsolateOn",
 "assets": "${ [ incident.Alerts[] | select(.Rules | any(.Name == \"Discovery_activity_on_the_host\")) | .Assets[]
| select(.Type == \"host\") | .ID] }",
 "params": {
 "exclusions": [],
 "exclusionsConflictBehavior": "replace",
 "isolationTimeoutSec": 28800
 }
 },
 "manualApprove": true,
 "timeout": {
 "scheduleToCloseTimeout": "24h"
 }
 }
 }
 ]
}
```

[KL][EDR] "Isolate host when Exfiltration activity is detected"

The **[KL][EDR] Isolate host when Exfiltration activity is detected** predefined playbook is designed to automatically respond to attempts at unauthorized data transfer from the device and connection to the attacker's command and control (C2) infrastructure. The playbook processes alerts linked to the incident, and if such activity is detected, it turns on network isolation for the device to prevent further data transfer and malicious activity.

The scope of the playbook is incidents.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "incidentLinkedWithAlertsBySystem" or . ==
"incidentLinkedWithAlertsByUser"))) and ([.Alerts[]? | .OriginalEvents // [] | select(any([.SA.KL_IoAAlert,
.SA.KL_IoAName] | transpose | map(select(.[0]) | .[1]) | any(. as $v | ["not_standard_directory_archive",
"compress_data_for_exfiltration_via_archive"] | index($v)) and any(. as $v | ["lolc2_connection_activity_network",
"lolc2_connection_activity_dns", "network_connection_to_cloud_storage_win"] | index($v)))) ] | any)"
```

ResponseFunction used by the playbook `netIsolateOn`.

At run time, the playbook uses the **Enable network isolation** response. This response enables network isolation of the device for 8 hours. User confirmation is required to enable network isolation.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "netIsolateOn",
 "assets": "${ [ incident.Alerts[] | .OriginalEvents[] | select([.SA.KL_IoAAlert, .SA.KL_IoAName] | transpose |
map(select(.[0]) | .[1]) | any(. as $v | [\"not_standard_directory_archive\",
\"compress_data_for_exfiltration_via_archive\"] | index($v)) and any(. as $v |
[\"lolc2_connection_activity_network\", \"lolc2_connection_activity_dns\",
\"network_connection_to_cloud_storage_win\"] | index($v))) | .AffectedAssets.assets[] | .OsmpID ] }",
 "params": {
 "exclusions": [],
 "exclusionsConflictBehavior": "replace",
 "isolationTimeoutSec": 28800
 }
 },
 "manualApprove": true,
 "timeout": {
 "scheduleToCloseTimeout": "24h"
 }
 }
 }
 ]
}
```

[KL][EDR] "Isolate host when reverse shell activity is detected from alert"

The **[KL][EDR] Isolate host when reverse shell activity is detected from alert** predefined playbook is designed to automatically respond to signs of reverse shell usage on the device. When such activity is detected, the playbook turns on network isolation for the device to prevent the attacker from exercising remote control of the device.

The scope of the playbook is alerts.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "alertChangedOriginalEvents"))) and ([.OriginalEvents //
[] | select(any([.SA.KL_IoAAlert, .SA.KL_IoAName] | transpose | any(.[1] as $ioaname | .[0] and
(["invoke_golang_reverse_shell", "invoke_lua_reverse_shell", "invoke_netcat_reverse_or_bind_shell",
"invoke_perl_reverse_shell", "invoke_php_reverse_shell", "invoke_reverse_shell_via_curl"] | index($ioaname))))) ]
| any)"
```

ResponseFunction used by the playbook `netIsolateOn`.

At run time, the playbook uses the **Enable network isolation** response. This response enables network isolation of the device for 8 hours. User confirmation is required to enable network isolation.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "action": {

 }
 ]
}
```

[KL][EDR] "Mitigate malicious activity from email attachments from alert"

The **[KL][EDR] Mitigate malicious activity from email attachments from alert** predefined playbook is designed to automatically respond to malicious activity associated with files received by email. If such activity is detected on the device, the playbook terminates the process associated with the malicious file and deletes this file from the device.

The scope of the playbook is alerts.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "alertChangedOriginalEvents"))) and ([ .OriginalEvents //
[] | select(any(. as $event | $event.SA.KL_IoAName | index("mail_utility_threatdetect") as $idx | if $idx != null
then $event.SA.KL_IoAAlert[$idx] else false end)) ] | any)"
```

ResponseFunction used by the playbook: `killProcess`, `deleteFile`.

During execution, the playbook uses the following responses:

- Terminate process

  If the process cannot be terminated, the playbook continues.

- Delete file

Events of the alert may refer to different devices and malicious files. The playbook triggers responses separately for each matching event. If there are no matching events in the alert, the playbook stops.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "loop": {

}
},
"onError": "continue",
"timeout": {
"scheduleToCloseTimeout": "24h"
}
}
}
],
"onError": "continue",
"batchSize": 1
}
}
]
}
```

[KL][EDR] "Mitigate malicious activity from email attachments from incident"

The **[KL][EDR] Mitigate malicious activity from email attachments from incident** predefined playbook is designed to automatically respond to malicious activity associated with files received by email. The playbook processes alerts related to the incident, and if it detects malicious activity on the device, it terminates the process associated with the malicious file and deletes this file from the device.

The scope of the playbook is incidents.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "incidentLinkedWithAlertsBySystem" or . ==
"incidentLinkedWithAlertsByUser"))) and ([ .Alerts[]? | .OriginalEvents // [] | select(any(. as $event |
$event.SA.KL_IoAName | index("mail_utility_threatdetect") as $idx | if $idx != null then
$event.SA.KL_IoAAlert[$idx] else false end)) ] | any)"
```

ResponseFunction used by the playbook: `killProcess`, `deleteFile`.

During execution, the playbook uses the following responses:

- Terminate process

  If the process cannot be terminated, the playbook continues.

- Delete file

Events of the alert may refer to different devices and malicious files. The playbook triggers responses separately for each matching event. If there are no matching events in the alert, the playbook stops.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "loop": {
 "input": "${ [ incident.Alerts[] | .OriginalEvents[] | select((.FileName == \"OUTLOOK.exe\" or .ParentFileName ==
\"OUTLOOK.exe\") and .ThreatObjectType == \"file\" and (.ThreatObjectFullname | test(\"\\\\w\\\\:\\\\\\\\\"))) ]
}",
 "steps": [
 {
 "action": {
 "function": {
 "type": "killProcess",
 "assets": "${ [ .[0].AffectedAssets.assets[] | .OsmpID ] }",
 "params": {

 }
 },
 "onError": "continue",
 "timeout": {
 "scheduleToCloseTimeout": "24h"
 }
 }
 }
 ],
 "onError": "continue",
 "batchSize": 1
 }
 }
 ]
 }
```

[KL][EDR] "Mitigate memory dumping activity from alert"

The **[KL][EDR] Mitigate memory dumping activity from alert** predefined playbook is designed to automatically respond to the creation of memory dumps that can be used to obtain credentials and other sensitive information. If such activity is detected on the device, the playbook terminates the process that created the memory dump and deletes the files created by this process.

The scope of the playbook is alerts.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "alertChangedOriginalEvents"))) and ([.OriginalEvents //
[] | select(any([.SA.KL_IoAAlert, .SA.KL_IoAName] | transpose | any(.[1] as $ioaname | .[0] and
(["createdump_lolbin_execution_process", "credentials_dumping_tools_epp",
"credentials_dumping_tools_file_artifacts_creation"] | index($ioaname))))) ] | any)"
```

ResponseFunction used by the playbook: `killProcess`, `deleteFile`.

During execution, the playbook uses the following responses:

- Terminate process

  > If the process cannot be terminated, the playbook continues.

- Delete file

Events of the alert may refer to different devices and malicious files. The playbook triggers responses separately for each matching event. If there are no matching events in the alert, the playbook stops.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "loop": {

}
```

[KL][EDR] "Mitigate memory dumping activity from incident"

The **[KL][EDR] Mitigate memory dumping activity from incident** predefined playbook is designed to automatically respond to the creation of memory dumps that can be used to obtain credentials and other sensitive information. The playbook processes alerts linked to the incident, and if such activity is detected on the device, terminates the process that created the memory dump and deletes the files created by this process.

The scope of the playbook is incidents.

The playbook trigger contains the following expression:

```
"(event.new or (event.updateOperations // [] | any(. == "incidentLinkedWithAlertsBySystem" or . ==
"incidentLinkedWithAlertsByUser"))) and ([.Alerts[]? | .OriginalEvents // [] | select(any([.SA.KL_IoAAlert,
.SA.KL_IoAName] | transpose | any(.[1] as $ioaname | .[0] and (["createdump_lolbin_execution_process",
"credentials_dumping_tools_epp", "credentials_dumping_tools_file_artifacts_creation"] | index($ioaname))))) ] |
any)"
```

ResponseFunction used by the playbook: `killProcess`, `deleteFile`.

During execution, the playbook uses the following responses:

- Terminate process

  If the process cannot be terminated, the playbook continues.

- Delete file

Events of the alert may refer to different devices and malicious files. The playbook triggers responses separately for each matching event. If there are no matching events in the alert, the playbook stops.

The playbook algorithm contains the following sequence of response actions:

```
{
 "version": "1",
 "dslSpecVersion": "1.1.0",
 "actionsSpecVersion": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "loop": {
 "input": "${ [ incident.Alerts[] | .OriginalEvents[] | select([.SA.KL_IoAAlert, .SA.KL_IoAName] | transpose |
any(.[1] as $ioaname | .[0] and ([\"createdump_lolbin_execution_process\", \"credentials_dumping_tools_epp\",
\"credentials_dumping_tools_file_artifacts_creation\"] | index($ioaname)))) ] }",
 "batchSize": 1,
 "steps": [
 {
 "action": {
 "function": {
 "type": "killProcess",

"assets": "${ [ .[0].AffectedAssets.assets[] | .OsmpID ] }",
"params": {
"path": "${ .[0].ProcessFileFullName }"
}
},
"onError": "continue",
"timeout": {
"scheduleToCloseTimeout": "24h"
}
}
}
],
"onError": "continue"
}
}
]
}
```

Playbook trigger

The playbook trigger is a filter that allows you to select alerts or incidents for which a playbook must be launched. The filter (trigger) is applied to each object (alert or incident) individually and takes a single value: either `true` or `false`. A trigger consists of expressions in the jq language that processes structured data in the JSON format. For more information about jq expressions, refer to jq Manual.

In Kaspersky EDR Expert, gojq is used. It is an implementation of jq written in the go language, which has the following differences from jq:

- Mathematical functions are implemented in a more convenient way.
- Errors messages have a clear indication of where to fix your query.
- Integer calculations are more accurate.
- Functions that work incorrectly in jq are improved in gojq.

For more information about the differences between gojq and jq, refer to GitHub.

How to write a trigger

You can write a trigger in the **Trigger** block in visual editor when creating or editing a playbook.

Depending on the option you select in the **Scope** list when creating or editing a playbook, alert data model or incident data model is used.

The names of parameters in a playbook trigger must be the same as in the data model. Note that elements of jq expressions are case-sensitive.

To avoid overloading the system, it is not recommended to specify `OriginalEvents, Observables, Extra,` and `Alerts` data in the trigger.

When you start writing a trigger, the following suggestions can be displayed:

- Names of functions.
- Special values.
- Fields that are specified as object identifiers in accordance with the data model.

The suitable values are filtered and displayed in the list of suggestions when you start typing. For convenience, some suggestions contain a search string. For example, if you want to specify an incident type ID or incident status ID, you can search the corresponding record by the name, and the ID will be specified in the trigger.

Note that the standard statuses (*New* and *Closed*) have the same IDs in different workflows. This means that the playbook is triggered for all incidents with a specified status ID. To limit the scope of incidents for which the playbook will run, in the trigger you have to specify the incident status ID and the incident type.

The jq language also provides syntax highlighting and validation of jq expressions. If the trigger has invalid expressions, you cannot save the playbook.

When writing a trigger, basic syntax rules are used.

To refer to structure properties, you must use dot "`.`" and specify the attribute, for example:

- `.MITRETactics[]`—To view the array of MITRE tactics associated with all triggered IOA rules in the alert.
- `.MITRETactics[0]`—To view the first element from the MITRE tactics array.

To refer to child properties, you can either use the pipe (|) or the same combination without the pipe, for example:

- `.Assignee.Name`—The expression outputs the name of the user to whom the alert is assigned.
- `.MITRETactics[0].ID` or `.MITRETactics[0] | .ID`—The expression outputs the ID of the first MITRE tactic.

To get a value, you have to use the following operators: ==, >, <, >=, <=, !=, for example:

- `.Assignee.Name == "user"`—The expression returns `true` if the alert is assigned to the user.
- `(.Severity == "high") and (.DetectSource == "KES")`—The expression returns `true` if the alert severity level is high and the source of data is Kaspersky Endpoint Security.

- `[ .DetectionTechnologies[] | . == "IOC" ] | any` —The expression returns `true` if the IOC detection technology is triggered.

- `.DetectionTechnologies | length > 1`—The expression returns `true` if more than one detection technology is triggered.

To enumerate values in an array of objects, you can use the `any` method, for example:

- `[.Assets[] | .Name == "W21H2-X64-3160"] | any`—The expression filters the alert where any element of the `Assets` array has the `W21H2-X64-3160` value in the `Name` field.

- `[.Observables[] | .Value == "127.0.0.1"] | any`—The expression filters the alert where any element of the `Observables` array has the `127.0.0.1` value in the `Value` field.

- `[.Assets[].ID]`—To output the array of IDs.

- `[.Assets[] | select(.AttackerOrVictim=="attacker") | .ID]`—To display an array of IDs for the assets filtered by the `AttackerOrVictim` field.

If you want to reuse calculations, specify a variable with `$`. For example, the expression `event.manual != true as $not_manual | [ .DetectionTechnologies[] | . == "IOC" ] | any and $not_manual` defines and uses the `$not_manual` variable that contains a flag that shows if the change is manual or not.

To work with dates, you can use the following functions:

- `now`—To get the current Unix time in seconds, for example, `now == 1690541520.537496`.

- `todate`—To convert the current Unix time to a date string, for example, `now | todate == "2023-07-28T10:47:36Z".`

- `fromdate`—To convert the date to seconds, for example:

  - `.CreatedAt | split(".")[0] + "Z"`—This command removes milliseconds and converts the string to the 2023-07-15T07:49:51Z format.

  - `(.CreatedAt | split(".")[0] + "Z") | fromdate == 1689407391`—The conversion to seconds is finished.

Jq uses iterators—an interface that provides access to elements of a collection, for example, an array, and allows you to navigate through them. Iterators are always the result of calculation. The difference is in the number of elements that the iterator contains. In Kaspersky EDR Expert, an iterator must have only one element; All other cases are considered an error.

To write a correct trigger, you have to wrap an iterator into square brackets (`[ ... ]`). For example, the `.DetectionTechnologies[] == "IOC"` trigger will cause an error because it returns an iterator with two elements. The correct trigger must have the following form: `[ .DetectionTechnologies == "IOC" ] | any`, where first you have to use `[]` to wrap the result of the comparison into an array, and then process it with the `any` method that returns `true` if at least one element of the array is `true`. Otherwise, `false` is returned.

When the trigger runs

The search for a suitable playbook starts when one of the following triggering events occurs:

- New alert/incident is created.
- Any field of an active alert/incident is changed.
- When creating or editing a playbook, the user selected the **Launch the playbook for all matching alerts or incidents. Note that the system may be overloaded** check box.

The following types of alert change events are supported:

- Assigning or removing an analyst.
- Changing an alert status.
- Changing basic events.
- Linking or unlinking an alert to or from an incident.
- Changing the value in the `ExternalReference` field.

The following types of incident change events are supported:

- Assigning or removing an analyst.
- Changing an incident status.
- Changing basic events.
- Linking or unlinking an alert to or from an incident.
- Changing an incident name.
- Editing the incident description
- Changing the incident priority
- Changing the value in the `ExternalReference` field.
- Merging incidents.

The alert/incident structure does not contain any data about the alert/incident changes. This data is transferred in additional information. If in a playbook trigger you want to refer to the changes, use the event function without arguments.

By default, manual changes to an alert or incident details are ignored. If you want a playbook to launch for manual changes, you have to use the `event.manual` function in the trigger, for example:

- `event.manual and ([ event.updateOperations[] | . == "alertReopened" ] | any)`—The trigger works only if the alert is manually reopened.
- `[ event.updateOperations[] | . == "alertLinkedWithIncidentBySystem" ] | any`—The trigger works only if the alert is automatically linked to an incident.
- `event.manual != null and (([ event.updateOperations[] | . == "alertChangedToNew" ] | any) | not)`—The trigger works if the alert status is changed to any status other than *New*, either manually or automatically.
- `event == null and .Status == "inIncident"`—The trigger works for all alerts with the *In incident* status, but only when the playbook is changed, not the alert.

If necessary, you can test examples of jq expressions, apply filters, and then view the results in the Jq playground service.

Playbook algorithm

Kaspersky EDR Expert allows you to respond to alerts and incidents manually or automatically by using playbooks. Responding to alerts or incidents may consist not of a single action, but of a whole set of steps and parameters. These steps depend on the specified conditions, the alert or incident data, and the results of previous response actions.

The playbook algorithm allows you to specify the sequence of response actions, the necessary conditions, and the required impact on the target objects, in the JSON format. The playbook algorithm steps are performed sequentially. You can specify the playbook algorithm when creating or editing a playbook.

After launch, the playbook obtains all the alert or incident data, and places them in global data. The playbook uses the following data:

- Global data

  Global data is readable at any step of the playbook. Global data contains information about the alert or incident for which the playbook was launched.

  > You cannot edit global data by using a playbook, or by changing alert or incident data. Global data remains unchanged for the entire lifetime of the playbook instance.

- Operational data

  Operational data is transferred between the steps of the playbook. You can manage operational data by using jq expressions, which are specified in the `input` and `output` parameters.

- Local data

  Local data is limited to a specific step. You can manage local data by using the `input` (local data generation) and `output` (generation of operational data from local data) parameters.

How to write an algorithm

The playbook algorithm is written in the JSON format and consists of two main parts:

- General information on the playbook:
  - Name (`name`)
  - Description (`description`)
  - Scope (`inputType`)
  - Transformation of the input data of the playbook (`input`)
  - Transformation of the output data of the playbook (`output`)
  - Playbook execution timeout (`playbookRunTimeout`)
  - Timeout policies that can be applied at specific steps (`timeouts`)
  - Playbook version (`version`)
  - DSL schema version (`dslSpecVersion`)
  - Response action schema version (`actionsSpecVersion`)
- Playbook execution steps (`executionFlow`).

The following parameters are required when writing the algorithm:

- `dslSpecVersion`. The required value: 1.1.0.
- `actionsSpecVersion`
- `version`
- `executionFlow` (at least one execution step)

> Each execution step has its own required fields.

If you try to save a playbook without filling in the required fields, an error will appear.

The playbook algorithm is case-sensitive. To use the asset data of the alert, you need to capitalize the `Assets` parameter. For example: `alert.Assets[]`. However, to use asset data in the input data when manually launching the playbook for target objects, do not capitalize the `assets` parameter. For example: `.input.assets[]`.

Depending on the scope you selected when creating or editing a playbook, you can use the alert data model or incident data model in expressions written in the jq language. To do that, write expressions with an `alert` or `incident` value (do not use dot "`.`" at the beginning of the value). For example:

```
"${[ alert.Assets[] | select(.Type == \"user\" and .IsAttacker) | .ID]}"
```

You can use alert or incident data in a jq expression at any execution step. The alert or incident data is only available in read mode. This data does not change during the operation of the playbook. If alert or incident data has changed after launching the playbook, it will not affect the playbook execution.

You also can use the jq expressions when using the playbook data in the algorithm. For more information about jq expressions, refer to jq Manual.

If you use quotation marks in the jq expression, you need to escape these marks with backslashes. For example: `"${[ alert.Assets[] | select(.Type == \"user\" and .IsAttacker) | .ID]}"`.

Backslashes that are not used to escape quotation marks must also be escaped by other backslashes. For example: `${\"add_firewall_rule --ip_address=\" + ([.input.observables[] | select(.type == \"ip\") | select(.value | test(\"^(10\\\\.|172\\\\.(1[6-9]|2[0-9]|3[01])\\\\.|192\\\\.168\\\\.|127\\\\.).*\") | not) | .value] | join(\",\"))}`.

If you want to launch the playbook for the specific object (observables or assets), use the `.input` parameter in the algorithm. These objects will be the input to the playbook when it is launched. For example:

```
"assets": "${ [.input.assets[] | select(.Type == \"host\") | .ID] }"
```

For details, refer to Launching playbooks for objects specified by users.

How to call hints

If you need a hint on the available fields when writing the algorithm, use quotation marks (`""`). A list of available fields appears.

To display hints on the alert or incident data,

in the jq expression, write `alert` or `incident` and include a dot "`.`" at the end.

The correct hint appears if there are no errors in the above expressions. Otherwise, the list of available fields may be incorrect.

How to call hints

You can call suggestions when writing the playbook algorithm. The suggestions contain a search string and help you specify the field value quickly. To view the suggestions, use quotation marks (`""`). A list of suggestions appears.

The suggestions also allow you to search by name. However, when you select the required value, the name will be automatically changed to an ID in the algorithm. For more details, see Editing incidents by using playbooks and Editing alerts by using playbooks.

If you select and then delete the parameter name specified between the quotation marks, suggestions for the parameter will not appear, even if you have specified a new parameter between the quotation marks.

To return to the suggestion mode for the parameter, do one of the following:

- Delete the quotation marks, and then add an opening double quotation mark. A closing double quotation mark will be added automatically, and a suggestion will appear.
- Type any character between the quotation marks, and then press **Backspace**. This will return you to the suggestion mode.

> If you delete the parameter name character by character, you will not exit the suggestion mode, even if you delete the parameter name completely.

Example of the playbook algorithm

```
{
 "actionsSpecVersion": "1",
 "dslSpecVersion": "1.1.0",
 "version": "1",
 "playbookRunTimeout": "24h",
 "executionFlow": [
 {
 "action": {
 "function": {
 "type": "blockLDAPAccount"
 "assets": "${[ alert.Assets[] | select(.Type == \"user\" and .IsAttacker) | .ID]}"
 },
 "onError": "stop"
 }
 },
 {
 "loop": {
 "batchSize": 1,
 "input": "${ [alert.OriginalEvents[] | [select(.DestinationProcessName != null and .DestinationProcessName !=
\"\")][] | .DestinationProcessName] }",
 "mode": "parallel",
 "onError": "stop",
 "steps": [
 {
 "action": {
 "function": {
 "type": "killProcess",
 "assets": "${[ alert.Assets[] | select(.Type == \"host\") | .ID]}",
 "params": {
 "path": "${ .[0] }"
 }
 }
 }
 }
 ]
 }
 },
 {
 "action": {
 "function": {
 "type": "avScan",
 "assets": "${[ alert.Assets[] | select(.Type == \"host\") | .ID]}",
 "params": {
 "scope": {
 "allowScanNetworkDrives": false,
 "area": "full"
 },
 "wait": false
 }
 },
 "onError": "stop"
 }
 }
```

```
  ]
}
```

Playbook parameters

Parameter ID	Description
`name`	Name of the playbook. Specified by the system when creating or updating a playbook. If the value is set in the algorithm, it will be replaced by the system.
`description`	Playbook description. Specified by the system when creating or updating a playbook. If the value is set in the algorithm, it will be replaced by the system.
`version`	Playbook version. The minimum length is 1. This parameter is required.
`dslSpecVersion`	DSL schema version. The minimum length is 1. This parameter is required.
`actionSpecVersion`	Response actions schema version. The minimum length is 1. This parameter is required.
`playbookRunTimeout`	The maximum execution time of the playbook, including waiting in the queue. The maximum value is 48 hours (`48h`). You can configure the maximum execution time in hours (h) and/or minutes (m). By default, the value is `24h`.
`inputType`	Inbound object type. The possible values: `alert` or `incident`. The inbound object type is specified by the system when creating or updating a playbook. If the value is set in the algorithm, it will be replaced by the system.
`input`	A jq expression that could be used to transform or filter incoming data before executing a playbook.
`output`	A jq expression that could be used to modify the output of the playbook before execution.
`timeouts`	Timeout definitions.
`executionFlow`	Steps of the playbook execution. This parameter is required.

Execution step parameters

The array of execution step elements describes a playbook's logic. The execution steps are performed in the order described in the playbook. There are several types of execution steps:

- Action
- Loop
- Parallel
- Decision
- UpdateData

Action parameters

The `Action` parameters call the response function.

Parameter ID	Description
`function`	An object that defines a response action. For more information, refer to ResponseFunction parameters.
`filterProduct`	This parameter allows you to filter components to perform a response action. When requested, the component plug-ins are filtered by allowed and restricted components. For example, the parameter can be specified as follows: `"filterProduct": { "allowed": ["PRODUCT_NAME"] }`
`output`	This parameter allows you to edit the value returned by the response action, by using a jq expression and placing it in the playbook data (local or operational).
`timeout`	This parameter allows you to set timeouts for calling the response function. You can specify the name of the timeout policy set in the playbook or set timeout values manually. If the value is not specified, the default timeout is applied.
`manualApprove`	This parameter allows you to configure a manual approval of a response action. Possible values: • Boolean value: • `true` —Manual approval is enabled with default parameters. • `false` —Manual approval is disabled. • Object `ManualApprove`.
`onError`	This parameter defines the behavior when an error occurs during the execution of a response action. Possible values: • `stop` —Defines the termination of the playbook in case of an error during the execution of the response action. • `continue` —Defines that the playbook execution will continue, even if one of the response actions completes with an error. In this case, the playbook launches the next response action specified in the algorithm. By default, the value is `stop`. Note that, if a system error occurs, the playbook execution completes with an error regardless of the specified value of the `onError` parameter.

Timeout policy

The timeout policy of execution steps. The system automatically determines the default timeout policy.

The default timeout policy can be reconfigured by using the default policy name. In this case, the new policy will be automatically applied to all execution steps.

Parameter ID	Description
`name`	Timeout policy name.
`scheduleToCloseTimeout`	The maximum execution time, including waiting in the queue and retries. The parameter is specified in the Go string format. If the value is not specified or 0, the value from the `playbookRunTimeout` field is used.

Output

The `output` parameter generates operational data at the end of a step, which will then be transferred to the next step. Specify the `output` parameter if you want to use the results of the current step of the playbook in the next step.

To avoid overloading the system, it is recommended to limit the data placed in the playbook data (local or operational).

Parameter ID	Description
`action`	This parameter defines whether the playbook data (local or operational) will be overwritten or merged. Possible values: • `merge` —The new data is merged with the current data. • `overwrite` —The current data is overwritten with new data.
`filter`	This parameter defines the jq expression for processing output data.

Manual approve

Parameter ID	Description
`timeout`	The timeout for manual approval in minutes. The minimum value is 10 minutes (`10m`), the maximum is 180 minutes (`180m`). By default, the value is 60 minutes (`60m`).
`emailNotifications`	This parameter allows you to configure the sending of email notifications.

Email notification settings

Parameter ID	Description
`enabled`	Flag for enabling email notifications.
`delay`	This parameter defines the delay before sending the email notification. The value is specified in minutes. The minimum value is 5 minutes (`5m`), the maximum is 30 minutes (`30m`). By default, the value is 10 minutes (`10m`).

Loop

Before specifying the `Loop` parameter, make sure that the `aggregate` parameter is also specified in the playbook algorithm.

The `Loop` parameters are used to split the array of incoming data by elements and to perform various actions on the elements.

Parameter ID	Description
`input`	A jq expression for composing an array or referencing an array.
`aggregate`	This parameter allows you to configure aggregation rules by using a jq expression.
`output`	Configuring how to apply the output data to the current playbook data. Possible values: • String constant: `merge` or `overwrite`. • Object `Output`.
`mode`	Loop operation mode. Possible values: • `parallel` —Defines that all elements are processed in parallel. The number of threads is controlled by the interpreter. • `sequence` —Defines that all elements are processed sequentially. By default, the value is `parallel`.
`batchSize`	This parameter allows you to specify the number of array elements that will be processed in one loop or one parallel thread. You can use this parameter if the plug-in function limits the number of input elements. For example, if a plug-in function can handle no more than 10 elements in one loop, you can specify the following parameter value: `batchSize=10`. By default, the value is `1`.

`onError`	This parameter defines the behavior when an error occurs in one of the branches. Possible values: • `stop` —Defines the termination of all branches if an error has occurred. The other branches will continue to run. • If `mode=sequence`, after an error occurs in one branch, all subsequent branches will be stopped. • If `mode=parallel`, after an error occurs in one branch, all branches will continue to run independently of each other. • `continue` —Defines the stop of one of the branches where the error occurred. The other branches will continue to run. By default, the value is `stop`.
`steps`	Array of execution steps.

Parallel

Before specifying the `Parallel` parameter, make sure that the `aggregate` parameter is also specified in the playbook algorithm.

The `Parallel` parameters are used to perform several actions on the data at the same time. Unlike Loop, `Parallel` transmits the same input data to different execution branches.

Parameter ID	Description
`input`	A jq expression for composing an array.
`aggregate`	This parameter allows you to configure aggregation rules by using a jq expression.
`output`	Configuring how to apply the output data to the current playbook data. Possible values: • String constant: `merge` or `overwrite`. • Object `Output`.
`onError`	This parameter defines the behavior when an error occurs in one of the branches. Possible values: • `stop` —Defines the termination of all branches if an error has occurred. The other branches will continue to run. • `continue` —Defines the stop of one of the branches where the error occurred. The other branches will continue to run. By default, the value is `stop`.
`branches`	Execution branches.

Branch

Parameter ID	Description
`name`	The name of the branch that is unique within `Parallel`.
`steps`	Array of execution steps.

Decision

The `Decision` execution step allows you to perform a step or set of steps according to a condition. Note that only the first verified condition is executed.

Parameter ID	Description
`conditions`	Array of conditions.

Condition

Parameter ID	Description
`condition`	A jq expression that contains execution conditions.
`steps`	Execution steps for the current branch.

UpdateData

The *UpdateData* parameter can be described either as a jq script with state change logic, or as an `Output` object.

ResponseFunction parameters

Parameter ID	Description
`action`	Response action name.
`params`	The parameter allows you to describe the parameters of a response action you want to launch. You can specify the parameter as a jq expression or as an object. Parameters of the response actions are described in the table below.
`assets`	The parameter allows you to use a jq expression or string array to specify a list of assets for which you want to launch a response action. The `assets` parameter is required for response actions with assets and is not applicable for response actions without assets.

Response action parameters

Response action name	Settings
`updateBases`	Update databases response action. Possible parameters: • `wait`. Possible values: • `true` • `false` To launch this response action, you need to specify the `asset` parameter of the response function.

`avScan`	Run malware scan response action. Possible parameters: • `wait`. Possible values: • `true` • `false` • `scope`. Possible values: • `full`—Perform a full scan of the device where the alert is detected. • `critical`—Perform a scan of the kernel memory, running processes, and disk boot sectors. • `selective`—Perform a scan of the specified files. To specify a path to the files, use the `path` parameter. • `allowScanNetworkDrives`. Possible values: • `true` • `false` By default, the value is `false`. This parameter is available only if you want to perform a full scan. Note that scanning network drives can overload the system. • `path`—A jq expression or a string with a path to the files you want to scan. You can also specify multiple file paths. To launch this response action, you need to specify the `asset` parameter of the response function.
`moveHostsToAdministrationGroup`	Move to group response action. Possible parameters: • `group`—Open Single Management Platform administration group path. For examples, `HQ/OrgUnit1`. To launch this response action, you need to specify the `asset` parameter of the response function.
`quarantineFile`	Move to quarantine response action. Possible parameters: • `path`—Path to the file you want to quarantine. • `md5`—MD5 hash of the file. • `sha256`—SHA256 hash of the file. You can specify the response action parameters in one of the following ways: • Specify the full path to the file you want to quarantine. In this case, you do not need to specify an MD5 hash or a SHA256 hash. • Specify the file path and the file hash (MD5 or SHA256). To launch this response action, you need to specify the `asset` parameter of the response function.
`restoreQuarantinedFile`	Restore file from quarantine response action. Possible parameters: • `path`—Path to the file you want to restore. • `md5`—MD5 hash of the file. • `sha256`—SHA256 hash of the file. To launch this response action, you need to specify the `asset` parameter of the response function.
`killProcess`	Terminate process response action. Possible parameters: • `pid`—Process identifier. • `path`—Path to the file you want to quarantine. • `md5`—MD5 hash of the file. • `sha256`—SHA256 hash of the file. To launch this response action, you need to specify the `asset` parameter of the response function.
`changeAuthorizationStatus`	Change authorization status response action. Possible parameter: • `authorized`. Possible values: • `true` • `false` To launch this response action, you need to specify the `asset` parameter of the response function.

`netIsolateOn`	Enable network isolation response action. Possible parameters: • `isolationTimeoutSec` —Network isolation period. You can specify this parameter in hours or days. The minimum value in hours is 1 hour, the maximum is 9999 hours. The network isolation period is specified in seconds. • `exclusions` —Exclusion rules. You can specify one or more exclusion rules. • `remoteIPV4Address` —Network traffic from the specified IPv4 address will be excluded from the block. For example, `192.168.2.15`. • `remoteIPV6Address` —Network traffic from the specified IPv6 address will be excluded from the block. For example, `2001:0db8:0000:0000:0000:ff00:0042`. • `remotePortRange` —Interval of remote ports. • `localPortRange` —Interval of local ports. If the `remotePortRange` and `localPortRange` are not specified, the exclusion rule applies to all ports. • `exclusionsConflictBehavior` —Defines the behavior if there is a conflict between different exclusion rules. Possible parameters: • `replace` • `skip` • `fail`
`netIsolateOff`	Disable network isolation response action. To launch this response action, you need to specify the `asset` parameter of the response function.
`executeCommand`	Run executable file response action. Possible parameters: • `commandLine` —Command to run or a full path to the executable file. • `workingDirectory` —Path to the working directory. • `commandLineParameters` —Command-line parameters that you want to apply to the command. To launch this response action, you need to specify the `asset` parameter of the response function.
`addFilePreventionRules`	Add prevention rule response action. Possible parameters: • `md5` —MD5 hash array. • `sha256` —SHA256 hash array. To launch this response action, you need to specify the `asset` parameter of the response function.
`deleteFilePreventionRules`	Delete prevention rule response action. Possible parameters: • `md5` —MD5 hash array. • `sha256` —SHA256 hash array. To launch this response action, you need to specify the `asset` parameter of the response function.
`resetFilePreventionRules`	Delete all prevention rules. To launch this response action, you need to specify the `asset` parameter of the response function.
`assignKasapGroup`	Assign KASAP group response action. Possible parameters: `groupId` —KASAP group identifier. To launch this response action, you need to specify the `asset` parameter of the response function.
`addToLDAPGroup`	Add user to security group response action. Possible parameters: `groupDN` —Distinguished name (DN) of the LDAP group. To launch this response action, you need to specify the `asset` parameter of the response function.
`removeFromLDAPGroup`	Delete user from security group response action. Possible parameters: `groupDN` —Distinguished name (DN) of the LDAP group. To launch this response action, you need to specify the `asset` parameter of the response function.
`blockLDAPAccount`	Lock account response action. To launch this response action, you need to specify the `asset` parameter of the response function.
`resetLDAPPassword`	Reset password response action. To launch this response action, you need to specify the `asset` parameter of the response function.

`executeCustomScript`	Execution of custom scripts. Possible parameters: • `commandLine` —Command to run. • `commandLineParameters` —Command-line parameters that you want to apply to the command. • `stdIn` —Standard input stream. Use this parameter if a script requires some additional data from the standard input. • `workingDirectory` —Path to the working directory.
`iocsEnrichment`	Data enrichment. Possible parameters: • `observables` —A jq expression with an array of observables that you want to enrich. • `fullEnrichment` —Defines the number of records to be requested. Possible values: • `true` —Request all records from the source. • `false` —Request the top 100 records from the source.

AI services

This section provides information about the AI services that Kaspersky EDR Expert works with.

AI asset score and status

The **AI asset score and status** service can be installed if your license covers the AI module.

The AI service helps with precisely assessing the severity of correlation events generated by triggered correlation rules.

The AI service gets correlation events with a non-empty **Affected assets** field from the available storage clusters, constructs the expected sequence of events, and trains the AI model. Based on the chain of triggered correlation rules, the AI service calculates whether such a sequence of events is typical for this infrastructure. Non-typical patterns increase the score of the asset.

The AI service calculates the **AI score** and the **AI status**, which become available in the asset card. If you remove the license key, the **Score AI** and **Status AI** fields are hidden from the asset card. If you add the license key again, the values of the **Score AI** and **Status AI** fields are shown again.

The score is a number that quantifies how non-typical the activity on the asset is, and whether it is worth paying attention to. Possible values of the **Status AI** field: **Low**, **Medium**, **High**, **Critical**. The score is a number in the range from 0 to 1.

There are four ranges that correspond to statuses:

Low: 0 ≤ score < 0.25

Medium: 0.25 ≤ score < 0.5

High: 0.5 ≤ score < 0.75

Critical: 0.75 ≤ score ≤ 1

You can apply a filter by the **Score AI** and **Status AI** fields when searching for assets. You can also set up proactive categorization of assets by the **Score AI** and **Status AI** fields, which moves the asset to the category corresponding to the risk level as soon as the AI service assigns a score to the asset.

You can create a structure of multiple categories and automatically populate these with assets in accordance with the calculated risk values.

In the **Settings** → **Asset audit** section, you can configure audit events to be generated when an asset is added to a category. Audit events can be taken into account in correlation rules, and you can monitor them on the dashboard and in reports.

To monitor asset category changes on the dashboard, create an **Events** widget with a query similar to the following:

```
SELECT count(ID) AS `metric`,
formatDateTime(toTimeZone(fromUnixTimestamp64Milli(Timestamp), 'Europe/Moscow'),
'%d.%m.%Y %H:%m:%S') AS `value` FROM `events`
```

```
where DeviceVendor = 'Kaspersky' and DeviceProduct = 'KUMA' and

DeviceEventCategory = 'Audit assets' and DeviceAction= 'asset added to category'

and DeviceCustomString1 = 'Main/Categorized assets/ML/score>0.5'

GROUP BY Timestamp ORDER BY value LIMIT 250
```

To monitor the distribution of assets by status on the dashboard, create an **Assets by severity** widget. The **Assets by severity** widget is available if the license includes the AI module. The pie chart indicates the numbers of assets grouped by status.

Every time the AI service is restarted, the AI service trains the model from scratch and reassesses the score of the assets mentioned in events of the current day.

The directory specified in the configuration file stores events that the AI service got from KUMA storage clusters for the specified number of days. For example, if the configuration file specifies 12 days, the AI service gets events for the past 12 days. The oldest events are deleted from the directory. The trained model is stored in the same directory.

The model is retrained at midnight UTC. The asset score is reassessed once an hour for all assets that were mentioned in events of the current day (UTC).

Service logs are stored in /var/log/syslog.

Installing the AI asset score and status service

Installing the AI asset score and status service

To install the service:

1. Extract the **mlservice-installer-XX.tgz** archive that is included in the distribution kit.

   The **mlservice-installer-XX.tgz** archive contains scripts for installing and removing the service, as well as the config.yaml configuration file.

2. In the config.yaml configuration file, in the `kuma_address` setting, specify the FQDN of the host on which KUMA Core is installed and the port on which the KUMA Core is to listen for AI service connections.

   In a high availability configuration, you must specify port 7226. You can keep default values for the rest of the settings. After installation, the service starts with the settings specified in the config.yaml file.

3. If you want to install the service on a remote host, specify the address of the remote host in the inventory.yaml file and make sure you have network access. By default, the service is installed on the local host as specified in inventory.yaml.

4. Get a Core certificate in the KUMA web interface. To do this, in the main window of the KUMA web interface, click the name of your user account in the lower part of window to open a menu and select **AI service certificate**. The certificate is downloaded to your default download directory.

   If necessary, you can reissue the AI service certificate**.**

5. Rename the downloaded certificate file to **core-external-ca.cert**.

6. Save the KUMA Core certificate file in the roles/mlservice/files directory under the installer directory.

7. Change to the directory with the service files and from that directory, run the following command:

   ```
   ./install < path to inventory.yaml >
   ```

8. If you accept the terms and conditions of the End User License Agreement, press `Y`. If you do not accept the terms and conditions of the End User License Agreement, you cannot proceed with the installation of the service. You can find the file with the text of the End User License Agreement in the mlservice-installer/eula directory.

9. The installer generates a certificate and a key during the installation process and places these in the directories specified in the config.yaml configuration file. You must upload the certificate to KUMA.

   In the KUMA web interface, in the **Settings** → **Integrations** → **AI services** section, in the **AI asset score and status** window, fill in the following fields:

   a. In the **URL** field, specify the FQDN of the KUMA Core host on and the port on which the KUMA Core listens for the AI service, for example: <FQDN of the KUMA Core host>:7226. The port number must match the port number specified in the configuration file. Make sure the port is not being used by other applications.

      For a KUMA installation in high-availability configuration, the **URL** field is not displayed in the interface, the port value is taken from the KUMA_APPRAISER_AI_API_PORT environment variable and the port is opened for all IP addresses of the KUMA Core host.

   b. In the **Certificate** drop-down list, select **Create new** to open the **Create secret** window; in that window, specify **Certificate** as the secret type and upload the certificate from the directory specified in the config.yaml configuration file.

   c. Turn on the **State** toggle switch. The toggle switch is turned off by default.

   d. Click **Save**.

   Immediately after installation, the service will make attempts to connect to KUMA for 15 minutes with 1-minute intervals. If no certificate is added in the KUMA web interface, the connection will fail and the service will stop. In this case, you can add a certificate and restart the AI service; the service makes new attempts to connect.

   After saving the settings, get the log of the Core server and make sure it does not contain the "<port number>: bind: address already in use" error

The AI service is installed.

Removing the AI asset score and status service

To remove the AI service, change to the directory with the AI service files, and from that directory, run the following:

```
./uninstall <path to inventory.yaml>
```

Reissuing the AI service certificate

To reissue the AI service certificate:

1. In the OSMP Console, go to the **Settings** → **Other** → **Common** section.
2. Under **Core settings**, for the **AI service certificate** setting, click the **Reissue** button.
3. Click **OK** to confirm the operation.
4. Replace the certificate in the /opt/kaspersky/mlservice directory with the new certificate.
5. Restart the Score AI and Status AI service by running the command `systemctl restart mlservice`; also restart the KUMA Core.

The new AI service certificate is applied.

Settings of the AI asset score and status service

Available AI service settings

Setting	Description
`cert_file_path`	Path to the directory that contains the certificate generated by the installer. Default path: /opt/kaspersky/mlservice/service.crt You can specify a different path. In this case, make sure that the user that starts the service has access to the specified directory.
`key_file_path`	Path to the directory that contains the key generated by the installer. Default path: /opt/kaspersky/mlservice/service.key You can specify a different path. In this case, make sure that the user that starts the service has access to the specified directory.
`kuma_address`	FQDN of the host on which the KUMA Core is installed and port on which the KUMA Core is to listen for the AI service. To install in a high availability configuration, you must specify port 7226. Example: <FQDN of the host on which KUMA Core is installed>:7226
`kuma_cert_file_path`	Path to the directory where the KUMA Core certificate is located. Default path: /opt/kaspersky/mlservice/core-external-ca.cert
`event_storage_path`	Path to the directory where the service is to place received correlation events. Default path: /var/mlservice/events
`model_storage_path`	Path to the directory where the service is to place the trained model. Default path: /var/mlservice/models
`period_for_train_days`	The number of days for which you want to get correlation events that involve your assets from the available storage clusters in order to train the model. The default setting is 12 days. This means that the directory will contain events for the past <N> days. The oldest events are deleted.

Setting	Description
`events_overlap_in_seconds`	Overlap time. When events for assessing the scores of assets are downloaded on a schedule, they are retrieved from the time of the last downloaded event for the current day minus the value of the events_overlap_in_seconds setting. The default value is 60 seconds. Example: the time when the last event was received is 8:58. The starting time for the next batch of events to be downloaded is 8:57.

Configuring integration with KIRA using an LLM provider

KIRA supports the following third-party LLM providers:

- GPT-5.4
- Deepseek-V4-Pro
- Kimi K2.6
- GLM-5.1
- MiniMax M2.7

To configure KIRA integration using a third-party LLM provider:

1. Get a license with the AI module and activate the functionality in KUMA.
2. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.
3. In the **Integrations** section, click **AI services**
4. This opens a window; in that window, go to the **Kaspersky Investigation & Response Assistant** tab.
5. Enable integration with KIRA by enabling the **Status** toggle switch.

   The toggle switch is turned off by default.
6. Under **Mode**, select the **Custom** mode of interaction with KIRA. By default, the **KSN** mode is selected.
7. In the **Base URL** field, enter the API address of the provider (for example, https://api.openai.com/v1). The address must start with http:// or https://
8. In the **API key** drop-down list, select or create a secret of the **token** type.

   To create a new secret, select **Create new**. If the API that you are using does not require a key, in the **API key** field, specify a secret with the **api-key** value.
9. In the **Model** field, specify the name of the model that your provider uses (for example, gpt-4-turbo, llama3-70b).
10. In the **Maximum prompt size** field, specify the maximum number of tokens in a request.
11. In the **Proxy server** drop-down list, select a previously created resource or create a new resource.

12. Select the KIRA response language, Russian or English. KUMA sends and stores KIRA responses in the language of your choice.

    Russian is selected by default.

13. Click the **Add JSON file** button to upload a file with the model parameters and HTTP headers.

    In this file, you can specify additional parameters of the request to the LLM provider (for example, `temperature`, `max_tokens`). You can also specify additional HTTP headers. To do this, you need to use the `"headers"` key. If multiple `"headers"` keys are specified in the file, only the first of those is used.

    Example of file content

    ```
    {
     "temperature": 0.5,
     "max_tokens": 20000,
     "headers": {
     "OpenAI-Organization": "ORG_ID"
     }
    }
    ```

    The AI service returns an error if at least one of the following parameters is specified in the JSON file: `messages`, `model`, `audio`, `function_call`, `functions`, `modalities`, `n`, `parallel_tool_calls`, `prediction`, `response_format`, `stop`, `stream`, `stream_options`, `tool_choice`, `tools`, `web_search_options`.

14. Click **Test connection** to make a test request to the specified API.

15. Click **Save**.

    After clicking **Save**, you are prompted to accept the terms and conditions of the End Use License Agreement. If you do not accept the End Use License Agreement, you cannot save the settings or continue to use the functionality.

    After saving the settings, the available number of tokens is displayed. The tokens are replenished every day.

Integration is configured, you can proceed to the analysis. Analysis is available for all events: new and previously received.

Analyzing alerts and incidents with KIRA

You can use Kaspersky Investigation & Response Assistant (KIRA) to analyze alerts and incidents. As a result of the analysis, you receive an automatically generated description of the alert or incident, including a short summary, a list of observables, an event timeline, an alert or incident report, and mitigation recommendations.

This functionality accelerates the investigation and initial analysis of alerts or security incidents and is available regardless of the event types included in the alert or incident.

When using a third-party LLM provider (**Custom** mode), the request is sent directly to the specified API. The user selects the provider, model, and parameters. Data processing is performed on the side of the selected service.

The functionality is available if the following conditions are satisfied:

- There is a current license covering the AI module.

  If the license has expired, the analysis results remain available through tasks during the lifetime of the cache, that is, for 14 days from the moment the result is cached.

- A connection to the third-party LLM provider's API was configured.
- The user has **Write** rights for the **Alerts and Incidents** functional area.

Analyzing using KIRA

After configuring the integration, you can analyze alerts and incidents using KIRA.

To perform an analysis:

1. Open the alert or incident details.
2. In the toolbar in the upper part of the alert or incident details, click **AI analysis** → **Analyze with KIRA**.

   If you have enough tokens, the analysis and the **Query in KIRA** task are started.

   Processing the request may take 30 seconds or longer.

   Tokens are expended even if the request returns an error saying that the requested topic is in the deny list; the information about remaining tokens is also updated.

The alert or incident is analyzed.

To view the analysis results, in the toolbar in the upper part of the alert or incident details, click **AI analysis** → **View report**. In the **Analyze with KIRA** window, the analysis result is displayed with the following details:

- A short summary of the alert or incident.
- The observables list.
- Alert or incident timeline with the event chronology.
- Case report.
- Date and time of the last request.
- Number of the expended tokens.

You can click the **Reanalyze** button to performs a new analysis disregarding the data of the previous analysis stored in the cache. This analysis expends tokens.

Possible errors of the Analyze using KIRA task

Errors may occur during alerts and incidents analysis using KIRA.

Possible errors

HTTP code	Description
400	Invalid request to the service or invalid client certificate. Possible reasons: required parameters are missing or contain invalid values; the client certificate used for KSN is expired or issued by an untrusted certification authority.
401	Authentication failed. The client certificate is valid, but there is no corresponding record in the limits database. Possible reasons: the record was deleted, was not created in time, or incorrect data was published due to a technical error.

HTTP code	Description
403	Daily token limit has been exceeded.
404	Unknown or unsupported user task
413	Request token limit exceeded. The request contains too many input tokens. The maximum allowed number is 16,000 tokens per request, including service parameters. If this limit is exceeded, analysis is not performed.
500	Internal service error. An unspecified error occurred while processing the request.
502	AI service is unavailable. KIRA is not reachable.
503	Service connection error. Failed to obtain an access token from KIRA.
Other	Connection error. Any other error code returned by the KSN service that is not listed above.
No code	Request processing error on the KUMA side. Possible reasons include failure to read the response from KSN, failure to save data to the database, or failure to retrieve integration settings.

Creating search queries in natural language by using KIRA

In the **Threat hunting** section, you can enter a search query using natural language, automatically convert the query using Kaspersky Investigation & Response Assistant (KIRA) to the database query syntax, check the correctness of the query and refine it if necessary, and then run the query generated by the system and get event search results. Each time a request is sent, an audit event is generated. If an error occurs when generating a request, an error code is displayed.

The token limit is shared across the following options:

- Making search queries in natural language using KIRA
- Analyze with KIRA

The total amount of tokens depends on the query and the response. You can preview the number of tokens that will be spent on a query and the response, and edit the response to spend fewer tokens.

This functionality is available in the RU region if the following conditions are satisfied:

- There is a current license covering the AI module.
- A certificate was uploaded when configuring the KIRA integration. You can get the certificate file in PFX format, packed in the <company name>.ZIP archive, and the password for the certificate from Technical Support.
- The user has one of the following roles with corresponding access rights: Main administrator, Administrator, Tier 2 analyst, Tier 1 analyst, and Junior analyst. Only a user with the Main administrator role can configure the integration.

Creating search queries in natural language and converting them into SQL queries by using KIRA

Having configured the KIRA integration, you can start generating search queries to find events.

To generate a natural-language search query and convert it to an SQL query using KIRA:

1. In the **Threat hunting** section, below the SQL query field click the button ( ).
2. This opens the **KIRA SQL query generator** window; in that window, in the query field, enter the text of the query that you want KIRA to convert to SQL.

   For example: "Show all events from January 15 to 16, 2024, where the file name was "file.txt"".

   The conversion of queries in the Russian and English languages is supported.
3. Click the **Generate** button.

   The generated SQL query is displayed in the output field.

   For example:

   ```
   SELECT *
   FROM events
   WHERE FileName = 'file.txt'
   ORDER BY Timestamp DESC
   ```

   The generated time period is displayed in the **Time period** field:

   For example:

   2024-01-15T00:00:00.000 - 2024-01-16T00:00:00.000

   If you have not specified the time range for your event search in your input, the period set on the **Events** tab is used. For example, "5 minutes" was set in **Events**, and the query was issued on January 15 at 15:30, the time period is set to 2026-01-15T15:25:00.000 - 2026-01-15T15:30:00.000

   You can edit the values in the **SQL query** and **Time interval** fields before applying the generated query.
4. If you want to know how many tokens will be spent on sending the query, click **Calculate cost in tokens**.
5. If you want to use the generated SQL query to perform an event search, click the **Apply** button.

   The **KIRA SQL query generator** window is automatically closed.

   The generated SQL query is automatically inserted into the main query field on the **Threat hunting** tab.

   The absolute time range field is automatically populated with values from the generated query.

   For example: 2026-01-15T00:00:00.000 - 2026-01-15T00:00:00.000
6. If you want to perform an event search using the generated SQL query, click **Run query**.

The natural-language search query is converted to an SQL query and an event search result is obtained.

Possible errors while creating a query in natural language

Possible errors

HTTP code	Description
400	Invalid client certificate.
404	Error in request.

401	Missing certificate information. Contact Technical Support.
403	Daily limit of tokens exhausted.
413	Maximum number of tokens for request reached. Make the request smaller.
422	Natural-language request cannot be converted to SQL syntax.
500	Unknown error of the service.
502	KIRA service unavailable.
503	Error getting access token in service.
Other	Unknown error.
No code	Error while processing the request.

Configuring DLL Hijacking detection

DLL Hijacking is an attack technique that involves delivering vulnerable legitimate software along with a malicious dynamic link library (DLL) to the target system. When the vulnerable software is launched, it does not verify the legitimacy of the dynamic library and loads it by file name. As a result, malicious code is executed in the context of legitimate software. A DLL Hijacking attack is difficult to detect because the software being launched is legitimate. To detect such attacks, the AI module is used. The AI module analyzes the launch and runtime parameters of applications and identifies suspicious launches of legitimate software with malicious libraries.

To get a status, KUMA sends a request to KSN. The request contains information from the event fields that is needed for analysis. In response to a request, KSN sends one of the following analysis results:

- `0` – **Unclassified**. To get a status, you need to re-send the request. You can configure the re-sending of requests using the **Perform a repeat request setting**.
- `1` – **Unknown**. The library is not considered malicious at the time when the status is received.
- `2` – **Suspicious**. Getting such a result creates an alert if you have the corresponding correlation rule configured.
- `3` – **Malware**. Getting such a result creates an alert if you have the corresponding correlation rule configured. The **Malware** verdict represents a higher-likelihood detection of DLL Hijacking than the **Suspicious** verdict.

The result is written to the KL_AI_DLLHijackingCheckResult field of the event as a numerical value and a text comment.

DLL Hijacking attacks are detected at the event enrichment stage. This is achieved using the **check DLL Hijacking** enrichment type. You can embed an enrichment of this type in the collector or the correlator. We recommend embedding this type of enrichment in the correlator. In this way, the load on the KSN service is significantly lower than when checking events in the collector.

To use an enrichment of the **check DLL Hijacking** type, your license must include the AI module. The Main administrator must also accept the additional KSN Statement in the **Kaspersky Security Network** section (**Settings** → **Integrations** → **AI services** → **Kaspersky Security Network**). If your instance of KUMA has multiple Main administrators, it is sufficient for one of them to accept the KSN Statement.

Detecting DLL Hijacking attacks using event enrichment in the correlator

To configure DLL Hijacking attack detection using event enrichment in the correlator:

1. In the application web interface, select **Resources** → **Correlators**.
2. Start creating a correlator or open the settings of an existing correlator.
3. Add an enrichment of the check DLL Hijacking type.

   When configuring the enrichment, you need to specify a list of fields corresponding to the parameters that are needed to create a KSN request. Make sure the fields you specify are populated as part of normalization in the collector.
4. In the enrichment settings, in the list under **Filter parameters**, select the following filter: **[OOTB] Events for DLLHijacking enrichment**. Filter for correlator. If this filter is missing from the list, import it from the repository. You can also configure the filter on your own.
5. If you want to configure the application to generate an alert when it gets a **Suspicious** or **Malware** verdict, create a correlation rule that does that. When creating the correlation rule, select the simple or standard type and on the **Selector** tab, specify two conditions in the filter parameters:

   `KL_AI_DLLHijackingCheckResult = 2` OR `KL_AI_DLLHijackingCheckResult = 3`

   Also, in the correlation rule, specify the fields that you specified when adding the enrichment (see step 3 of the instructions). The fields must be listed in the **Propagated fields** setting if you created a correlation rule of the simple type, or in the **Identical fields** setting if you created a correlation rule of the standard type.

Detecting DLL Hijacking attacks using event enrichment in the collector

We do not recommend using the **DLL Hijacking** enrichment in the collector. This increases the load on the KSN service. Instead, add an enrichment of this type to the correlator.

To configure DLL Hijacking attack detection using event enrichment in the collector:

1. In the application web interface, select **Resources** → **Collectors**.
2. Start creating a collector or open the settings of an existing collector.
3. Add an enrichment of the check DLL Hijacking type.

   When configuring the enrichment, you need to specify a list of fields corresponding to the parameters that are needed to create a KSN request. Make sure the fields you specify are populated as part of normalization in the collector.
4. In the enrichment settings, in the list under **Filter parameters**, select the following filter: **[OOTB] Events for DLLHijacking enrichment**. Filter for collector. If this filter is missing from the list, import it from the repository. You can also configure the filter on your own.

5. If you want to configure the application to generate an alert when it gets a **Suspicious** or **Malware** verdict, create a correlation rule that does that. When creating the correlation rule, select the simple or standard type and on the **Selector** tab, specify two conditions in the filter parameters:

   `KL_AI_DLLHijackingCheckResult = 2` OR `KL_AI_DLLHijackingCheckResult = 3`

   Also, in the correlation rule, specify the fields that you specified when adding the enrichment (see step 3 of the instructions) as well as the KL_AI_DLLHijackingCheckResult field. The fields must be listed in the **Propagated fields** setting if you created a correlation rule of the simple type, or in the **Identical fields** setting if you created a correlation rule of the standard type.

Configuring Detection of Compromise Accounts

To detect attacks involving compromised account usage, a periodical correlation rule is used. This rule operates on statistical data: machine-learning algorithms create a profile of the users' normal behavior and identifies deviations from this behavior based on statistical indicators. Anomaly detection is performed at regular intervals specified in the `correlation-rules.yaml` file, based on the accumulated data, and not at the moment when each event is received.

You can create a correlation rule of the **periodical** type only using the correlator-ng correlator.

A **periodical** correlation rule works in two stages:

1. **Accumulation and aggregation of data**

   At the first stage, the correlation rule accumulates user behavior statistics. This stage corresponds to the cold start period, during which no anomalies are detected. The accumulation of statistics begins with the first event that is passed to the rule. None of the events created earlier are taken into account.

   At the data accumulation and aggregation stage, the following takes place:

   - Events for successful and unsuccessful attempts to log in to the user account are received.
   - The addresses from which and to which the logon is performed are extracted.
   - The data is aggregated on a per-user basis: unique values are saved, new addresses are counted for each authentication events grouping period.

   The duration of the cold start period is fixed and is specified in the configuration of the correlation rule. A cold start can be performed in the following ways:

   - By processing the event stream arriving at the correlator.
   - By using the retroscan procedure to download events from storage.
   - By using a combined method, in which some data is downloaded via retroscan, and the remaining data is accumulated by processing the event stream.

   When using the retroscan procedure, the correlation rule processes downloaded events in the same way as events arriving from the stream. If the storage contains user authentication events for the minimum period required for statistics accumulation, the rule begins periodically detecting anomalies immediately after these events are downloaded.

   It is acceptable to load data for a period not longer than the cold start duration, and then continue accumulating statistics by processing the event stream until the cold start period is completed.

2. **Anomaly detection**

After the end of the cold start period, the rule starts periodically analyzing the accumulated data at certain intervals. For each user and each analyzed indicator:

- The value of the indicator for the last authentication event grouping period is used.

  If the anomaly detection period coincides with the grouping period, the value of the indicator for the most recently completed period is used for analysis. If the detection period is shorter than the grouping period, the analysis is performed based on data from the current (ongoing) period, which allows getting results before the whole grouping period runs out.

- Statistical indicators are calculated.

- The results are compared to the thresholds that are configured in the correlation rule.

If indicators of anomalous user activity exceed any thresholds, a correlation event is generated. If necessary, the rule can additionally create an alert.

Indicators of anomalous user activity

To detect anomalies, two indicators are used together:

- **Relative Score**

  This indicator shows by how many times the user's current activity exceeds the user's average activity level, and is calculated using the following formula:

  Relative Score = (**Current activity** + 1) / (**Average activity** + 1)

  Where:

  Current activity is the current activity value.

  Average activity is the average activity level during the period for which the indicator is calculated.

- **Z-Score (standard score)**

  This indicator quantifies the deviation of the current value from the average value, taking into account dispersion, and is calculated using the following formula:

  Z-Score = (**Current activity** – **Average activity**) / **Standard deviation**

  Where:

  Current activity is the current activity value.

  Average activity is the average activity level during the period for which the indicator is calculated.

  Standard deviation is a measure of dispersion of activity values during the choosing period.

Abnormal user activity is logged if the value of one of the indicators (**Relative Score** or **Z-Score**) exceeds the specified threshold. For each analyzed property, the rule selects the most appropriate indicator depending on the user behavior statistics.

Using two indicators allows evaluating anomalies in different behavior scenarios, reducing the number of false positives. When an anomaly is detected, the rule creates a correlation event with information about the user, time, analyzed property, indicator type, indicator value, the threshold that was exceeded, as well as anomalous values for anomaly analysis.

Managing objects in repositories

In Kaspersky EDR Expert, there is a storage where you can place objects for processing. For example, you can upload a file to scan it immediately or later, or you can move an infected file to quarantine for safety and restore the file later if necessary.

For each type of object, there is a specific *repository*. In the OSMP Console interface, you can find repositories in the **Operations** section.

Uploading files for scan

You can upload a file and then scan it, either immediately or later. Kaspersky EDR Expert uses the Anti-Malware Engine and YARA technologies for scanning, and also sends the file to Sandbox.

To upload a file for scan:

1. In the main menu, go to **Operations** → **Repositories** → **Files**.
2. Click **Upload**.

   The **Upload file** window opens.
3. Select a tenant to be associated with the file.
4. If you want the file to be scanned immediately after the upload is complete,make sure that the **Scan after uploading** toggle button is switched on. You can switch off this toggle button and scan the file later.
5. Upload a file by dragging and dropping or by clicking **Upload a file**. You can upload multiple files.
6. Click **Upload**.

Kaspersky EDR Expert starts uploading a file. After the upload is complete, Kaspersky EDR Expert start scanning if the **Scan after uploading** toggle button is on.

Scanning files in the File repository manually

You can manually start scanning if the file has not been scanned or if you want to rescan it. Kaspersky EDR Expert uses the Anti-Malware Engine and YARA technologies for scanning, and also sends the file to Sandbox.

To scan files in the File repository:

1. In the main menu, go to **Operations** → **Repositories** → **Files**.
2. Select a file or multiple files in the list.
3. Click the **Scan** button above the list.

Kaspersky EDR Expert start scanning the selected files. You can find the status of scanning in the **Scan status** column.

Viewing scan status and results

To view the status and results of file scanning:

1. In the main menu, go to **Operations** → **Repositories** → **Files**.

   The **Scan status** column in the list of files contains basic information about scan status and results:

   - **Not scanned**

     The file has not been scanned yet.

   - **Scanning**

     The file is being scanned.

   - **Not detected**

     The file has been scanned, no threats detected.

   - **Detected**

     The file has been scanned, some threats have been detected.

2. For more detailed information, click the name of the file that you want to know more about.

   In the window that opens, you can find information about the file, including the detailed results of the file scan.

Downloading files from Quarantine and File backups

You can download files from Quarantine and Backup only if one of the two conditions is met: either the **Do not disconnect from the Administration Server** option is enabled in the settings of the device, or a connection gateway is in use. Otherwise, the downloading is not possible.

To save a copy of file from Quarantine or File backups to a hard drive:

1. Do one of the following:

   - If you want to save a copy of file from Quarantine, in the main menu, go to **Operations** → **Repositories** → **Quarantine**.

   - If you want to save a copy of file from Backup, in the main menu, go to **Operations** → **Repositories** → **File backups**.

2. In the window that opens, select a file that you want to download and click **Download**.

   The download starts.

