   If you skip this rule-setting stage, all the newly discovered devices go to the **Unassigned devices** group and stay there. If you want, you can move these devices to the **Managed devices** group manually. If you move the devices to the **Managed devices** group manually, you can analyze information about each device and decide whether you want to move it to an administration group, and, if so, to which group.

Results

Completion of the scenario yields the following:

- Kaspersky Security Center Administration Server discovers the devices that are on the network and provides you with information about them.
- Future polls are set up and are conducted according to the specified schedule.

Newly discovered devices are allocated in accordance with the specified rules. If no rules are configured, the devices stay in the **Unassigned devices** group.

Windows network polling

About Windows network polling

Kaspersky EDR Expert Administration Server does not support Windows network polling. Use Windows-based distribution points to poll Windows networks.

During a quick poll, distribution points only retrieve information from the list of the NetBIOS names of devices in all network domains and workgroups. During a full poll, the following information is requested from each client device:

- Operating system name
- IP address

- DNS name
- NetBIOS name

Both quick polls and full polls require the following:

- Ports UDP 137/138, TCP 139, UDP 445, TCP 445 must be available in the network.
- The SMB protocol is enabled.
- The Microsoft Computer Browser service must be used, and the primary browser computer must be enabled on the Administration Server.
- The Microsoft Computer Browser service must be used, and the primary browser computer must be enabled on the client devices:
  - On at least one device, if the number of networked devices does not exceed 32.
  - On at least one device for each 32 networked devices.

The full poll can run only if the quick poll has run at least once.

IP range polling

Kaspersky EDR Expert allows you to poll an IP range only by using a distribution point. The distribution point attempts to perform reverse name resolution for every IPv4 address from the specified range to a DNS name, by using standard DNS requests. If this operation succeeds, the distribution point sends an `ICMP ECHO REQUEST` (the same as the `ping` command) to the received name. If the device responds, information about it is added to the Kaspersky EDR Expert database. The reverse name resolution is necessary to exclude network devices that can have an IP address but are not computers, for example, network printers or routers.

This polling method relies upon a correctly configured local DNS service. It must have a reverse lookup zone. If this zone is not configured, IP subnet polling will yield no results.

Initially, the distribution point gets IP ranges for polling from the network settings of the device assigned as a distribution point. If the device address is 192.168.0.1 and the subnet mask is 255.255.255.0, the network 192.168.0.0/24 is included in the list of polling address automatically. The distribution point polls all addresses from 192.168.0.1 to 192.168.0.254.

If only IP range polling is enabled, the distribution point discovers devices only with IPv4 addresses. If your network includes IPv6 devices, turn on Zeroconf polling of devices.

For all Linux-based hosts within a Microsoft Active Directory or Samba domain controller, specify the `netbios name` and `workgroup` parameters in the `/etc/samba/smb.conf` file. Otherwise, polling results may contain duplicate hosts.

IP range polling by using a distribution point

To configure IP range polling by using the distribution point:

1. Open the distribution point properties.
2. Go to the **IP range polling** section, and then select the **Enable range polling** option.

   The **IP range** window opens.
3. Specify the name of a new IP range.
4. Click **Add**, and then specify the IP range by using the address and subnet mask, or by using the start and end IP address. You can also add an existing subnet by clicking the **Browse** button.
5. Click the **Set polling schedule** button to specify the polling schedule options, if needed.

   Polling starts only according to the specified schedule. A manual start of polling is not available.

   Polling schedule options:

   - **Every N days**

     The polling runs regularly, with the specified interval in days, starting from the specified date and time.

     By default, the polling runs every day, starting from the current system date and time.

   - **Every N minutes**

     The polling runs regularly, with the specified interval in minutes, starting from the specified time.

   - **By days of week**

     The polling runs regularly, on the specified days of week, and at the specified time.

   - **Monthly on selected weekday**

     The polling runs regularly, on the specified days of each month, and at the specified time.

   - **Run missed tasks**

     If the Administration Server is switched off or unavailable during the time for which the poll is scheduled, the Administration Server can either start the poll immediately after it is switched on, or wait for the next time for which the poll scheduled.

     If this option is enabled, the Administration Server starts polling immediately after it is switched on.

     If this option is disabled, the Administration Server waits for the next time for which the polling is scheduled.

     By default, this option is disabled.
6. Enable the **Use Zeroconf to poll IPv6 networks** option, to automatically poll the IPv6 network by using zero-configuration networking (also referred to as *Zeroconf*).

   In this case, the specified IP ranges are ignored because the distribution point polls the whole network. The **Use Zeroconf to poll IPv6 networks** option is available if the distribution point runs Linux. To use Zeroconf IPv6 polling, you must install the avahi-browse utility on the distribution point.

After the polling is completed, the newly discovered devices are automatically included in the **Managed devices** group, if you set up and enabled device moving rules. If no moving rules have been enabled, the newly discovered devices are automatically included in the **Unassigned devices** group.

Domain controller polling

Open Single Management Platform supports polling of the following domain controller types:

- Microsoft Active Directory
- Samba
- FreeIPA
- ALD Pro

For a Samba domain controller, Samba 4 is used as an Active Directory domain controller.

When you poll a domain controller, Administration Server or a distribution point retrieves information about the domain structure, user accounts, security groups, and DNS names of the devices that are included in the domain.

We recommend using domain controller polling if all networked devices are members of a domain. If some of the networked devices are not included in the domain, these devices cannot be discovered by domain controller polling.

Prerequisites

Before you poll a domain controller, ensure that the following protocols are enabled:

- Simple Authentication and Security Layer (SASL)
- Lightweight Directory Access Protocol (LDAP)

Ensure that the following ports are available on the domain controller device:

- 389 for SASL
- 636 for TLS

For all Linux-based hosts within a Microsoft Active Directory, Samba, FreeIPA, or ALD Pro domain controller, you need to specify the `netbios name` and `workgroup` parameters in the `/etc/samba/smb.conf` file. Otherwise, polling results may contain duplicate hosts.

If a Microsoft Active Directory domain contains multiple domain controllers, selecting a specific controller during domain polling is not supported. The connection is established with the first detected domain controller. To ensure proper authentication with the Microsoft Active Directory domain, the Subject Alternative Name (SAN) field of the certificate must include all addresses of the domain controllers included in this domain, as well as the NetBIOS name of the Microsoft Active Directory domain.

Domain controller polling by using Administration Server

To poll a domain controller by using Administration Server:

1. In the main menu, go to **Discovery & deployment** → **Discovery** → **Domain controllers**.
2. Click **Configure polling settings**.

   The **Domain controller polling settings** window opens.
3. In the **Polling** field, switch the toggle button to the **Enabled** position.
4. In the **Poll specified domains**, click **Add**, then specify the address and user credentials of the domain controller, and click **OK**.
5. In the **Domain controller polling settings** window, do the following:

   - Select the type of the domain controller to be polled: **Active Directory or Samba 4**, **FreeIPA**, **ALD Pro**.
   - If necessary, set the polling schedule. The default period is one hour. The data received at the next polling completely replaces old data.

     The following polling schedule options are available:

     - **Every N days**

       The polling runs regularly, with the specified interval in days, starting from the specified date and time.

       By default, the polling runs every day, starting from the current system date and time.

     - **Every N minutes**

       The polling runs regularly, with the specified interval in minutes, starting from the specified time.

     - **By days of week**

       The polling runs regularly, on the specified days of week, and at the specified time.

     - **Monthly on selected weekday**

       The polling runs regularly, on the specified days of each month, and at the specified time.

     - **Run missed tasks**

       If the Administration Server is switched off or unavailable during the time for which the poll is scheduled, the Administration Server can either start the poll immediately after it is switched on, or wait for the next time for which the poll scheduled.

       If this option is enabled, the Administration Server starts polling immediately after it is switched on.

       If this option is disabled, the Administration Server waits for the next time for which the polling is scheduled.

       By default, this option is disabled.

If you change user accounts in a security group of the domain, these changes will be displayed in Open Single Management Platform an hour after you poll the domain controller.

6. If necessary, change the tenant to be assigned to the discovered user accounts. To do this, select the required tenant from the **Tenant** drop-down list.

   By default, the Administration Server tenant is specified. You can select multiple tenants.

7. Click **Save** to apply changes.

8. If you want to perform the poll immediately, click the **Start poll** button.

Domain controller polling by using a distribution point

You can also poll a domain controller by using a distribution point. A Windows- or Linux-based managed device can act as a distribution point.

> For a Linux distribution point, polling of all domain controller types is supported.
> For a Windows distribution point, only polling of a Microsoft Active Directory domain controller is supported.
> Polling with a Mac distribution point is not supported.

To configure domain controller polling by using the distribution point:

1. Open the distribution point properties.

2. Select the **Domain controller polling** section.

3. In the **Polling** field, switch the toggle button to the **Enabled** position.

4. If you use a Linux distribution point, select the type of the domain controller to be polled: **Active Directory or Samba 4**, **FreeIPA**, **ALD Pro**.

   This is not necessary that you specify the same domain controller type when configuring polling by using a distribution point and by using Administration Server.

5. Select the domain controller that you want to poll.

   If you use a Linux distribution point, in the **Poll specified domains** section, click **Add**, and then specify the address and user credentials of the domain controller.

   If you use a Windows distribution point, you can select one of the following options:

   - **Poll current domain**
   - **Poll entire domain forest**
   - **Poll specified domains**

6. Click the **Set polling schedule** button to specify the polling schedule options, if needed.

   Polling starts only according to the specified schedule. A manual start of polling is not available.

After the polling is completed, the domain structure will be displayed in the **Domain controllers** section.

If you set up and enabled device moving rules, the newly discovered devices are automatically included in the **Managed devices** group. If no moving rules have been enabled, the newly discovered devices are automatically included in the **Unassigned devices** group.

The discovered user accounts can be used for domain authentication in OSMP Console over the Kerberos protocol.

Authentication and connection to a domain controller

On initial connection to the domain controller the Administration Server identifies the connection protocol. This protocol is used for all future connections to the domain controller.

The initial connection to a domain controller proceeds as follows:

1. Administration Server attempts to connect to the domain controller over TLS.

   By default, certificate verification is not required. Set the KLNAG_LDAP_TLS_REQCERT flag to 1 to enforce certificate verification.

   By default, the OS-dependent path to the certificate authority (CA) is used to access the certificate chain. Use the KLNAG_LDAP_SSL_CACERT flag to specify a custom path.

2. If the TLS connection fails, Administration Server attempts to connect to the domain controller over SASL (DIGEST-MD5).

3. If the SASL (DIGEST-MD5) connection fails, Administration Server uses Simple Authentication over non-encrypted TCP connection to connect to the domain controller.

You can use the KDT command to configure flags. For example, you can enforce certificate verification. To do this, on the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke ksc --action klscflag --param klscflag_param=' -fset -pv klserver -n
KLNAG_LDAP_TLS_REQCERT -t d -v 1'
```

Configuring a Samba domain controller

Open Single Management Platform supports a Linux domain controller running only on Samba 4.

A Samba domain controller supports the same schema extensions as a Microsoft Active Directory domain controller. You can enable full compatibility of a Samba domain controller with a Microsoft Active Directory domain controller by using the Samba 4 schema extension. This is an optional action.

> We recommend enabling full compatibility of a Samba domain controller with a Microsoft Active Directory domain controller. This will ensure the correct interaction between Open Single Management Platform and the Samba domain controller.

To enable full compatibility of a Samba domain controller with a Microsoft Active Directory domain controller:

1. Execute the following command to use the RFC2307 schema extension:

   ```
   samba-tool domain provision --use-rfc2307 --interactive
   ```

2. Enable the schema update in a Samba domain controller. To do this, add the following line to the `/etc/samba/smb.conf` file:

   ```
   dsdb:schema update allowed = true
   ```

If the schema update completes with an error, you need to perform a full restore of the domain controller that acts as a schema master.

For all Linux-based hosts within a Samba domain controller, specify the `netbios name` and `workgroup` parameters in the `/etc/samba/smb.conf` file. Otherwise, polling results may contain duplicate hosts.

Using VDI dynamic mode on client devices

A virtual infrastructure can be deployed on a corporate network using temporary virtual machines. Kaspersky EDR Expert detects temporary virtual machines and adds information about them to the Administration Server database. After a user finishes using a temporary virtual machine, the machine is removed from the virtual infrastructure. However, a record about the removed virtual machine can be saved in the database of the Administration Server. Also, nonexistent virtual machines can be displayed in OSMP Console.

To prevent information about nonexistent virtual machines from being saved, Kaspersky EDR Expert supports dynamic mode for Virtual Desktop Infrastructure (VDI). The administrator can enable support of dynamic mode for VDI in the properties of the installation package of Network Agent to be installed on the temporary virtual machine.

When a temporary virtual machine is disabled, Network Agent notifies the Administration Server that the machine has been disabled. If the virtual machine has been disabled successfully, it is removed from the list of devices connected to the Administration Server. If the virtual machine is disabled with errors and Network Agent does not send a notification about the disabled virtual machine to the Administration Server, a backup scenario is used. In this scenario, the virtual machine is removed from the list of devices connected to the Administration Server after three unsuccessful attempts to synchronize with the Administration Server.

Enabling VDI dynamic mode in the properties of an installation package for Network Agent

To enable VDI dynamic mode:

1. In the main menu, go to **Software management** → **Installation packages**.
2. In the context menu of the Network Agent installation package, select **Properties**.

   The **Properties** window opens.
3. In the **Properties** window, select the **Advanced** section.
4. In the **Advanced** section, select the **Enable dynamic mode for VDI** option.

The device on which Network Agent is to be installed becomes a part of VDI.

Moving devices from VDI to an administration group

To move devices that are part of VDI to an administration group:

1. Go to **Asset management** → **Moving rules**.
2. Click the **Add** button.
3. On the **Rule conditions** tab, select the **Virtual machines** tab.
4. Set the **This is a virtual machine** rule to **Yes** and **Part of Virtual Desktop Infrastructure** to **Yes.**
5. Click **Save**.

Managing client devices

Kaspersky EDR Expert allows you to manage client devices:

- View settings and statuses of managed devices, including clusters and server arrays.
- Configure distribution points.
- Manage tasks.

You can use administration groups to combine client devices in a set that can be managed as a single unit. A client device can be included in only one administration group. Devices can be allocated to a group automatically based on **Rule conditions**:

- Creating device moving rules.
- Copying device moving rules.
- Conditions for a device moving rule.

You can use device selections to filter devices based on a condition. You can also tag devices for creating selections, for finding devices, and for distributing devices among administration groups.

Settings of a managed device

To view the settings of a managed device:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.

   The list of managed devices is displayed.

2. In the list of managed devices, click the link with the name of the required device.

The properties window of the selected device is displayed.

The following tabs are displayed in the upper part of the properties window representing the main groups of the settings:

General

This tab comprises the following sections:

- The **General** section displays general information about the client device. Information is provided on the basis of data received during the last synchronization of the client device with the Administration Server:

  - **Name**

    In this field, you can view and modify the client device name in the administration group.

  - **Description**

    In this field, you can enter an additional description for the client device.

  - **Device status**

    Status of the client device assigned on the basis of the criteria defined by the administrator for the status of anti-virus protection on the device and the activity of the device on the network.

  - **Device owner**

    Name of the device owner. You can assign or remove a user as a device owner by clicking the **Manage device owner** link.

  - **Full group name**

    Administration group, which includes the client device.

  - **Protection last updated**

    Date the anti-virus databases or applications were last updated on the device.

  - **Connected to Administration Server**

    Date and time Network Agent installed on the client device last connected to the Administration Server.

  - **Last seen at**

    Date and time the device was last visible on the network.

  - **Network Agent version**

    Version of the installed Network Agent.

  - **Created**

    Date of the device creation within Open Single Management Platform.

  - **Force synchronization**

    Although Open Single Management Platform automatically synchronizes the status, settings, tasks, and policies for managed devices, in some cases the administrator needs to know exactly whether synchronization has already been performed for a specified device at the present moment.

If you click the **Force synchronization** button, the application synchronizes the selected device with the Administration Server.

- **Do not disconnect from the Administration Server**

  If this option is enabled, continuous connectivity between the managed device and the Administration Server is maintained. You may want to use this option if you are not using push servers, which provide such connectivity.

  If this option is disabled and push servers are not in use, the managed device only connects to the Administration Server to synchronize data or to transmit information.

  The maximum total number of devices with the **Do not disconnect from the Administration Server** option selected is 300.

  This option is disabled by default on managed devices. This option is enabled by default on the device where the Administration Server is installed and stays enabled even if you try to disable it.

- **Sessions**

  This section contains a table with information about the users currently logged in to the device. The table displays the following data in the corresponding columns:

  - User name.
  - SAM account name
  - User principal name
  - Email address.

  To correctly display information about domain users' sessions, you must use domain controller polling.

- The **Network** section displays the following information about the network properties of the client device:

  - **IP address**

    Device IP address.

  - **Windows domain**

    Workgroup that contains the device.

  - **DNS name**

    DNS domain name of the client device.

  - **NetBIOS name**

    Name of the client device.

  - **IPv6 address**

    IPv6 address of the client device.

- The **System** section provides information about the operating system installed on the client device:

  - **OS**
  - **CPU architecture**

- **Device name**
- **Virtual machine type**

  The virtual machine manufacturer.
- **Dynamic virtual machine as part of VDI**

  This row displays whether the client device is a dynamic virtual machine as part of VDI.
- **OS build**

- The **Protection** section provides the following information about the current status of anti-virus protection on the client device:
  - **Visible**

    Visibility status of the client device.
  - **Device status**

    Status of the client device assigned on the basis of the criteria defined by the administrator for the status of anti-virus protection on the device and the activity of the device on the network.
  - **Status description**

    Status of the client device protection and connection to Administration Server.
  - **Protection status**

    This field shows the current status of real-time protection on the client device.

    When the status changes on the device, the new status is displayed in the device properties window only after the client device is synchronized with the Administration Server.
  - **Last full scan**

    Date and time the last malware scan was performed on the client device.
  - **Virus detected**

    Total number of threats detected on the client device since installation of the security application (first scan), or since the last reset of the threat counter.
  - **Objects that have failed disinfection**

    Number of unprocessed files on the client device.

    This field ignores the number of unprocessed files on mobile devices.
  - **Disk encryption status**

    The current status of file encryption on the local drives of the device. For a description of the statuses, see the Kaspersky Endpoint Security for Windows Help.

    Files can be only encrypted on the managed devices on which Kaspersky Endpoint Security for Windows is installed.

- **View data encryption errors**

  Information about data encryption errors on the devices. The encryption is performed by the Encryption data function of Kaspersky applications. The managed application transfers data from the device to Administration Server through Network Agent.

- The **Device status defined by application** section provides information about the device status that is defined by the managed application installed on the device. This device status can differ from the one defined by Kaspersky EDR Expert.

Applications

This tab lists all Kaspersky applications installed on the client device. This tab contains the **Start** and **Stop** buttons that start and stop the selected Kaspersky application (except for Network Agent). You can use these buttons if port 15000 UDP is available on the managed device for receipt push-notifications from Administration Server. If the managed device is unavailable for push-notifications, but the mode of continuous connection to Administration Server is enabled (the **Do not disconnect from the Administration Server** option in the **General** section is enabled), the **Start** and **Stop** buttons are available too. Otherwise, when you try to start or stop the application, an error message is displayed. Also you can click the application name to view general information about the application, a list of events that have occurred on the device, and the application settings.

Active policies and policy profiles

This tab lists the policies and policy profiles that are currently assigned to the managed device.

Tasks

On the **Tasks** tab, you can manage client device tasks: view the list of existing tasks, create new ones, remove, start and stop tasks, modify their settings, and view execution results. The list of tasks is provided based on data received during the last session of client synchronization with the Administration Server. The Administration Server requests the task status details from the client device. If port 15000 UDP is available on the managed device for receipt push-notifications from Administration Server, the task status is displayed and buttons for managing the task are enabled. If a push server cannot reach the managed device, but the mode of continuous connection to Administration Server is enabled (the **Do not disconnect from the Administration Server** option in the **General** section is enabled), the actions with tasks are available too.

If connection is not established, the status is not displayed and buttons are disabled.

Events

The **Events** tab displays events logged on the Administration Server for the selected client device.

You can export, copy, and delete the device events.

Security issues

In the **Security issues** tab, you can view, edit, and create security issues for the client device. Security issues can be created either automatically, through managed Kaspersky applications installed on the client device, or manually by the administrator. For example, if some users regularly move malware from their removable drives to devices, the administrator can create a security issue. The administrator can provide a brief description of the case and recommended actions (such as disciplinary actions to be taken against a user) in the text of the security issue, and can add a link to the user or users.

A security issue for which all of the required actions have been taken is called *processed*. The presence of unprocessed security issues can be chosen as the condition for a change of the device status to *Critical* or *Warning*.

This section contains a list of security issues that have been created for the device. Security issues are classified by severity level and type. The type of a security issue is defined by the Kaspersky application, which creates the security issue. You can highlight processed security issues in the list by selecting the check box in the **Processed** column.

Tags

In the **Tags** tab, you can manage the list of keywords that are used for finding client devices: view the list of existing tags, assign tags from the list, configure auto-tagging rules, add new tags and rename old tags, and remove tags.

Advanced

This tab comprises the following sections:

- **Applications registry**. In this section, you can view the registry of applications installed on the client device and their updates; you can also set up the display of the applications registry.

  Information about installed applications is provided if Network Agent installed on the client device sends required information to the Administration Server. You can configure sending of information to the Administration Server in the properties window of Network Agent or its policy, in the **Repositories** section.

  Clicking an application name opens a window that contains the application details and a list of the update packages installed for the application.

- **Executable files**. This section displays executable files found on the client device.

- **Distribution points**. This section provides a list of distribution points with which the device interacts.

  - **Export to file**

    Click the **Export to file** button to save to a file a list of distribution points with which the device interacts. By default, the application exports the list of devices to a CSV file.

  - **Properties**

    Click the **Properties** button to view and configure the distribution point with which the device interacts.

- **Hardware registry**. In this section, you can view information about hardware installed on the client device.

  If Network Agent is installed on a device running Windows, it sends to the Administration Server the following information about the device hardware:

  - RAM
  - Mass storage devices
  - Motherboard
  - CPU
  - Network adapters
  - Monitors
  - Video adapter
  - Sound card

  If Network Agent is installed on a device running Linux or macOS, it sends to the Administration Server the following information about the device hardware, if this information is provided by the operating system:

  - Total RAM volume
  - Total volume of mass storage devices

- Motherboard
- CPU
- Network adapters

- **Available updates**. This section displays a list of software updates found on this device but not installed yet.
- **Software vulnerabilities**. This section provides information about vulnerabilities in third-party applications installed on client devices.

  To save the vulnerabilities to a file, select the check boxes next to the vulnerabilities that you want to save, and then click the **Export to CSV** button or **Export to TXT** button.

  The section contains the following settings:

  - **Show only vulnerabilities that can be fixed**

    If this option is enabled, the section displays vulnerabilities that can be fixed by using a patch.

    If this option is disabled, the section displays both vulnerabilities that can be fixed by using a patch, and vulnerabilities for which no patch has been released.

    By default, this option is enabled.

  - **Vulnerability properties**

    Click a software vulnerability name in the list to view the properties of the selected software vulnerability in a separate window. In the window, you can do the following:

    - Ignore software vulnerability on this managed device (in OSMP Console).
    - View the list of recommended fixes for the vulnerability.
    - Manually specify the software updates to fix the vulnerability (in OSMP Console).
    - View vulnerability instances.
    - View the list of existing tasks to fix vulnerability and create new tasks to fix vulnerability.

- **Remote diagnostics**. In this section, you can perform remote diagnostics of client devices.

If you use a PostgreSQL, MariaDB or MySQL DBMS, the **Events** tab may display an incomplete list of events for the selected client device. This occurs when the DBMS stores a very large amount of events. You can increase the number of displayed events by doing either of the following:

- Removing unnecessary events.
- Reducing the storage term for unnecessary events.

To see a full list of events logged on the Administration Server for the device, use Reports.

Manually checking the connection between a client device and the Administration Server. klnagchk utility

You can check the connection, and obtain detailed information about the settings of the connection, between a client device and Administration Server by using the klnagchk utility. The klnagchk utility is located in the Network Agent installation folder.

When started from the command line, the klnagchk utility can perform the following actions (depending on the keys in use):

- Display on the screen or logs the values of the settings used for connecting Network Agent installed on the device to Administration Server.
- Record into an event log file Network Agent statistics (since its last startup) and utility operation results, or displays the information on the screen.
- Attempt to establish a connection between Network Agent and Administration Server.

  If the connection attempt fails, the utility sends an ICMP packet to check the status of the device on which Administration Server is installed.

To check the connection between a client device and Administration Server by using the klnagchk utility,

On the device with Network Agent installed, start the klnagchk utility from the command line under a local administrator account.

Utility command line syntax:

```
klnagchk [-logfile <file name>] [-sp] [-savecert <path to certificate file>] [-
restart][-sendhb]
```

Descriptions of the keys:

- `-logfile <file name>`—Records in a log file with the values of the connection settings between Network Agent and Administration Server, and the utility operation results.

  By default, information is saved in the standard output stream (stdout). If the key is not in use, settings, results, and error messages are displayed on the screen.
- `-sp`—Shows the password for the user's authentication on the proxy server.

  The key is in use if connection to the Administration Server is established through a proxy server.
- `-savecert <file name>`—Saves the certificate used to access the Administration Server, in a specified file.
- `-restart`—Starts Network Agent after the utility has completed.
- `-sendhb`—Starts the synchronization of Network Agent with Administration Server.

After startup, the klnagchk utility accesses the configuration files of Network Agent and displays the connection parameters. These parameters are specified during the Network Agent installation and in the Network Agent policy settings:

- `Current device`—Windows network name of the client device.
- `Network Agent version`—Full number of the Network Agent version (with patches) installed on the device.
- `Server address`—Address of Administration Server.
- `Use SSL`—Parameter that indicates whether a secure connection is used when connecting to the Administration Server.

  Possible values:

  - 0—Secure connection is not used.
  - 1—Secure connection is used.
- `Compress traffic`—Parameter that indicates whether the traffic between the client device and Administration Server is compressed.
- `Server SSL ports`—Numbers of valid ports for communication with Administration Server when using a secure connection.
- `Server ports`—Numbers of valid ports for communication with the Administration Server when using an ordinary connection.
- `Use proxy server`—Parameter that indicates whether a proxy server is used.

  Possible values:

  - 0—Proxy server is not used.
  - 1—Proxy server is used.
- `Address`—Address and port of the proxy server, separated by a colon. This parameter is displayed only if a proxy server is used.
- `User name`—User name for accessing the proxy server. This parameter is displayed only if a proxy server is used.
- `Password`—Password for accessing the proxy server. This parameter is displayed only if a proxy server is used. To show the proxy server password, you need to use the `sp` key in the command.
- `Certificate`—Parameter that indicates whether the client device has an Administration Server certificate. A certificate may not exist, for example, if Network Agent has never successfully connected to Administration Server.

  Possible values:

  - `not installed`—Client device does not have an Administration Server certificate.
  - `present`—Client device has an Administration Server certificate.
- `Open UDP port`—Parameter that indicates whether Network Agent uses the UDP port to receive synchronization requests from Administration Server.

Possible values:

- 0—UDP port is closed for receiving synchronization requests from Administration Server.
- 1—UDP port is opened for receiving synchronization requests from Administration Server.

- `UDP ports`—Numbers of UDP ports that can be used by Network Agent.
- `Location name`—Network location of the device.
- `State of network location`—Parameter that indicates whether the client device can be switched from one Administration Server connection profile to another.

  Possible values:

  - `Enabled`—Administration Server connection profile can be switched for the client device.
  - `Disabled`—Administration Server connection profile cannot be switched for the client device.
- `Profile to use`—Connection profile for Administration Server.
- `Condition`—IP address and subnet mask of the network to which the client device is connected.
- `Ping period, minutes`—Standard interval between synchronizations.
- `Conn timeout, s`—Connection timeout.
- `RW timeout, s`—Connection timeout of read-write operations.
- `Host ID`—Device identifier in the network. The `Device ID` is unique among the client devices managed by a particular Administration Server.
- `Locations of connection gateways`—Parameters for connecting the client device to Administration Server through the connection gateway.
- `Location of distribution points`—Parameters for connecting the client device to Administration Server through the distribution point.
- `Connection with server`—Parameter that indicates whether the connection gateway has a continuous connection to Administration Server. The parameter shows only if the client device acts as a connection gateway.

  Possible values:

  - `active`—The connection gateway has a continuous connection to Administration Server.
  - `inactive`—The connection gateway does not have a continuous connection to Administration Server.
- `Connection with server through connection gateway`—Parameter that indicates whether the connection to Administration Server through a connection gateway is established correctly. The parameter shows only if the client device acts as a connection gateway.

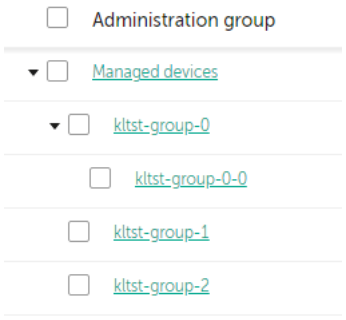
Possible values:

- `active`—The connection to Administration Server through a connection gateway is established correctly.
- `inactive`—The connection to Administration Server through a connection gateway is established incorrectly.

Also, the klnagchk utility output can contain one of the following lines:

- `Administration Server is installed on this device`—The klnagchk utility is run on the Administration Server device.
- `This device has been assigned a connection gateway but is not yet registered on Administration Server`—The klnagchk utility is run on the device on which Network Agent is installed, in the connection gateway mode. The configured connection gateway is waiting for a connection from Administration Server, but Administration Server does not list the device among managed devices. You need to ensure Administration Server initiates a connection to the connection gateway.
- `This device is a connection gateway`—The klnagchk utility is run on the device that acts as a connection gateway.
- `Acts as a distribution point`—The klnagchk utility is run on the device that acts as a distribution point.

The klnagchk utility checks the status of the Network Agent service. If the service is not running, the utility stops. If the service is running, the utility displays the following connection statistics:



- `Ping count`—Number of attempts to connect the client device to Administration Server.
- `Succ. pings`—Number of successful attempts to connect the client device to Administration Server.
- `Sync count`—Number of attempts to synchronize the client device settings with the Administration Server settings.
- `Succ. syncs`—Number of successful attempts to synchronize the client device settings with Administration Server.
- `Last ping`—Date and time of the last connection.

You need to use the `Ping count` and `Succ. pings` parameters when analyzing the connection between Administration Server and Network Agent. The client device settings synchronize with the Administration Server settings only if the Administration Server settings were changed (for example, if new tasks were added or policy settings were modified). Otherwise, the `Ping count` and `Succ. pings` parameter values remain unchanged.

For more information on how to troubleshoot issues with connecting Network Agent to Administration Server, refer to Open Single Management Platform FAQ.

Creating administration groups

Immediately after Kaspersky EDR Expert installation, the hierarchy of administration groups contains only one administration group called **Managed devices**. When creating a hierarchy of administration groups, you can add devices and virtual machines to the **Managed devices** group, and add nested groups (see the figure below).

Viewing administration groups hierarchy

To create an administration group:

1. In the main menu, go to **Asset management** → **Hierarchy of groups**.
2. In the administration group structure, select the administration group that is to include the new administration group.
3. Click **Add**.
4. In the **Name of the new administration group** window that opens, enter a name for the group, and then click the **Add** button.

A new administration group with the specified name appears in the hierarchy of administration groups.

To create a structure of administration groups:

1. In the main menu, go to **Asset management** → **Hierarchy of groups**.
2. Click **Import**.

The New Administration Group Structure Wizard starts. Follow the steps of the wizard.

Device moving rules

We recommend that you automate the allocation of devices to administration groups through *device moving rules*. A device moving rule consists of three main parts: a name, an execution condition (logical expression with the device attributes), and a target administration group. A rule moves a device to the target administration group if the device attributes meet the rule execution condition.

All device moving rules have priorities. The Administration Server checks the device attributes as to whether they meet the execution condition of each rule, in ascending order of priority. If the device attributes meet the execution condition of a rule, the device is moved to the target group, so the rule processing is complete for this device. If the device attributes meet the conditions of multiple rules, the device is moved to the target group of the rule with the highest priority (that is, has the highest rank in the list of rules).

Device moving rules can be created implicitly. For example, in the properties of an installation package or a remote installation task, you can specify the administration group to which the device must be moved after Network Agent is installed on it. Also, device moving rules can be created explicitly by the administrator of Kaspersky EDR Expert, in the **Asset management** → **Moving rules** section.

By default, a device moving rule is intended for one-time initial allocation of devices to administration groups. The rule moves devices from the unassigned devices group only once. If a device once was moved by this rule, the rule will never move it again, even if you return the device to the unassigned devices group manually. This is the recommended way of applying moving rules.

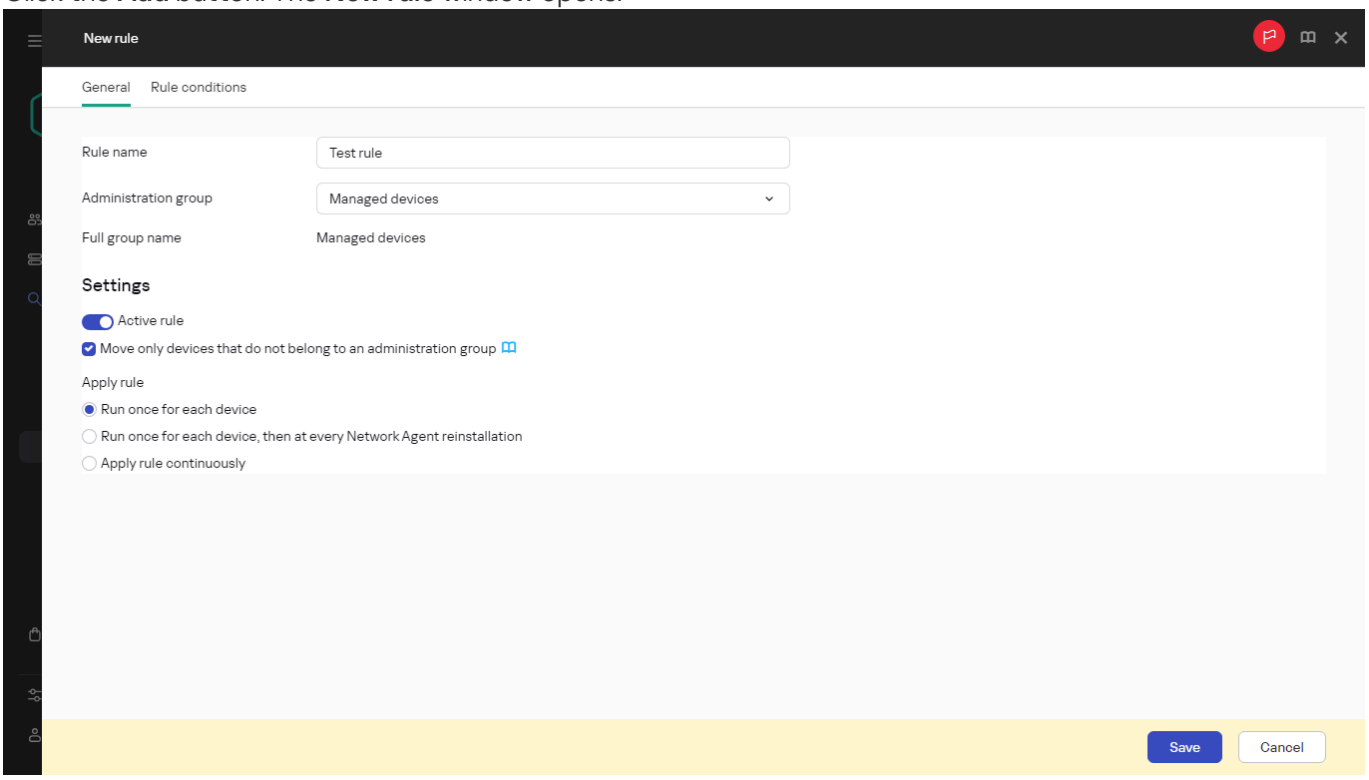
You can move devices that have already been allocated to some of the administration groups. To do this, in the properties of a rule, clear the **Move only devices that do not belong to an administration group** check box.

Applying moving rules to devices that have already been allocated to some of the administration groups, significantly increases the load on the Administration Server.

The **Move only devices that do not belong to an administration group** check box is locked in the properties of automatically created moving rules. Such rules are created when you add the *Install application remotely* task or create a stand-alone installation package.

You can create a moving rule that would affect a single device repeatedly.

We strongly recommend that you avoid moving a single device from one group to another repeatedly (for example, in order to apply a special policy to that device, run a special group task, or update the device through a specific distribution point).



Such scenarios are not supported, because they increase the load on Administration Server and network traffic to an extreme degree. These scenarios also conflict with the operating principles of Kaspersky EDR Expert (particularly in the area of access rights, events, and reports). Another solution must be found, for example, through the use of policy profiles, tasks for device selections, assignment of Network Agents according to the standard scenario.

Creating device moving rules

You can set up device moving rules, that is, rules that automatically allocate devices to administration groups.

To create a moving rule:

1. In the main menu, go to **Asset management** → **Moving rules**.
2. Click the **Add** button. The **New rule** window opens.

Creating a new moving rule

3. In the window that opens, specify the following information on the **General** tab:

- **Rule name**

  Enter a name for the new rule.

  If you are copying a rule, the new rule gets the same name as the source rule, but an index in () format is added to the name, for example: (1).

- **Administration group**

  Select the administration group into which the devices are to be moved automatically.

- **Active rule**

  If this option is enabled, the rule is enabled and starts working after it is saved.

  If this option is disabled, the rule is created, but not enabled. It will not work until you enable this option.

- **Priority**

  You can specify the moving rule's priority. The highest priority is 1. The greater the **Priority** value, the lower the rule's priority and its position in the list.

  If no priority is assigned, the rule is assigned the lowest priority.

  When copying a rule, the rule's copy is assigned the priority of the original rule. The original rule's priority is then increased by 1.

- **Move only devices that do not belong to an administration group**

  If this option is enabled, only unassigned devices will be moved to the selected group.

  If this option is disabled, devices that already belong to other administration groups, as well as unassigned devices, will be moved to the selected group.

- **Apply rule**

  You can select one of the following options:

  - **Run once for each device**

    The rule is applied once for each device that matches your criteria.

  - **Run once for each device, then at every Network Agent reinstallation**

    The rule is applied once for each device that matches your criteria, then only when Network Agent is reinstalled on these devices.

  - **Apply rule continuously**

    The rule is applied according to the schedule which the Administration Server sets up automatically (usually every several hours).

4. On the **Rule conditions** tab, specify at least one criterion by which the devices are moved to an administration group.

5. Click **Save**.

The moving rule is created. It is displayed in the list of moving rules.

The higher the position is on the list, the higher the priority of the rule.

To change the priority of a moving rule:

1. In the main menu, go to **Asset management** → **Moving rules**.

2. In the list of moving rules, select the check box next to the moving rule for which you want to change the priority.

3. Do one of the following:

   - Click the **Change priority** button, and, in the window that opens, specify the new priority.

   - Move the rule up or down in the list by clicking the **Move up** or **Move down** buttons.

4. Click the **Save** button.

If the **Apply rule continuously** option is selected, the moving rule is applied regardless of the priority settings. Such rules are applied according to the schedule that the Administration Server sets up automatically.

If the device attributes meet the conditions of multiple rules, the device is moved to the target group of the rule with the highest priority (that is, has the highest rank in the list of rules).

Copying device moving rules

You can copy moving rules, for example, if you want to have several identical rules for different target administration groups.

To copy an existing a moving rule:

1. Do one of the following:

   - In the main menu, go to **Asset management** → **Moving rules**.
   - In the main menu, go to **Discovery & deployment** → **Deployment & assignment** → **Moving rules**.

   The list of moving rules is displayed.

2. Select the check box next to the rule you want to copy.
3. Click **Copy**.
4. In the window that opens, change the following information on the **General** tab—or make no changes if you only want to copy the rule without changing its settings:

   - **Rule name**

     Enter a name for the new rule.

     If you are copying a rule, the new rule gets the same name as the source rule, but an index in () format is added to the name, for example: (1).

   - **Administration group**

     Select the administration group into which the devices are to be moved automatically.

   - **Active rule**

     If this option is enabled, the rule is enabled and starts working after it is saved.

     If this option is disabled, the rule is created, but not enabled. It will not work until you enable this option.

   - **Priority**

     You can specify the moving rule's priority. The highest priority is 1. The greater the **Priority** value, the lower the rule's priority and its position in the list.

     If no priority is assigned, the rule is assigned the lowest priority.

     When copying a rule, the rule's copy is assigned the priority of the original rule. The original rule's priority is then increased by 1.

   - **Move only devices that do not belong to an administration group**

     If this option is enabled, only unassigned devices will be moved to the selected group.

     If this option is disabled, devices that already belong to other administration groups, as well as unassigned devices, will be moved to the selected group.

- **Apply rule**

  You can select one of the following options:

  - **Run once for each device**

    The rule is applied once for each device that matches your criteria.

  - **Run once for each device, then at every Network Agent reinstallation**

    The rule is applied once for each device that matches your criteria, then only when Network Agent is reinstalled on these devices.

  - **Apply rule continuously**

    The rule is applied according to the schedule which the Administration Server sets up automatically (usually every several hours).

Properties of the device moving rule

5. On the **Rule conditions** tab, specify at least one criterion for the devices that you want to be moved automatically.

6. Click **Save**.

The new moving rule is created. It is displayed in the list of moving rules.

Conditions for a device moving rule

When you create or copy a rule to move client devices to administration groups, on the **Rule conditions** tab you set conditions for moving the devices. To determine which devices to move, you can use the following criteria:

- Tags assigned to client devices.
- Network parameters. For example, you can move devices with IP addresses from a specified range.
- Device owner, his or her role and security group membership.

- Managed applications installed on client devices, for instance, Network Agent or Administration Server.
- Virtual machines, which are the client devices.
- Domain controller organizational units.
- Cloud segments.

Below, you can find the description on how to specify this information in a device moving rule.

If you specify several conditions in the rule, the AND logical operator works and all the conditions apply at the same time. If you do not select any options or keep some fields blank, such conditions do not apply.

Tags tab

On this tab, you can configure a device moving rule based on device tags that were previously added to the descriptions of client devices. To do this, select the required tags. Also, you can enable the following options:

Apply to devices without the specified tags

If this option is enabled, all devices with the specified tags are excluded from a device moving rule. If this option is disabled, the device moving rule applies to devices with all the selected tags.

By default, this option is disabled.

Apply if at least one specified tag matches

If this option is enabled, a device moving rule applies to client devices with at least one of the selected tags. If this option is disabled, the device moving rule applies to devices with all the selected tags.

By default, this option is disabled.

Network tab

On this tab, you can specify the network data of devices that a device moving rule considers:

Device name on the Windows network

Windows network name (NetBIOS name) of the device, or the IPv4 or IPv6 address.

Windows domain

A device moving rule applies to all devices included in the specified Windows domain.

DNS name of the device

DNS domain name of the client device that you want to move. Fill this field if your network includes a DNS server.

> If case sensitive collation is set for the database that you use for Open Single Management Platform, keep case when you specify a device DNS name. Otherwise, the device moving rule will not work.

DNS domain

A device moving rule applies to all devices included in the specified main DNS suffix. Fill this field if your network includes a DNS server.

IP range

If this option is enabled, you can enter the initial and final IP addresses of the IP range in which the relevant devices must be included.

By default, this option is disabled.

IP address for connection to Administration Server

If this option is enabled, you can set the IP addresses by which client devices are connected to Administration Server. To do this, specify the IP range that includes all necessary IP addresses.

By default, this option is disabled.

Device is located in a subgroup of the Domains group

If this option is enabled, you can select a subgroup of the Domains group. The relevant devices must be located in the selected subgroup.

By default, this option is disabled.

Device is in IP range

If this option is enabled, you can select an IP range that you previously added in the **IP ranges** section. The relevant devices must be included in the selected IP range.

By default, this option is disabled.

Connection profile changed

Select one of the following values:

- **Yes**. A device moving rule only applies to client devices with a changed connection profile.
- **No**. The device moving rule only applies to the client devices whose connection profile has not changed.
- **No value is selected**. The condition does not apply.

Managed by a different Administration Server

Select one of the following values:

- **Yes**. A device moving rule only applies to client devices managed by other Administration Servers. These Servers are different from the Server on which you configure the device moving rule.
- **No**. The device moving rule only applies to client devices managed by the current Administration Server.
- **No value is selected**. The condition does not apply.

Device owner tab

On this tab, you can configure a device moving rule based on the device owner, security group membership, and role:

Device owner

Select a device owner's user name from an internal security group. Learn more about users and user roles in this section.

> No more than one user can be registered as the device owner.

Device owner's membership in Active Directory security group

Select an external Active Directory security group that the device owner belongs to.

> The user can be a part of an Active Directory security group or a part of a group that is included in this Active Directory security group.

Device owner's role

Select the device owner's assigned role. Learn more about user roles in this article.

Device owner's membership in an internal security group

Select an internal security group that the device owner belongs to.

Applications tab

On this tab, you can configure a device moving rule based on the managed applications and operating systems installed on client devices:

Network Agent is installed

Select one of the following values:

- **Yes**. A device moving rule only applies to client devices with Network Agent installed.
- **No**. The device moving rule only applies to client devices on which Network Agent is not installed.
- **No value is selected**. The condition does not apply.

Applications

Specify what managed applications should be installed on client devices, so a device moving rule applies to these devices. For example, you can select **Kaspersky Security Center 16.3 Network Agent** or **Kaspersky Security Center 16.3 Administration Server**.

If you do not select any managed application, the condition does not apply.

OS version

You can cull client devices based on the operating system version. For this purpose, specify operating systems that should be installed on the client devices. As a result, a device moving rule applies to the client devices with the selected operating systems.

If you do not enable this option, the condition does not apply. By default, this option is disabled.

OS architecture

You can cull client devices by the operating system bit sizes. In the **Operating system architecture** field, you can select one of the following values:

- **Unknown.**
- **x86**
- **AMD64**
- **IA64**

To check the operating system bit size of the client devices:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section.
2. Click the settings icon (⚙) on the right.
3. Select the **OS architecture** option, and then click the **Save** button.

   After that, the operating system bit size is displayed for every managed device.

OS package manager

You can cull client devices by the operating system package manager. In the **OS package manager** field, you can select one of the following values:

- rpm—for devices running Red Hat Enterprise Linux, CentOS, Fedora, SUSE, Oracle Linux operating systems
- apt (dpkg)—for devices running Debian, Ubuntu, Kali operating systems
- pkg—for devices running FreeBSD, OpenBSD operating systems

To check the operating system package manager of the client devices:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section.
2. Click the **Columns settings** button (⚙) on the right.
3. Select the **OS package manager** option, and then click the **Save** button.

The operating system package manager is displayed for every managed device.

OS service pack version

In this field, you can specify the package version of the operating system (in the *X.Y* format), which will determine how the moving rule is applied to the device. By default, no version value is specified.

User certificate

Select one of the following values:

- **Installed**. A device moving rule only applies to mobile devices with a mobile certificate.
- **Not installed**. The device moving rule only applies to mobile devices without a mobile certificate.
- **No value is selected**. The condition does not apply.

OS build

> This setting is applicable to Windows operating systems only.

You can specify whether the selected operating system must have an equal, earlier, or later release number. You can also configure a device moving rule for all build numbers except the specified one.

OS release number

> This setting is applicable to Windows operating systems only.

You can specify whether the selected operating system must have an equal, earlier, or later release number. You can also configure a device moving rule for all release numbers except the specified one.

Virtual machines tab

On this tab, you can configure a device moving rule according to whether client devices are virtual machines or part of a virtual desktop infrastructure (VDI):

This is a virtual machine

In the drop-down list, you can select one of the following:

- **N/A**. The condition does not apply.
- **No**. Move devices that are not virtual machines.
- **Yes**. Move devices that are virtual machines.

Virtual machine type

Part of Virtual Desktop Infrastructure

In the drop-down list, you can select one of the following:

- **N/A**. The condition does not apply.
- **No**. Move devices that are not part of VDI.
- **Yes**. Move devices that are part of VDI.

Domain controller tab

On this tab, you can specify that it is necessary to move devices included in the domain organizational unit. You can also move devices from all child organizational units of the specified domain organizational unit:

Device is included in the following organizational unit

If this option is enabled, a device moving rule applies to devices from the domain controller organizational unit specified in the list under the option.

By default, this option is disabled.

Include child organizational units

If this option is enabled, the selection includes devices from all child organizational units of the specified domain controller organizational unit.

By default, this option is disabled.

Move devices from child units to corresponding subgroups

Create subgroups corresponding to containers of newly detected devices

Delete subgroups that are not present in the domain

Device is included in the following domain security group

If this option is enabled, a device moving rule applies to devices from the domain security group specified in the list under the option.

By default, this option is disabled.

Cloud segments tab

On this tab, you can specify that it is necessary to move devices included in the cloud segment. You can also move devices from all child organizational units of the specified domain organizational unit:

Device is in a cloud segment

If you select this option, a device moving rule applies to the client devices that belong to a cloud segment. You can select the required cloud segment up to a subnet in the list under the option.

By default, this option is disabled.

Include child objects

If this option is enabled, the selection includes devices from all child organizational units of the specified cloud segment.

By default, this option is disabled.

Move devices from nested objects to corresponding subgroups

Create subgroups corresponding to containers of newly detected devices

Delete subgroups for which no match is found in the cloud segments

Device discovered by using the API

In the drop-down list, you can select one of the following:

- No value is selected. The condition does not apply.
- **No**. Move devices that are not discovered by using the API.
- **AWS**. Move devices that are discovered by AWS API.
- **Azure**. Move devices that are discovered by Azure API.
- **Google Cloud**. Move devices that are discovered by Google Cloud API.

After that, depending on the selected value, you can fill in the following fields:

- **Cloud device subnet**.
- **Cloud device availability zone**.
- **Cloud device placement group**.

Adding devices to an administration group manually

You can move devices to administration groups automatically by creating device moving rules or manually by moving devices from one administration group to another or by adding devices to a selected administration group. This section describes how to manually add devices to an administration group.

To add manually one or more devices to a selected administration group:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.
2. Select the administration group to which you want to add the devices:
   - For the root group:

     In this case you can proceed to the next step.
   - For a subgroup:

     a. Click the **Show hierarchy** button at the top of the page.

     The button name changes to **Hide hierarchy**.

     b. In the window that opens, click the name of the subgroup.

     The path to the selected group is displayed at the top of the page. If necessary, you can click a link with the administration group name to go to the group. By default, the last link in the path is inactive. Also, you can close the hierarchy window by clicking the **Hide hierarchy** button.
3. Click the **Add devices** button.

   The Move devices wizard starts.

4. Make a list of the devices that you want to add to the administration group.

   You can add only devices for which information has already been added to the Administration Server database either upon connection of the device or after device discovery.

   Select how you want to add devices to the list:

   - Click the **Add devices** button, and then specify the devices in one of the following ways:
     - Select devices from the list of devices detected by the Administration Server.
     - Specify a device IP address or an IP range.

       The IP range must not contain more than 1,048,576 addresses.

     - Specify a device DNS name.

       The device name field must not contain space characters, backspace characters, or the following prohibited characters: , \ / * ' " ; : & ` ~ ! @ # $ ^ ( ) = + [ ] { } | < > %

   - Click the **Import devices from file** button to import a list of devices from a .txt file. Each device address or name must be specified on a separate line.

     The file must not contain space characters, backspace characters, or the following prohibited characters: , \ / * ' " ; : & ` ~ ! @ # $ ^ ( ) = + [ ] { } | < > %

5. View the list of devices to be added to the administration group. You can edit the list by adding or removing devices.

6. After making sure that the list is correct, click the **Next** button.

   The wizard processes the device list and displays the result. The successfully processed devices are added to the administration group and are displayed in the list of devices under names generated by Administration Server.

Moving devices or clusters to an administration group manually

You can move devices from one administration group to another, or from the group of unassigned devices to an administration group.

You can also move clusters or server arrays from one administration group to another. When you move a cluster or server array to another group, all of its nodes move with it, because a cluster and any of its nodes always belong to the same administration group. When you select a single cluster node on the **Devices** tab, the **Move to group** button becomes unavailable.

To move one or several devices or clusters to a selected administration group:

1. Open the administration group from which you want to move the devices. To do so, follow one of these steps:
   - To open an administration group, in the main menu, go to **Asset management** → **Assets (Devices)**, and then select the required administration group.
     - For the root group, you can proceed to the next step.
     - For a subgroup, click the **Show hierarchy** button at the top of the page, and then, in the window that opens, select a required administration group.
   - To open the **Unassigned devices** group, in the main menu, go to **Asset management** → **Unassigned devices**.
2. If the administration group contains clusters or server arrays, the **Assets (Devices)** section is divided into two tabs—the **Devices** tab and the **Clusters and server arrays** tab. Open the tab for the object that you want to move.
3. Select the check boxes next to the devices or clusters that you want to move to a different group.
4. Click the **Move to group** button.
5. In the hierarchy of administration groups, select the check box next to the administration group to which you want to move the selected devices or clusters.
6. Click the **Move** button.

The selected devices or clusters are moved to the selected administration group.

About clusters and server arrays

Kaspersky EDR Expert supports cluster technology. If Network Agent sends information to Administration Server confirming that an application installed on a client device is part of a server array, this client device becomes a cluster node.

If an administration group contains clusters or server arrays, the **Assets (Devices)** page displays two tabs—one for individual devices, and one for clusters and server arrays. After the managed devices are detected as cluster nodes, the cluster is added as an individual object to the **Clusters and server arrays** tab.

The cluster or server array nodes are listed on the **Devices** tab, along with other managed devices. You can view properties of the nodes as individual devices and perform other operations, but you cannot delete a cluster node or move it to another administration group separately from its cluster. You can only delete or move an entire cluster.

You can perform the following operations with clusters or server arrays:

- View properties
- Move the cluster or server array to another administration group

  When you move a cluster or server array to another group, all of its nodes move with it, because a cluster and any of its nodes always belong to the same administration group.

- Delete

  It is reasonable to delete a cluster or server array only when the cluster or server array does not exist in the organization network any longer. If a cluster is still visible on your network and Network Agent and the Kaspersky security application are still installed on the cluster nodes, Open Single Management Platform returns the deleted cluster and its nodes back to the list of managed devices automatically.

Properties of a cluster or server array

To view the settings of a cluster or server array:

1. In the main menu, go to **Asset management → Assets (Devices) → Clusters and server arrays**.

   The list of clusters and server arrays is displayed.

2. Click the name of the required cluster or server array.

The properties window of the selected cluster or server array is displayed.

General

The **General** section displays general information about the cluster or server array. Information is provided on the basis of data received during the last synchronization of the cluster nodes with the Administration Server:

Name

Description

Windows domain

Windows domain or workgroup, which contains the cluster or server array.

NetBIOS name

Windows network name of the cluster or server array.

DNS name

Name of the DNS domain of the cluster or server array.

Tasks

In the **Tasks** tab, you can manage the tasks assigned to the cluster or server array: view the list of existing tasks; create new ones; remove, start, and stop tasks; modify task settings; and view execution results. The listed tasks relate to the Kaspersky security application installed on the cluster nodes. Open Single Management Platform receives the task list and the task status details from the cluster nodes. If a connection is not established, the status is not displayed.

Nodes

This tab displays a list of nodes included into the cluster or server array. You can click a node name to view the device properties window.

Kaspersky application

The properties window may also contain additional tabs with the information and settings related to the Kaspersky security application installed on the cluster nodes.

Adjustment of distribution points and connection gateways

A structure of administration groups in Kaspersky EDR Expert performs the following functions:

- Sets the scope of policies

  There is an alternate way of applying relevant settings on devices, by using *policy profiles*.

- Sets the scope of group tasks

  There is an approach to defining the scope of group tasks that is not based on a hierarchy of administration groups: use of tasks for device selections and tasks for specific devices.

- Sets access rights to devices, virtual Administration Servers, and secondary Administration Servers

- Assigns distribution points

When building the structure of administration groups, you must take into account the topology of the organization's network for the optimum assignment of distribution points. The optimum distribution of distribution points allows you to save traffic on the organization's network.

Depending on the organizational schema and network topology, the following standard configurations can be applied to the structure of administration groups:

- Single office

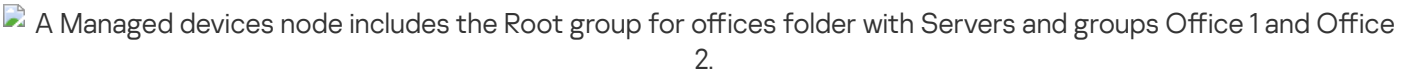
- Multiple small remote offices

Devices functioning as distribution points must be protected, including physical protection, against any unauthorized access.

Standard configuration of distribution points: Single office

In a standard "single-office" configuration, all devices are on the organization's network so they can "see" each other. The organization's network may consist of a few separate parts (networks or network segments) linked by narrow channels.

The following methods of building the structure of administration groups are possible:



- Building the structure of administration groups taking into account the network topology. The structure of administration groups may not reflect the network topology with absolute precision. A match between the separate parts of the network and certain administration groups would be enough. You can use automatic assignment of distribution points or assign them manually.

- Building the structure of administration groups, without taking the network topology into account. In this case, you must disable automatic assignment of distribution points, and then assign one or several devices to act as distribution points for a root administration group in each of the separate parts of the network, for example, for the **Managed devices** group. All distribution points will be at the same level and will feature the same scope spanning all devices on the organization's network. In this case, each Network Agent will connect to the distribution point that has the shortest route. The route to a distribution point can be traced with the tracert utility.

Standard configuration of distribution points: Multiple small remote offices

This standard configuration provides for a number of small remote offices, which may communicate with the head office over the internet. Each remote office is located behind the NAT, that is, connection from one remote office to another is not possible because offices are isolated from one another.

The configuration must be reflected in the structure of administration groups: a separate administration group must be created for each remote office (groups **Office 1** and **Office 2** in the figure below).

Remote offices are included in the administration group structure

One or multiple distribution points must be assigned to each administration group that correspond to an office. Distribution points must be devices at the remote office that have a sufficient amount of free disk space. Devices deployed in the **Office 1** group, for example, will access distribution points assigned to the **Office 1** administration group.

If some users move between offices physically, with their laptops, you must select two or more devices (in addition to the existing distribution points) in each remote office and assign them to act as distribution points for a top-level administration group (**Root group for offices** in the figure above).

Example: A laptop is deployed in the **Office 1** administration group and then is moved physically to the office that corresponds to the **Office 2** administration group. After the laptop is moved, Network Agent attempts to access the distribution points assigned to the **Office 1** group, but those distribution points are unavailable. Then, Network Agent starts attempting to access the distribution points that have been assigned to the **Root group for offices**. Because remote offices are isolated from one another, attempts to access distribution points assigned to the **Root group for offices** administration group will only be successful when Network Agent attempts to access distribution points in the **Office 2** group. That is, the laptop will remain in the administration group that corresponds to the initial office, but the laptop will use the distribution point of the office where it is physically located at the moment.

Calculating the number and configuration of distribution points

The more client devices a network contains, the more distribution points it requires. We recommend that you not disable automatic assignment of distribution points. When automatic assignment of distribution points is enabled, Administration Server assigns distribution points if the number of client devices is quite large and defines their configuration.

Using exclusively assigned distribution points

If you plan to use certain specific devices as distribution points (that is, exclusively assigned servers), you can opt out of using automatic assignment of distribution points. In this case, make sure that the devices that you intend to make distribution points have sufficient volume of free disk space, are not shut down regularly, and have Sleep mode disabled.

Number of dedicated distribution points in a network containing one network segment, depending on the number of devices in the network

Number of client devices per network segment	Number of distribution points
Less than 300	0 (Do not assign distribution points)
More than 300	Acceptable: (N/10,000 + 1), recommended: (N/5000 + 2), where N is the number of networked devices

Number of dedicated distribution points in a network containing multiple network segments, depending on the number of devices in the network

Number of client devices in each network segment	Number of distribution points
Less than 10	0 (Do not assign distribution points)
10–100	1
More than 100	Acceptable: (N/10,000 + 1), recommended: (N/5000 + 2), where N is the number of networked devices

Using standard client devices (workstations) as distribution points

If you plan to use standard client devices (that is, workstations) as distribution points, we recommend that you assign distribution points as shown in the tables below in order to avoid excessive load on the communication channels and on Administration Server:

Number of workstations functioning as distribution points on a network that contains a single network segment, based on the number of networked devices

Number of client devices per network segment	Number of distribution points
Less than 300	0 (Do not assign distribution points)
More than 300	(N/300 + 1), where N is the number of networked devices; there must be at least 3 distribution points

Number of workstations functioning as distribution points on a network that contains multiple network segments, based on the number of networked devices

Number of client devices per network segment	Number of distribution points
Less than 10	0 (Do not assign distribution points)
10–30	1
31–300	2
More than 300	(N/300 + 1), where N is the number of networked devices; there must be at least 3 distribution points

If a distribution point is shut down (or not available for some other reason), the managed devices in its scope can access the Administration Server for updates.

Assigning distribution points automatically

We recommend that you assign distribution points automatically. In this case, Kaspersky EDR Expert will select on its own which devices must be assigned distribution points.

Devices running Microsoft Windows on Arm cannot act as distribution points.

To assign distribution points automatically:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Distribution points** section.

3. Select the **Automatically assign distribution points** option.

   If automatic assignment of devices as distribution points is enabled, you cannot configure distribution points manually or edit the list of distribution points.

4. Click the **Save** button.

Administration Server assigns and configures distribution points automatically.

Assigning distribution points manually

Kaspersky EDR Expert allows you to manually assign devices to act as distribution points.

We recommend that you assign distribution points automatically. In this case, Kaspersky EDR Expert will select on its own which devices must be assigned distribution points. However, if you have to opt out of assigning distribution points automatically for any reason (for example, if you want to use exclusively assigned servers), you can assign distribution points manually after you Calculating the number and configuration of distribution points.

Devices functioning as distribution points must be protected, including physical protection, against any unauthorized access.

Devices running Microsoft Windows on Arm cannot act as distribution points.

To manually assign a device to act as distribution point:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Distribution points** section.

3. Select the **Manually assign distribution points** option.

4. Click the **Assign** button.

5. Select the device that you want to make a distribution point.

   When selecting a device, keep in mind the operation features of distribution points and the requirements set for the device that acts as distribution point.

6. Select the administration group that you want to include in the scope of the selected distribution point.

7. Click **OK**.

   The distribution point that you have added will be displayed in the list of distribution points, in the **Distribution points** section.

8. Click the newly added distribution point in the list to open its properties window.

9. Configure the distribution point in the properties window:

   - The **General** section contains the settings of interaction between the distribution point and client devices.

     - **SSL port**

       The number of the SSL port for encrypted connection between client devices and the distribution point using SSL.

       The default port number is 13000.

     - **Enabled**

       If this option is enabled, IP multicasting will be used for automatic distribution of installation packages to client devices within the group.

       IP multicasting decreases the time required to install an application from an installation package to a group of client devices, but increases the installation time when you install an application to a single client device.

- **IP multicast address**

  IP address that will be used for multicasting. You can define an IP address in the range of 224.0.0.0 – 239.255.255.255

  By default, Kaspersky EDR Expert automatically assigns a unique IP multicast address within the given range.

- **IP multicast port number**

  Number of the port for IP multicasting.

  By default, the port number is 15001. If the device with Administration Server installed is specified as the distribution point, port 13001 is used for SSL connection by default.

- **Distribution point address for remote devices**

  The network address through which remote devices connect to the distribution point.

- **Deploy updates**

  Updates are distributed to managed devices from the following sources:

  - This distribution point, if this option is enabled.
  - Other distribution points, Administration Server, or Kaspersky update servers, if this option is disabled.

  If you use distribution points to deploy updates, you can save traffic because you reduce the number of downloads. Also, you can relieve the load on the Administration Server and relocate the load between the distribution points. You can Calculating the number and configuration of distribution points the number of distribution points for your network to optimize the traffic and load.

  If you disable this option, the number of update downloads and load on the Administration Server may increase. By default, the option is enabled.

- **Deploy installation packages**

  Installation packages are distributed to managed devices from the following sources:

  - This distribution point, if this option is enabled.
  - Other distribution points, Administration Server, or Kaspersky update servers, if this option is disabled.

  If you use distribution points to deploy installation packages, you can save traffic because you reduce the number of downloads. Also, you can relieve the load on the Administration Server and relocate the load between the distribution points. You can Calculating the number and configuration of distribution points the number of distribution points for your network to optimize the traffic and load.

  If you disable this option, the number of installation package downloads and load on the Administration Server may increase. By default, the option is enabled.

- **Run push server**

  In Open Single Management Platform, a distribution point can work as a push server for the devices managed through the mobile protocol and for the devices managed by Network Agent. For example, a push server must be enabled if you want to be able to force synchronization of KasperskyOS devices with Administration Server. A push server has the same scope of managed devices as the distribution point on which the push server is enabled. If you have several distribution points assigned for the same administration group, you can enable push server on each of the distribution points. In this case, Administration Server balances the load between the distribution points.

- **Push server port**

  The port number for the push server. You can specify number of any unoccupied port.

- In the **Scope** section, specify administration groups to which the distribution point will distribute updates.
- In the **Source of updates** section, you can select a source of updates for the distribution point:

  - **Source of updates**

    Select an update source for the distribution point:

    - To allow the distribution point to receive updates from the Administration Server, select **Retrieve from Administration Server**.
    - To allow the distribution point to receive updates by using a task, select **Use update download task**, and then specify a *Download updates to the repositories of distribution points* task:
      - If such a task already exists on the device, select the task in the list.
      - If no such task yet exists on the device, click the **Create task** link to create a task. The New task wizard starts. Follow the steps of the wizard.

  - **Download diff files**

    This option enables the downloading diff files feature.

    By default, the option is enabled.

- If your distribution points use proxy server when connecting to the internet, in the **Internet connection settings** subsection, you can specify the following settings:

  - **Use proxy server**

    If this check box is selected, an internet proxy server is used to connect distribution points to Kaspersky update servers. In the entry fields you can configure the proxy server connection.

    This check box is cleared by default.

  - **Proxy server address**

    Address of the proxy server.

  - **Port number**

    Port number that is used for connection.

  - **Bypass proxy server for local addresses**

    If this option is enabled, no proxy server is used to connect to devices on the local network.

    By default, this option is disabled.

  - **Proxy server authentication**

    If this check box is selected, in the entry fields you can specify the credentials for proxy server authentication.

    This check box is cleared by default.

- **User name**

  User account under which connection to the proxy server is established.

- **Password**

  Password of the account under which the task will be run.

- In the **KSN Proxy** section, you can configure the application to use the distribution point to forward KSN requests from the managed devices:

  - **Enable KSN Proxy on the distribution point side**

    The KSN proxy service is run on the device that is used as a distribution point. Use this feature to redistribute and optimize traffic on the network.

    The distribution point sends the KSN statistics, which are listed in the Kaspersky Security Network statement, to Kaspersky.

    By default, this option is disabled. Enabling this option takes effect only if the **Use Administration Server as a proxy server** and **I agree to use Kaspersky Security Network** options are enabled in the Administration Server properties window.

    You can assign a node of an active-passive cluster to a distribution point and enable KSN proxy server on this node.

  - **Forward KSN requests to Administration Server**

    The distribution point forwards KSN requests from the managed devices to the Administration Server.

    By default, the option is enabled.

  - **Access KSN Cloud/KPSN directly over the internet**

    The distribution point forwards KSN requests from managed devices to the KSN Cloud or KPSN. The KSN requests generated on the distribution point itself are also sent directly to the KSN Cloud or KPSN.

  - **Ignore proxy server settings when connecting to KPSN**

    Enable this option, if you have the proxy server settings configured in the distribution point properties or in the Network Agent policy, but your network architecture requires that you use KPSN directly. Otherwise, requests from the managed applications cannot reach KPSN.

    This option is available if you select the **Access KSN Cloud/KPSN directly over the internet** option.

  - **Port**

    The number of the TCP port that the managed devices will use to connect to KSN proxy server. The default port number is 13111.

  - **Use UDP port**

    If you need the managed devices to connect to KSN proxy server through a UDP port, enable the **Use UDP port** option and specify a UDP port number. By default, the option is enabled.

  - **UDP port**

    The number of the UDP port that the managed devices will use to connect to KSN proxy server. The default UDP port to connect to the KSN proxy server is 15111.

- **Use HTTPS**

  If you need the managed devices to connect to KSN proxy server through an HTTPS port, enable the **Use HTTPS** option and specify an **HTTPS through port** number. The default HTTPS port to connect to the KSN proxy server is 17111.

- **HTTPS port**

  The number of the HTTPS port that the managed devices will use to connect to KSN proxy server. The default HTTPS port to connect to the KSN proxy server is 17111.

- In the **Connection gateway** section, you can configure the distribution point to act as a gateway for connection between Network Agent instances and Administration Server:

  - **Connection gateway**

    If a direct connection between Administration Server and Network Agents cannot be established due to organization of your network, you can use the distribution point to act as the connection gateway between Administration Server and Network Agents.

    Enable this option if you need the distribution point to act as a connection gateway between Network Agents and Administration Server. By default, this option is disabled.

  - **Establish connection to gateway from Administration Server (if gateway is in DMZ)**

    If Administration Server is located outside the demilitarized zone (DMZ), on local area network, Network Agents installed on remote devices cannot connect to Administration Server. You can use a distribution point as the connection gateway with reverse connectivity (Administration Server establishes a connection to distribution point).

    Enable this option if you need to connect Administration Server to the connection gateway in DMZ.

  - **Open local port for Kaspersky Security Center Web Console**

    Enable this option if you need the connection gateway in DMZ to open a port for Web Console that is in DMZ or on the internet. Specify the port number that will be used for the connection from Web Console to the distribution point. The default port number is 13299.

    This option is available if you enable the **Establish connection to gateway from Administration Server (if gateway is in DMZ)** option.

  When connecting mobile devices to Administration Server via the distribution point that acts as a connection gateway, you can enable the following options:

  - **Open port for mobile devices (SSL authentication of the Administration Server only)**

    Enable this option if you need the connection gateway to open a port for mobile devices and specify the port number that mobile devices will use for connection to distribution point. The default port number is 13292. The mobile device will check the Administration Server certificate. When establishing the connection, only Administration Server is authenticated.