If you performed the action from the **Quarantine** section, a copy of the file that had been placed in the quarantine directory on the client device is downloaded to your computer. The file is saved in a password-protected ZIP archive. The password is the following: infected.

Restoring files from quarantine

If you have reasons to believe that the file you moved to quarantine is safe, you can restore the file on the device in one of the following ways:

- From the **Quarantine** section of the main menu.
- From the results of the **Move to quarantine** response action.

You can also configure this action to run automatically when creating or editing a playbook.

Restoring a file from the Quarantine section

To restore a file from the Quarantine section:

1. In the main menu, go to **Repositories** → **Quarantine**.
2. Do one of the following:
   - Select the file to be restored from quarantine.

     You can select several files.
   - Click the name of the file to be restored from quarantine.

   The file details open.
3. Click the **Restore** button, and then confirm the operation.

   If necessary, in the **Description** field you can write a comment before confirming the operation.

If the operation is completed successfully, an appropriate message is displayed on the screen. The file is restored on the device on which you previously moved it to quarantine and located on the original path (the one that you specified at step 5 in the Moving files to quarantine scenario). Otherwise, an error message is displayed.

Restoring a file from the results of the **Move to quarantine** response action

To restore a file from the results of the Move to quarantine response action:

1. Open the result of the **Move to quarantine** response action in one of the following ways:
   - In the main menu, go to **Monitoring** → **Response history**.
   - In the main menu, go to **Monitoring**, and then select the **Alerts** or **Incidents** section. In the **ID** column, click the ID of the alert or incident that includes the asset or observable for which you performed the **Move to quarantine** response action. In the alert or incident details that open, move to the **History** tab.

2. For the result of the **Move to quarantine** response action, in the **Action status** column, click the **Success** link.

3. In the details window that opens, click the **Restore** button, and then confirm the operation.

4. If necessary, in the **Description** field, you can write a comment before confirming the operation.

   If the operation is completed successfully, an appropriate message is displayed on the screen. The file is restored on the device on which you previously moved it to quarantine and located on the original path (the one that you specified at step 5 in the Moving files to quarantine scenario). Otherwise, an error message is displayed.

Viewing the result of file restoration

If Kaspersky Endpoint Security with a built-in agent is installed on your device, the result of file restoration is displayed in **Response history** section.

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the file restoration completed successfully, the **Success** message is displayed. Otherwise, the **Error** message and the information about the reason of the error are displayed.

If you want to view the Launch ID and the JSON with the file restoration result, move to the **Debug data** tab.

Deleting files from quarantine

To perform this action, you must have one of the following roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst.

You can delete an infected file from the quarantine directory on the device in one of the following ways:

- From the **Quarantine** section of the OSMP Console menu.
- From the results of the **Move to quarantine** response action

You can also configure this action to run automatically when creating or editing a playbook.

Deleting a file in the Quarantine section

To delete a file in the Quarantine section:

1. In the main menu, go to **Repositories** → **Quarantine**.

2. Do one of the following:

   - Select the file to be deleted from quarantine.

     You can select several files.

- Click the name of the file to be deleted from quarantine.

  The file details open.

3. Click the **Delete** button, and then confirm the operation.

If the operation is completed successfully, an appropriate message is displayed on the screen. The file is permanently deleted from the quarantine directory on the device where it was located. Otherwise, an error message is displayed.

Deleting a file in the results of the **Move to quarantine** response action

To delete a file in the results of the Move to quarantine response action:

1. Open the result of the **Move to quarantine** response action in one of the following ways:

   - In the main menu, go to **Monitoring** → **Response history**.

   - In the main menu, go to **Monitoring**, and then select the **Alerts** or **Incidents** section. In the **ID** column, click the ID of the alert or incident that includes the asset or observable for which you performed the **Move to quarantine** response action. In the alert or incident details that open, move to the **History** tab.

2. For the result of the **Move to quarantine** response action, in the **Action status** column, click the **Success** link.

3. In the details window that opens, click the **Delete** button, and then confirm the operation.

   If the operation is completed successfully, an appropriate message is displayed on the screen. The file is permanently deleted from the quarantine directory on the device where it was located. Otherwise, an error message is displayed.

Viewing the result of file deletion

If Kaspersky Endpoint Security with a built-in agent is installed on your device, the result of file deletion is displayed in **Response history** section.

After you click the link in the **Action status** column, a window opens with the **Result** tab selected. If the file deletion completed successfully, the **Success** message is displayed. Otherwise, the **Error** message and the information about the reason of the error are displayed.

If you want to view the Launch ID and the JSON with the file deletion result, move to the **Debug data** tab.

About removing objects from the Quarantine, File backups, or Active threats repositories

When Kaspersky security applications installed on client devices place objects to the Quarantine, Backup, or Active threats repositories, they send the information about the added objects to the **Quarantine**, **File backups**, or **Active threats** sections in Open Single Management Platform. When you open one of these sections, you can remove the required object.

For the **File backups** or **Active threats** section, select an object from the list and click the **Remove** button.

For the **Quarantine** section, you can do one of the following:

- Select the check box next to the name of an object to be removed, and then in the toolbar, click the **Delete** button.
- Click the name of the object to be removed, and in the details window that opens, in the toolbar, click the **Delete** button.

  In this case, the object is deleted, a corresponding notification is displayed on the screen, and the details window is closed.

Open Single Management Platform either removes the selected object from the list, or deletes the selected object from the repository. The action to perform is defined by the Kaspersky application that placed the selected object to the repository. The Kaspersky application is specified in the **Entry added by** field.

For details about which action is to be performed, refer to the documentation of the Kaspersky application.

Managing assets

Asset management in Kaspersky EDR Expert includes the following possibilities:

- You can manage assets in KUMA: view information about assets, search for assets, add, edit or delete assets, and export asset data to a CSV file.
- You can run tasks and apply Kaspersky application policies to assets in the **Assets (Devices)** section of the OSMP Console interface.
- You can get general information about assets on the **Assets** widget in the **Analysis and response** tab of the OSMP Console Dashboard.
- You can find asset details in the **Monitoring** section.

Integration with other solutions

Integration with other solutions allows you to enrich the functionality of Kaspersky EDR Expert.

Kaspersky EDR Expert supports integration with the following Kaspersky solutions:

- Kaspersky Managed Detection and Response
- Kaspersky Security Network
- Kaspersky Threat Intelligence Portal

Integration with Kaspersky Managed Detection and Response

Kaspersky Managed Detection and Response (hereinafter also "MDR") detects and prevents fraud in the client's infrastructure. MDR provides continuous managed protection and allows organizations to automatically discover hard-to-detect threats while freeing up IT security personnel to work on issues requiring their participation.

If you have enabled MDR in OSMP, only MDR incidents creation from Open Single Management Platform incidents will be available.

If sending data from Open Single Management Platform to MDR is enabled in MDR, the MDR SOC will also receive additional detection information. This requires additional consent from the MDR client in the MDR plug-in.

You can create a Kaspersky Managed Detection and Response incident from an EDR incident if the incident's alerts meet the following conditions:

- MDR integration is enabled in OSMP
- The detection source is endpoint
- At least one related asset is included
- The detection technology is any of the following:
  - IOA rules
  - SB (Sandbox)
  - AM (Anti-Malware Engine)
  - YARA
  - IOC

For details, refer to Kaspersky Managed Detection and Response documentation.

Integration with Kaspersky Security Network

To protect the user's computer more effectively, Kaspersky EDR Expert uses data that is obtained from users around the globe. *Kaspersky Security Network* is designed to obtain such data.

Kaspersky Security Network (hereinafter also "KSN") is an infrastructure of online services that provides users with access to the Kaspersky online knowledge base containing information on the reputation of files, web resources, and software. Use of data from Kaspersky Security Network ensures that Kaspersky EDR Expert responds faster to new objects that have not yet been added to the anti-virus databases, improves the performance of some protection components, and reduces the likelihood of false alarms.

Thanks to users who participate in Kaspersky Security Network, Kaspersky is able to promptly receive information about the types and sources of objects that have not yet been added to the anti-virus databases, develop solutions for neutralizing them, and minimize the number of false alarms. User participation also helps other users of Kaspersky Security Network promptly receive information about threats to the IT infrastructure of their organizations.

When you participate in Kaspersky Security Network, Kaspersky EDR Expert sends requests to Kaspersky Security Network about the reputation of files, web resources and software, and receives a response containing data about the reputation of those objects.

Personal information of the user is not collected, processed, or stored. For information about data that Kaspersky EDR Expert sends to Kaspersky Security Network, refer to the KSN Statement.

Participation in Kaspersky Security Network is voluntary. You can start or stop using KSN at any moment.

If you do not want to participate in KSN, you can use Kaspersky Private Security Network (hereinafter also referred to as "KPSN"). KPSN is a solution that allows users to access the reputation databases of Kaspersky Security Network and other statistical data without actually sending data from their own computers to Kaspersky Security Network.

If you want to purchase the Kaspersky Private Security Network application, please contact Kaspersky partners in your region.

Updates functionality (including providing anti-virus signature updates and codebase updates), as well as KSN functionality may not be available in the software in the U.S.

Setting up access to KSN

You can set up access to Kaspersky Security Network (KSN) on the Administration Server and on a distribution point.

To set up Administration Server access to KSN:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **KSN Proxy settings** section.

3. Switch the toggle button to the **Enable KSN Proxy on Administration Server [Enabled]** position.

   Data is sent from client devices to KSN in accordance with the Kaspersky Endpoint Security policy, which is active on those client devices. If this check box is cleared, no data will be sent to KSN from the Administration Server and client devices through Open Single Management Platform. However, client devices can send data to KSN directly (bypassing Open Single Management Platform), in accordance with their respective settings. The Kaspersky Endpoint Security policy, which is active on client devices, determines which data will be sent directly (bypassing Open Single Management Platform) from those devices to KSN.

4. Switch the toggle button to the **Use Kaspersky Security Network [Enabled]** position.

   If this option is enabled, client devices send patch installation results to Kaspersky. When enabling this option, make sure to read and accept the terms of the KSN Statement.

   If you are using KPSN, switch the toggle button to the **Use Kaspersky Private Security Network [Enabled]** position and click the **Select file with KSN Proxy settings** button to download the settings of KPSN (files with the extensions pkcs7 and pem). After the settings are downloaded, the interface displays the provider's name and contacts, as well as the creation date of the file with the settings of KPSN.

   When you switch the toggle button to the **Use Kaspersky Private Security Network [Enabled]** position, a message appears with details about KPSN.

   The following Kaspersky applications support KPSN:

   - Open Single Management Platform
   - Kaspersky Endpoint Security for Linux
   - Kaspersky Endpoint Security for Windows

   If you enable KPSN in Open Single Management Platform, these applications receive information about supporting KPSN. In the settings window of the application, in the **Kaspersky Security Network** subsection of the **Advanced Threat Protection** section, the information about selected KSN provider is displayed — KSN or KPSN.

   > Open Single Management Platform does not send any statistical data to Kaspersky Security Network if KPSN is configured in the **KSN Proxy settings** section of the Administration Server properties window.

5. If you have the proxy server settings configured in the Administration Server properties, but your network architecture requires that you use KPSN directly, enable the **Ignore KSC Proxy server settings when connecting to Private KSN** option. Otherwise, requests from the managed applications cannot reach KPSN.

6. Under **Connection settings**, configure the Administration Server connection to the KSN proxy service:

   - The TCP port 13111 is used for connecting to the KSN proxy server. For the root Administration Server, this port number cannot be changed.
   - If you want the Administration Server to connect to the KSN proxy server through a UDP port, enable the **Use UDP port** option. By default, this option is disabled, and TCP port is used. If this option is enabled, the UDP port 15111 is used by default. For the root Administration Server, this port number cannot be changed.

7. Switch the toggle button to the **Connect secondary Administration Servers to KSN through primary Administration Server [Enabled]** position.

   If this option is enabled, secondary Administration Servers use the primary Administration Server as the KSN proxy server. If this option is disabled, secondary Administration Servers connect to KSN on their own. In this case, managed devices use secondary Administration Servers as KSN proxy servers.

Secondary Administration Servers use the primary Administration Server as a proxy server if in the right pane of the **KSN Proxy settings** section, in the properties of secondary Administration Servers the toggle button is switched to the **Enable KSN Proxy on Administration Server [Enabled]** position.

8. Click **Save**.

The KSN access settings will be saved.

You can also set up distribution point access to KSN, for example, if you want to reduce the load on the Administration Server. The distribution point that acts as a KSN proxy server sends KSN requests from managed devices to Kaspersky directly, without using the Administration Server.

To set up distribution point access to Kaspersky Security Network (KSN):

1. Make sure that the distribution point is assigned manually.
2. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.
3. On the **General** tab, select the **Distribution points** section.
4. Click the name of the distribution point to open its properties window.
5. In the distribution point properties window, in the **KSN Proxy** section, enable the **Enable KSN Proxy on distribution point side** option, and then enable the **Access KSN Cloud / Private KSN directly over the Internet** option.
6. Click **OK**.

The distribution point will act as a KSN proxy server.

Please note that the distribution point does not support managed device authentication by using the NTLM protocol.

Enabling and disabling participation in KSN and KPSN

Users with the following roles can view and edit the status of participation in Kaspersky Security Network and Kaspersky Private Security Network:

- Main administrator
- SOC administrator
- Tenant administrator (editing the status is available only for a root tenant, for other tenants in the hierarchy, settings are applied automatically)

Users with the Auditor role can only view the status of participation in Kaspersky Security Network and Kaspersky Private Security Network.

To enable participation in Kaspersky Security Network:

1. In the main menu, go to **Settings** → **Kaspersky Security Network**.
2. In the **Kaspersky EDR Expert** section, select the **KSN** connection mode.
3. Switch the **Participate in KSN** toggle button on.
4. Carefully read the KSN Statement.
5. If you agree with the terms and conditions of the KSN Statement, select the **I confirm that I have fully read, understand, and accept the terms and conditions of KSN Statement** option and click **Accept**.

   The KSN is enabled and Open Single Management Platform sends statistics to KSN for analysis by Kaspersky specialists.
6. If you do not agree with the terms and conditions of the KSN Statement, click **Decline**.

   The KSN will not be enabled.

To enable participation in Kaspersky Private Security Network:

1. In the main menu, go to **Settings** → **Kaspersky Security Network**.
2. In the **Kaspersky EDR Expert** section, select the **KPSN** connection mode.
3. Switch the **Participate in KPSN** toggle button on.
4. Click the **Upload** button, select the KPSN configuration file (file with the .pkcs7 or .pem extension) and click **Open**.

Participation in KPSN is enabled.

To disable participation in KSN or KPSN:

1. In the main menu, go to **Settings** → **Kaspersky Security Network**.
2. If you want to disable participation in KSN, select the **KSN** connection mode, and switch the **Participate in KSN** toggle button off.

   Participation in KSN is disabled.
3. If you want to disable participation in KPSN, select the **KPSN** connection mode, and switch the **Participate in KPSN** toggle button off.

   Participation in KPSN is disabled.

Configuring the connection to a local reputation database of KPSN

Kaspersky EDR Expert can save information about Sandbox component alerts to the local reputation database of KPSN. In this case, the *Untrusted* status is assigned to objects. Data of local reputation databases is available only to corporate LAN computers.

The application allows users with the following roles to view and edit Kaspersky Private Security Network API integration settings:

- Main administrator
- SOC administrator
- Tenant administrator (settings editing is available only for a root tenant, for other tenants in the hierarchy, settings are applied automatically)

Users with the Auditor role can only view Kaspersky Private Security Network API integration settings.

To configure the connection of Kaspersky EDR Expert to a local KPSN reputation database:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Click the **Root tenant** and go to the **Settings** → **KPSN reputation database** subsection.
3. In the **Asset** field, specify the IP address of the KPSN server on which the local reputation database of KPSN is stored.
4. Click **Upload** to the right of the **Public key for user certificate** field and select the required .pem certificate.
5. Click **Upload** to the right of the **Private key for user certificate** field and select the required .pem certificate.
6. Click **Upload** to the right of the **Trusted root certificate for KPSN server** field and select the required .pem certificate.
7. Click **Save**.

The connection to the local reputation database of KPSN will be configured.

Setting up sending detected objects to the KPSN denylist

The application allows users with roles Tier 1 analyst and Tier 2 analyst to enable or disable automatic sending of malicious file hashes scanned by the Sandbox to the KPSN denylist. The configuration of this parameter is individual for each tenant. It can be changed only in the root tenant of the OSMP installation: in child tenants, the option cannot be changed.

Before enabling automatic sending of detected objects to the KPSN denylist, make sure the KPSN usage is enabled and the connection to a local reputation database of KPSN is configured.

To enable automatic sending of detected objects to the KPSN denylist:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Click the **Root tenant** and go to the **Settings** → **KPSN reputation database** subsection.
3. Turn on the **Assign the "Untrusted" status to objects** toggle button.
4. Click **Save**.

Viewing Kaspersky Security Network Statement

When you enable Kaspersky Security Network, you must read and accept the KSN Statement. You can view the accepted KSN Statement at any time.

To view the accepted KSN Statement:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **KSN Proxy** section.

3. Click the **View Kaspersky Security Network Statement** link.

In the window that opens, you can view the text of the accepted KSN Statement.

Integration with Kaspersky Threat Intelligence Portal

The Kaspersky Threat Intelligence Portal combines all of Kaspersky's knowledge about cyberthreats and how they're related into a single web service. When integrated with Kaspersky EDR Expert, it helps users to make faster and better-informed decisions, providing them with data about web addresses, domains, IP addresses, WHOIS / DNS data.

Access to the Kaspersky TIP is provided based on a fee. License certificates are created by Kaspersky experts. To obtain a certificate for Kaspersky TIP, contact your Technical Account Manager.

Before configuring the settings, you have to create an authorization token for API requests on Kaspersky TIP or Kaspersky OpenTIP.

To configure integration between Open Single Management Platform and Kaspersky TIP:

1. On the **General** tab, select the **Tenants** section.

   The list of tenants is displayed.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Go to the **Settings** tab, and then select the **Kaspersky TIP** section.

   You can edit the **Kaspersky TIP** section if you are assigned one of the following roles: Main administrator, Tenant administrator, or SOC administrator.

4. If at step 2 you selected the Root tenant, you can turn on the **Proxy** toggle button to use a proxy server for interaction with Kaspersky TIP.

   The proxy server is configured in the root Administration Server properties.

5. In the **Cache TTL** field, specify the period of cache storage and the units: days or hours.

   By default, 7 days is set. If you do not specify any value, the period of cache storage is unlimited.

   > You set the period of cache storage for all connections.

6. Turn on the **Integration** toggle button for one of the following services:

   - **Kaspersky Threat Intelligence Portal (General access)**

     After you add an authorization token, you will be able to obtain information from Kaspersky TIP about the following types of observables listed at the **Observables** tab in the alert or incident details: domain, URL, IP, MD5, SHA256. The information is updated in the **Enrichment** column. Quota is consumed when you request data.

   - **Kaspersky Threat Intelligence Portal (Premium access)**

     After you add an authorization token, you will be able to do the following:

     - Obtain information from Kaspersky TIP about the following types of observables listed at the **Observables** tab in the alert or incident details: domain, URL, IP, MD5, SHA256. The information is updated in the **Enrichment** column. Quota is consumed when you request data.

     - Obtain information from Kaspersky TIP about the following types of observables listed at the **Observables** tab in the alert or incident details: domain, URL, IP, MD5, SHA256. The information is updated in the **Status update** column. Quota is not consumed when you request data.

7. Click the **Add token** button.

8. In the window that opens, enter the authorization token, and then click the **Add** button.

   > For details about generating an authorization token for API requests, refer to the Kaspersky TIP or Kaspersky OpenTIP help.

   After you add the token, you can change it by clicking the **Replace** button, and then entering a new token in the window that opens. This may be necessary if the token is expired.

9. Click **Save**.

Managing Sandbox

Sandbox is a security component that utilizes virtual machines (VMs) with operating system images to analyze the behavior of objects, such as files, programs, or scripts, for potential malicious activity and signs of targeted attacks to the corporate IT infrastructure.

For Sandbox to process objects, you need to configure it, and then install virtual machines in it.

Initial Sandbox setup

Before installing virtual machines, you need to configure Sandbox:

- Configure database updates.
- Ensure that internet access was configured correctly during Sandbox installation. Adjust settings if necessary.

Optionally, you can change the administrator password and configure authentication policies.

Configuring database updates for Sandbox

During the license validity period, Sandbox obtains update packages automatically once every hour.

To configure database updates for Sandbox:

1. In the Sandbox web interface, go to **Database update**.
2. In the **Update source** settings group, select a source from which you want to receive updates:
   - **Kaspersky update servers**

     Sandbox connects to the Kaspersky update server over HTTP and downloads up-to-date databases.
   - **Kaspersky update servers (secure connection)**

     Sandbox connects to the Kaspersky update server over HTTPS to download up-to-date databases. It is recommended to use HTTPS for secure updates.
   - **Custom server**

     Sandbox connects to your FTP or HTTP server or to the folder with program databases on your computer to download up-to-date databases.

3. If you selected **Custom server**:

   - If you want to specify an FTP or HTTP server as the update source, in the field below this setting, specify the full path to the application database update package directory to download up-to-date databases.
   - If you want to specify the Kaspersky EDR Expert server hosting the Sandbox component as the update source, in the field below this setting, specify the following address of the update source to download up-to-date databases:

     ```
     http://updater.<smp_domain>:8083/retranslation
     ```

4. Decide whether to use a proxy server when downloading updates:

   - To enable the proxy server, turn on the toggle switch next to the **Proxy server** settings group name, and then specify the settings to connect to the proxy server:
     - Proxy server address and port number.
     - Proxy server user name and password.
   - To disable the proxy server, turn off the toggle switch next to the **Proxy server** settings group name.

5. Click **Apply** to save the settings.

Sandbox network interfaces

Configuring Sandbox network interfaces includes setting up DNS servers, configuring management network interfaces, managing internet access for processed objects, and adding static network routes.

Configuring DNS settings