- **Open port for mobile devices (two-way SSL authentication)**

  Enable this option if you need connection gateway to open a port that will be used for two-way authentication of Administration Server and mobile devices. Mobile device will check the Administration Server certificate, and Administration Server will check the mobile device certificate. Specify the following settings:

  - Port number that mobile devices will use for connection to the distribution point. The default port number is 13293.

  - DNS domain names of the connection gateway that will be used by mobile devices. Separate domain names with commas. The specified domain names will be included in the distribution point certificate. If the domain names used by mobile devices do not match the common name in the distribution point certificate, mobile devices do not connect to the distribution point.

    The default DNS domain name is the FQDN name of the connection gateway.

In both cases, the certificates are checked during the TLS session establishment on distribution point only. The certificates are not forwarded to be checked by the Administration Server. After a TLS session with the mobile device is established, the distribution point uses the Administration Server certificate to create a tunnel for synchronization between the mobile device and Administration Server. If you open the port for two-way SSL authentication, the only way to distribute the mobile device certificate is via an installation package.

- Configure Windows network polling by the Windows-based distribution point.

  - **Windows domains**

    You can enable device discovery for Windows domains and set the schedule for the discovery.

- Configure domain controller polling by the distribution point.

  - **Domain controller polling**

    You can enable device discovery for domain controllers.

    In the **Polling** field, after you switch the toggle button to the **Enabled** position, you can select domain controllers for polling and also specify the polling schedule for them.

    If you use a Linux distribution point, in the **Poll specified domains** section, click **Add**, and then specify the address and user credentials of the domain controller. Also, you can specify the type of domain to be polled: Active Directory or Samba, FreeIPA, ALD Pro.

    If you use a Windows distribution point, you can select one of the following options:

    - **Poll current domain**

    - **Poll entire domain forest**

    - **Poll specified domains**

- Configure the polling of IP ranges by the distribution point.

  - **IP ranges polling**

    You can enable device discovery for IPv4 ranges and IPv6 networks.

    If you enable the **Enable range polling** option, you can add scanned ranges and set the schedule for them. You can add IP ranges to the list of scanned ranges.

If you enable the **Use Zeroconf to poll IPv6 networks** option, the distribution point automatically polls the IPv6 network by using zero-configuration networking (also referred to as *Zeroconf*). In this case, the specified IP ranges are ignored because the distribution point polls the whole network. The **Use Zeroconf to poll IPv6 networks** option is available if the distribution point runs Linux. To use Zeroconf IPv6 polling, you must install the avahi-browse utility on the distribution point.

- In the **Advanced** section, specify the folder that the distribution point must use to store distributed data.
  - **Use default folder**

    If you select this option, the application uses the Network Agent installation folder on the distribution point.

  - **Use specified folder**

    If you select this option, in the field below, you can specify the path to the folder. It can be a local folder on the distribution point, or it can be a folder on any device on the corporate network.

    The user account used on the distribution point to run Network Agent must have read/write access to the specified folder.

10. Click **OK**.

The selected devices act as distribution points.

Modifying the list of distribution points for an administration group

You can view the list of distribution points assigned to a specific administration group and modify the list by adding or removing distribution points.

To view and modify the list of distribution points assigned to an administration group:

1. In the main menu, go to **Asset management → Assets (Devices)**.
2. Select an administration group for which you want to view the assigned distribution points by clicking the **Show hierarchy** button at the top of the page, and then in the window that opens, click the name of the required group.

   This enables the **Distribution points** menu item.

   The path to the selected group is displayed at the top of the page. If necessary, in this path you can click a link with the administration group name to go to the group. By default, the last link in the path is inactive.
3. In the main menu, go to **Asset management → Distribution points**.
4. To add new distribution points for the administration group, click the **Assign** button.
5. To remove the assigned distribution points, select devices from the list and click the **Unassign** button.

Depending on your modifications, the new distribution points are added to the list or existing distribution points are removed from the list.

Enabling a push server

In Open Single Management Platform, a distribution point can work as a push server for the devices managed through the mobile protocol and for the devices managed by Network Agent. For example, a push server must be enabled if you want to be able to force synchronization of KasperskyOS devices with Administration Server. A push server has the same scope of managed devices as the distribution point on which the push server is enabled. If you have several distribution points assigned for the same administration group, you can enable push server on each of the distribution points. In this case, Administration Server balances the load between the distribution points.

You might want to use distribution points as push servers to make sure that there is continuous connectivity between a managed device and the Administration Server. Continuous connectivity is needed for some operations, such as running and stopping local tasks, receiving statistics for a managed application, or creating a tunnel. If you use a distribution point as a push server, you do not have to use the **Do not disconnect from the Administration Serve**r option on managed devices or send packets to the UDP port of the Network Agent.

A push server supports the load of up to 50,000 simultaneous connections.

To enable push server on a distribution point:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Distribution points** section.

3. Click the name of the distribution point on which you want to enable the push server.

   The distribution point properties window opens.

4. On the **General** section, enable the **Enabled** option.

5. In the **Push server port** field, type the port number. You can specify number of any unoccupied port.

6. In the **Address for remote hosts** field, specify the IP address or the name of the distribution point device.

7. Click **OK**.

The push server is enabled on the selected distribution point.

About device statuses

Kaspersky EDR Expert assigns a status to each managed device. The particular status depends on whether the conditions defined by the user are met. In some cases, when assigning a status to a device, Kaspersky EDR Expert takes into consideration the device's visibility flag on the network (see the table below). If Kaspersky EDR Expert does not find a device on the network within two hours, the visibility flag of the device is set to *Not Visible*.

The statuses are the following:

- *Critical* or *Critical/Visible*
- *Warning* or *Warning/Visible*
- *OK* or *OK/Visible*

The table below lists the default conditions that must be met to assign the *Critical* or *Warning* status to a device, with all possible values.

Conditions for assigning a status to a device

Condition	Condition description	Available values
Security application is not installed	Network Agent is installed on the device, but a security application is not installed.	• Toggle button is on. • Toggle button is off.
Too many viruses detected	Some viruses have been found on the device by a task for virus detection, for example, the Malware scan task, and the number of viruses found exceeds the specified value.	More than 0.
Real-time protection level differs from the level set by the Administrator	The device is visible on the network, but the real-time protection level differs from the level set (in the condition) by the administrator for the device status.	• Stopped. • Suspended. • Running.
Malware scan has not been performed in a long time	The device is visible on the network and a security application is installed on the device, but neither the *Malware scan* task nor a local scan task has been run within the specified time interval. The condition is applicable only to devices that were added to the Administration Server database 7 days ago or earlier.	More than 1 day.
Databases are outdated	The device is visible on the network and a security application is installed on the device, but the anti-virus databases have not been updated on this device within the specified time interval. The condition is applicable only to devices that were added to the Administration Server database 1 day ago or earlier.	More than 1 day.
Not connected in a long time	Network Agent is installed on the device, but the device has not connected to an Administration Server within the specified time interval, because the device was turned off.	More than 1 day.
Active threats are detected	The number of unprocessed objects in the **Active threats** folder exceeds the specified value.	More than 0 items.
Time since restart required	The device is visible on the network, but a restart has been required by an application for longer than the specified time interval.	More than 0 minutes.
Restart reason	The device is visible on the network, but an application requires a device restart for one of the selected reasons.	• Unknown reason • Application will not run until restart • Restart is required to complete update; application is running • Restart is required to launch update • Restart is required to complete scan or disinfection • Restart is required to complete remote installation/uninstallation • Completing data encryption on disk
Incompatible applications are installed	The device is visible on the network, but software inventory performed through Network Agent has detected incompatible applications installed on the device.	• Toggle button is off. • Toggle button is on.
Software vulnerabilities have been detected	The device is visible on the network and Network Agent is installed on the device, but the *Find vulnerabilities and required updates* task has detected vulnerabilities with the specified severity level in applications installed on the device.	• Critical • High. • Medium. • Ignore if the vulnerability cannot be fixed. • Ignore if an update is assigned for installation.
License expired	The device is visible on the network, but the license has expired.	• Toggle button is off. • Toggle button is on.

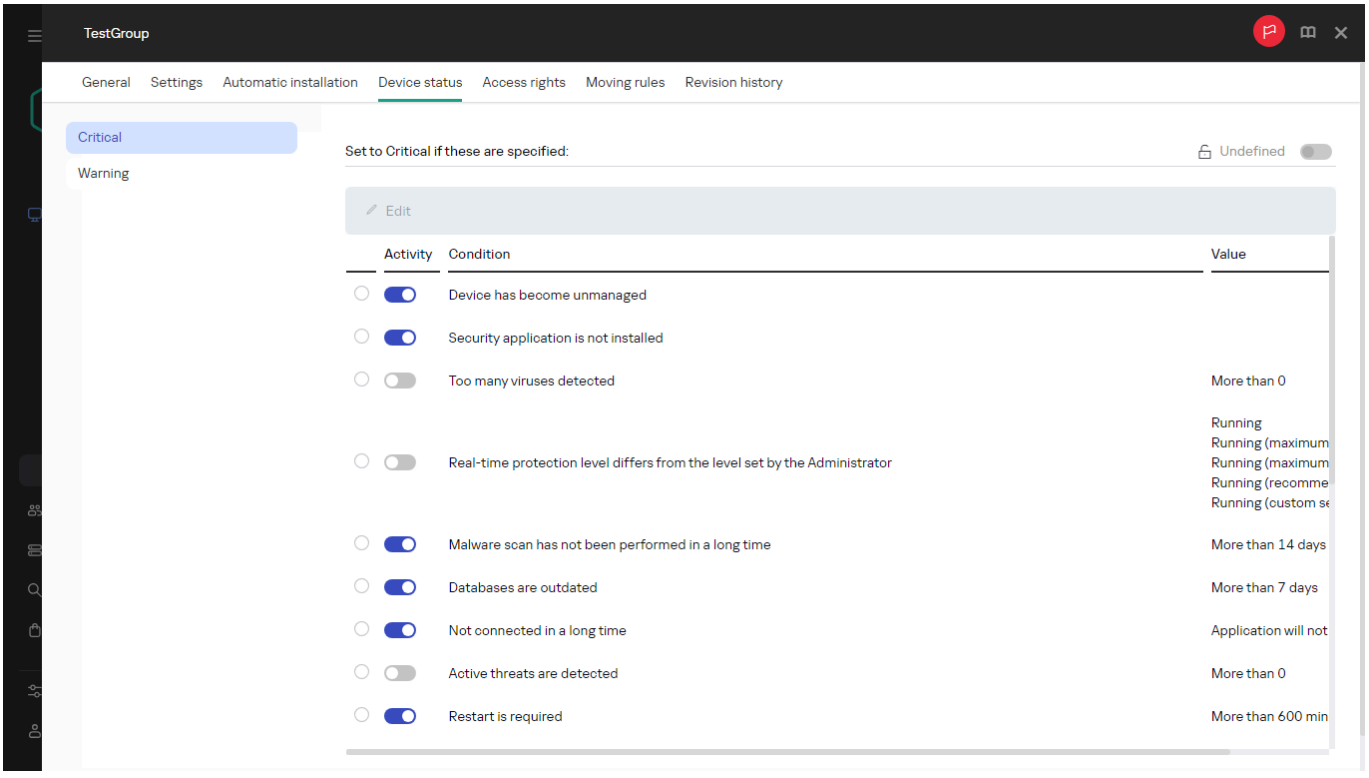
Condition	Condition description	Available values
License expires soon	The device is visible on the network, but the license will expire on the device in less than the specified number of days.	Less than 0 days.
Check for Windows Update updates has not been performed in a long time	The device is visible on the network, but the *Find vulnerabilities and required updates* task has not been run within the specified time interval.	More than 1 day.
Invalid encryption status	Network Agent is installed on the device, but the device encryption result is equal to the specified value.	• Does not comply with the policy due to the user's refusal (for external devices only). • Does not comply with the policy due to an error. • Restart is required when applying the policy. • No encryption policy is specified. • Not supported. • When applying the policy.
Mobile device settings do not comply with the policy	The mobile device settings are other than the settings that were specified in the Kaspersky Endpoint Security for Android policy during the check of compliance rules.	• Toggle button is off. • Toggle button is on.
Unprocessed security issues detected	Some unprocessed security issues have been found on the device. Security issues can be created either automatically, through managed Kaspersky applications installed on the client device, or manually by the administrator.	• Toggle button is off. • Toggle button is on.
Device status defined by application	The status of the device is defined by the managed application.	• Toggle button is off. • Toggle button is on.
Device is out of disk space	Free disk space on the device is less than the specified value, or the device could not be synchronized with the Administration Server. The *Critical* or *Warning* status is changed to the *OK* status when the device is successfully synchronized with the Administration Server and free space on the device is greater than or equal to the specified value.	More than 0 MB.
Device has become unmanaged	During device discovery, the device was recognized as visible on the network, but more than three attempts to synchronize with the Administration Server failed.	• Toggle button is off. • Toggle button is on.
Protection is disabled	The device is visible on the network, but the security application on the device has been disabled for longer than the specified time interval. In this case, the state of the security application is *stopped* or *failure*, and differs from the following: *starting*, *running*, or *suspended*.	More than 0 minutes.
Security application is not running	The device is visible on the network and a security application is installed on the device but is not running.	• Toggle button is off. • Toggle button is on.

Kaspersky EDR Expert allows you to set up automatic switching of the status of a device in an administration group when specified conditions are met. When the specified conditions are met, the client device is assigned one of the following statuses: *Critical* or *Warning*. When the specified conditions are not met, the client device is assigned the *OK* status.

Different statuses may correspond to different values of one condition. For example, by default, if the **Databases are outdated** condition has the **More than 3 days** value, the client device is assigned the *Warning* status; if the value is **More than 7 days**, the *Critical* status is assigned.

When Kaspersky EDR Expert assigns a status to a device, for some conditions (see the Condition description column in the table above) the visibility flag is taken into consideration. For example, if a managed device was assigned the *Critical* status because the Databases are outdated condition was met, and later the visibility flag was set for the device, then the device is assigned the *OK* status.

Configuring the switching of device statuses



You can change conditions to assign the *Critical* or *Warning* status to a device.

To enable changing the device status to Critical:

1. In the main menu, go to **Asset management** → **Hierarchy of groups**.
2. Go to the properties of the administration group for which you want to change the device statuses in one of the following ways:

   - Click the name of the administration group.
   - Click the **Show hierarchy** button at the top of the page. In the navigation pane that opens, hover the mouse cursor over the name of the required group, and then click the settings icon (⚙).

   The administration group properties window opens.
3. In the properties window, select the **Device status** tab.
4. In the left pane, select **Critical**.
5. In the right pane, in the **Set to Critical if the following settings are specified** section, enable the condition to switch a device to the *Critical* status.

> You can change only settings that are not locked in the parent policy.

6. Select the radio button next to the condition in the list.
7. In the upper-left corner of the list, click the **Edit** button.

8. Set the required value for the selected condition.

   Values cannot be set for every condition.

9. Click **OK**.

10. Click **Save** to save changes.

When specified conditions are met, the managed device is assigned the *Critical* status.

To enable changing the device status to Warning:

1. In the main menu, go to **Asset management** → **Hierarchy of groups**.

2. In the list of groups that opens, click the link with the name of a group for which you want to change switching the device statuses.

3. In the properties window that opens, select the **Device status** tab.

4. In the left pane, select **Warning**.

5. In the right pane, in the **Set to Warning if the following settings are specified** section, enable the condition to switch a device to the *Warning* status.

   > You can change only settings that are not locked in the parent policy.

6. Select the radio button next to the condition in the list.

7. In the upper-left corner of the list, click the **Edit** button.

8. Set the required value for the selected condition.

   Values cannot be set for every condition.

9. Click **OK**.

10. Click **Save** to save changes.

When specified conditions are met, the managed device is assigned the *Warning* status.

Device selections

Device selections are a tool for filtering devices according to specific conditions. You can use device selections to manage several devices: for example, to view a report about only these devices or to move all of these devices to another group.

Open Single Management Platform provides a broad range of *predefined selections* (for example, **Devices with Critical status**, **Protection is disabled**, **Active threats are detected**). Predefined selections cannot be deleted. You can also create and configure additional *user-defined selections*.

In user-defined selections, you can set the search scope and select all devices, managed devices, or unassigned devices. Search parameters are specified in the conditions. In the device selection you can create several conditions with different search parameters. For example, you can create two conditions and specify different IP ranges in each of them. If several conditions are specified, a selection displays the devices that meet any of the conditions. By contrast, search parameters within a condition are superimposed. If both an IP range and the name of an installed application are specified in a condition, only those devices will be displayed where both the application is installed and the IP address belongs to the specified range.

Viewing the device list from a device selection

Open Single Management Platform allows you to view the list of devices from a device selection.

To view the device list from the device selection:

1. In the main menu, go to the **Asset management** → **Device selections** or **Discovery & deployment** → **Device selections** section.
2. In the selection list, click the name of the device selection.

   The page displays a table with information about the devices included in the device selection.
3. You can group and filter the data of the device table as follows:

   - Click the settings icon (⚙), and then select the columns to be displayed in the table.
   - Click the filter icon (▽), and then specify and apply the filter criterion in the invoked menu.

     The filtered table of devices is displayed.

You can also run tasks for device selections. To do this, select one or more devices, then click the **Run task** button and select: **Create task** to be applied to these devices, or Apply existing task.

To move the selected devices of the device selection to another administration group, click the **Move to group** button, and then select the target administration group.

Creating a device selection

To create a device selection:

1. In the main menu, go to **Asset management** → **Device selections**.

   A page with a list of device selections is displayed.
2. Click the **Add** button.

   The **Device selection settings** window opens.
3. Enter the name of the new selection.

4. Specify the group that contains the devices to be included in the device selection:

   - **Find any devices**—Searching for devices that meet the selection criteria and included in the **Managed Devices** or **Unassigned devices** group.
   - **Find managed devices**—Searching for devices that meet the selection criteria and included in the **Managed Devices** group.
   - **Find unassigned devices**—Searching for devices that meet the selection criteria and included in the **Unassigned devices** group.

   You can enable the **Include data from secondary Administration Servers** check box to enable searching for devices that meet the selection criteria and managed by secondary Administration Servers.

5. Click the **Add** button.
6. In the window that opens, specify conditions that must be met for including devices in this selection, and then click the **Save** button.
7. Click the **Save** button.

The device selection is created and added to the list of device selections.

Configuring a device selection

To configure a device selection:

1. In the main menu, go to **Asset management** → **Device selections**.

   A page with a list of device selections is displayed.

2. Select the relevant user-defined device selection, and click the **Properties** button.

   The **Device selection settings** window opens.

3. On the **General** tab, click the **New condition** link.
4. Specify conditions that must be met for including devices in this selection.
5. Click the **Save** button.

The settings are applied and saved.

Below are descriptions of the conditions for assigning devices to a selection. Conditions are combined by using the OR logical operator: the selection will contain devices that comply with at least one of the listed conditions.

General

In the **General** section, you can change the name of the selection condition and specify whether that condition must be inverted:

Invert selection condition

By default, this option is disabled.

If you enable this option, the specified selection condition will be inverted. The selection will include all devices that do not meet the condition.

The following example shows the logic of the inversion work:

- **Condition**: On your device, there is an operating system with the Linux type and the 00.0.000 build number.
- **Inverted condition**: On your device, there is an operating system with NOT (the Linux type and the 00.0.000 build number), which is equivalent to the following:

  There is an operating system with the type NOT Linux OR build number NOT 00.0.000.

Thus, the selection will include the devices with an operating system, for example, of the Windows type and the 00.0.000 build number, or the Linux type and any build number other than 00.0.000.

Network infrastructure

In the **Network** subsection, you can specify the criteria that will be used to include devices in the selection according to their network data:

Device name

Windows network name (NetBIOS name) of the device, or the IPv4 or IPv6 address.

Domain

Displays all devices included in the specified workgroup.

Administration group

Displays devices included in the specified administration group.

Description

Text in the device properties window: in the **Description** field of the **General** section.

To describe text in the **Description** field, you can use the following characters:

- Within a word:
  - *****. Replaces any string with any number of characters.

    Example:

    To describe words such as **Server** or **Server's**, you can enter **Server***.
  - **?.** Replaces any single character.

    Example:

    To describe phrases such as **SUSE Linux Enterprise Server 12** or **SUSE Linux Enterprise Server 15**, you can enter **SUSE Linux Enterprise Server 1?**.

    Asterisk (*****) or question mark (**?**) cannot be used as the first character in the query.

- To find several words:
  - Space. Displays all the devices whose descriptions contain any of the listed words.

  Example:

  To find a phrase that contains **Secondary** or **Virtual** words, you can include **Secondary Virtual** line in your query.

  - **+**. When a plus sign precedes a word, all search results will contain this word.

  Example:

  To find a phrase that contains both **Secondary** and **Virtual**, enter the **+Secondary+Virtual** query.

  - **-**. When a minus sign precedes a word, no search results will contain this word.

  Example:

  To find a phrase that contains **Secondary** and does not contain **Virtual**, enter the **+Secondary-Virtual** query.

  - **"<some text>"**. Text enclosed in quotation marks must be present in the text.

  Example:

  To find a phrase that contains **Secondary Server** word combination, you can enter **"Secondary Server"** in the query.

IP range

If this option is enabled, you can enter the initial and final IP addresses of the IP range in which the relevant devices must be included.

By default, this option is disabled.

Managed by a different Administration Server

Select one of the following values:

- **Yes**. A device moving rule only applies to client devices managed by other Administration Servers. These Servers are different from the Server on which you configure the device moving rule.
- **No**. The device moving rule only applies to client devices managed by the current Administration Server.
- **No value is selected**. The condition does not apply.

In the **Domain controller** subsection, you can configure criteria for including devices into a selection based on domain membership:

Device is in a domain organizational unit

If this option is enabled, the selection includes devices from the domain organizational unit specified in the entry field.

By default, this option is disabled.

This device is a member of the domain security group

If this option is enabled, the selection includes devices from the domain security group specified in the entry field.

By default, this option is disabled.

In the **Network activity** subsection, you can specify the criteria that will be used to include devices in the selection according to their network activity:

Acts as a distribution point

In the drop-down list, you can set up the criterion for including devices in the selection when performing search:

- **Yes**. The selection includes devices that act as distribution points.
- **No**. Devices that act as distribution points are not included in the selection.
- **No value is selected**. The criterion will not be applied.

Do not disconnect from the Administration Server

In the drop-down list, you can set up the criterion for including devices in the selection when performing search:

- **Enabled**. The selection will include devices on which the **Do not disconnect from the Administration Server** check box is selected.
- **Disabled**. The selection will include devices on which the **Do not disconnect from the Administration Server** check box is cleared.
- **No value is selected**. The criterion will not be applied.

Connection profile switched

In the drop-down list, you can set up the criterion for including devices in the selection when performing search:

- **Yes**. The selection will include devices that connected to the Administration Server after the connection profile was switched.
- **No**. The selection will not include devices that connected to the Administration Server after the connection profile was switched.
- **No value is selected**. The criterion will not be applied.

Last connected to Administration Server

You can use this check box to set a search criterion for devices according to the time they last connected to the Administration Server.

If this check box is selected, in the entry fields you can specify the time interval (date and time) during which the last connection was established between Network Agent installed on the client device and the Administration Server. The selection will include devices that fall within the specified interval.

If this check box is cleared, the criterion will not be applied.

This check box is cleared by default.

New devices detected by network poll

Searches for new devices that have been detected by network polling over the last few days.

If this option is enabled, the selection only includes new devices that have been detected by device discovery over the number of days specified in the **Detection period (days)** field.

If this option is disabled, the selection includes all devices that have been detected by device discovery.

By default, this option is disabled.

Device is visible

In the drop-down list, you can set up the criterion for including devices in the selection when performing search:

- **Yes**. The application includes in the selection devices that are currently visible in the network.
- **No**. The application includes in the selection devices that are currently invisible in the network.
- **No value is selected**. The criterion will not be applied.

Device statuses

In the **Managed device status** subsection, you can configure criteria for including devices into a selection based on the description of the devices status from a managed application:

Device status

Drop-down list in which you can select one of the device statuses: *OK*, *Critical*, or *Warning*.

Real-time protection status

Drop-down list, in which you can select the real-time protection status. Devices with the specified real-time protection status are included in the selection.