To configure DNS:

1. In the Sandbox web interface, go to **Network interfaces**.
2. In the **Host name** field, specify the name of the server to install Sandbox. The name of the server must be in the FQDN format.
3. Click the **Add** button to the right of **DNS servers**.
4. In the empty field that appears, specify the IP address of the primary DNS server in IPv4 format.
5. Click the ✓ button to the right of the specified IP address.

The DNS server is added.

To add more DNS servers, repeat steps 2 through 5.

To remove a previously added DNS server, click to the right of the specified DNS server IP address. Note that you can only remove additional DNS servers, not the primary DNS server. If you have added two and more DNS servers, you can remove any of them. The remaining DNS server becomes the primary server.

Configuring a management network interface

A management network interface is intended for providing access to the Sandbox server via the SSH protocol. Sandbox also receives objects via this interface.

Management network interface is initially configured during Sandbox installation. After Sandbox is installed, you can change the management network interface settings from the Sandbox web interface as described below.

To configure a management network interface:

1. In the Sandbox web interface, go to **Network interfaces**.
2. In the **Management interface** settings group from the **Interface** drop-down list, select a network interface that you want to use as a management interface.
3. Configure the management interface parameters:
   - **IP**: the IP address that you want to assign to this network interface if no IP address is assigned.
   - **Mask**: the mask of the network in which you want to use this network interface.
4. Click **Apply**.

The management network interface is configured.

Configuring Internet access for processed objects

Objects processed by Sandbox may attempt to act on the Internet via the network interface configured for Internet access. In this case, Sandbox can analyze the behavior of these objects on the Internet. If you block Internet access, the Sandbox analyzes the behavior of objects excluding their actions on the Internet.

Security risks and considerations

If your organization's security policy blocks internet access from local network computers, and the Sandbox network interface for internet access is open, the following scenario becomes possible:

1. A hacker adds a malicious application to a random file and then sends it to Sandbox for scanning from a local network computer.
2. The file is transferred outside the local network during the scan.

If Internet access for processed object is blocked, this risk is eliminated. However, this also means the reduced quality of alerts, because processed objects cannot be properly analyzed.

To configure the network interface used for Internet access of processed objects:

1. In the Sandbox web interface, go to **Network interfaces**.
2. In the **Internet interface** settings group from the **Interface** list, select a network interface that you want to use for Internet access of processed objects.
3. Configure the interface parameters:
   - **IP**: the IP address that you want to assign to this network interface if no IP address is assigned.
   - **Mask**: the mask of the network in which you want to use this network interface.
   - **Default gateway**: gateway address of the network in which you want to use this network interface.
4. Click **Apply**.

The network interface used for Internet access of processed objects is configured.

Adding a static network route

To add a static network route:

1. In the Sandbox web interface, go to **Network interfaces**.
2. In the **Static routes** settings group, click the **Add** button.
   A set of empty fields appears in the list of static network routes.
3. Configure the route parameters:
   - **IP**: the IP address of the server for which you want to configure a static network route.
   - **Mask**: the subnet mask.
   - **Gateway**: the IP address of the gateway.
4. From the **Interface** list, select a network interface for which you want to add a static network route.
5. Click the ✓ button to the right of the specified route.
6. Click **Apply**.

The static network route is added.

After adding a static network route, you can further manage it by clicking the 🗑 button to delete it or the ✎ button to modify it. When modifying, you will need to specify the same parameters as when creating a new route as described above.

Changing the Sandbox administrator account password

To change the Sandbox administrator account password:

1. In the Sandbox web interface, go to **Administration** → **Change password**.
2. In the **Current password** field, enter the password you have used to log in into Sandbox.
3. In the **New password** and **Confirm password** fields, enter a new password.
4. Click **Change password**.

Sandbox authentication policies

You can configure Sandbox authentication policies for Kaspersky EDR Expert users.

Termination of inactive sessions

If the user is not doing anything (the session is idle), we recommend terminating such a session. This reduces the risk of unauthorized access to Sandbox in cases when the user is actually done working with the application, but did not end the session.

Notifications about failed authentication attempts

Frequent failed attempts to log in to the web interface may indicate that a cybercriminal is trying to gain access to Sandbox by brute-forcing the password. To prevent such unauthorized access, we recommend enabling notifications about the failed authentication attempt limit being exceeded.

Terminating inactive Sandbox sessions

If the user is not doing anything (the session is idle), we recommend terminating such a session. This reduces the risk of unauthorized access to Sandbox in cases when the user is actually done working with the application, but did not end the session.

To enable and configure the termination of inactive sessions:

1. In the Sandbox web interface, go to **Authentication policies**.
2. In the **Terminate inactive sessions** section, specify the time after which you want the user session to be terminated if the user does not perform any actions. Enter the time in minutes in the **Terminate inactive sessions after** field.
3. Click **Apply**.

Sandbox terminates inactive user sessions after the specified time.

Notifications about failed Sandbox authentication attempts

Frequent failed attempts to log in to the web interface may indicate that a cybercriminal is trying to gain access to Sandbox by brute-forcing the password. To prevent such unauthorized access, we recommend enabling notifications about the failed authentication attempt limit being exceeded.

To enable and configure notifications about failed authentication attempts:

1. In the Sandbox web interface, go to **Authentication policies**.
2. In the **Count authentication attempts** section set the **Count attempts** toggle switch to **Enabled**.
3. In the **Counting period** field, enter the time period for which you want to count failed authentication attempts. The time is specified in minutes. If a user attempts to log in to the web interface or the management console and fails more than two times in a row, the following takes place:

   - A record about the user's failed authentication attempts is written to the user activity log.
   - If a rule has been created for sending notifications about too many failed authentication attempts, an email message is sent to the addresses specified in the notification rule. The message contains information about the failed user authentication attempts.

   In the **Counting period** field, you may specify `0`, in which case all failed authentication attempts are counted, regardless of the how much time has passed between them.
4. Click **Apply**.

Making virtual machines ready for work

Sandbox uses virtual machines to run objects on various operating systems in order to analyze the behavior of the objects and detect their malicious activity.

You can install virtual machines of two types:

- *Preconfigured*, or *default*. These are virtual machines based on operating system images (ISO files) from the distribution kit. You cannot modify these images or the applications installed there.

  > The default operating systems and applications may require activation. Activation is performed using your licenses.

- *Custom*. These are virtual machines based on operating systems you choose. You can install any applications on these operating systems.

You can use custom and default operating system images at the same time.

Installing virtual machines involves the following steps:

1. *Optional*. Uploading images to Storage. You may skip this step and upload an image directly from your computer when creating a template.
2. Making a template by either importing a preconfigured template or creating a custom virtual machine template.
3. *For custom templates*. Configuring the operating system and software.
4. Creating a virtual machine.
5. Installing a virtual machine.

Uploading images to Storage

To upload an image to Storage:

1. In the Sandbox web interface, go to **Templates & Storage** → **Storage**.
2. Click **Upload**.
3. Select the .ISO file that you want to upload to Storage, and then click **Open**.

Importing a template

Importing a template is the first step if you want to install a preconfigured virtual machine.

You can also import a template of a custom virtual machine if you have created and exported it earlier.

To import a virtual machine template:

1. In the Sandbox web interface, go to **Templates & Storage** → **Templates**.
2. From the **Add** drop-down list, select **Import template**.
3. Select a file to import, and then click **Open**.

Creating a custom virtual machine template

To create a custom virtual machine template:

1. In the Sandbox web interface, go to **Templates & Storage** → **Templates**.
2. From the **Add** drop-down list, select **Create template**.
   Template creation window opens.
3. At the **Preparing the image** step:
   a. Specify image **Name** and optional **Description**.
   b. To specify an operating system for the template, do one of the following:
      - Select an image from the list of available images in the **OS image** drop-down list.
      - Upload the operating system image: click **Upload**, select an ISO-file, and then click **Open**.
   c. Click **Proceed**.
4. At the **Customizing the template** step:
   a. In the **Mount ISO** drop-down list, select the image of the application that you want to install in the operating system.
      For the image to be displayed in the list, do one of the following:
      - Upload the image to Storage.
      - Upload the application image file: click **Upload**, select an ISO-file, and then click **Open**.
   b. When the application is installed, unmount the installed image: in the **Mount ISO** drop-down list, click the ⏏ icon next to the image.
   c. Configure the operating system and installed software.

Configuring the operating system and software

Preparing operating systems for use

When installing Windows 7, 8.1, or 10 operating systems, you must satisfy the following requirements:

- Disable the screen saver.
- Select the Always On power plan.

- Disable automatic updates.
- Disable Windows Firewall.

If you are using Windows 7, support of the SHA-2 hash algorithm is required. To make sure this hash algorithm is supported, install the Security Update for Windows 7 for x64-based Systems (KB3033929). For 32-bit Windows 7 operating systems, update KB3033929 must also be installed.

> Do not install update KB4474419. This update may cause a crash during virtual machine deployment.

To use Windows 7, you must enable TLS 1.1 and TLS 1.2 in the operating system settings. To do this, in Windows 7, in the **Control Panel** → **Internet Options** → **Advanced** section, select the **Use TLS 1.1** and **Use TLS 1.2** check boxes.

When using Windows 8.1 or 10, you must disable fast boot and enable automatic logon.

Localization of operating systems

You can select a localization language when installing the system or install the system with English localization and additionally install a localization package in that system. You can select one of the following languages: Russian, English, Chinese (Simplified), Arabic, Spanish (Mexico). If you select a different localization, the quality of object scanning is diminished.

> For the Windows XP operating system, only Russian and English are supported.

Configuring operating systems

When the operating system is installed:

- Make sure the default command shell is configured.
- Activate the operating system and other licensed software.

You can do the following with the installed operating system:

- Assign a static name to the computer.
- Create user accounts.

  > In this case, you need to configure automatic logon.

- Install software.

Limitations on software installation:

- Only one image at a time can be connected to one template. After the template has been saved, you can disconnect one image and mount another.
- Versions of Microsoft Office later than 2016 are not supported.
- Installing the following types of software is strongly discouraged:
  - Software that injects its code into another running process
  - Drivers for protection
  - Anti-virus applications including Windows Defender
- Detection of malicious activity of files that rely on highly specialized software to run is not guaranteed.

Kaspersky EDR Expert does not notify about problems with software installed on the operating system.

Creating a virtual machine

To create a virtual machine with a custom operating system image, internet access is required.

To create a virtual machine:

1. *For custom templates*. Make sure that the template used to create a virtual machine is turned off:
   a. In the Sandbox web interface, go to **Templates & Storage** → **Templates**.
   b. Select the template.
   c. If the template is turned on, select one of the options in the **Shut down** drop-down list:
      - **Shut down** if you want to shut down the system while saving the results of running applications.
      - **Power off** if you want to shut down the system without saving the results.
2. In the Sandbox web interface, go to **Virtual machines**.
3. Click **Create VM**.
4. In the **Template** drop-down list, select a template.
5. *For custom operating systems*: Specify the virtual machine **Name** and optional **Description**.
6. Click **Save**.
7. *For the preconfigured operating systems*: Some operating systems from the distribution kit require accepting the terms of end user license agreement. Read the text of the end user license agreement and click **Accept**.
8. *For custom operating systems*: If internet access is not configured for the server on which you are creating the virtual machine, the *No internet access* error message is displayed in the **Templates** window. To complete the virtual machine creation process, you must download debug symbols.

Installing a virtual machine

To install a virtual machine with a preconfigured operating system:

1. In the Sandbox web interface, go to **Virtual machines** → **Preconfigured**.
2. In the **Not installed virtual machines** section, click **Install ready VMs**.

To install a virtual machine with a custom operating system:

1. In the Sandbox web interface, go to **Virtual machines** → **Custom**.
2. Find the virtual machine in the list, and then click **Install** in the **Actions** column.
3. When the virtual machine is installed, in the **Actions** column, click **Enable**.

Downloading debug symbols

If internet access is not configured for the server on which the virtual machine with the custom image is installed, you must download the Microsoft debug symbols to correctly complete the virtual machine installation.

For debug symbols to download correctly, the operating system used for the virtual machine template must have Windows Debug Tools installed and the name of the host connected to the network (hostname) must contain only Latin letters, numerals, and special characters.

To download debug symbols:

1. In the Sandbox web interface, go to **Templates & Storage** → **Templates**.
2. Select the template.
3. In the window with the **No internet access** error, click **Download manifesto**.

   Download manifesto is not available until the virtual machine gets the **Failed** status.

4. Unpack the downloaded archive.
5. Run sbsymtool.ps1 using Windows PowerShell.
   This script downloads an archive with the debug symbols.
6. In the Sandbox web interface, go to **Templates & Storage** → **Templates**.
7. Select the template for which you have downloaded debug symbols.
8. In the **Actions** drop-down list, select **Upload symbols**.
9. In the window that opens, select the archive with the debug symbols, and then click **Open**.

Debug symbols are downloaded.

Configuring OSMP to use detection technologies

Kaspersky EDR Expert detects threat by using different detection technologies such as Anti-Malware Engine or Sandbox. You need to configure OSMP to be able to use the detection technologies.

Anti-Malware Engine

For Anti-Malware Engine, do the following:

- Configure getting updates for anti-virus databases.
- Create a list of passwords for password-protected archives.

Sandbox

After you have installed and configured Sandbox and installed virtual machines in it, you need to do the following:

- Configure getting updates for anti-virus databases.
- Select operating systems for scanning objects.
- Create custom Sandbox rules if you are going to use custom operating systems.
- Configure sending files from Endpoint Agents.

YARA

For YARA scanning, do the following:

Import YARA rules

IOC

For IOC scanning, do the following:

- Configuring IOC scanning on schedule
- Importing IOC rules

Updating anti-virus databases for Sandbox and Anti-Malware Engine

When scanning objects, Sandbox and Anti-Malware Engine require up-to-date anti-virus databases, so the anti-virus databases should be updated regularly. As a source of updates, you can use one of Kaspersky server or your own source, which can be an HTTP server, FTP server, or folder.

Kaspersky EDR Expert automatically looks for new update packages in the specified source once every 30 minutes. You can also update the anti-virus databases manually at any time.

To configure getting updates for Sandbox and Anti-Malware Engine, you must have one of the following EDR roles: Main administrator, SOC administrator, Tenant administrator, Auditor.
Users with the Auditor role can only view the current update source. Users with the other role can view and change the update source.

To configure getting updates for Sandbox and Anti-Malware Engine:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the **Root** tenant (update settings cannot be changed in other tenants).

   The tenant's properties window opens.

3. Select the **Settings** tab.

4. In the **Scanning** section, select the **Update databases** tab.

5. In the **Update source** drop-down list, select one of update sources:

   - **Kaspersky update servers (secure connection)**

     Kaspersky EDR Expert connects to Kaspersky update server over HTTPS and downloads up-to-date databases. It is recommended to use HTTPS to download database updates.

   - **Kaspersky update servers**

     Kaspersky EDR Expert connects to Kaspersky update server over HTTP and downloads up-to-date databases.

- **Custom server**

  Kaspersky EDR Expert connects to your update source to download up-to-date databases. Specify the path to your update source in **URL or folder path**. It can be either a URL for HTTP or FTP server, or a full path to the folder containing an update package.

6. If you want to update the anti-virus databases immediately, click **Update**.

7. Click the **Save** button.

Getting updates for Sandbox and Anti-Malware Engine is configured. Kaspersky EDR Expert displays information about the latest update in the **Updated on** field.

You can update the anti-virus databases manually at any time by clicking **Update**.

Creating a list of passwords for password-protected archives

By default, Kaspersky EDR Expert cannot scan objects in password-protected archives. Such archives must be unpacked first. You can create a list of passwords commonly used for archives in your organization. Kaspersky EDR Expert tries passwords from the list when scanning an archive. If one of the passwords matches, Kaspersky EDR Expert unpacks the archive and scans objects in it.

To work with the list of passwords for password-protected archives, you must have one of the following EDR roles: Main administrator, Tenant administrator, Tier 1 analyst, Tier 2 analyst, Auditor.
Users with the Auditor role can only view the list of passwords. Users with the other role can view and edit the list.

To create a list of passwords for unpacking password-protected archives:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the **Root** tenant (the list of passwords cannot be changed in other tenants).

   The tenant's properties window opens.

3. Select the **Settings** tab.

4. In the **Scanning** section, select the **Archives** tab.

5. In the **Password for archives** field, add passwords for unpacking password-protected archives, each password on a new line.

6. If you want to restrict access to the list of passwords, turn on the **Require a password to access the password list** toggle switch, and then specify the password in the **Set access password** pane. You can share this password with the OSMP users who need access to the list of passwords for password-protected archives.

   Click **Save** to save the access password.

   You can change this password later if necessary by clicking **Change password** on the **Archives** tab.

7. Click **Save** or **Save and close** to save the list of passwords for password-protected archives.

Selecting operating systems for scanning objects in Sandbox

The Sandbox component runs objects in several operating systems and analyzes the behavior of these objects to detect malicious activity and indicators of targeted attacks and intrusions into the corporate IT infrastructure.

You can choose operating systems for scanning objects. It can be one of predefined sets, a custom set or their combination.

To select a set of operating systems:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Select the **Settings** tab.

4. In the **Sandbox servers** section, click the link next to **Operating systems to check**.

5. In the **Edit operating system set** pane that opens, under **Set of operating systems**, select either one of the predefined sets of operating systems or **Custom**.

   If you want to combine preset operating systems with custom operating systems, select **Custom**.

6. If you have selected **Custom**, the list of available operating systems is displayed under **Set contents**.

   This list always includes preset operating systems. If there is no virtual machine running a preset operating system on Sandbox, this operating system has the **Unknown** status.

   The list includes a custom operating system if there is a virtual machine running this operating system on the Sandbox server.

   Select the check boxes next to the operating systems that you want to include in the set.

7. Click the **Save** button.

The set of operating systems for scanning objects is ready.

For a custom set of operating systems, you also need to create custom rules.

Creating custom Sandbox rules

If you have selected custom operating systems for scanning objects, you also need to create custom rules that define what kind of objects should be scanned and on which operating system.

You do not need to create rules for sending objects for scanning to the preset operating systems, Kaspersky EDR Expert sends objects there automatically.

Custom Sandbox rules apply only to custom virtual machines created in the Sandbox web interface.

To add a custom Sandbox rule:

1. In the main menu, go to **Monitoring → Resources and services → Sandbox rules**.
2. Click **Add**.

   Rule creation window opens.
3. Configure the following settings:
   - Turn on the **Rule status** toggle switch if you want to enable the rule immediately after it is created.
   - Select the tenant owner.
   - Select the virtual machine on which files should be scanned.

     You can only choose from virtual machines running custom operating systems that you have selected.
   - Under **Matching criteria**, select whether you want to use a **Mask**, a **File category** or **Both** as a matching criteria.
   - If you have selected **Mask** or **Both** as a matching criteria:
     - Specify a **Mask** for the names of files to be sent to Sandbox according to the rule.

       You can specify multiple values, each value on its own line.

       You can use the * and ? wildcard characters. Other wildcard characters are not supported.
     - Specify an optional **Mask exclusion** for files that must be excluded from scanning even if their file extensions match the mask specified earlier.

       You can specify multiple values, each value on its own line.

       You can use the * and ? wildcard characters. Other wildcard characters are not supported.

     You can use the **Mask exclusion** field if only virtual machines tagged as **Custom** are selected in the **Custom set** list of the **Sandbox servers** settings. If both a custom virtual machine and a preconfigured virtual machine are selected, the **Mask exclusion** field is ignored.
   - If you have selected **File category** or **Both** as a matching criteria:

     In the **File category** drop down list, select categories of files to be sent to Sandbox according to the rule.
   - To limit the size of files to be sent to Sandbox, click **Add file size**, and then specify the **Minimum** and **Maximum** size of a file. This way you can set multiple size ranges.
4. Click the **Save** button.

The rule appears in the list of custom Sandbox rules.

Specifics of scanning archives

Archives are scanned as follows:

1. Kaspersky EDR Expert unpacks the archive.
2. If some files from the archive match the rule, Kaspersky EDR Expert sends them for scanning.

Files with the MSI extension are processed similar to archives.

Configuring sending of files from Endpoint Agents to Sandbox

Endpoint Agents can send files to Sandbox for scanning in several ways:

- Endpoint Agent **automatically** detects objects and submits them to Sandbox for scanning.
- Endpoint Agent user **manually** submits a file for scanning.
- Endpoint Agent sends a file that has triggered an **IOA rule**. When an IOA rule is triggered on a device, and this IOA rule contains a condition for sending detected objects to Sandbox, Kaspersky EDR Expert automatically initiates the **Get file** response with the **Scan file** option enabled.

Automatic sending of files to Sandbox may significantly increase the load on OSMP.

To configure sending of files to be scanned in Sandbox:

1. Make sure Sandbox is integrated with OSMP.
2. In the main menu, go to **Settings** → **Tenants**.
   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.
3. Click the name of the required tenant.
   The tenant's properties window opens.
4. Select the **Settings** tab.
5. In the **Scanning** section, select the **Sandbox** tab.
6. Configure the settings:
   - To enable **automatic** sending of files detected by Endpoint Agent:
     Under **Send files from devices for analysis to Sandbox**, turn on the **Send files automatically** toggle switch.
     By default, this option is disabled.
   - To enable **manual** sending of files by a user:

Under **Send files from devices for analysis to Sandbox**, turn on the **Send files manually** toggle switch.

By default, this feature is enabled.

- To enable sending of files when an **IOA rule** is triggered:

  Under **Send files to Sandbox automatically**, turn on the **Send files** toggle switch.

  By default, this option is disabled.

7. Click **Save and close**.

Sending of files to Sandbox is configured. Based on the results of the scan, Kaspersky EDR Expert may create an alert.

About indicators of compromise, IOC files and IOC rules

Kaspersky EDR Expert can scan devices for indicators of compromise. Indicators of compromise (IOCs) are digital objects like file hashes or IP addresses that might signal a cyberattack. You can learn more about IOCs in Kaspersky IT encyclopedia.and on Securelist.

IOC files

Multiple IOCs can be combined into a structured description in an *IOC file*. There is a standard *OpenIOC format* for such files.

Below is an example of a simple IOC file.

```
<?xml version="1.0" encoding="us-ascii"?>
<ioc xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xmlns:xsd="http://www.w3.org/2001/XMLSchema" id="unique
ID in the UUID format" last-modified="date of the last modification of the rule in the YYYY-MM-DDThh:mm:ss format"
xmlns="http://schemas.mandiant.com/2010/ioc">
 <short_description>Rule name</short_description>
 <authored_by>Rule name</authored_by>
 <authored_date>file creation date in the YYYY-MM-DDThh:mm:ss format</authored_date>
 <links />
 <definition>
 <Indicator operator="OR" id="Unique ID in the UUID format">
 <IndicatorItem id="Unique ID in the UUID format" condition="is">
 <Context document="FileItem" search="FileItem/Md5sum" type="mir" />
 <Content type="md5">MD5 hash of the file</Content>
 </IndicatorItem>
 </Indicator>
 </definition>
</ioc>
```

You can create your own IOC file in a text editor and save it with the .ioc extension. Depending on your Endpoint Agent application, you can use OpenIOC terms listed in files:

OpenIOC terms for Kaspersky Endpoint Security for Windows

OpenIOC terms for Kaspersky Endpoint Security for Linux

There is no OpenIOC terms list for Kaspersky Endpoint Security for Mac, because Kaspersky EDR Expert does not send IOC scan tasks to Kaspersky Endpoint Security for Mac.

IOC rules

When you import an IOC rule, Kaspersky EDR Expert extracts the structured description from an IOC file and creates a rule based on the description.

IOC rules are available in the IOC rules list in the OSMP Console interface → **Monitoring** → **Resources and services** → **IOC rules**.

Configuring IOC scanning on schedule

You can configure the schedule for IOC scanning on devices with the Endpoint Agent component installed. If the scanning schedule is set, Endpoint Agents search for indicators of compromise on devices daily according to IOC rules that have scheduled scan enabled.

By default, the IOC scanning is performed daily. You can either change the start time and the duration of the scanning, or disable the daily scanning.

To configure IOC scanning on schedule:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Select the **Settings** tab.

4. In the **Scanning settings** section, select the **IOC scanning schedule** tab.

5. Turn on the **Daily scanning** toggle switch, and then specify the settings for the scanning schedule:

   - **Start time (UTC)**. The time when the IOC scan starts. The time is specified in the time zone of the OSMP server on which you are performing the configuration.

     If an Endpoint Agent gets the new scan schedule later than the time specified in **Start time (UTC)**, the next scan is initiated the next day at the time specified in **Start time (UTC)**.

   - **Maximum scan duration (hours)**. Time limit for IOC scanning, in hours. When the limit is reached, Endpoint Agent finishes the scanning process regardless of its completeness.

6. Click **Save** or **Save and close** to save the settings.

The new schedule for IOC scanning becomes active immediately after changes are saved. If the scan detects a threat, the IOC alert is created.

Limitations for Kaspersky Endpoint Security for Windows

If the IOC search scope defined in an IOC rule includes the RegistryItem data type, Kaspersky Endpoint Security for Windows scans the limited set of registry keys.

Import IOC rules

Kaspersky EDR Expert imports IOC rules from a file containing IOC ules. One file can contain only one IOC rule, so the list of IOC rules is also the list of IOC files from which the rules were created.

The list of IOC rules is available in the OSMP Console interface → **Monitoring** → **Resources and services** → **IOC rules**.

To import an IOC rule:

1. In the main menu, go to **Monitoring** → **Resources and services** → **IOC rules**.

   The list of IOC rules opens.

2. Click **Import**.

3. In the **Import IOC rules** pane that opens, configure the following settings:

   - In the **Tenant** drop-down list, select the tenant.
   - In the **Importance** drop-down list, select the importance of the rule. Kaspersky EDR Expert assigns this value to an alert created as the result of the IOC rule being triggered.
   - If you want Kaspersky EDR Expert to regularly scan devices for indicators of compromise described in the rule, turn on the **Scheduled scan** toggle switch (the scheduled scan must be configured).

     You can also enable scheduled scan later by turning on a toggle switch in the **Scheduled scan** column of the IOC rules list.

4. Upload a file containing an IOC rule.

5. Click **Import**.

Imported rule appears in the list of IOC rules.

Import YARA rules

Kaspersky EDR Expert uses YARA rules to scan files sent to OSMP and to scan devices.

Kaspersky EDR Expert imports YARA rules from a file containing YARA rules. One file can contain multiple YARA rules. Kaspersky EDR Expert parses the file, extracts the rules and adds them to the list of rules. Successful import of a file with over 65,535 rules is not guaranteed.

The list of YARA rules is available in the OSMP Console interface → **Monitoring** → **Resources and services** → **YARA rules**.

To import YARA rules:

1. In the main menu, go to **Monitoring → Resources and services → YARA rules**.

   The list of YARA rules opens.

2. Click **Import**.

3. In the **Import YARA rules** pane that opens, configure the following settings:

   - In the **Tenant** drop-down list, select the tenant.
   - The importance of any YARA rule is **High** by default, you cannot change it. Kaspersky EDR Expert assigns this value to an alert created as the result of the YARA rule being triggered.
   - If you want Kaspersky EDR Expert to use all imported rules to scan files sent to OSMP, turn on the **File scanning** toggle switch.

     You can also include any rule to the set of rules for file scanning later by turning on a toggle switch in the **File scanning** column of the YARA rules list.

     > This feature is only available for the Root tenant.

   - Specify the description (optional).

4. Upload a file containing YARA rules.

   When the file is uploaded, Kaspersky EDR Expert extracts rules from the file and shows information about the extracted rules.

5. Click **Import**.

Imported rules appear in the list of YARA rules.

Working with Open Single Management Platform

Open Single Management Platform (hereinafter referred to as OSMP) is an open technology platform that allows you to integrate Kaspersky applications and third-party applications into a single security system, and provide cross-application scenarios. Kaspersky EDR Expert is based on OSMP. To manage Kaspersky EDR Expert, the OSMP web interface (hereinafter referred to as OSMP Console) is used.

The OSMP Console lets you do the following:

- Manage the status of the organization's security system.
- View information about the security of your organization's network.
- Configure the detection, hunting, and response of threats.
- Manage policies created for assets on your network.
- Manage tasks for applications installed on your network devices.
- Manage users and roles.
- Configure the migration of data to Kaspersky EDR Expert.
- Install Kaspersky applications on devices on your network and manage installed applications.
- Poll the network to discover client devices, and distribute the devices to administration groups manually or automatically.
- Manage Kaspersky EDR Expert integrations with other applications.

OSMP Console is a multi-language web interface. You can change the interface language at any time, without reopening the application.

The default authentication method in OSMP Console is to enter user name, password, and an additional single-use security code for two-factor authentication. Starting with Kaspersky EDR Expert 8.0, two-factor authentication is enabled automatically and the option to configure two-factor authentication at sign-in is disabled by default.

You can configure domain authentication over the Kerberos protocol. Domain authentication allows you to enable secure authentication in OSMP Console without having to re-enter the password on the corporate network (single sign-on).

Configuring Administration Server

This section describes the configuration process and properties of Administration Server.

Configuring the Administration Server connection address

The Administration Server connection address is the network address used for the following purposes:

- As a default address when creating the Network Agent installation packages

  After the installation of the Network Agent, managed devices connect to the Administration Server at this address.

- As the KSN proxy server address

  Managed devices connect to the KSN proxy server via this address.

To configure the Administration Server connection address:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **General** section.

3. In the window that opens, in the **Administration Server connection address** field, specify the new Administration Server connection address.

   The maximum length of the connection address is 255 characters.

   You can specify the Administration Server connection address as the NetBIOS name, FQDN, or the IP address of the Administration Server.

4. Click the **Save** button.

The specified address is used as the Administration Server address and the KSN proxy server address.

Configuring the OSMP Console connection to Administration Server

You can configure the connection of OSMP Console to Administration Server through the Administration Server properties or by using the Administration Server policy settings.

To set the connection ports through the Administration Server properties:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Connection ports** section.

3. If necessary, specify the **SSL port for Web Console** setting or specify other Administration Server connection ports.

The main connection settings of the selected Server are specified.

To set the connection ports through the Administration Server policy settings:

1. In the main menu, go to **Asset management** → **Policies**.
2. Click the name of the Administration Server policy, and then go to the **Application settings** tab.
3. If necessary, specify the **SSL port for Web Console** setting or specify other Administration Server connection ports.

   If you disable the **Open port for Web Console** option and this policy setting will be applied to the device, you will not be able to connect to the Administration Server by using OSMP Console. In this case, the connection will be terminated. If you have an Administration Server on which this policy is not applied, you can reconnect to this Administration Server through OSMP Console.

The main connection settings of the selected Server are specified.

Configuring internet access settings

An internet connection is required for proper operation of Kaspersky EDR Expert components and can be used for specific integrations, both Kaspersky and third-party. For example, you must configure internet access for Administration Server to use Kaspersky Security Network and to download updates of anti-virus databases for Kaspersky EDR Expert and managed Kaspersky applications.

The integration settings of some Kaspersky applications contain an option to enable or disable the usage of proxy server. For example, such an option is available when you configure integration with Kaspersky Threat Intelligence Portal.

To specify the internet access settings:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.
2. On the **General** tab, select the **Configuring internet access** section.
3. Enable the **Use proxy server** option if you want to use a proxy server when connecting to the internet. If this option is enabled, the fields are available for entering settings. Specify the following settings for a proxy server connection:

   - **Address**

     Address of the proxy server used for Kaspersky EDR Expert connection to the internet.

   - **Port number**

     Number of the port through which Kaspersky EDR Expert proxy connection will be established.

   - **Bypass proxy server for local addresses**

     No proxy server will be used to connect to devices in the local network.

- **Proxy server authentication**

  If this check box is selected, in the entry fields you can specify the credentials for proxy server authentication.

  This entry field is available if the **Use proxy server** check box is selected.

- **User name**

  User account under which connection to the proxy server is established (this field is available if the **Proxy server authentication** check box is selected).

- **Password**

  Password set by the user under whose account the proxy server connection is established (this field is available if the **Proxy server authentication** check box is selected).

  To see the entered password, click and hold the **Show** button for as long as you require.

Certificates for work with Open Single Management Platform

This section contains information about Open Single Management Platform certificates and describes how to issue and replace certificates for OSMP Console and how to renew a certificate for Administration Server if the Server interacts with OSMP Console.

About Open Single Management Platform certificates

Open Single Management Platform uses the following types of certificates to enable a secure interaction between the application components:

- Administration Server certificate
- OSMP Console Server certificate
- OSMP Console certificate

By default, Open Single Management Platform uses self-signed certificates (that is, issued by Open Single Management Platform itself). If necessary, you can replace the self-signed certificates with user certificates in accordance to your organization's security standards. After Administration Server verifies whether a user certificate meets all applicable requirements, this certificate assumes the same functional scope as a self-signed certificate. The only difference is that a user certificate is not reissued automatically upon expiration. You replace certificates with custom ones by means of the klsetsrvcert utility or through the Administration Server properties section in OSMP Console, depending on the certificate type. When you use the klsetsrvcert utility, you need to specify a certificate type by using one of the following values:

- C—Common certificate for ports 13000 and 13291.
- CR—Common reserve certificate for ports 13000 and 13291.

The maximum validity period for any of the Administration Server certificates must be 397 days or less.

Administration Server certificates

An Administration Server certificate is required for the following purposes:

- Authentication of Administration Server when connecting to OSMP Console
- Secure interaction between Administration Server and Network Agent on managed devices
- Authentication when the primary Administration Servers are connected to secondary Administration Servers.

The Administration Server certificate is created automatically during installation of the Administration Server component and it is stored in the /var/opt/kaspersky/klnagent_srv/1093/cert/ folder. You specify the Administration Server certificate when you create a response file to install OSMP Console. This certificate is called common ("C").

The Administration Server certificate is valid for 397 days. Open Single Management Platform automatically creates a common reserve ("CR") certificate 90 days before the expiration of the common certificate. The common reserve certificate is subsequently used for seamless replacement of the Administration Server certificate. When the common certificate is about to expire, the common reserve certificate is used to maintain the connection with Network Agent instances installed on managed devices. With this purpose, the common reserve certificate automatically becomes the new common certificate 24 hours before the old common certificate expires.

> The maximum validity period for any of the Administration Server certificates must be 397 days or less.

If necessary, you can assign a user certificate for the Administration Server. For example, this may be necessary for better integration with the existing PKI of your enterprise or for custom configuration of the certificate fields. When replacing the certificate, all Network Agents that were previously connected to Administration Server through SSL will lose their connection and will return "*Administration Server authentication error.*" To eliminate this error, you will have to restore the connection after the certificate replacement.

If the Administration Server certificate is lost, you must reinstall the Administration Server component, and then restore the data in order to recover it.

You can also back up the Administration Server certificate separately from other Administration Server settings in order to move Administration Server from one device to another without data loss.

Mobile certificates

A mobile certificate ("M") is required for authentication of the Administration Server on mobile devices. You specify the mobile certificate in the Administration Server properties.

Also, a mobile reserve ("MR") certificate exists: it is used for seamless replacement of the mobile certificate. Open Single Management Platform automatically generates this certificate 90 days before the expiration of the common certificate. When the mobile certificate is about to expire, the mobile reserve certificate is used to maintain the connection with Network Agent instances installed on managed mobile devices. With this purpose, the mobile reserve certificate automatically becomes the new mobile certificate 24 hours before the old mobile certificate expires.

If the connection scenario requires the use of a client certificate on mobile devices (connection involving two-way SSL authentication), you can generate those certificates by means of the certificate authority for auto-generated user certificates ("MCA"). Also, in the Administration Server properties, you can specify custom client certificates issued by a different certification authority, while integration with the domain Public Key Infrastructure (PKI) of your organization enables you to issue client certificates by means of your domain certification authority.

Web Server certificate

Web Server, a component of Kaspersky Security Center Administration Server, uses a special type of certificate. This certificate is required for publishing Network Agent installation packages that you subsequently download to managed devices. For this purpose, Web Server can use various certificates.

Web Server uses one of the following certificates, in order of priority:

1. Custom Web Server certificate that you specified manually by means of OSMP Console
2. Common Administration Server certificate ("C")

OSMP Console certificate

The OSMP Console Server has its own certificate. When you open a website, a browser verifies whether your connection is trusted. The Web Console certificate allows you to authenticate the Web Console and is used to encrypt traffic between a browser and the Web Console.

When you open the Web Console, the browser may inform you that the connection to the OSMP Console is not private and the OSMP Console certificate is invalid. This warning appears because the OSMP Console certificate is self-signed and automatically generated by Open Single Management Platform. To remove this warning, you can do one of the following:

- Replace the Web Console certificate with a custom one (recommended option). Create a certificate that is trusted in your infrastructure and that meets the requirements for custom certificates.
- Add the Web Console certificate to the list of trusted browser certificates. We recommend that you use this option only if you cannot create a custom certificate.

Requirements for custom certificates used in Open Single Management Platform

The table below shows the requirements for user certificates specified for different components of Open Single Management Platform.

Certificate type	Requirements	Comments
Common certificate, Common reserve certificate ("C", "CR")	Minimum key length: 2048. Basic constraints: • Path Length Constraint: None Key Usage: • Digital signature • Certificate signing • Key encryption • CRL Signing Extended Key Usage (optional): server authentication, client authentication. The certificate must include a valid Subject Alternative Name (SAN) that contains the Administration Server loopback address: • For IPv4: 127.0.0.1 • For IPv6: 0:0:0:0:0:0:0:1	Extended Key Usage parameter is optional. Path Length Constraint value may be an integer different from "None", but not less than 1.
Mobile certificate, Mobile reserve certificate ("M", "MR")	Minimum key length: 2048. Basic constraints: • CA: true • Path Length Constraint: None Key Usage: • Digital signature • Certificate signing • Key encryption • CRL Signing Extended Key Usage (optional): server authentication.	Extended Key Usage parameter is optional. Path Length Constraint value may be an integer different from "None", if Common certificate has a Path Length Constraint value not less than 1.
Certificate CA for auto-generated user certificates ("MCA")	Minimum key length: 2048. Basic constraints: • CA: true • Path Length Constraint: None Key Usage: • Digital signature • Certificate signing • Key encryption • CRL Signing Extended Key Usage (optional): server authentication, client authentication.	Extended Key Usage parameter is optional. Path Length Constraint value may be an integer different from "None," if Common certificate has a Path Length Constraint value not less than 1.
Web Server certificate	Extended Key Usage: server authentication. The PKCS #12 / PEM container from which the certificate is specified includes the entire chain of public keys. The Subject Alternative Name (SAN) of the certificate is present; that is, the value of the `subjectAltName` field is valid. The certificate meets the effective requirements of browsers imposed on server certificates, as well as the current baseline requirements of the CA/Browser Forum.	—
OSMP Console certificate	The PEM container from which the certificate is specified includes the entire chain of public keys. The Subject Alternative Name (SAN) of the certificate is present; that is, the value of the `subjectAltName` field is valid. The certificate meets the effective requirements of browsers to server certificates, as well as the current baseline requirements of the CA/Browser Forum.	OSMP Console does not support encrypted certificates.
Intermediate certificate for public Kaspersky EDR Expert services	The PEM container that contains the complete certificate chain (or only one certificate) and an unencrypted private key. The intermediate certificate must be issued by your organization's private key infrastructure (PKI). The validity period for the custom intermediate certificate must be 399 days or more.	—

Reissuing the certificate for OSMP Console

Most browsers impose a limit on the validity term of a certificate. To fall within this limit, the validity term of the OSMP Console certificate is limited to 397 days. You can replace an existing certificate received from a certification authority (CA) by issuing a new self-signed certificate manually. Alternatively, you can reissue your expired OSMP Console certificate.

> Automatically reissuing the certificate for OSMP Console is not supported. You have to manually reissue the expired certificate.

When you open the OSMP Console, the browser may inform you that the connection to the OSMP Console is not private and the OSMP Console certificate is invalid. This warning appears because the OSMP Console certificate is self-signed and automatically generated by Open Single Management Platform. To remove or prevent this warning, you can do one of the following:

- Specify a user certificate when you reissue it (recommended option). Create a certificate that is trusted in your infrastructure and that meets the requirements for user certificates.
- Add the OSMP Console certificate to the list of trusted browser certificates after you reissue the certificate. We recommend that you use this option only if you cannot create a user certificate.

To reissue the expired OSMP Console certificate:

Reinstall OSMP Console by performing one of the following:

- If you want to use the same installation file of OSMP Console, remove OSMP Console, and then install the same OSMP Console version.
- If you want to use an installation file of an upgraded version, run the upgrade command.

The OSMP Console certificate is reissued for another validity term of 397 days.

Replacing certificate for OSMP Console

By default, when you install OSMP Console Server (also referred to as OSMP Console), a browser certificate for the application is issued automatically. You can replace the automatically generated certificate with a custom one.

To assign an OSMP Console user certificate:

1. Save the file with the certificate and the file with the private key in the following directory:

   /var/opt/kaspersky/ksc-web-console/certificates/external/

   > Supported file format: PEM.
   > Reading and writing to the directory requires root privileges. The user that the interactive web console service runs as only has the read permission.

2. Name the files as follows:

   - web-console.crt: the file with the certificate.
   - web-console.key: the file with the private key without a password.

   A custom primary certificate is assigned and Web Console is using it.

If you want to replace the user certificate:

- If you want to replace the user certificate with another user certificate, follow the same instructions.
- If you want to replace the user certificate with a self-signed certificate, delete one or both of the user certificate files.

When a user certificate expires, the Web Console displays a corresponding notification and continues to use the expired certificate.

If the user primary certificate that you specified is invalid, the Web Console displays a corresponding notification, releases a self-signed primary certificate, and switches to it.

The notification is first displayed 14 days before the certificate expires.

Converting a PFX certificate to the PEM format

To use a PFX certificate in OSMP Console, you must first convert it to the PEM format by using any convenient OpenSSL-based cross-platform utility.

To convert a PFX certificate to the PEM format in the Linux operating system:

1. In an OpenSSL-based cross-platform utility, execute the following commands:

   ```
   openssl pkcs12 -in <filename.pfx> -clcerts -nokeys | sed -ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' > server.crt
   ```

   ```
   openssl pkcs12 -in <filename.pfx> -nocerts -nodes | sed -ne '/-BEGIN PRIVATE KEY-/,/-END PRIVATE KEY-/p' > key.pem
   ```

2. Make sure that the certificate file and the private key are generated to the same directory where the .pfx file is stored.

3. OSMP Console does not support passphrase-protected certificates. Therefore, run the following command in an OpenSSL-based cross-platform utility to remove a passphrase from the .pem file:

   ```
   openssl rsa -in key.pem -out key-without-passphrase.pem
   ```

   > Do not use the same name for the input and output .pem files.

   As a result, the new .pem file is unencrypted. You do not have to enter a passphrase to use it.

The .crt and .pem files are ready to use, so you can specify them in the OSMP Console installer.

Scenario: Specifying the custom Administration Server certificate

You can assign the custom Administration Server certificate, for example, for better integration with the existing public key infrastructure (PKI) of your enterprise or for custom configuration of the certificate fields. It is useful to replace the certificate immediately after installation of Administration Server.

The maximum validity period for any of the Administration Server certificates must be 397 days or less.

Prerequisites

The new certificate must be created in the PKCS#12 format (for example, by means of the organization's PKI) and must be issued by trusted certification authority (CA). Also, the new certificate must include the entire chain of trust and a private key, which must be stored in the file with the pfx or p12 extension. For the new certificate, the requirements listed below must be met.

Certificate type: Common certificate, common reserve certificate ("C", "CR")

Requirements:

- Minimum key length: 2048.
- Basic constraints:
  - CA: true
  - Path Length Constraint: None

    Path Length Constraint value may be an integer different from "None", but not less than 1.
- Key Usage:
  - Digital signature
  - Certificate signing
  - Key encryption
  - CRL Signing
- Extended Key Usage (EKU): server authentication and client authentication. The EKU is optional, but if your certificate contains it, the server and client authentication data must be specified in the EKU.
- The certificate must include a valid Subject Alternative Name (SAN).

- The `subjectAltName` field must contain the Administration Server loopback address:
  - For IPv4: 127.0.0.1
  - For IPv6: 0:0:0:0:0:0:0:1

Certificates issued by a public CA do not have the certificate signing permission. To use such certificates, make sure that you installed Network Agent version 13 or later on distribution points or connection gateways in your network. Otherwise, you will not be able to use certificates without the signing permission.

Stages

Specifying the Administration Server certificate proceeds in stages:

1. **Replacing the Administration Server certificate**

   Use the command-line klsetsrvcert utility for this purpose.

2. **Specifying a new certificate and restoring connection of Network Agents to the Administration Server**

   When the certificate is replaced, all Network Agents that were previously connected to Administration Server through SSL lose their connection and return "Administration Server authentication error." To specify the new certificate and restore the connection, use the command-line klmover utility.

Results

When you finish the scenario, the Administration Server certificate is replaced and the server is authenticated by Network Agents on the managed devices.

Replacing the Administration Server certificate by using the klsetsrvcert utility

To replace the Administration Server certificate,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke ksc --action klsetsrvcert \
--param ksc_server_certificate="<path_to_new_certificate>" \
--param ksc_server_cert_pass="<password>"
```