Device status description

In this field, you can select the check boxes next to conditions that, if met, assign one of the following statuses to the device: *OK, Critical*, or *Warning*.

In the **Status of components in managed applications** subsection, you can configure criteria for including devices in a selection according to the statuses of components in managed applications:

Data Leakage Prevention status

Search for devices by the status of Data Leakage Prevention (*No data from device, Stopped, Starting, Paused, Running, Failed*).

Collaboration servers protection status

Search for devices by the status of server collaboration protection (*No data from device*, *Stopped*, *Starting*, *Paused*, *Running*, *Failed*).

Anti-virus protection status of mail servers

Search for devices by the status of Mail Server protection (*No data from device, Stopped, Starting, Paused, Running, Failed*).

Endpoint Sensor status

Search for devices by the status of the Endpoint Sensor component (*No data from device, Stopped, Starting, Paused, Running, Failed*).

In the **Status-affecting problems in managed applications** subsection, you can specify the criteria that will be used to include devices in the selection according to the list of possible problems detected by a managed application. If at least one problem that you select exists on a device, the device will be included in the selection. When you select a problem listed for several applications, you have the option to select this problem in all of the lists automatically.

You can select check boxes for descriptions of statuses from the managed application; upon receipt of these statuses, the devices will be included in the selection. When you select a status listed for several applications, you have the option to select this status in all of the lists automatically.

System details

In the **OS** section, you can specify the criteria that will be used to include devices in the selection according to their operating system type.

Platform type

If the check box is selected, you can select an operating system from the list. Devices with the specified operating systems installed are included in the search results.

OS service pack version

In this field, you can specify the package version of the operating system (in the *X.Y* format), which will determine how the moving rule is applied to the device. By default, no version value is specified.

OS architecture

In the drop-down list, you can select the architecture for the operating system, which will determine how the moving rule is applied to the device (**Unknown**, **x86**, **AMD64**, or **IA64**). By default, no option is selected in the list so that the operating system's architecture is not defined.

OS build

> This setting is applicable to Windows operating systems only.

The build number of the operating system. You can specify whether the selected operating system must have an equal, earlier, or later release number. You can also configure searching for all build numbers except the specified one.

OS release number

> This setting is applicable to Windows operating systems only.

The release identifier (ID) of the operating system. You can specify whether the selected operating system must have an equal, earlier, or later release ID. You can also configure searching for all release ID numbers except the specified one.

In the **Virtual machines** section, you can set up the criteria to include devices in the selection according to whether these are virtual machines or part of virtual desktop infrastructure (VDI):

This is a virtual machine

In the drop-down list, you can select the following options:

- **Undefined**.
- **No**. Find devices that are not virtual machines.
- **Yes**. Find devices that are virtual machines.

Virtual machine type

In the drop-down list, you can select the virtual machine manufacturer.

This drop-down list is available if the **Yes** or **Not important** value is selected in the **This is a virtual machine** drop-down list.

Part of Virtual Desktop Infrastructure

In the drop-down list, you can select the following options:

- **Undefined**.
- **No**. Find devices that are not part of Virtual Desktop Infrastructure.
- **Yes**. Find devices that are part of the Virtual Desktop Infrastructure (VDI).

In the **Hardware registry** subsection, you can configure criteria for including devices into a selection based on their installed hardware:

Ensure that the lshw utility is installed on Linux devices from which you want to fetch hardware details. Hardware details fetched from virtual machines may be incomplete depending on the hypervisor used.

Device

In the drop-down list, you can select a unit type. All devices with this unit are included in the search results.

The field supports the full-text search.

Vendor

In the drop-down list, you can select the name of a unit manufacturer. All devices with this unit are included in the search results.

The field supports the full-text search.

Device name

The device with the specified name is included in the selection.

Description

Description of the device or hardware unit. Devices with the description specified in this field are included in the selection.

A device's description in any format can be entered in the properties window of that device. The field supports the full-text search.

Device vendor

Name of the device manufacturer. Devices produced by the manufacturer specified in this field are included in the selection.

You can enter the manufacturer's name in the properties window of a device.

Serial number

All hardware units with the serial number specified in this field will be included in the selection.

Inventory number

Equipment with the inventory number specified in this field will be included in the selection.

User

All hardware units of the user specified in this field will be included in the selection.

Location

Location of the device or hardware unit (for example, at the HQ or a branch office). Computers or other devices that are deployed at the location specified in this field will be included in the selection.

You can describe the location of a device in any format in the properties window of that device.

CPU clock rate, in MHz, from

The minimum clock rate of a CPU. Devices with a CPU that matches the clock rate range specified in the entry fields (inclusive) will be included in the selection.

CPU clock rate, in MHz, to

The maximum clock rate of a CPU. Devices with a CPU that matches the clock rate range specified in the entry fields (inclusive) will be included in the selection.

Number of virtual CPU cores, from

The minimum number of virtual CPU cores. Devices with a CPU that matches the range of the virtual cores number specified in the entry fields (inclusive) will be included in the selection.

Number of virtual CPU cores, to

The maximum number of virtual CPU cores. Devices with a CPU that matches the range of the virtual cores number specified in the entry fields (inclusive) will be included in the selection.

Hard drive volume, in GB, from

The minimum volume of the hard drive on the device. Devices with a hard drive that matches the volume range specified in the entry fields (inclusive) will be included in the selection.

Hard drive volume, in GB, to

The maximum volume of the hard drive on the device. Devices with a hard drive that matches the volume range specified in the entry fields (inclusive) will be included in the selection.

RAM size, in MB, from

The minimum size of the device RAM. Devices with RAM that matches the range of values in the entry fields (inclusive) are included in the selection.

RAM size, in MB, to

The maximum size of the device RAM. Devices with RAM that matches the size range specified in the entry fields (inclusive) will be included in the selection.

Third-party software details

In the **Applications registry** subsection, you can set up the criteria to search for devices according to applications installed on them:

Application name

Drop-down list in which you can select an application. Devices on which the specified application is installed, are included in the selection.

Application version

Entry field in which you can specify the version of selected application.

Vendor

Drop-down list in which you can select the manufacturer of an application installed on the device.

Application status

A drop-down list in which you can select the status of an application (*Installed*, *Not installed*). Devices on which the specified application is installed or not installed, depending on the selected status, will be included in the selection.

Find by update

If this option is enabled, search will be performed using the details of updates for applications installed on the relevant devices. After you select the check box, the **Application name**, **Application version**, and **Application status** fields change to **Update name**, **Update version**, and **Status** respectively.

By default, this option is disabled.

Name of incompatible security application

Drop-down list in which you can select third-party security applications. During the search, devices on which the specified application is installed, are included in the selection.

Application tag

In the drop-down list, you can select the application tag. All devices that have installed applications with the selected tag in the description are included in the device selection.

Apply to devices without the specified tags

If this option is enabled, the selection includes devices with descriptions that contain none of the selected tags.

If this option is disabled, the criterion is not applied.

By default, this option is disabled.

In the **Vulnerabilities and updates** subsection, you can specify the criteria that will be used to include devices in the selection according to their Windows Update source:

WUA is switched to Administration Server

You can select one of the following search options from the drop-down list:

- **Yes**. If this option is selected, the search results will include devices that receive updates through Windows Update from the Administration Server.
- **No**. If this option is selected, the results will include devices that receive updates through Windows Update from another sources.

Details of Kaspersky applications

In the **Kaspersky applications** subsection, you can configure criteria for including devices in a selection based on the selected managed application:

Application name

In the drop-down list, you can set a criterion for including devices in a selection when search is performed by the name of a Kaspersky application.

The list provides only the names of applications with management plug-ins installed on the administrator's workstation.

If no application is selected, the criterion will not be applied.

Application version

In the entry field, you can set a criterion for including devices in a selection when search is performed by the version number of a Kaspersky application.

If no version number is specified, the criterion will not be applied.

Critical update name

In the entry field, you can set a criterion for including devices in a selection when search is performed by application name or by update package number.

If the field is left blank, the criterion will not be applied.

Application status

A drop-down list in which you can select the status of an application (*Installed*, *Not installed*). Devices on which the specified application is installed or not installed, depending on the selected status, will be included in the selection.

Select the period of the last update of modules

You can use this option to set a criterion for searching devices by time of the last update of modules of applications installed on those devices.

If this check box is selected, in the entry fields you can specify the time interval (date and time) during which the last update of modules of applications installed on those devices was performed.

If this check box is cleared, the criterion will not be applied.

This check box is cleared by default.

Device is managed through Administration Server

In the drop-down list, you can include in the selection the devices managed through Kaspersky EDR Expert:

- **Yes**. The application includes in the selection devices managed through Kaspersky EDR Expert.
- **No**. The application includes devices in the selection if they are not managed through Kaspersky EDR Expert.
- **No value is selected**. The criterion will not be applied.

Security application is installed

In the drop-down list, you can include in the selection all devices with the security application installed:

- **Yes**. The application includes in the selection all devices with the security application installed.
- **No**. The application includes in the selection all devices with no security application installed.
- **No value is selected**. The criterion will not be applied.

In the **Anti-virus protection** subsection, you can set up the criteria for including devices in a selection based on their protection status:

Databases released

If this option is selected, you can search for client devices by anti-virus database release date. In the entry fields you can set the time interval, on the basis of which the search is performed.

By default, this option is disabled.

Database records count

If this option is enabled, you can search for client devices by number of database records. In the entry fields you can set the lower and upper threshold values for anti-virus database records.

By default, this option is disabled.

Last scanned

If this check option is enabled, you can search for client devices by time of the last malware scan. In the entry fields you can specify the time period within which the last malware scan was performed.

By default, this option is disabled.

Threats detected

If this option is enabled, you can search for client devices by number of viruses detected. In the entry fields you can set the lower and upper threshold values for the number of viruses found.

By default, this option is disabled.

In the **Encryption** subsection, you can configure the criterion for including devices in a selection based on the selected encryption algorithm:

Encryption algorithm

Advanced Encryption Standard (AES) symmetrical block cipher algorithm. In the drop-down list, you can select the encryption key size (56-bit, 128-bit, 192-bit, or 256-bit).

Available values: *AES56*, *AES128*, *AES192*, and *AES256*.

The **Application components** subsection contains the list of components of those applications that have corresponding management plug-ins installed in OSMP Console.

In the **Application components** subsection, you can specify criteria for including devices in a selection according to the statuses and version numbers of the components that refer to the application that you select:

Status

Search for devices according to the component status sent by an application to the Administration Server. You can select one of the following statuses: *N/A, Stopped*, *Paused*, *Starting*, *Running*, *Failed, Not installed, Not supported by license*. If the selected component of the application installed on a managed device has the specified status, the device is included in the device selection.

Statuses sent by applications:

- *Stopped*—The component is disabled and not working at the moment.
- *Paused*—The component is suspended, for example, after the user has paused protection in the managed application.
- *Starting*—The component is currently in the process of initialization.
- *Running*—The component is enabled and working properly.
- *Failed*—An error has occurred during the component operation.
- *Not installed*—The user did not select the component for installation when configuring custom installation of the application.
- *Not supported by license*—The license does not cover the selected component.

Unlike other statuses, the *N/A* status is not sent by applications. This option shows that the applications have no information about the selected component status. For example, this can happen when the selected component does not belong to any of the applications installed on the device, or when the device is turned off.

Version

Search for devices according to the version number of the component that you select in the list. You can type a version number, for example `3.4.1.0`, and then specify whether the selected component must have an equal, earlier, or later version. You can also configure searching for all versions except the specified one.

Tags

In the **Tags** section, you can configure criteria for including devices into a selection based on key words (tags) that were previously added to the descriptions of managed devices:

Apply if at least one specified tag matches

If this option is enabled, the search results will show devices with descriptions that contain at least one of the selected tags.

If this option is disabled, the search results will only show devices with descriptions that contain all the selected tags.

By default, this option is disabled.

To add tags to the criterion, click the **Add** button, and select tags by clicking the **Tag** entry field. Specify whether to include or exclude the devices with the selected tags in the device selection.

All devices that have this tag

If this option is selected, the search results will display the devices whose descriptions contain the selected tag. To find devices, you can use the asterisk, which stands for any string with any number of characters.

By default, this option is selected.

All devices that do not have this tag

If this option is selected, the search results will display the devices whose descriptions do not contain the selected tag. To find devices, you can use the asterisk, which stands for any string with any number of characters.

Users

In the **Users** section, you can set up the criteria to include devices in the selection according to the accounts of users who have logged in to the operating system.

Last user who logged in to the system

If this option is enabled, you can select the user account for configuring the criterion. The search results include devices on which the selected user performed the last login to the system.

User who logged in to the system at least once

If this option is enabled, click the **Browse** button to specify a user account. The search results include devices on which the specified user logged in to the system at least once.

Device owner

In the **Device owner** section, you can set up the criteria to include devices in the selection according to the registered owners of the device, their roles, and their membership in security groups:

Device owner

Select a device owner's user name from an internal security group. Learn more about users and user roles in this section.

> No more than one user can be registered as the device owner.

Device owner's membership in Active Directory security group

Select an external Active Directory security group that the device owner belongs to.

> The user can be a part of an Active Directory security group or a part of a group that is included in this Active Directory security group.

Device owner's role

Select the device owner's assigned role. Learn more about user roles in this article.

Device owner's membership in an internal security group

Select an internal security group that the device owner belongs to.

Exporting the device list from a device selection

Open Single Management Platform allows you to save information about devices from a device selection and export it as a CSV or a TXT file.

To export the device list from the device selection:

1. Open the table with the devices from the device selection.
2. Use one of the following ways to select the devices that you want to export:
   - To select particular devices, select the check boxes next to them.
   - To select all devices from the current table page, select the check box in the device table header, and then select the **Select all on current page** check box.
   - To select all devices from the table, select the check box in the device table header, and then select the **Select all** check box.
3. Click the **Export to CSV** or **Export to TXT** button. All information about the selected devices included in the table will be exported.

Note that if you applied a filter criterion to the device table, only the filtered data from the displayed columns will be exported.

Removing devices from administration groups in a selection

When working with a device selection, you can remove devices from administration groups right in this selection, without switching to the administration groups from which these devices must be removed.

To remove devices from administration groups:

1. In the main menu, go to **Asset management** → **Device selections** or **Discovery & deployment** → **Device selections**.
2. In the selection list, click the name of the device selection.

   The page displays a table with information about the devices included in the device selection.
3. Select the devices that you want to remove, and then click **Delete**.

   The selected devices are removed from their respective administration groups.

Device tags

This section describes device tags, and provides instructions for creating and modifying them as well as for tagging devices manually or automatically.

Device tags

Open Single Management Platform allows you to *tag* devices. A tag is the string value that can be used for grouping, describing, or finding devices. Tags assigned to devices can be used for creating selections, for finding devices, and for distributing devices among administration groups.

You can tag devices manually or automatically. If you want to tag an individual device, you can use manual tagging. Auto-tagging is performed by Open Single Management Platform in one of the following ways:

- In accordance with the specified tagging rules.
- By an application.

> We do not recommend that you use different ways of tagging to assign the same tag. For example, if the tag is assigned by the rule, it is not recommended to manually assign this tag to devices.

If the tags are assigned by rules, devices are tagged automatically when the specified rules are met. An individual rule corresponds to each tag. Rules are applied to the network properties of the device, operating system, applications installed on the device, and other device properties. For example, you can set up a rule that will assign the `[CentOS]` tag to all devices running CentOS operating system. Then, you can use this tag when creating a device selection; this will help you sort all CentOS devices and assign them a task.

> You can add only one auto-tagging rule per tag. If you create a new rule for the same tag, the previous one will be replaced.

A tag is automatically removed from a device in the following cases:

- When the device stops meeting conditions of the rule that assigns the tag.
- When the rule that assigns the tag is disabled or deleted.

The list of tags and the list of rules on each Administration Server are independent of all other Administration Servers, including a primary Administration Server or subordinate virtual Administration Servers. A rule is applied only to devices from the same Administration Server on which the rule is created.

Creating a device tag

To create a device tag:

1. In the main menu, go to **Repositories** → **Device tags**.
2. On the **Device tags** tab, click the **Add** button.
   A new tag window opens.
3. In the **Tag** field, enter the tag name.
4. Click **Save** to save changes.

The new tag appears in the list of device tags.

Renaming a device tag

To rename a device tag:

1. In the main menu, go to **Repositories** → **Device tags**.
2. On the **Device tags** tab, select the tag that you want to rename.
   A tag properties window opens.
3. In the **Tag** field, change the tag name.
4. Click **Save** to save the changes.

The updated tag appears in the list of device tags.

Deleting a device tag

You can delete only manually assigned tags.

To delete a manually assigned device tag:

1. In the main menu, go to **Repositories** → **Device tags**.
   The list of tags is displayed.
2. On the **Device tags** tab, select device tags that you want to delete.

3. Next, click the **Delete** button.

4. In the window that opens, click **Yes**.

   The device tag is deleted. The deleted tag is automatically removed from all of the devices to which it was assigned.

When you delete a tag assigned to the device by an auto-tagging rule, the rule is not deleted, and the tag will be assigned to a new device when the device first meets the rule conditions. If you delete an auto-tagging rule, the tag specified in the rule conditions will be removed from all devices to which it was assigned but will not be deleted from the list of tags. If necessary, you can manually delete the tag from the list.

The deleted tag is not removed automatically from the device if this tag is assigned to the device by an application or Network Agent. To manage such tags, use the klscflag utility.

Viewing devices to which a tag is assigned

To view devices to which a tag is assigned:

1. In the main menu, go to **Repositories** → **Device tags**.

2. On the **Device tags** tab, click the **View devices** link next to the tag for which you want to view the list of assigned devices.

   You will be redirected to the **Assets (Devices)** section of the main menu, with the devices filtered by the tag for which you clicked the **View devices** link.

3. If you want to return to the list of device tags, click the **Back** button of your browser.

After you view the devices to which the tag is assigned, you can either create and assign a new tag or assign the existing tag to other devices. In this case, you have to remove the filter by tag, select the devices, and then assign the tag.

Viewing tags assigned to a device

To view tags assigned to a device:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.

2. Click the name of the device whose tags you want to view.

3. In the device properties window that opens, select the **Tags** tab.

   The list of tags assigned to the selected device is displayed. In the **Tag assigned** column you can view how the tag was assigned.

In the toolbar, you can do the following:

- Assign another tag to the device.
- Remove an already assigned tag.
- View all device tags that exist on the Administration Server.

> You cannot view the assigned tags locally on the device.

Tagging a device manually

To assign a tag to a device manually:

1. View tags assigned to the device to which you want to assign another tag.
2. Click **Add**.
3. In the window that opens, do one of the following:
   - To create and assign a new tag, select **Create new tag**, and then specify the name of the new tag.
   - To select an existing tag, select **Assign existing tag**, and then select the necessary tag in the drop-down list.
4. Click **OK** to apply the changes.
5. Click **Save** to save changes.

The selected tag is assigned to the device.

Removing an assigned tag from a device

To remove a tag from a device:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.
2. Click the name of the device whose tags you want to view.
3. In the device properties window that opens, select the **Tags** tab.
4. Select the check box next to the tag that you want to remove.

5. At the top of the list, click the **Unassign tag** button.

6. In the window that opens, click **OK**.

   The tag is removed from the device.

The unassigned device tag is not deleted. If you want, you can delete it manually.

You cannot manually remove tags assigned to the device by applications or Network Agent. To manage such tags, use the klscflag utility.

Viewing rules for tagging devices automatically

To view rules for tagging devices automatically,

Do one of the following:

- In the main menu, go to **Repositories** → **Device tags** → **Auto-tagging rules**.
- View tags assigned to a device and then click the **Set up auto-tagging rules** button.

The list of rules for auto-tagging devices appears.

Editing a rule for tagging devices automatically

To edit a rule for tagging devices automatically:

1. View rules for tagging devices automatically.
2. Click the name of the rule that you want to edit.
   A rule settings window opens.
3. Edit the general properties of the rule:
   a. In the **Rule name** field, change the rule name.
      The name cannot contain more than 256 characters.
   b. Do one of the following:
      - Enable the rule by switching the toggle button to **Rule enabled**.
      - Disable the rule by switching the toggle button to **Rule disabled**.

4. Do one of the following:

   - If you want to add a new condition, click the **Add** button, and specify the settings of the new condition in the window that opens.
   - If you want to edit an existing condition, click the name of the condition that you want to edit, and then edit the condition settings.
   - If you want to delete a condition, select the check box next to the name of the condition that you want to delete, and then click **Delete**.

5. Click **OK** in the conditions settings window.
6. Click **Save** to save changes.

The edited rule is shown in the list.

Creating a rule for tagging devices automatically

To create a rule for tagging devices automatically:

1. View rules for tagging devices automatically.
2. Click the **Add** button.

   A new rule settings window opens.
3. Configure the general properties of the rule:

   a. In the **Rule name** field, enter the rule name.

   The name cannot be more than 256 characters long.

   b. Do one of the following:

   - Enable the rule by switching the toggle button to **Rule enabled**.