where:

- `< path_to_new_certificate >` is the path to the container with the certificate and a private key in the PKCS #12 format (file with the .P12 or .PFX extension).
- `< password >` is the password used for protection of the PKCS #12 container. The certificate and a private key are stored in the container, therefore, the password is required to decrypt the file with the container.

  If the password contains double quotes, escape them with backslashes (`\"`).

By default, certificate validation parameters are not specified, a user certificate without signing permission is used. You can replace the common certificate for port 13000.

You do not need to download the klsetsrvcert utility. It is included in the Kubernetes cluster and is not available for direct running. You can run the klsetsrvcert utility only by using KDT from the administrator host.

Connecting Network Agents to Administration Server by using the klmover utility

After you replace the Administration Server certificate by using the command-line klsetsrvcert utility, you need to establish the SSL connection between Network Agents and Administration Server because the connection is broken.

To specify the new Administration Server certificate and restore the connection:

From the command line, run the following utility:

```
klmover [-address <server address>] [-pn <port number>] [-ps <SSL port number>] [-nossl] [-cert <path to certificate file>]
```

This utility is automatically copied to the Network Agent installation folder, when Network Agent is installed on a client device.

The description of the klmover utility parameters is presented in the table below.

Values of the klmover utility parameters

Setting	Value
`-address < server address >`	Address of the Administration Server for connection. You can specify an IP address or the DNS name.
`-pn < port number >`	Number of the port through which non-encrypted connection to the Administration Server is established. The default port number is 14000.
`-ps < SSL port number >`	Number of the SSL port through which encrypted connection to the Administration Server is established by using SSL. The default port number is 13000. Port 13000 is used for the root Administration Server; this port number cannot be changed.
`-nossl`	Use non-encrypted connection to the Administration Server. If the key is not in use, Network Agent is connected to the Administration Server by using encrypted SSL protocol.
`-cert < path to certificate file >`	Use the specified certificate file for authentication of access to Administration Server.

Hierarchy of Administration Servers

Some client companies, for example MSP, may run multiple Administration Servers. It can be inconvenient to administer several separate Administration Servers, so a hierarchy can be applied. Each Administration Server can have several secondary Administration Servers on different nesting levels of the hierarchy. The root Administration Server can only act as a primary Server.

In a hierarchy, a Linux-based Administration Server can work both as a primary Server and as a secondary Server. The primary Linux-based Server can manage both Linux-based and Windows-based secondary Servers. A primary Windows-based Server can manage a secondary Linux-based Server.

A "primary/secondary" configuration for two Administration Servers provides the following options:

- A secondary Administration Server inherits policies, tasks, user roles, and installation packages from the primary Administration Server, thus preventing duplication of settings.
- Selections of devices on the primary Administration Server can include devices from secondary Administration Servers.
- Reports and event selections on the primary Administration Server can contain data (including detailed information) from secondary Administration Servers.
- A primary Administration Server can be used as a source of updates for a secondary Administration Server.

The primary Administration Server only receives data from non-virtual secondary Administration Servers within the scope of the options listed above. This limitation does not apply to virtual Administration Servers, which share the database with their primary Administration Server.

Creating a hierarchy of Administration Servers: adding a secondary Administration Server

In a hierarchy, a Linux-based Administration Server can work both as a primary Server and as a secondary Server. The primary Linux-based Server can manage both Linux-based and Windows-based secondary Servers. A primary Windows-based Server can manage a secondary Linux-based Server. The root Administration Server can only act as a primary Server.

You can add an Administration Server as a secondary Administration Server, thus establishing a "primary/secondary" hierarchy.

To add a secondary Administration Server that is available for connection through OSMP Console:

1. Make sure that port 13000 of the future primary Administration Server is available for receipt of connections from secondary Administration Servers.

2. Go to the properties of the future primary Administration Server:

   a. In the main menu, select any section (except for **Marketplace**, **Console navigation**, and **Settings**), and then at the top of the page, click the **Show hierarchy** button.

   b. In the navigation pane that opens, hover the mouse cursor over the name of the required Administration Server, and then click the settings icon (⚙).

   Alternately, you can click the Administration Server name, and then, after the name is displayed in the main menu, click it in the main menu to open the server properties window.

3. In the properties window that opens, click the **Administration Servers** tab.

4. Select the check box next to the name of the administration group to which you want to add the Administration Server.

5. In the menu line, click **Connect secondary Administration Server**.

   The Add secondary Administration Server wizard starts. Proceed through the Wizard by using the **NEXT** button.

6. Fill in the following fields:

   - **Secondary Administration Server display name**

     A name by which the secondary Administration Server will be displayed in the hierarchy. If you want, you can enter the IP address as a name, or you can use a name like, for example, "Secondary Server for group 1".

   - **Secondary Administration Server address (optional)**

     Specify the IP address or the domain name of the secondary Administration Server.

     This parameter is required if the **Connect primary Administration Server to secondary Administration Server in DMZ** option is enabled.

   - **Administration Server SSL port**

     Specify the number of the SSL port on the primary Administration Server. The default port number is 13000.

     Port 13000 is used for the root Administration Server; this port number cannot be changed.

   - **Administration Server API port**

     The number of the port that Web Console will use for receiving connections from the secondary Administration Server over OpenAPI. The default port number is 13299.

     While building the hierarchy, Web Console connects to the future secondary Server, requests credentials, retrieves the public certificate, and performs the initial setup.

     After the hierarchy of Administration Server is built, port 13299 will no longer be used. Administration Servers will interact over port 13000.

- **Connect primary Administration Server to secondary Administration Server in DMZ**

  Select this option if the secondary Administration Server is in a demilitarized zone (DMZ).

  If this option is selected, the primary Administration Server initiates connection to the secondary Administration Server. Otherwise, the secondary Administration Server initiates connection to the primary Administration Server.

7. Specify the certificate of the future secondary Server.

   The wizard is complete.

8. Send the certificate file of the future primary Administration Server to the system administrator of the office where the future secondary Administration Server is located. (You can, for example, write the file to an external device, such as a flash drive, or send it by email.)

   The certificate file is located on the future primary Administration Server, at /var/opt/kaspersky/klnagent_srv/1093/cert/.

9. Prompt the system administrator in charge of the future secondary Administration Server to do the following:

   a. Click the Administration Server name.

   b. On the properties page that opens, proceed to the **Hierarchy of Administration Servers** section of the **General** tab.

   c. Select the **This Administration Server is secondary in the hierarchy** option.

      > The root Administration Server can only act as a primary Server.

   d. In the **Primary Administration Server address** field, enter the network name of the future primary Administration Server.

   e. Select the previously saved file with the certificate of the future primary Administration Server by clicking **Browse**.

   f. If necessary, select the **Connect primary Administration Server to secondary Administration Server in DMZ** check box.

   g. If the connection to the future primary Administration Server is performed through a proxy server, select the **Use proxy server** check box and specify the connection settings.

   h. Click the **Save** button.

The "primary/secondary" hierarchy is built. The primary Administration Server starts receiving connection from the secondary Administration Server using port 13000. The tasks and policies from the primary Administration Server are received and applied. The secondary Administration Server is displayed on the primary Administration Server, in the administration group where it was added.

Viewing the list of secondary Administration Servers

To view the list of the secondary (including virtual) Administration Servers:

1. In the main menu, select a section (except for **Marketplace**, **Console navigation**, and **Settings**).
2. At the top of the page, click the **Show hierarchy** button.

In the navigation pane that opens, the list of the secondary (including virtual) Administration Servers is displayed. You can proceed to any of these Administration Servers by clicking its name.

You cannot proceed to virtual Administration Servers if you opened the navigation pane from the **IP ranges** and **Deleted objects** sections.
The administration groups are shown, too. The groups are available for management if you opened the navigation pane from the following sections: **Assets (Devices)**, **Policies**, **Tasks**, and **Distribution points**. Otherwise, the groups are grayed-out.

If you are connected to your primary Administration Server in OSMP Console, and can not connect to a virtual Administration Server that is managed by a secondary Administration Server, you can use one of the following ways:

- **Modify the existing installation of OSMP Console by adding the secondary Server to the list of trusted Administration Servers.** After that, you can connect to the virtual Administration Server in OSMP Console.

  1. On the device where OSMP Console is installed, run the OSMP Console installation file corresponding to the Linux distribution installed on your device under an account with administrative privileges.

     The Setup Wizard will start. Proceed through the Wizard by using the **NEXT** button.

  2. Select the **Upgrade** option.
  3. On the **Modification type** step, select the **Edit connection settings** option.
  4. On the **Trusted Administration Servers** step, add the required secondary Administration Server.
  5. On the last step, click **Modify** to apply the new settings.
  6. After the application reconfiguration successfully completes, click the **Finish** button.

- Use OSMP Console to connect directly to the secondary Administration Server where the virtual Server was created. Then you will be able to switch to the virtual Administration Server in OSMP Console.

Managing virtual Administration Servers

This section describes the following actions to manage virtual Administration Servers:

- Create virtual Administration Servers
- Enable and disable virtual Administration Servers

- Assign an administrator for a virtual Administration Server
- Change the Administration Server for client devices
- Delete virtual Administration Servers

Creating a virtual Administration Server

You can create virtual Administration Servers and add them to administration groups.

When you create a virtual Administration Server, it inherits the user list and all of the user rights of the primary Administration Server. If a user has access rights to the primary Server, this user has access rights to the virtual Server as well. After creation, you configure the access rights to the Servers independently.

To create and add a virtual Administration Server:

1. In the main menu, click the Administration Server name.
2. On the page that opens, proceed to the **Administration Servers** tab.
3. Select the administration group to which you want to add a virtual Administration Server.
   The virtual Administration Server will manage devices from the selected group (including the subgroups).
4. On the menu line, click **New virtual Administration Server**.
5. On the page that opens, define the properties of the new virtual Administration Server:
   - **Name of virtual Administration Server**.
   - **Administration Server connection address**.
     You can specify the name or the IP address of your Administration Server.
6. From the list of users, select the virtual Administration Server administrator. If you want, you can edit one of the existing accounts before assigning it the administrator's role, or create a new user account.
   If necessary, you can create a new account that will act as a virtual Administration Server administrator by using the kladduser utility. To do that, use the following command:

   ```
   kladduser -n <user_name> -p <password> -vs <virtual_server_name>
   ```

   where virtual_server_name is the name of the virtual Administration Server.
7. Click the **Save** button.

The new virtual Administration Server is created, added to the administration group and displayed on the **Administration Servers** tab.

If you are connected to your primary Administration Server in OSMP Console, and can not connect to a virtual Administration Server that is managed by a secondary Administration Server, you can use one of the following ways:

- **Modify the existing installation of OSMP Console by adding the secondary Server to the list of trusted Administration Servers.** After that, you can connect to the virtual Administration Server in OSMP Console.

  1. On the device where OSMP Console is installed, run the OSMP Console installation file corresponding to the Linux distribution installed on your device under an account with administrative privileges.

     The Setup Wizard will start. Proceed through the Wizard by using the **NEXT** button.

  2. Select the **Upgrade** option.

  3. On the **Modification type** step, select the **Edit connection settings** option.

  4. On the **Trusted Administration Servers** step, add the required secondary Administration Server.

  5. On the last step, click **Modify** to apply the new settings.

  6. After the application reconfiguration successfully completes, click the **Finish** button.

- Use OSMP Console to connect directly to the secondary Administration Server where the virtual Server was created. Then you will be able to switch to the virtual Administration Server in OSMP Console.

Enabling and disabling a virtual Administration Server

When you create a new virtual Administration Server, it is enabled by default. You can disable or enable it again at any time. Disabling or enabling a virtual Administration Server is equal to switching off or on a physical Administration Server.

To enable or disable a virtual Administration Server:

1. In the main menu, click the Administration Server name.

2. On the page that opens, proceed to the **Administration Servers** tab.

3. Select the virtual Administration Server that you want to enable or disable.

4. On the menu line, click the **Enable / disable virtual Administration Server** button.

The virtual Administration Server state is changed to enabled or disabled, depending on its previous state. The updated state is displayed next to the Administration Server name.

Assigning an administrator for a virtual Administration Server

When you use virtual Administration Servers in your organization, you might want to assign a dedicated administrator for each virtual Administration Server. For example, this might be useful when you create virtual Administration Servers to manage separate offices or departments of your organization, or if you are an MSP provider and you manage your tenants through virtual Administration Servers.

When you create a virtual Administration Server, it inherits the user list and all of the user rights of the primary Administration Server. If a user has access rights to the primary Server, this user has access rights to the virtual Server as well. After creation, you configure the access rights to the Servers independently. If you want to assign an administrator for a virtual Administration Server only, make sure that the administrator does not have access rights on the primary Administration Server.

You assign an administrator for a virtual Administration Server by granting the administrator access rights to the virtual Administration Server. You can grant the required access rights in one of the following ways:

- Configure access rights for the administrator manually
- Assign one or more user roles for the administrator

To sign in to OSMP Console, an administrator of a virtual Administration Server specifies the virtual Administration Server name, user name, and password. OSMP Console authenticates the administrator and opens the virtual Administration Server to which the administrator has access rights. The administrator cannot switch between Administration Servers.

Prerequisites

Before you start, ensure that the following conditions are met:

- The virtual Administration Server is created.
- On the primary Administration Server, you have created an account for the administrator that you want to assign for the virtual Administration Server.
- You have the **Modify object ACLs** right in the **General features → User permissions** functional area.

Configuring access rights manually

To assign an administrator for a virtual Administration Server:

1. Switch to the required virtual Administration Server:

   a. In the main menu, select a section (except for **Marketplace**, **Console navigation**, and **Settings**), and then at the top of the page, click the **Show hierarchy** button.

   b. In the navigation pane that opens, click the name of the required virtual Administration Server.

   > You cannot switch to a virtual Administration Server from the **IP ranges** and **Deleted objects** sections.

   In the main menu, the Administration Server changes to the one that you selected.

2. Move to the properties of the administration Server by clicking its name in the main menu.

   Alternately, in the navigation pane, hover the mouse cursor over the name of the required virtual Administration Server, and then click the settings icon (⚙).

The Administration Server properties window opens.

3. On the **Access rights** tab, click the **Add** button.

   A unified list of users of the primary Administration Server and the current virtual Administration Server opens.

4. From the list of users, select the account of the administrator that you want to assign for the virtual Administration Server, and then click the **OK** button.

   The application adds the selected user to the user list on the **Access rights** tab.

5. Select the check box next to the added account, and then click the **Access rights** button.

6. Configure the rights that the administrator will have on the virtual Administration Server.

   For successful authentication, at minimum, the administrator must have the following rights:

   - **Read** right in the **General features** → **Basic functionality** functional area
   - **Read** right in the **General features** → **Virtual Administration Servers** functional area

The application saves the modified user rights to the administrator account.

To assign an administrator for multiple virtual Administration Servers:

1. In the main menu, click the primary Administration Server name.

2. On the page that opens, proceed to the **Access rights** tab, and then click **Assign**.

   In the **Add users or groups** window that opens, select the check box near the user that you want to assign as an administrator.

3. You can switch to the **Groups** tab to select the user groups.

4. Click **Next**.

5. Select the servers to which you want to assign an administrator, and then click **Next**.

6. Select the administrator roles which you want to set for the user, if necessary.

   If you want to set custom roles for the current Administration Server for the user, go to the properties of the required Administration Server, click **Set roles**, and then select the custom roles.

7. Click **Finish** to apply the changes.

The administrator with the selected roles is now assigned to multiple virtual Administration Servers.

To revoke the administrator access rights:

1. Switch to the required Administration Server.

2. In the main menu, click the Administration Server name.

3. On the page that opens, proceed to the **Access rights** tab.

4. Select the check box near the user from whom you want to revoke the access rights.

5. Click **Revoke** and confirm your action.

The selected user's access rights are revoked.

Configuring access rights by assigning user roles

Alternatively, you can grant the access rights to a virtual Administration Server administrator through user roles. For example, this might be useful if you want to assign several administrators on the same virtual Administration Server. If this is the case, you can assign the administrators' accounts the same one or more user roles instead of configuring the same user rights for several administrators.

To assign an administrator for a virtual Administration Server by assigning user roles:

1. On the primary Administration Server, create a new user role, and then specify all of the required access rights that an administrator must have on the virtual Administration Server. You can create several roles, for example, if you want to separate access to different functional areas.

2. Switch to the required virtual Administration Server:

   a. In the main menu, select a section (except for **Marketplace**, **Console navigation**, and **Settings**), and then at the top of the page, click the **Show hierarchy** button.

   b. In the navigation pane that opens, click the name of the required virtual Administration Server.

   > You cannot switch to a virtual Administration Server from the **IP ranges** and **Deleted objects** sections.

   In the main menu, the Administration Server changes to the one that you selected.

3. Assign the new role or several roles to the administrator account.

The application assigns the roles to the administrator account.

Configuring access rights at the object level

In addition to assigning access rights at the functional area level, you can configure access to specific objects on the virtual Administration Server, for example, to a specific administration group or a task. To do this, switch to the virtual Administration Server, and then configure the access rights in the object's properties.

Changing the Administration Server for client devices

You can change the Administration Server that manages client devices to a different Server using the *Change Administration Server* task. After the task completion, the selected client devices will be put under the management of the Administration Server that you specify.

You cannot use the *Change Administration Server* task for client devices connected to Administration Server through connection gateways. For such devices you have to either reconfigure Network Agent or reinstall Network Agent and specify connection gateway.

To change the Administration Server that manages client devices to a different Server:

1. In the main menu, go to **Tasks**.
2. Click the **Add** button.

   The New task wizard starts. Proceed through the wizard by using the **Next** button.
3. At the **New task settings** step of the wizard, specify the following settings:

   a. In the **Application** drop-down list, select **Open Single Management Platform**.

   b. In the **Task type** field, select **Change Administration Server**.

   c. In the **Task name** field, specify the name for the task that you are creating.

   The task name cannot be more than 100 characters long and cannot include any special characters ("*<>?\:|).

   d. Select devices to which the task will be assigned:

   Assign task to an administration group

   The task is assigned to devices included in an administration group. You can specify one of the existing groups or create a new one.

   For example, you may want to use this option to run a task of sending a message to users if the message is specific for devices included in a specific administration group.

   If a task is assigned to an administration group, the **Security** tab is not displayed in the task properties window because group tasks are subject to the security settings of the groups to which they apply.

   Specify device addresses manually or import addresses from a list

   You can specify DNS names, IP addresses, and IP subnets of devices to which you want to assign the task.

   You may want to use this option to execute a task for a specific subnet. For example, you may want to install a certain application on devices of accountants or to scan devices in a subnet that is probably infected.

   Assign task to a device selection

   The task is assigned to devices included in a device selection. You can specify one of the existing selections.

   For example, you may want to use this option to run a task on devices with a specific operating system version.
4. At the **Task scope** step of the wizard, specify an administration group, devices with specific addresses, or a device selection.
5. At this step of the wizard, confirm that you agree to the terms of changing the Administration Server for client devices.
6. At this step of the wizard, select the Administration Server that you want to use to manage the selected devices:

Change to another primary Administration Server

To move client devices to another primary Administration Server, specify the following Administration Server connection settings:

1. In the **Administration Server address** field, specify the address of the new primary Administration Server.
2. In the **Port number** field, specify the port number to connect to Administration Server.

   The default port number is 14000.
3. In the **SSL port** field, specify the number of the SSL port on the primary Administration Server.

   The default port number is 13000.
4. If necessary, enable the **Use proxy server** option.

   If this option is disabled, direct connection is used to connect the device to the Administration Server.

   If this option is enabled, specify the proxy server parameters:

   - **Proxy server address**
   - **Proxy server port**

   If your proxy server requires authentication, in the **User name** and **Password** fields, specify the credentials of the account under which connection to the proxy server is established. We recommend that you specify the credentials of an account that has minimum privileges required only for the proxy server authentication.
5. If necessary, upload a new Administration Server certificate.

Change to another virtual Server on this primary Server

Select this option to move client devices to virtual Administration Server on the current primary Administration Server. To do this, in the **Name of virtual Administration Server** drop-down list, select the necessary virtual Administration Server.

7. At the **Selecting an account to run the task** step of the wizard, specify the account settings:

   Default account

   The task will be run under the same account as the application that performs this task.

   By default, this option is selected.

   Specify account

   Fill in the **Account** and **Password** fields to specify the details of an account under which the task is run. The account must have sufficient rights for this task.

   Account

   Account under which the task is run.

   Password

   Password of the account under which the task will be run.
8. If you want to change the default task settings, at the **Finish task creation** step of the wizard, enable the **Open task details when creation is complete** option.

   If you do not enable this option, the task will be created with the default settings. You can change the default settings later, at any time.

9. Click the **Finish** button.

   The task is created and displayed in the list of tasks.

10. Click the name of the created task to open the task properties window.

11. If you want to change the default task settings, in the task properties window, specify the general task settings according to your needs.

12. Click the **Save** button.

    The task is created and configured.

13. Run the created task.

After the task is completed, the client devices for which it was created are put under the management of the Administration Server specified in the task settings.

Deleting a virtual Administration Server

When you delete a virtual Administration Server, all of the objects created on the Administration Server, including policies and tasks, will be deleted as well. The managed devices from the administration groups that were managed by the virtual Administration Server will be removed from the administration groups. To return the devices under management of Kaspersky EDR Expert, run the network polling, and then move the found devices from the Unassigned devices group to the administration groups.

To delete a virtual Administration Server:

1. Switch to the primary physical Administration Server to which the virtual Administration Server to be deleted belongs:

   a. In the main menu, select any section (except for the **Marketplace**, **Console navigation**, and **Settings**), and then at the top of the page, click the **Show hierarchy** button.

   b. In the navigation pane that opens, click the name of the primary physical Administration Server.

      In the main menu, the Administration Server changes to the one that you selected.

2. Move to the properties of the primary physical Administration Server in one of the following ways:

   - In the navigation pane, hover the mouse cursor over the name of the required Administration Server, and then click the settings icon (⚙).

   - In the main menu, click the Administration Server name.

3. On the properties window that opens, proceed to the **Administration Servers** tab.

4. Select the virtual Administration Server that you want to delete.

5. On the menu line, click the **Delete** button.

The virtual Administration Server is deleted.

Configuring Administration Server connection events logging

The history of connections and attempts to connect to the Administration Server during its operation can be saved to a log file. The information in the file allows you to track not only connections inside your network infrastructure, but unauthorized attempts to access the server as well.

To log events of connection to the Administration Server:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Connection ports** section.

3. Enable the **Log Administration Server connection events** setting.

All further events of inbound connections to the Administration Server, authentication results, and SSL errors will be saved to the file /var/opt/kaspersky/klnagent_srv/logs/SC.syslog.

Setting the maximum number of events in the event repository

In the **Events repository** section of the Administration Server properties window, you can edit the settings of events storage in the Administration Server database by limiting the number of event records and record storage term. When you specify the maximum number of events, the application calculates an approximate amount of storage space required for the specified number. You can use this approximate calculation to evaluate whether you have enough free space on the disk to avoid database overflow. The default capacity of the Administration Server database is 400,000 events. The maximum recommended capacity of the database is 45 million events.

The application checks the database every 10 minutes. If the number of events reaches the specified maximum value plus 10,000, the application deletes the oldest events so that only the specified maximum number of events remains.

When the Administration Server deletes old events, it cannot save new events to the database. During this period, information about events that were rejected is written to the operating system log. The new events are queued and then saved to the database after the deletion operation is complete. By default, the event queue is limited to 20,000 events. You can customize the queue limit by editing the KLEVP_MAX_POSTPONED_CNT flag value.

To limit the number of events that can be stored in the events repository on the Administration Server:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Events repository** section. Specify the maximum number of events stored in the database.

3. Click the **Save** button.

Additionally, you can do the following:

- Change the settings of any task to save events related to the task progress, or save only task execution results.
- Reduce or disable the storage period for the events of Administration Server, Network Agent, and Kaspersky applications installed on managed devices.

In doing so, you will reduce the number of events in the database, increase the speed of execution of scenarios associated with analysis of the event table in the database, and lower the risk that critical events will be overwritten by a large number of events.

Changing DBMS credentials

Sometimes, you may need to change DBMS credentials, for example, in order to perform a credential rotation for security purposes.

Changing the Administration Server database credentials

To change Administration Server and IAM database credentials in a Linux environment:

1. Stop Administration Server. Depending on the deployment type of Kaspersky Security Center Linux, run one of the following commands under the root account:

   - For a Kaspersky Security Center Linux failover cluster:

     On the active node, run the following command:

     ```
     /opt/kaspersky/ksc64/sbin/klfoc -stopcluster --stp klfoc
     ```

   - For a geo-distributed Kaspersky Security Center Linux failover cluster:

     On both nodes, run the following command:

     ```
     crm node standby
     ```

   - For a non-cluster Administration Server deployment:

     Run the following commands:

     ```
     systemctl stop kladminserver_srv.service
     systemctl stop kliam_srv.service
     ```

2. Connect to the Administration Server database with DBMS superuser privileges and run the following command:

   ```
   REASSIGN OWNED BY <old_kscdbadmin> TO <new_kscdbadmin>;
   ```

   where `<old_kscdbadmin>` is the previous DBMS account used by the Administration Server to connect to its database, and `<new_kscdbadmin>` is the new DBMS account.

3. Connect to the IAM database with DBMS superuser privileges and run the following command:

```
REASSIGN OWNED BY <old_iamdbadmin> TO <new_iamdbadmin>;
```

where `<old_iamdbadmin>` is the previous DBMS account used by the Administration Server to connect to its database, and `<new_iamdbadmin>` is the new DBMS accounts.

4. Locate the IAM configuration file: /var/opt/kaspersky/klnagent_srv/iam/iam_config.yaml

5. In the `dbms_iam` section, specify new account credentials in the user and password fields. Ensure that the account exists in the DBMS and is specified as the IAM database owner.

6. Run Administration Server. Depending on the deployment type of Kaspersky Security Center Linux, run one of the following commands under the root account:

   - For a Kaspersky Security Center Linux failover cluster:

     On the active node, run the following command:

     ```
     /opt/kaspersky/ksc64/sbin/klfoc -startcluster --stp klfoc
     ```

   - For a geo-distributed Kaspersky Security Center Linux failover cluster:

     On both nodes, run the following command:

     ```
     crm node online
     ```

   - For a non-cluster Administration Server deployment:

     Run the following commands:

     ```
     systemctl start kladminserver_srv.service
     systemctl start kliam_srv.service
     ```

7. Run the klsrvconfig utility:

```
sudo /opt/kaspersky/ksc64/sbin/klsrvconfig -set_dbms_cred
```

8. Specify a new account name. You should specify credentials of an account that exists in the DBMS.

9. Enter a new password.

10. Specify the new password for confirmation.

11. Wait until the Administration Server resumes operation and a syslog entry on the active node appears stating that the Administration Server is ready for GUI operations.

The Administration Server database credentials are changed.

Deleting a hierarchy of Administration Servers

If you no longer want to have a hierarchy of Administration Servers, you can disconnect them from this hierarchy.

To delete a hierarchy of Administration Servers:

1. In the main menu, click the Administration Server name.
2. On the page that opens, proceed to the **Administration Servers** tab.
3. In the administration group from which you want to delete the secondary Administration Server, select the secondary Administration Server.
4. On the menu line, click **Delete**.
5. In the window that opens, click **OK** to confirm that you want to delete the secondary Administration Server.

The former primary Administration Server and the former secondary Administration Server are now independent of each other. The hierarchy no longer exists.

Access to public DNS servers

If access to Kaspersky servers by using the system DNS is not possible, Open Single Management Platform can use the following public DNS servers, in the following order:

1. Google Public DNS (8.8.8.8)
2. Cloudflare DNS (1.1.1.1)
3. Alibaba Cloud DNS (223.6.6.6)
4. Quad9 DNS (9.9.9.9)
5. CleanBrowsing (185.228.168.168)

Requests to these DNS servers may contain domain addresses and the public IP address of the Administration Server, because the application establishes a TCP/UDP connection to the DNS server. If Open Single Management Platform is using a public DNS server, data processing is governed by the privacy policy of the relevant service.

To configure the use of public DNS by using the klscflag utility:

1. On the administrator host where the KDT utility is located, run the following command to disable the use of public DNS:

```
./kdt invoke ksc --action klscflag --param klscflag_param=' -fset -pv
".core/.independent" -s Transport -n ForceUseSystemDNS -t d -v 1'
```

2. To enable the use of public DNS, run the following command:

```
./kdt invoke ksc --action klscflag --param klscflag_param=' -fset -pv
".core/.independent" -s Transport -n ForceUseSystemDNS -t d -v 0'
```

Configuring the interface

You can configure the OSMP Console interface to display and hide sections and interface elements, depending on the features being used.

To configure the OSMP Console interface in accordance with the currently used set of features:

1. In the main menu, go to **Settings** → **Interface options**.
2. Enable or disable the **Show data encryption and protection** option.
3. Click **Save**.

After the required options are enabled, the console displays the corresponding sections in the main menu.

Encrypt communication with TLS

To fix vulnerabilities on your organization's corporate network, you can enable traffic encryption by using the TLS protocol. You can enable TLS encryption protocols and supported cipher suites on Administration Server. Open Single Management Platform supports the TLS protocol versions 1.0, 1.1, 1.2, and 1.3. You can select the required encryption protocol and cipher suites.

Open Single Management Platform uses self-signed certificates. You can also use your own certificates. We recommend using certificates issued by trusted certificate authorities.

To configure allowed encryption protocols and cipher suites on Administration Server:

1. On the administrator host where the KDT utility is located, run the following command:

   ```
   ./kdt invoke ksc --action klscflag --param klscflag_param=' -fset -pv
   ".core/.independent" -s Transport -n SrvUseStrictSslSettings -v <value> -t d'
   ```

   Use the SrvUseStrictSslSettings flag to configure allowed encryption protocols and cipher suites on Administration Server.

   Specify the <value> parameter of the SrvUseStrictSslSettings flag:

   - 4—Only the TLS 1.2 and TLS 1.3 protocols are enabled. Also, cipher suites with TLS_RSA_WITH_AES_256_GCM_SHA384 are enabled (these cipher suites are needed for backward compatibility with Kaspersky Security Center 11). This is the default value.

     Cipher suites supported for the TLS 1.2 protocol:

     - ECDHE-RSA-AES256-GCM-SHA384
     - ECDHE-RSA-AES256-SHA384
     - ECDHE-RSA-CHACHA20-POLY1305
     - AES256-GCM-SHA384 (cipher suite with TLS_RSA_WITH_AES_256_GCM_SHA384)

- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-SHA256

Cipher suites supported for the TLS 1.3 protocol:

- TLS_AES_256_GCM_SHA384
- TLS_CHACHA20_POLY1305_SHA256
- TLS_AES_128_GCM_SHA256
- TLS_AES_128_CCM_SHA256

- 5—Only the TLS 1.2 and TLS 1.3 protocols are enabled. For the TLS 1.2 and TLS 1.3 protocols, the specific cipher suites listed below are supported.

  Cipher suites supported for the TLS 1.2 protocol:

  - ECDHE-RSA-AES256-GCM-SHA384
  - ECDHE-RSA-AES256-SHA384
  - ECDHE-RSA-CHACHA20-POLY1305
  - ECDHE-RSA-AES128-GCM-SHA256
  - ECDHE-RSA-AES128-SHA256

  Cipher suites supported for the TLS 1.3 protocol:

  - TLS_AES_256_GCM_SHA384
  - TLS_CHACHA20_POLY1305_SHA256
  - TLS_AES_128_GCM_SHA256
  - TLS_AES_128_CCM_SHA256

We do not recommend using 0, 1, 2, or 3 as the parameter value of the SrvUseStrictSslSettings flag. These parameter values correspond to insecure TLS protocol versions (the TLS 1.0 and TLS 1.1 protocols) and insecure cipher suites, and are used only for backward compatibility with earlier Kaspersky Security Center versions.

2. Restart the following Open Single Management Platform services:

   - Administration Server
   - Web Server
   - Activation Proxy

Traffic encryption by using the TLS protocol is enabled.

You can use the KLTR_TLS12_ENABLED and KLTR_TLS13_ENABLED flags to enable the support of the TLS 1.2 and TLS 1.3 protocols, respectively. These flags are enabled by default.

To enable or disable the support of the TLS 1.2 and TLS 1.3 protocols,

On the administrator host where the KDT utility is located, run one of the following commands:

- To enable or disable the support of the TLS 1.2 protocol:

```
./kdt invoke ksc --action klscflag --param klscflag_param=' -fset -pv
".core/.independent" -s Transport -n KLTR_TLS12_ENABLED -v <value> -t d'
```

- To enable or disable the support of the TLS 1.3 protocol:

```
./kdt invoke ksc --action klscflag --param klscflag_param=' -fset -pv
".core/.independent" -s Transport -n KLTR_TLS13_ENABLED -v <value> -t d'
```

Specify the `<value>` parameter of the flag:

- `1`—To enable the support of the TLS protocol.
- `0`—To disable the support of the TLS protocol.

Discovering networked devices

This section describes search and discovery of networked devices.

Open Single Management Platform allows you to find devices on the basis of specified criteria. You can save search results to a text file.

The search and discovery feature allows you to find the following devices:

- Managed devices in administration groups of Open Single Management Platform Administration Server and its secondary Administration Servers.
- Unassigned devices managed by Administration Server and its secondary Administration Servers.

Scenario: Discovering networked devices

You must perform device discovery before installation of the security applications. When all networked devices are discovered, you can receive information about them and manage them through policies. Regular network polls are needed to discover if there are any new devices and whether previously discovered devices are still on the network.

Discovery of networked devices proceeds in stages:

1. **Initial device discovery**

   Perform device discovery manually.

2. **Configuring future polls**

Make sure that IP range polling is enabled and that the poll schedule meets the needs of your organization. When configuring the poll schedule, use the recommendations for network polling frequency.

You can also enable Zeroconf polling if your network includes IPv6 devices.

If networked devices are included in a domain, it is recommended to use domain controller polling.

Use Windows-based distribution points to poll Windows networks.

> You can perform IP range polling and Zeroconf polling only by using a distribution point.

3. **Setting up rules for adding discovered devices to administration groups (optional)**

   New devices appear on the network as a result of being detected as part of network polls. These automatically fall into the **Unassigned devices** group. If you want, you can set up the rules for automatically moving these devices to the **Managed devices** group. You can also establish retention rules.