   - Disable the rule by switching the toggle button to **Rule disabled**.

   c. In the **Tag** field, enter the new device tag name or select one of the existing device tags from the list.

   The name cannot be more than 256 characters long.
4. In the conditions section, click the **Add** button to add a new condition.

   A new condition settings window open.
5. Enter the condition name.

   The name cannot be more than 256 characters long. The name must be unique within a rule.

6. Configure the rule to trigger on the following conditions (you can select multiple conditions):

   - **Network**—Network properties of the device, such as DNS name of the device or device inclusion in an IP subnet.

     If case sensitive collation is set for the database that you use for Open Single Management Platform, keep case when you specify a device DNS name. Otherwise, the auto-tagging rule will not work.

   - **Applications**—Presence of Network Agent on the device, operating system type, version, architecture, and package manager.
   - **Virtual machines**—Device belongs to a specific type of virtual machine.
   - **Applications registry**—Presence of applications of different vendors on the device.

7. Click **OK** to save the changes.

   If necessary, you can set multiple conditions for a single rule. In this case, the tag will be assigned to a device if it meets at least one condition.

8. Click **Save** to save changes.

The newly created rule is enforced on devices managed by the selected Administration Server. If the settings of a device meet the rule conditions, the device is assigned the tag.

Later, the rule is applied in the following cases:

- Automatically and periodically, depending on the server workload
- After you edit the rule
- When you run the rule manually
- After Administration Server detects a change in the settings of a device that meets the rule conditions or the settings of a group that contains such a device

You can create multiple tagging rules. A single device can be assigned multiple tags if you have created multiple tagging rules and if the respective conditions of these rules are met simultaneously. You can view the list of all assigned tags in the device properties.

Running rules for auto-tagging devices

When a rule is run, the tag specified in properties of this rule is assigned to devices that meet conditions specified in properties of the same rule. You can run only active rules.

To run rules for auto-tagging devices:

1. View rules for tagging devices automatically.
2. Select check boxes next to active rules that you want to run.
3. Click the **Run rule** button.

The selected rules are run.

Deleting a rule for tagging devices automatically

To delete a rule for tagging devices automatically:

1. View rules for tagging devices automatically.
2. Select the check box next to the rule that you want to delete.
3. Click the **Delete** button.
4. In the window that opens, click **OK**.

The selected rule is deleted. The tag that was specified in properties of this rule is unassigned from all of the devices that it was assigned to.

The unassigned device tag is not deleted. If you want, you can delete it manually.

Data encryption and protection

Data encryption reduces the risk of unintentional leakage of sensitive and corporate data if your laptop or hard drive is stolen or lost. Also, data encryption allows you to prevent access by unauthorized users and applications.

You can use the data encryption feature if your network includes Windows-based managed devices with Kaspersky Endpoint Security for Windows installed. In this case, on devices running a Windows operating system, you can manage the following types of encryption:

- BitLocker Drive Encryption
- Kaspersky Disk Encryption

We do not recommend enabling encryption in VDI.

By using these components of Kaspersky Endpoint Security for Windows, you can, for example, enable or disable encryption, view the list of encrypted drives, or generate and view reports about encryption.

To configure encryption, define the Kaspersky Endpoint Security for Windows policy in Open Single Management Platform. Kaspersky Endpoint Security for Windows performs encryption and decryption according to the active policy. For detailed instructions on how to configure rules and for a description of encryption features, see the Kaspersky Endpoint Security for Windows Help.

Encryption management for a hierarchy of Administration Servers is currently not available in the Web Console. Use the primary Administration Server to manage encrypted devices.

You can show or hide some of the interface elements related to the encryption management feature by using the user interface settings.

Viewing the list of encrypted drives

In Open Single Management Platform, you can view details about encrypted drives and devices that are encrypted at the drive level. After the information on a drive is decrypted, the drive is automatically removed from the list.

To view the list of encrypted drives,

In the main menu, go to **Operations** → **Data encryption and protection** → **Encrypted drives**.

If the section is not on the menu, this means that it is hidden. In the user interface settings, enable the **Show data encryption and protection** option to display the section.

You can export the list of encrypted drives to a CSV or TXT file. To do this, click the **Export to CSV** or **Export to TXT** button.

Viewing the list of encryption events

When running data encryption or decryption tasks on devices, Kaspersky Endpoint Security for Windows sends Open Single Management Platform information about events of the following types:

- Cannot encrypt or decrypt a file, or create an encrypted archive, due to a lack of free disk space.
- Cannot encrypt or decrypt a file, or create an encrypted archive, due to license issues.
- Cannot encrypt or decrypt a file, or create an encrypted archive, due to missing access rights.
- The application has been prohibited from accessing an encrypted file.
- Unknown errors.

To view a list of events that occurred during data encryption on devices,

In the main menu, go to **Operations** → **Data encryption and protection** → **Encryption events**.

If the section is not on the menu, this means that it is hidden. In the user interface settings, enable the **Show data encryption and protection** option to display the section.

You can export the list of encrypted drives to a CSV or TXT file. To do this, click the **Export to CSV** or **Export to TXT** button.

Alternatively, you can examine the list of encryption events for every managed device.

To view the encryption events for a managed device:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section.
2. Click on the name of a managed device.
3. On the **General** tab, go to the **Protection** section.
4. Click the **View data encryption errors** link.

Creating and viewing encryption reports

You can generate the following reports:

- Report on encryption status of managed devices. This report provides details about the data encryption of various managed devices. For example, the report shows the number of devices to which the policy with configured encryption rules applies. Also, you can find out, for instance, how many devices need to be rebooted. The report also contains information about the encryption technology and algorithm for every device.
- Report on encryption status of mass storage devices. This report contains similar information as the report on the encryption status of managed devices, but it provides data only for mass storage devices and removable drives.
- Report on rights to access encrypted drives. This report shows which user accounts have access to encrypted drives.
- Report on file encryption errors. This report contains information about errors that occurred when the data encryption or decryption tasks were run on devices.
- Report on blockage of access to encrypted files. This report contains information about blocking application access to encrypted files. This report is helpful if an unauthorized user or application tries to access encrypted files or drives.

You can generate any report in the **Monitoring** → **Reports** section. Alternatively, in the **Operations** → **Data encryption and protection** section, you can generate the following encryption reports:

- Report on encryption status of mass storage devices
- Report on rights to access encrypted drives
- Report on file encryption errors

*To generate an encryption report in the **Data encryption and protection** section:*

1. Make sure that you enabled the **Show data encryption and protection** option in the Interface options.
2. In the main menu, go to **Operations** → **Data encryption and protection**.

3. Open one of the following sections:

   - **Encrypted drives** generates the report on encryption status of mass storage devices or the report on rights to access encrypted drives.
   - **Encryption events** generates the report on file encryption errors.

4. Click the name of the report that you want to generate.

The report generation starts.

Granting access to an encrypted drive in offline mode

A user can request access to an encrypted device, for example, when Kaspersky Endpoint Security is not installed on the managed device. After you receive the request, you can create an access key file and send it to the user. All of the use cases and detailed instructions are provided in the Kaspersky Endpoint Security Help for the required platform.

To grant access to an encrypted drive in offline mode in Kaspersky Endpoint Security for Windows:

1. Get a request access file from a user (a file with the FDERTC extension). Follow the instructions in the Kaspersky Endpoint Security for Windows Help to generate the file in Kaspersky Endpoint Security for Windows.
2. In the main menu, go to **Operations** → **Data encryption and protection** → **Encrypted drives**.

   A list of encrypted drives appears.
3. Select the drive to which the user requested access.
4. Click the **Grant access to the device in offline mode** button.
5. In the window that opens, select the Kaspersky Endpoint Security for Windows plug-in.
6. Follow the instructions provided in the Kaspersky Endpoint Security for Windows Help (see the instructions for OSMP Console at the end of the section).

After that, the user applies the received file to access the encrypted drive and read data stored on the drive.

Transmitting encryption keys between Administration Servers

If the data encryption feature is enabled on a managed device, the encryption key is stored on the Administration Server. The encryption key is used to access encrypted data and to manage the encryption policy.

The encryption key must be transmitted to another Administration Server in the following cases:

- Reconfiguring Network Agent on a managed device to assign the device to another Administration Server. If this device contains encrypted data, the encryption key must be transmitted to the target Administration Server. Otherwise, the data cannot be decrypted.

- Encrypting a removable drive connected to a device D1 that is managed by the Administration Server S1, and then you connect this removable drive to a device D2 managed by the Administration Server S2. To access to the data on the removable drive, the encryption key must be transmitted from the Administration Server S1 to the Administration Server S2.

- Encrypting a file on a device D1 managed by the Administration Server S1, and then you try to access the file on a device D2 managed by the Administration Server S2. To access the file, the encryption key must be transmitted from the Administration Server S1 to the Administration Server S2.

You can transmit encryption keys the following ways:

- Automatically, by enabling the **Use hierarchy of Administration Servers to obtain encryption keys** option in the properties of two Administration Servers between which an encryption key must be transmitted. If this option is disabled for one of the Administration Servers, the automatic transmission of encryption keys is not possible.

  When you enable the **Use hierarchy of Administration Servers to obtain encryption keys** option in an Administration Server properties, the Administration Server sends all of the encryption keys stored in its repository to the primary Administration Server (if any) one level up in the hierarchy.

  When you try to access encrypted data, the Administration Server first searches the encryption key in its own repository. If the **Use hierarchy of Administration Servers to obtain encryption keys** option is enabled and the required encryption key has not been found in the repository, the Administration Server additionally sends a request to the primary Administration Servers (if any) to provide the required encryption key. The request will be sent to all of the primary Administration Servers up to the server on the highest level of the hierarchy.

- Manually from one Administration Server to another by exporting and importing the file containing the encryption keys.

  The export and import of encryption keys are actions that are included in the Encryption key management feature. To perform these actions, configure the access rights to the feature for users of Open Single Management Platform as follows:

  - Grant the **Read** access right to the Encryption key management feature for a user that exports encryption keys from the secondary Administration Server.

  - Grant the **Write** access right to the Encryption key management feature for a user that imports encryption keys to the target Administration Server.

To enable automatic transmission of encryption keys between Administration Servers within the hierarchy:

1. Go to the properties of the required Administration Server:

   a. In the main menu, select a section (except for **Marketplace**, **Console navigation**, and **Settings**), and then at the top of the page, click the **Show hierarchy** button.

   b. In the navigation pane that opens, hover the mouse cursor over the name of the required Administration Server, and then click the settings icon (⚙).

      Alternately, you can click the Administration Server name, and then, after the name is displayed in the main menu, click it in the main menu to open the server properties window.

2. In the properties window that opens, select the **Encryption algorithm** section.

3. Enable the **Use hierarchy of Administration Servers to obtain encryption keys** option.

4. Click **Save** to apply changes.

The encryption keys will be transmitted to primary Administration Servers (if any) at the next synchronization (the heartbeat). This Administration Server will also provide, upon request, an encryption key from its repository to a secondary Administration Server.

To transmit encryption keys between Administration Servers manually:

1. Go to the properties of the Administration Server from which you want to export encryption keys:

   a. In the main menu, select a section (except for **Marketplace**, **Console navigation**, and **Settings**), and then at the top of the page, click the **Show hierarchy** button.

   b. In the navigation pane that opens, hover the mouse cursor over the name of the required Administration Server, and then click the settings icon (⚙).

   Alternately, you can click the Administration Server name, and then, after the name is displayed in the main menu, click it in the main menu to open the server properties window.

2. In the properties window that opens, select the **Encryption algorithm** section.

3. Click **Export encryption keys**.

   Make sure that a user that exports encryption keys from the Server is granted the **Read** access right to the Encryption key management feature.

4. In the **Export encryption keys from Administration Server?** window do the following:

   a. Specify a password to protect the file from unauthorized access.

   b. Specify where you want to save the file.

   Remember the password. A lost password cannot be retrieved. If the password is lost, you have to repeat the export procedure. Therefore, make a note of the password and keep it handy.

5. Transmit the file to another Administration Server, for example, through a shared folder or removable drive.

6. Go to the properties of the Administration Server to which you want to import the encryption keys.

7. In the properties window, select the **Encryption algorithm** section.

8. Click **Import encryption keys**.

   Make sure that a user that imports encryption keys to the Server is granted the **Write** access right to the Encryption key management feature.

9. Select the file containing the encryption keys.

10. Enter the password and click **OK**.

The encryption keys are transmitted to the target Administration Server.

Changing the Administration Server for client devices

You can change the Administration Server to a different one for specific client devices. For this purpose, use the *Change Administration Server* task.

To change the Administration Server that manages client devices to a different Server:

1. Connect to the Administration Server that manages the devices.
2. Create the Administration Server change task.

   The New task wizard starts. Follow the steps of the wizard. In the **New task** window of the New task wizard, select the **Kaspersky Security Center 16.3** application and the **Change Administration Server** task type. After that, specify the devices for which you want to change the Administration Server:

   - **Assign task to an administration group**

     The task is assigned to devices included in an administration group. You can specify one of the existing groups or create a new one.

     For example, you may want to use this option to run a task of sending a message to users if the message is specific for devices included in a specific administration group.

     If a task is assigned to an administration group, the **Security** tab is not displayed in the task properties window because group tasks are subject to the security settings of the groups to which they apply.

   - **Specify device addresses manually or import addresses from a list**

     You can specify DNS names, IP addresses, and IP subnets of devices to which you want to assign the task.

     You may want to use this option to execute a task for a specific subnet. For example, you may want to install a certain application on devices of accountants or to scan devices in a subnet that is probably infected.

   - **Assign task to a device selection**

     The task is assigned to devices included in a device selection. You can specify one of the existing selections.

     For example, you may want to use this option to run a task on devices with a specific operating system version.

3. Run the created task.

After the task is completed, the client devices for which it was created are put under the management of the Administration Server specified in the task settings.

If the Administration Server supports encryption and data protection and you are creating a *Change Administration Server* task, a warning is displayed. The warning states that if any encrypted data is stored on devices, after the new Server begins managing the devices, users will be able to access only the encrypted data with which they previously worked. In other cases, no access to encrypted data is provided. For detailed descriptions of scenarios in which access to encrypted data is not provided, refer to the Kaspersky Endpoint Security for Windows Help.

Viewing and configuring the actions when devices show inactivity

If client devices within a group are inactive, you can get notifications about it. You can also automatically delete such devices.

To view or configure the actions when the devices in the group show inactivity:

1. In the main menu, go to **Asset management** → **Hierarchy of groups**.
2. Go to the properties of the required administration group in one of the following ways:
   - Click the name of the administration group.
   - Click the **Show hierarchy** button at the top of the page. In the navigation pane that opens, hover the mouse cursor over the name of the required group, and then click the settings icon (⚙).

   The administration group properties window opens.
3. In the properties window, go to the **Settings** tab.
4. In the **Inheritance** section, enable or disable the following options:
   - **Inherit from parent group**

     The settings in this section will be inherited from the parent group in which the client device is included. If this option is enabled, the settings under **Device Activity** are locked from any changes.

     This option is available only if the administration group has a parent group.

     By default, the option is enabled.
   - **Force inheritance of settings in child groups**

     The setting values will be distributed to child groups but in the properties of the child groups these settings are locked.

     By default, this option is disabled.

Administration group properties

5. In the **Device activity** section, enable or disable the following options:

   - **Notify the administrator if the device has been inactive for longer than (days)**

     If this option is enabled, the administrator receives notifications about inactive devices. You can specify the time interval after which the **Device has remained inactive on the network in a long time** event is created. The default time interval is 7 days.

     By default, the option is enabled.

   - **Remove the device from the group if it has been inactive for longer than (days)**

     If this option is enabled, you can specify the time interval after which the device is automatically removed from the group. The default time interval is 60 days.

By default, the option is enabled.

Administration group properties

6. Click the **Save** button.

Your changes are saved and applied.

Remote access to managed devices

Open Single Management Platform allows you to establish a remote connection to managed devices. The administrator can obtain remote access to the managed device through a Network Agent installed on the device. Remote connection to a device through the Network Agent is possible even if the TCP and UDP ports of the client device are closed. Upon establishing a connection with the device, the administrator gains full access to information stored on this device and can manage applications installed on it.

The methods for establishing a remote connection depend on which platform is used on the device with OSMP Console. OSMP Console can be installed on a device other than the Administration Server device, on a Windows- or a Linux-based device.

From OSMP Console installed on a Linux device, you can establish the following connections:

- To a Linux-based managed device by using:
  - Remote desktop connection (RDP)
  - Virtual Network Computing (VNC)
- To a Windows-based managed device by using:
  - Remote desktop connection (RDP)
  - Virtual Network Computing (VNC)

From OSMP Console installed on a Windows device, you can establish the following connections:

- To a Linux-based managed device by using:
  - Remote desktop connection (RDP)
  - Virtual Network Computing (VNC)
- To a Windows-based managed device by using:
  - Remote desktop connection (RDP)
  - Windows Desktop Sharing (WDS)

Remote connection to managed devices is not supported when accessing the OSMP Console from a device running Microsoft Windows on Arm.

To establish a remote connection to a device, you must have the following:

- klsctunnel utility

  The Kaspersky utility is used for tunneling the connection between a managed device and Administration Server.

  Open Single Management Platform allows tunneling TCP connections from OSMP Console via the Administration Server and then via Network Agent to a specified port on a managed device. Tunneling is designed for connecting a client application on a device with OSMP Console installed to a TCP port on a managed device—if no direct connection is possible between OSMP Console and the target device.

  Connection tunneling between a remote client device and Administration Server is required if the port used for connection to Administration Server is not available on the device. The port on the device may be unavailable in the following cases:

  - The remote device is connected to a local network that uses the NAT mechanism.
  - The remote device is part of the local network of Administration Server, but its port is closed by a firewall.

  The utility can be downloaded when a remote connection is established through OSMP Console or manually. The klsctunnel utility is installed on the Administration Server device.

  The klsctunnel utility is used for all types of the remote connection (RDP, VNC, WDS).

- RDP or VNC client

  An RDP or VNC client is installed on the Administration Server device. This client allows you to obtain remote access to the managed device by using the address and port for the local connection provided by the klsctunnel utility.

  An RDP connection to the current remote desktop session of the user is established without the user's knowledge. Once the administrator connects to the session, the device user is disconnected from the session without notification.

- Windows Desktop Sharing (only for Windows-based managed devices)

  This feature allows you to connect to an existing session on a client device without disconnecting the user in this session. In this case, the administrator and the session user on the device share access to the desktop.

  When connecting to an existing session of the remote desktop, the session user on the device receives a connection request from the administrator. No information about remote activity on the device and its results will be saved in reports created by Kaspersky EDR Expert.

The administrator can configure an audit of user activity on a remote client device. During the audit, the application saves information about files on the client device that have been opened and/or modified by the administrator.

Remote access from a Linux-based device with OSMP Console to a Linux-based managed device

Prerequisites

Before you start, make sure that you have done the following:

- On the managed device running Linux, Network Agent version 15.3 or later is installed.
- On the managed device running Linux, the RDP server is installed (if you connect to the managed device by using Remote Desktop Connection).
- On the managed device running Linux, the VNC server is installed (if you connect to the managed device by using Virtual Network Computing).
- The administrator has the **Start RDP sessions** right to establish RDP connections (if you connect to the managed device by using Remote Desktop Connection).
- The administrator has the **Initiate tunneling** right to establish the tunnel connection for VNC (if you connect to the managed device by using Virtual Network Computing).

To connect to a Linux-based managed device by using RDP or VNC through OSMP Console opened on a Linux-based device:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section or open a device selection.
2. Select the check box next to the managed device to which you want to connect remotely, and then click the **Connect to Remote Desktop** button.

   The **Connect to Remote Desktop** window opens.

   If you select multiple devices, a mobile device, or a device running macOS, the **Connect to Remote Desktop** button will be disabled.
3. Download the klsctunnel utility by clicking the **Download** button, and then run it.

   When downloading the utility, take into account the following:

   - To get an up-to-date version of the klsctunnel utility, make sure that Administration Server has access to Kaspersky update servers.

     You can run the *Download updates to the Administration Server repository* task and select Kaspersky update servers as a source of updates. If the task finishes successfully, Administration Server has access to Kaspersky update servers.
   - If the utility file is unavailable for download, an error message is displayed. In this case, download the utility manually, and then place it on the Administration Server device in the /var/opt/kaspersky/klnagent_srv directory.

4. In the **Connect to Remote Desktop** window, specify the connection port. The default port number is 3389.

5. Generate a text blob with encoded connection parameters by clicking the **Generate blob** button, and then copy and paste the text into the corresponding field in the klsctunnel utility.

   A blob contains the settings required to establish a connection between Administration Server and the managed device. A blob is valid for three minutes. If it has expired, generate a new blob.

6. In the klsctunnel utility, if you use a proxy server, specify the proxy server connection settings.

   The klsctunnel utility displays the address and port for the local connection of a remote access client.

   The utility allows the administrator to close the tunnel connection. If the tunnel connection is closed, the current connection to the remote desktop is terminated.

7. Run a remote access client (RDP or VNC) and connect it to the managed device by using the address and port provided by the klsctunnel utility.

The connection with the managed device is established. The desktop is available in the remote access client window.

Remote access from a Linux-based device with OSMP Console to a Windows-based managed device

Remote desktop connection (RDP)

Prerequisites

Before you start, make sure that you have done the following:

- A remote connection is allowed in the operating system settings of the managed device.
- On the managed device running Windows, Network Agent version 13 or later is installed.
- The administrator has the **Start RDP sessions** right to establish RDP connections.

To connect to a Windows-based managed device by using RDP through OSMP Console opened on a Linux-based device:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section or open a device selection.

2. Select the check box next to the managed device to which you want to connect remotely, and then click the **Connect to Remote Desktop** button.

   The **Connect to Remote Desktop** window opens.

   If you select multiple devices, a mobile device, or a device running macOS, the **Connect to Remote Desktop** button will be disabled.

3. In the **Connect to Remote Desktop** window, select the **RDP** connection type.

4. If a remote connection is not allowed in the operating system settings of the managed device, allow the remote connection centrally by clicking the **Change settings** button.

If the settings are applied correctly, a notification is displayed. Also, on the managed device, in the **Settings** → **System** → **Remote Desktop** section, the **Enable Remote Desktop** option is enabled.

If the remote connection is allowed in the operating system settings of the managed device, the **Change settings** button is not displayed.

5. Download the klsctunnel utility by clicking the **Download** button, and then run it.

   If the utility file is unavailable for download, an error message is displayed. In this case, download the utility manually.

6. Generate a text blob with encoded connection parameters by clicking the **Generate blob** button, and then copy and paste the text into the corresponding field in the klsctunnel utility.

   A blob contains the settings required to establish a connection between Administration Server and the managed device. A blob is valid for three minutes. If it has expired, generate a new blob.

7. In the klsctunnel utility, if you use a proxy server, specify the proxy server connection settings.

   The klsctunnel utility displays the address and port of the connection to the remote device.

   The utility allows the administrator to close the tunnel connection. If the tunnel connection is closed, the current connection to the remote desktop is terminated.

8. Run an RDP client and connect it to the managed device by using the address and port provided by the klsctunnel utility.

A connection to the managed device is established, The desktop is available in the RDP client window.

Connection to the current remote desktop session of the user is established without the user's knowledge. Once the administrator connects to the session, the device user is disconnected from the session without notification.

Virtual Network Computing system (VNC)

Prerequisites

Before you start, make sure that you have done the following:

- On the managed device running Windows, Network Agent version 13 or later is installed.
- On the managed device running Windows, the VNC server is installed.
- The administrator has the **Initiate tunneling** right to establish the tunnel connection for VNC.

To connect to a Windows-based managed device by using VNC through OSMP Console opened on a Linux-based device:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section or open a device selection.

2. Select the check box next to the managed device to which you want to connect remotely, and then click the **Connect to Remote Desktop** button.

   The **Connect to Remote Desktop** window opens.

   If you select multiple devices, a mobile device, or a device running macOS, the **Connect to Remote Desktop** button will be disabled.

3. In the **Connect to Remote Desktop** window, select the connection type **VNC**.

4. Download the klsctunnel utility by clicking the **Download** button, and then run it.

   When downloading the utility, take into account the following:

   - To get an up-to-date version of the klsctunnel utility, make sure that Administration Server has access to Kaspersky update servers.

     You can run the *Download updates to the Administration Server repository* task and select Kaspersky update servers as a source of updates. If the task finishes successfully, Administration Server has access to Kaspersky update servers.

   - If the utility file is unavailable for download, an error message is displayed. In this case, download the utility manually, and then place it on the Administration Server device in the /var/opt/kaspersky/klnagent directory.

5. In the **Connect to Remote Desktop** window, specify the VNC connection port. The default port number is 5900.

6. Generate a text blob with encoded connection parameters by clicking the **Generate blob** button, and then copy and paste the text into the corresponding field in the klsctunnel utility.

   A blob contains the settings required to establish a connection between Administration Server and the managed device. A blob is valid for three minutes. If it has expired, generate a new blob.

7. In the klsctunnel utility, if you use a proxy server, specify the proxy server connection settings.

   The klsctunnel utility displays the address and port for the local connection of the VNC client.

   The utility allows the remote user to close the tunnel connection. If the tunnel connection is closed, the current connection to the remote desktop is terminated.

8. Run a VNC client and connect it to the managed device by using the address and port provided by the klsctunnel utility.

The connection with the managed device is established. The desktop is available in the VNC client window.

Remote access from a Windows-based device with OSMP Console to a Linux-based managed device

Remote desktop connection (RDP)

Prerequisites

Before you start, make sure that you have done the following:

- On the managed device running Linux, the RDP server is installed.
- On the managed device running Linux, Network Agent version 15.3 or later is installed.
- The administrator has the **Start RDP sessions** right to establish RDP connections.

To connect to a Linux-based managed device by using RDP through OSMP Console opened on a Windows-based device:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section or open a device selection.

2. Select the check box next to the managed device to which you want to connect remotely, and then click the **Connect to Remote Desktop** button.

   The **Connect to Remote Desktop** window opens.

   If you select multiple devices, a mobile device, or a device running macOS, the **Connect to Remote Desktop** button will be disabled.

3. In the **Connect to Remote Desktop** window, select the **RDP** connection type.

4. Download the klsctunnel utility by clicking the **Download** button, and then run it.

   If the utility file is unavailable for download, an error message is displayed. In this case, download the utility manually.

5. Generate a text blob with encoded connection parameters by clicking the **Generate blob** button, and then copy and paste the text into the corresponding field in the klsctunnel utility.

   A blob contains the settings required to establish a connection between Administration Server and the managed device. A blob is valid for three minutes. If it has expired, generate a new blob.

6. In the klsctunnel utility, if you use a proxy server, specify the proxy server connection settings.

   To do this, select the **Use proxy server** check box, and then specify the connection settings.

7. Click the **Open port** button.

   The Remote Desktop Connection login window opens.

8. Specify the credentials of the account under which you are currently logged in to OSMP Console, and then connect to the managed device.

   The klsctunnel utility displays the address and port of the connection to the remote device.

   The utility allows the administrator to close the tunnel connection. If the tunnel connection is closed, the current connection to the remote desktop is terminated.

When connection to the device is established, the desktop is available in the Remote Desktop Connection window of Microsoft Windows.

Connection to the current remote desktop session of the user is established without the user's knowledge. Once the administrator connects to the session, the device user is disconnected from the session without notification.

Virtual Network Computing system (VNC)

Prerequisites

Before you start, make sure that you have done the following:

- On the managed device running Linux, Network Agent version 15.3 or later is installed.
- On the managed device running Linux, the VNC server is installed.
- The administrator has the **Initiate tunneling** right to establish the tunnel connection for VNC.

To connect to a Linux-based managed device by using VNC through OSMP Console opened on a Windows-based device:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section or open a device selection.
2. Select the check box next to the managed device to which you want to connect remotely, and then click the **Connect to Remote Desktop** button.

   The **Connect to Remote Desktop** window opens.

   If you select multiple devices, a mobile device, or a device running macOS, the **Connect to Remote Desktop** button will be disabled.
3. In the **Connect to Remote Desktop** window, select the connection type **VNC**.
4. Download the klsctunnel utility by clicking the **Download** button, and then run it.

   When downloading the utility, take into account the following:

   - To get an up-to-date version of the klsctunnel utility, make sure that Administration Server has access to Kaspersky update servers.

     You can run the *Download updates to the Administration Server repository* task and select Kaspersky update servers as a source of updates. If the task finishes successfully, Administration Server has access to Kaspersky update servers.
   - If the utility file is unavailable for download, an error message is displayed. In this case, download the utility manually, and then place it on the Administration Server device in the /var/opt/kaspersky/klnagent directory.
5. In the **Connect to Remote Desktop** window, specify the VNC connection port. The default port number is 5900.
6. Generate a text blob with encoded connection parameters by clicking the **Generate blob** button, and then copy and paste the text into the corresponding field in the klsctunnel utility.

   A blob contains the settings required to establish a connection between Administration Server and the managed device. A blob is valid for three minutes. If it has expired, generate a new blob.
7. In the klsctunnel utility, if you use a proxy server, specify the proxy server connection settings.

   To do this, select the **Use proxy server** check box, and then specify the connection settings.
8. Click the **Open port** button.

   The klsctunnel utility displays the address and port for the local connection of the VNC client.

The utility allows the remote user to close the tunnel connection. If the tunnel connection is closed, the current connection to the remote desktop is terminated.

9. Run a VNC client and connect it to the managed device by using the address and port provided by the klsctunnel utility.

The connection with the managed device is established. The desktop is available in the VNC client window.

Remote access from a Windows-based device with OSMP Console to a Windows-based managed device

Remote desktop connection (RDP)

Prerequisites

Before you start, make sure that you have done the following:

- On the managed device running Windows, Network Agent version 13 or later is installed.
- The administrator has the **Start RDP sessions** right to establish RDP connections.
- A remote connection is allowed in the operating system settings of the managed device.

To connect to a Windows-based managed device by using RDP through OSMP Console opened on a Windows-based device:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section or open a device selection.
2. Select the check box next to the managed device to which you want to connect remotely, and then click the **Connect to Remote Desktop** button.

   The **Connect to Remote Desktop** window opens.

   If you select multiple devices, a mobile device, or a device running macOS, the **Connect to Remote Desktop** button will be disabled.
3. In the **Connect to Remote Desktop** window, select the **Remote Desktop Connection** connection type.
4. If a remote connection is not allowed in the operating system settings of the managed device, allow the remote connection centrally by clicking the **Change settings** button.

   If the settings are applied correctly, a notification is displayed. Also, on the managed device, in the **Settings** → **System** → **Remote Desktop** section, the **Enable Remote Desktop** option is enabled.

   If the remote connection is allowed in the operating system settings of the managed device, the **Change settings** button is not displayed.
5. Download the klsctunnel utility by clicking the **Download** button, and then run it.

   If the utility file is unavailable for download, an error message is displayed. In this case, download the utility manually.

6. Generate a text blob with encoded connection parameters by clicking the **Generate blob** button, and then copy and paste the text into the corresponding field in the klsctunnel utility.

   A blob contains the settings required to establish a connection between Administration Server and the managed device. A blob is valid for three minutes. If it has expired, generate a new blob.

7. In the klsctunnel utility, if you use a proxy server, specify the proxy server connection settings.

   To do this, select the **Use proxy server** check box, and then specify the connection settings.

8. Click the **Open port** button.

   The Remote Desktop Connection login window opens.

9. Specify the credentials of the account under which you are currently logged in to OSMP Console, and then connect to the managed device.

   The klsctunnel utility displays the address and port of the connection to the remote device.

   The utility allows the administrator to close the tunnel connection. If the tunnel connection is closed, the current connection to the remote desktop is terminated.

When connection to the device is established, the desktop is available in the Remote Desktop Connection window of Microsoft Windows.

Connection to the current remote desktop session of the user is established without the user's knowledge. Once the administrator connects to the session, the device user is disconnected from the session without notification.

Windows Desktop Sharing (WDS)

Prerequisites

Before you start, make sure that you have done the following:

- On the managed device running Windows, Network Agent version 13 or later is installed.
- The administrator has the **Connect to existing RDP sessions** right to establish the WDS connection.
- The license for Vulnerability and patch management is available.
- Microsoft Windows Vista or later is installed on the administrator's workstation. The type of operating system of the device hosting Administration Server imposes no restrictions on connection through Windows Desktop Sharing.

  Check whether the Windows Desktop Sharing feature is included in your Windows edition, and make sure that the CLSID\{32BE5ED2-5C86-480F-A914-0FF8885A1B3F} key exists in the Windows Registry.

- Microsoft Windows Vista or later is installed on the client device.

To connect to a Windows-based managed device by using VNC through OSMP Console opened on a Windows-based device:

1. In the main menu, go to the **Asset management** → **Assets (Devices)** section or open a device selection.
2. Select the check box next to the managed device to which you want to connect remotely, and then click the **Connect to Remote Desktop** button.

The **Connect to Remote Desktop** window opens.

If you select multiple devices, a mobile device, or a device running macOS, the **Connect to Remote Desktop** button will be disabled.

3. In the **Connect to Remote Desktop** window, select the connection type **Windows Desktop Sharing**.

   If the Vulnerability and patch management license is not available, an error message is displayed.

4. Download the klsctunnel utility by clicking the **Download** button, and then run it.

   When downloading the utility, take into account the following:

   - To get an up-to-date version of the klsctunnel utility, make sure that Administration Server has access to Kaspersky update servers.

     You can run the *Download updates to the Administration Server repository* task and select Kaspersky update servers as a source of updates. If the task finishes successfully, Administration Server has access to Kaspersky update servers.

   - If the utility file is unavailable for download, an error message is displayed. In this case, download the utility manually, and then place it on the Administration Server device in the /var/opt/kaspersky/klnagent directory.

5. In the list of available user sessions active on the selected device, select the session to which you want to connect.

   The remote user must allow the connection. If the remote user refuses to connect or if the remote user does not allow the connection during the timeout period, an error message is displayed.

6. Generate a text blob with encoded connection parameters by clicking the **Generate blob** button, and then copy and paste the text into the corresponding field in the klsctunnel utility.

   A blob contains the settings required to establish a connection between Administration Server and the managed device. A blob is valid for three minutes. If it has expired, generate a new blob.

7. In the klsctunnel utility, if you use a proxy server, specify the proxy server connection settings.

   To do this, select the **Use proxy server** check box, and then specify the connection settings.

8. Click the **Open port** button.

   The klsctunnel utility displays the address and port for the local connection of the VNC client.

   The utility allows the remote user to close the tunnel connection. If the tunnel connection is closed, the current connection to the remote desktop is terminated.

Desktop sharing starts in a new window. If you want to interact with the device, click the menu icon () in the upper-left corner of the window, and then select **Interactive mode**.

Managing assets

Assets represent the computers of the organization. You can add assets to OSMP; in that case, OSMP automatically adds asset IDs when enriching events, and when you analyze events, you can get additional information about computers in the organization.

You can add assets to OSMP in the following ways:

- Import assets:
  - From MaxPatrol VM.
  - On a schedule from **Kaspersky Security Center** and KICS for Networks.

    All assets that are protected by this program are registered in Kaspersky Security Center. Information about assets protected by Kaspersky Security Center can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

    KUMA imports the following device information received from Kaspersky Security Center Network Agents:

    - Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
    - Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

    To import information about the Kaspersky Security Center assets:

    1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
    2. Click **Import**, and then select one of the following actions:
       - To import information about the basic attributes of assets, click **Import KSC assets**.

         This opens the **Import KSC assets** window.
       - To import information about other attributes of assets, click **Import KSC assets attributes**.

         This opens the **Import KSC assets attributes** window.
    3. In the drop-down list, select the tenant for which you want to perform the import.

       In this case, the program downloads information about all assets of all Kaspersky Security Center servers that have been configured to connect to the selected tenant.

       If you want to import information about all assets of all Kaspersky Security Center servers for all tenants, select **All**.
    4. Click the **Import** button.

    The asset information will be imported.

    Also, in a tenant properties window, you can schedule regular import of asset information or run import manually.

    By default, assets are imported every 12 hours, this frequency can be configured. On-demand import of assets is also possible; such on-demand import does not affect the scheduled import time. From the Kaspersky Security Center database, OSMP imports information about devices with installed Kaspersky Security Center Network Agent that has connected to Kaspersky Security Center, that is, has a non-empty 'Connection time' field in the SQL database. OSMP imports the following information about the computer: name, address, time of connection to Kaspersky Security Center, information about hardware and software, including the operating system, as well as vulnerabilities, that is, information received from Kaspersky Security Center Network Agents.

- Create assets manually through the web interface or via the API.

  You can add assets manually. In this case, you must manually specify the following information: address, FQDN, name and version of the operating system, hardware information. Information about the vulnerabilities of assets cannot be added through the web interface. You can provide information about vulnerabilities if you add assets using the API.

You can manage OSMP assets: view information about assets, search for assets, add, edit or delete assets, and export asset data to a CSV file.

From the moment an asset is added to OSMP, it takes approximately 2 minutes before the solution can start enriching events with this asset. For example, if a correlation event occurs within two minutes after adding an asset, this asset is not displayed in the generated alert.

Asset categories

You can categorize the assets and then use the categories in filter conditions or correlation rules. For example, you can create alerts of a higher severity level for assets from a higher-severity category. By default, all assets fall into the **Uncategorized assets** category. A device can be added to multiple categories.

By default, OSMP assigns the following severity levels to asset categories: Low, Medium, High, Critical. You can create custom categories, categories can be nested.

Categories can be populated in the following ways:

- **Manually**

- **Active**: dynamic if the asset **meets the specified conditions**. For example, the moment the asset is upgraded to a specified OS version or placed in a specified subnet, the asset is moved to the specified category.

  1. In the **Repeat categorization every** drop-down list, specify how often assets will be linked to a category. You can select values ranging from once per hour to once per 24 hours.

     You can forcibly start categorization by selecting **Start categorization** in the category context menu.

  2. Under **Conditions**, specify the filter for matching assets to attach to an asset category.

     You can add conditions by clicking the **Add condition** buttons. Groups of conditions can be added by clicking the **Add group** buttons. Group operators can be switched between **AND**, **OR**, and **NOT** values.

     Categorization filter operands and operators

Operand	Operators	Comment
Build number	>, >=, =, <=, <	
OS	=, like	The "like" operator ensures that the search is not case sensitive.
Single IP address	inSubnet, inRange	The IP address is indicated in CIDR notation (for example: 192.168.0.0/24). When the inRange operator is selected, you can indicate only addresses from private ranges of IP addresses (for example: 10.0.0.0–10.255.255.255). Both addresses must be in the same range.
FQDN	=, like	The "like" operator ensures that the search is not case sensitive.
CVE	=, in	The "in" operator lets you specify an array of values.
Software	=, like	
CII	in	More than one value can be selected.

Anti-virus databases last updated	>=,<=	
Last update of the information	>=,<=	
Protection last updated	>=,<=	
System last started	>=,<=	
KSC extended status	in	Extended status of the device. More than one value can be selected.
Real-time protection status	=	Status of Kaspersky applications installed on the managed device.
Encryption status	=	
Spam protection status	=	
Anti-virus protection status of mail servers	=	
Data Leakage Prevention status	=	
KSC extended status ID	=	
Endpoint Sensor status	=	
Last seen at	>=,<=	

3. Use the **Test conditions** button to make sure that the specified filter is correct. When you click the button, you should see the **Assets for given conditions** window containing a list of assets that satisfy the search conditions.

- **Reactive**—When a correlation rule is triggered, the asset is moved to the specified group.

In OSMP, assets are categorized by tenant and by category. Assets are arranged in a tree structure, where the tenants are located at the root, and the asset categories branch from them. You can view the tree of tenants and categories in the **Assets** → **All assets** section. When a tree node is selected, the assets assigned to it are displayed in the right part of the window. Assets from the subcategories of the selected category are displayed if you specify that you want to display assets recursively. You can select the check boxes next to the tenants whose assets you want to view.

To open the context menu of a category, hover the mouse cursor over the category and click the ellipsis icon that is displayed to the right of the category name. The following actions are available in the context menu:

Category context menu items

Action	Description
Show assets	Display assets of the selected category in the right part of the window.
Show assets recursively	View assets from subcategories of the selected category. If you want to exit recursive viewing mode, select another category to view.
Show info	View information about the selected category in the **Category information** details area displayed in the right part of the web interface window.
Start categorization	Start automatic binding of assets to the selected category. This option is available for categories that have active categorization.
Add subcategory	Add a subcategory to the selected category.
Edit category	Edit the selected category.
Delete category	Delete the selected category. You can only delete categories that have no assets or subcategories. Otherwise the **Delete category** option is inactive.
Pin as tab	Display the selected category on a separate tab. You can undo this action by selecting **Unpin as tab** in the context menu of the relevant category.

Adding an asset category

To add an asset category:

1. In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Open the category creation window:
   - Click the **Add category** button.
   - If you want to create a subcategory, select **Add subcategory** in the context menu of the parent category.

   The **Add category** details area appears in the right-hand part of the console window.
3. Add information about the category:
   - In the **Name** field, enter the name of the category. The name must contain 1 to 128 Unicode characters.
   - In the **Parent** field, indicate the position of the category within the categories tree hierarchy:

     a. Click the button.

     This opens the **Select categories** window showing the categories tree. If you are creating a new category and not a subcategory, the window may show multiple asset category trees, one for each tenant that you can access. Your tenant selection in this window cannot be undone.

     b. Select the parent category for the category you are creating.

     c. Click **Save**.

     Selected category appears in **Parent** fields.
   - The **Tenant** field displays the tenant in whose structure you selected the parent category. The tenant category cannot be changed.
   - Assign a severity to the category in the **Priority** drop-down list.
   - If necessary, in the **Description** field, you can add a note consisting of up to 256 Unicode characters.
4. In the **Categorization kind** drop-down list, select how the category will be populated with assets. Depending on your selection, you may need to specify additional settings:
   - **Manually**—assets can only be manually linked to a category.
   - **Active**—assets will be assigned to a category at regular intervals if they satisfy the defined filter.

     Active category of assets

     1. In the **Repeat categorization every** drop-down list, specify how often assets will be linked to a category. You can select values ranging from once per hour to once per 24 hours.

        You can forcibly start categorization by selecting **Start categorization** in the category context menu.
     2. Under **Conditions**, specify the filter for matching assets to attach to an asset category.

You can add conditions by clicking the **Add condition** buttons. Groups of conditions can be added by clicking the **Add group** buttons. Group operators can be switched between **AND**, **OR**, and **NOT** values.

Categorization filter operands and operators

Operand	Operators	Comment
Build number	>, >=, =, <=, <	
OS	=, like	The "like" operator ensures that the search is not case sensitive.
Single IP address	inSubnet, inRange	The IP address is indicated in CIDR notation (for example: 192.168.0.0/24). When the inRange operator is selected, you can indicate only addresses from private ranges of IP addresses (for example: 10.0.0.0–10.255.255.255). Both addresses must be in the same range.
FQDN	=, like	The "like" operator ensures that the search is not case sensitive.
CVE	=, in	The "in" operator lets you specify an array of values.
Software	=, like	
CII	in	More than one value can be selected.
Anti-virus databases last updated	>=,<=	
Last update of the information	>=,<=	
Protection last updated	>=,<=	
System last started	>=,<=	
KSC extended status	in	Extended status of the device. More than one value can be selected.
Real-time protection status	=	Status of Kaspersky applications installed on the managed device.
Encryption status	=	
Spam protection status	=	
Anti-virus protection status of mail servers	=	
Data Leakage Prevention status	=	
KSC extended status ID	=	
Endpoint Sensor status	=	
Last seen at	>=,<=	

3. Use the **Test conditions** button to make sure that the specified filter is correct. When you click the button, you should see the **Assets for given conditions** window containing a list of assets that satisfy the search conditions.

- **Reactive**—the category will be filled with assets by using correlation rules.

5. Click **Save**.

The new category will be added to the asset categories tree.

Configuring the table of assets

In OSMP, you can configure the contents and order of columns displayed in the assets table. These settings are stored locally on your machine.

To configure the settings for displaying the assets table:

1. In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Click the **Settings** icon (⫰) in the upper-right corner of the assets table.
3. In the drop-down list, select the check boxes next to the parameters that you want to view in the table:
   - **Name**
   - **FQDN**
   - **Single IP address**
   - **Categories**
   - **MAC address**
   - **Asset source**
   - **OS**
   - **Created by**
   - **Updated on**
   - **Last seen at**
   - **Tenant**—when the check box is selected and the column is displayed in the table of assets, the following assets filtering options are available on the drop-down list of the **Tenant** column:
     - **Show child instances only**—displays only assets of child instances within the selected tenant hierarchy level.
     - **Show parent instances only**—displays only assets of parent instances within the selected tenant hierarchy level.

       These options allow you to filter assets by the position of instances in the hierarchy that they belong to, helping you focus on either higher-level (parent) or lower-level (child) instances. The selected filter is applied immediately to the assets table.
   - **CII category**
   - **Archived**—when the check box is selected and the column is displayed in the table of assets, the following assets filtering options are available on the drop-down list of the **Archived** column:
     - **Yes**—displays only archived assets.
     - **No**—displays only active assets.
   - **Weight**
   - **KSC group**
   - **Telemetry received on**

- **Telemetry status**
- **EDR status**
- **Last connection to KSC**
- **Last connection to EDR**
- **EDR license**
- **EDR agent version**
- **EDR isolation**
- **AI score**

When you select a check box, the assets table is updated and a new column is added. When a check box is cleared, the column disappears. The table can be sorted based on multiple columns.

4. If you need to change the order of columns, click the left mouse button on the column name and drag it to the desired location in the table.

The assets table display settings are configured.

Searching assets

OSMP has two asset search modes. You can switch between the search modes using the buttons in the upper left part of the window:

- – simple search by the following asset settings: **Name**, **FQDN**, **IP address**, **MAC address**, and **Owner**.
- – advanced search for assets using filters by conditions and condition groups.

You can select the check boxes next to the found assets to export their data to a CSV file.

Simple search

To find an asset using simple search,

in the **Asset management** → **Assets (Devices)** → **Analysis and response** section, enter your search query in the **Search** field.

The table displays the assets with the **Name**, **FQDN**, **IP address**, **MAC address**, and **Owner** settings matching the search criteria.

Advanced search

To find an asset using advanced search:

1. In the **Asset management** → **Assets (Devices)** → **Analysis and response** section, click the funnel icon ( ).

   The asset filtering settings are displayed in the upper part of the window.

2. Specify the asset filtering settings and click the **Search** button.

   For details on asset filtering settings, see the table below.

The table displays the assets that meet the search criteria.

An advanced asset search is performed using the filtering conditions that can be specified in the upper part of the window:

- You can use the **Add condition** button to add a string containing fields for identifying the condition.
- You can use the **Add group** button to add a group of filters. Group operators can be switched between **AND**, **OR**, and **NOT**.
- Conditions and condition groups can be dragged with the mouse.
- Conditions, groups, and filters can be deleted by using the × button.
- You can collapse the filtering options by clicking the **Collapse** button. In this case, the resulting search expression is displayed. Clicking it displays the search criteria in full again.
- The filtering options can be reset by clicking the **Clear** button.
- The condition operators and available values of the right operand depend on the selected left operand:

Left operand	Available operators	Right operand
Build number	=, ilike	An arbitrary value.
OS	=, ilike	An arbitrary value.
IP address	inSubnet, inRange	An arbitrary value or a range of values. The filtering condition for the inSubnet operator is met if the IP address in the left operand is included in the subnet that is specified in the right operand. For example, the subnet for the IP address 10.80.16.206 should be specified in the right operand using slash notation as follows: `10.80.16.206/25`.
FQDN	=, ilike	An arbitrary value.
CVE	=, in	An arbitrary value. The **in** operator lets you specify an array of CVE (Common Vulnerabilities and Exposures) IDs, for example, `CVE-2017-0143`.
CVSS	>, >=, =, <=, <	A number from 0 to 10 (possible severity levels of the asset's CVE vulnerability). Not applicable for vulnerabilities from the Open Single Management Platform.

CVE count	>, >=, =, <=, <	Number. The number of unique vulnerabilities with the CVE attribute for the asset. Vulnerabilities without CVEs do not count towards this figure.
		If `0` is specified as the right operand and the `=` or `<=` operator is selected, the search results include assets that do not have CVE vulnerabilities.
		For searching by the number of CVEs of a certain severity level, you can use a combined condition. For example:
		`CVE count >= 1`
		`CVSS >= 6.5`

Software	=, ilike	An arbitrary value.
Software version	=, ilike, in	An arbitrary value. Version (build) number of the software installed on the asset.
Asset source	in	• Open Single Management Platform. • KICS/KATA. • Created manually
CII	in	• Information resource is not a CII object. • CII object without a significance category. • CII object of the third category of significance. • CII object of the second category of significance. • CII object of the first category of significance.
RAM (bytes)	=, >, >=, <, <=	Number.
Number of disks	=, >, >=, <, <=	Number.
Number of network cards	=, >, >=, <, <=	Number.
Disk free bytes	=, >, >=, <, <=	Number.
KSC group	=, ilike	An arbitrary value. The name of the Open Single Management Platform administration group to which the asset belongs.
Anti-virus databases last updated	>=, <=	For searching, the time is specified as UTC time, and then converted in the KUMA interface to the local time zone set in the browser. You can specify the date and time for this operand in one of the following ways: • Select the exact date in the calendar. • Select a period relative to the present time in the **Relative period** list. • Enter a value manually: an exact date and time or a relative period, or a combination of both. For details, check the *Using time values* subsection below.
Last update of the information	>=, <=	For searching, the time is specified as UTC time, and then converted in the KUMA interface to the local time zone set in the browser. You can specify the date and time for this operand in one of the following ways: • Select the exact date in the calendar. • Select a period relative to the present time in the **Relative period** list. • Enter a value manually: an exact date and time or a relative period, or a combination of both. For details, check the *Using time values* subsection below.
Protection last updated	>=, <=	For searching, the time is specified as UTC time, and then converted in the KUMA interface to the local time zone set in the browser. You can specify the date and time for this operand in one of the following ways: • Select the exact date in the calendar. • Select a period relative to the present time in the **Relative period** list. • Enter a value manually: an exact date and time or a relative period, or a combination of both. For details, check the *Using time values* subsection below.

System last started	>=, <=	For searching, the time is specified as UTC time, and then converted in the KUMA interface to the local time zone set in the browser. You can specify the date and time for this operand in one of the following ways: • Select the exact date in the calendar. • Select a period relative to the present time in the **Relative period** list. • Enter a value manually: an exact date and time or a relative period, or a combination of both. For details, check the *Using time values* subsection below.
KSC extended status	in	• The host with the Network Agent installed is connected to the network, but the Network Agent is not active • Anti-virus application is installed, but real-time protection is not running. • Anti-virus application is installed but not running. • Number of viruses detected is too high. • Anti-virus application is installed but the real-time protection status differs from the one set by the security administrator. • Anti-virus application is not installed. • Full scan for viruses performed too long ago. • Anti-virus bases were updated too long ago. • Network Agent has been inactive too long. • Old license. • Number of uncured objects is too high. • Reboot is required. • Incompatible applications are installed on the host • Host has one or more vulnerabilities. • The last scan for operating system updates on the host was too long ago • Invalid encryption status of the host • Mobile device settings do not meet the requirements of the security policy. • There are unhandled incidents. • Host status was suggested by the managed application. • Insufficient disk space on the host. Synchronization errors occur, or not enough disk space
Real-time protection status	=	• Unknown. • Stopped. • Suspended. • Starting. • Running (if anti-virus application does not support categories of state Running). • Running with maximum protection. • Running for maximum speed. • Running with recommended settings. • Running with custom settings. • Error.
Encryption status	=	• Encryption rules are not configured on the host. • Encryption is in progress. • Encryption was canceled by the user. • Encryption error occurred. • All host encryption rules are met. • Encryption is in progress, the host must be restarted. • Encrypted files without specified encryption rules are detected on the host.
Spam protection status	=	• Unknown. • Stopped. • Suspended. • Starting. • Running. • Error. • Not installed. • No license.
Anti-virus protection status of mail servers	=	• Unknown. • Stopped. • Suspended. • Starting. • Running. • Error. • Not installed. • No license.
Data Leakage Prevention status	=	• Unknown. • Stopped. • Suspended. • Starting. • Running. • Error. • Not installed. • No license.
KSC extended	=	• OK

status ID		• Critical. • Warning.
Endpoint Sensor status	=	• Unknown. • Stopped. • Suspended. • Starting. • Running. • Error. • Not installed. • No license.
Last visible	>=, <=	For searching, the time is specified as UTC time, and then converted in the KUMA interface to the local time zone set in the browser. You can specify the date and time for this operand in one of the following ways: • Select the exact date in the calendar. • Select a period relative to the present time in the **Relative period** list. • Enter a value manually: an exact date and time or a relative period, or a combination of both. For details, check the *Using time values* subsection below.
Score ML	=, >, >=, <, <=	Number. Asset score assigned by AI services.
Status	=, in	Asset status assigned by AI services: • Low. • Medium. • High. • Critical.
Custom asset field	=, ilike	An arbitrary value. Search custom fields of assets.

Using time values

Some conditions, for example, **Anti-virus databases last updated** or **System last started**, use date and time as the operand value. For these conditions, you can use an exact date and time or a relative period.

To specify a date and time value:

1. Select an operand, an operator and click the date field.
2. Do one of the following:

   - Select the exact date in the calendar.

     By default, the current time is automatically added to the selected date, with millisecond precision. Changing the date in the calendar does not change the specified time. The date and time are displayed in the time zone of the browser. If necessary, you can edit the date and time in the field.

   - In the **Relative period** list, select a relative period.

     The period is calculated relative to the start time of the current search and takes into account asset information that is up-to-date at that moment. For example, for the condition **Anti-virus databases last updated**, you can select **1 hour** and the **>=** operator to find those assets for which the anti-virus databases have not been updated for more than 1 hour.

   - In the date and time field, enter a value manually.

     You can enter an exact date and time in the **DD.MM.YYYY HH:mm:ss.SSS** format for the Russian localization and **YYYY-MM-DD HH:mm:ss.SSS** for the English localization or a relative period as a formula. You can also combine these methods if necessary.

     If you do not specify milliseconds when entering the exact date, 000 is substituted automatically.

In the relative period formulas, you can use the **now** parameter for the current date and time and the interval parameterization language: **+**, **-**, **/** (rounding to the nearest), as well as time units: **y** (year), **M** (month), **w** (week), **d** (day), **h** (hour), **m** (minute), **s** (second).

For example, for the **Information last updated** condition, you can specify **now-2d** with the **>=** operator and **now-1d** with the **>=** operator to find assets whose information was last updated the day before the search was started; or you can specify **now/w** with the **<=** operator to find assets whose information was last updated between the start of the first day of the current week (00:00:00:000 UTC) and the current time, **now**.

KUMA stores time values in UTC, but in the user interface time is converted to the time zone of your browser. This is relevant to the relative periods: **Today**, **Yesterday**, **This week**, and **This month**. For example, if the time zone in your browser is UTC+3, and you select **Today** as the period, the category will cover assets from 03:00:00.000 until now, not from 00:00:00.000 until now.

If you want to take your time zone into account when selecting a relative period, such as **Today**, **Yesterday**, **This week**, or **This month**, you need to manually add a time offset in the date and time field by adding or subtracting the correct number of hours. For example, if your browser's time zone is UTC+3 and you want the categorization to cover the **Yesterday** period, you need to change the value to **now-1d/d-3h**. If you want the categorization to cover the **Today** period, change the value to **now/d-3h**.

Exporting asset data

You can export data about the assets displayed in the assets table as a CSV file.

To export asset data:

1. Configure the assets table.

   Only the data specified in the table is written to the file. The display order of the asset table columns is preserved in the exported file.

2. Find the desired assets and select the check boxes next to them.

   You can select all the assets in the table at a time by selecting the check box in the left part of the assets table header.

3. Click the **Export CSV** button.

The asset data is written to the assets_<export date>_<export time>.csv file. The file is downloaded according to your browser settings.

Viewing asset details

To view information about an asset, open the asset information window in one of the following ways:

- In the main menu, select the **Asset management** section → select a category with the relevant assets → select an asset.
- In the main menu, select **Alerts** → click the link with the relevant alert → select the asset in the **Related endpoints** section.
- In the main menu, select the **Events** section → search and filter events → select the relevant event → click the link in one of the following fields: SourceAssetID, DestinationAssetID, or DeviceAssetID.

The following information may be displayed in the asset details window:

- **Name, ID**—asset name, ID.

  Assets imported into OSMP retain the names that were assigned to them at the source. You can change these asset names in the OSMP web interface.

- **Tenant**—the name of the tenant that owns the asset.

- **Archived**—archival status of the asset. Possible values: Yes, No.

- **KSC group**—the KSC server group to which the asset belongs.

- **Asset source**—source of information about the asset. There may be multiple sources. For instance, information can be added in the OSMP web interface or by using the API, or it can be imported from the Open Single Management Platform and KICS/KATA.

  When using multiple sources to add information about the same asset to OSMP, you should take into account the rules for merging asset data.

- **Created**—date and time when the asset was added to OSMP.

- **Updated**—date and time when the asset information was most recently modified.

- **Owner**—owner of the asset, if provided.

- **IP address**—IP address of the asset (if any).

  > If there are several assets with identical IP addresses in OSMP, the asset that was added the latest is returned in all cases when assets are searched by IP address. If assets with identical IP addresses can coexist in your organization's network, plan accordingly and use additional attributes to identify the assets. For example, this may become important during correlation.

- **FQDN**—Fully Qualified Domain Name of the asset, if provided.

- **MAC address**—MAC address of the asset (if any).

- **Operating system**—operating system of the asset.

- The **Score AI** is a number that quantifies how non-typical the activity on the asset is, and whether it is worth paying attention to. Possible values of the **Status AI** field: **Low**, **Medium**, **High**, **Critical**. The score is a number in the range from 0 to 1.

- **Isolation status** is the network isolation status of the asset. You can view and change the device's network isolation status by clicking the **Settings** link next to the status. This field is displayed if the Kaspersky Endpoint Security application with a built-in agent is installed on an asset (device).

- **CII category**—information about whether an asset is a critical information infrastructure (CII) object.

- **Related alerts**—alerts associated with the asset (if any).

  To view the list of alerts related to an asset, click the **Find in Alerts** link. This opens the **Alerts** tab with the search expression set to filter all assets with the corresponding asset ID.

- **Software info** and **Hardware info**—if the asset software and hardware parameters are provided, they are displayed in this section.

- Asset vulnerability information:
  - **Kaspersky Security Center vulnerabilities**—vulnerabilities of the asset, if provided. This information is available for the assets imported from the Open Single Management Platform.

    You can learn more about the vulnerability by clicking the icon, which opens the Kaspersky Threats portal. You can also update the vulnerabilities list by clicking the **Update** link and requesting updated information from Open Single Management Platform.
  - **KICS/KATA vulnerabilities**—vulnerabilities of the asset, if any. This information is available for the assets imported from KICS/KATA.
- Asset source information:
  - **Last visible**—time when information about the asset was last received from Open Single Management Platform. This information is available for the assets imported from the Open Single Management Platform.
  - **Host ID**—ID of the Open Single Management Platform *Network Agent* from which the asset information was received. This information is available for the assets imported from the Open Single Management Platform. This ID is used to determine the uniqueness of the asset in Open Single Management Platform.
  - **KICS/KATA server IP address** and **KICS/KATA connector ID**—data on the KICS/KATA instance from which the asset was imported.
- **Custom fields**—data written to the asset custom fields.
- Additional information about the protection settings of an asset with Kaspersky Endpoint Security for Windows or Kaspersky Endpoint Security for Linux installed:
  - **KSC extended status ID** – asset status. It can have the following values:
    - OK
    - Critical
    - Warning
  - **KSC extended status** – information about the asset status. For example, **Anti-virus databases were updated too long ago**.
  - **Real-time protection status** – status of Kaspersky applications installed on the asset. For example: **Running (if anti-virus application does not support categories of state Running)**.
  - **Encryption status** – information about asset encryption. For example: **Host doesn't have any encryption rules**.
  - **Spam protection status** – status of anti-spam protection. For example, **Starting**.
  - **Anti-virus protection status of mail servers** – status of the virus protection of mail servers. For example, **Starting**.
  - **Data Leakage Prevention status** – status of data leak protection. For example, **Starting**.
  - **Endpoint Sensor status** – status of data leak protection. For example, **Starting**.
  - **Anti-virus databases last updated** – the version of the downloaded anti-virus databases.

- **Protection last updated** – the time when the anti-virus databases were last updated.
- **System last started**—the time when the system was last started.
- **Information last updated** is the time of the last appearance of the asset on the network. For searching, the time is specified as UTC time, and then converted in the interface to the local time zone set in the browser.

  This information is displayed if the asset was imported from Open Single Management Platform.

- **Categories**—categories associated with the asset (if any).

By clicking the **Move to KSC group** button, you can move the asset that you are viewing between Open Single Management Platform administration groups. You can also click the **Start task** drop-down list to run tasks available on the asset:

- By clicking the **KSC response** button, you can start an Open Single Management Platform task on the asset.
- By clicking the **KEDR response** button, you can run a Kaspersky Endpoint Detection and Response task on the asset.
- By clicking the **Refresh KSC asset** button, you can run a task to refresh information about the asset from Open Single Management Platform.

The tasks are available when integrated with Open Single Management Platform and when integrated with Kaspersky Endpoint Detection and Response.

Adding assets

You can add asset information in the following ways:

- Manually.

  You can add an asset using OSMP Console or the API.

- Import assets.

  You can import assets **from Kaspersky Security Center**, KICS for Networks and MaxPatrol VM.

  All assets that are protected by this program are registered in Kaspersky Security Center. Information about assets protected by Kaspersky Security Center can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

  KUMA imports the following device information received from Kaspersky Security Center Network Agents:

  - Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
  - Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

To import information about the Kaspersky Security Center assets:

1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Click **Import**, and then select one of the following actions:
   - To import information about the basic attributes of assets, click **Import KSC assets**.

     This opens the **Import KSC assets** window.
   - To import information about other attributes of assets, click **Import KSC assets attributes**.

     This opens the **Import KSC assets attributes** window.
3. In the drop-down list, select the tenant for which you want to perform the import.

   In this case, the program downloads information about all assets of all Kaspersky Security Center servers that have been configured to connect to the selected tenant.

   If you want to import information about all assets of all Kaspersky Security Center servers for all tenants, select **All**.
4. Click the **Import** button.

The asset information will be imported.

Also, in a tenant properties window, you can schedule regular import of asset information or run import manually.

When assets are added, assets that already exist in OSMP can be merged with the assets being added.

Asset merging algorithm:

1. Checking uniqueness of Kaspersky Security Center or KICS for Networks assets.
   - The uniqueness of an asset imported from Kaspersky Security Center is determined by the **Host ID** parameter, which contains the Kaspersky Security Center Network Agent *Network Agent* identifier. If two assets' IDs differ, they are considered to be separate assets and are not merged.
   - The uniqueness of an asset imported from KICS for Networks is determined by the combination of the **IP address**, **KICS for Networks server IP address**, and **KICS for Networks connector ID** parameters. If any of the parameters of two assets differ they are considered to be separate assets and are not merged.

   If the compared assets match, the algorithm is performed further.
2. Make sure that the values in the **IP**, **MAC**, and **FQDN** fields match.

   If at least two of the specified fields match, the assets are combined, provided that the other fields are blank.

   Possible matches:
   - The FQDN and IP address of the assets match. The **MAC** field is blank.

     The check is performed against the entire array of IP address values. If the IP address of an asset is included in the FQDN, the values are considered to match.
   - The FQDN and MAC address of the assets match. The **IP** field is blank.

     The check is performed against the entire array of MAC address values. If at least one value of the array fully matches the FQDN, the values are considered to match.

- The IP address and MAC address of the assets match. The **FQDN** field is blank.

  The check is performed against the entire array of IP- and MAC address values. If at least one value in the arrays is fully matched, the values are considered to match.

3. Make sure that the values of at least one of the **IP**, **MAC**, or **FQDN** fields match, provided that the other two fields are not filled in for one or both assets.

   Assets are merged if the values in the field match. For example, if the FQDN and IP address are specified for a KUMA asset, but only the IP address with the same value is specified for an imported asset, the fields match. In this case, the assets are merged.

   For each field, verification is performed separately and ends on the first match.

Examples of asset field comparison are displayed here.

Information about assets can be generated from various sources. If the added asset and the OSMP asset contain data received from the same source, this data is overwritten. For example, a Kaspersky Security Center asset receives a fully qualified domain name, software information, and host ID when imported into OSMP. When importing an asset from Kaspersky Security Center with an equivalent fully qualified domain name, all this data will be overwritten (if it has been defined for the added asset). All fields in which the data can be refreshed are listed in the Updatable data table.

Updatable data

Field name	Update procedure
Name	Selected according to the following priority: • Manually defined. • Received from Kaspersky Security Center. • Received by KICS for Networks.
Owner	The first value from the sources is selected according to the following priority: • Received from Kaspersky Security Center. • Manually defined.
Single IP address	The data is merged. If the array of addresses contains identical addresses, the copy of the duplicate address is deleted.
FQDN	The first value from the sources is selected according to the following priority: • Received from Kaspersky Security Center. • Received by KICS for Networks. • Manually defined.
MAC address	The data is merged. If the array of addresses contains identical addresses, one of the duplicate addresses is deleted.
Operating system	The first value from the sources is selected according to the following priority: • Received from Kaspersky Security Center. • Received by KICS for Networks. • Manually defined.
Vulnerabilities	KUMA asset data is supplemented with information from the added assets. In the asset details, data is grouped by the name of the source. Vulnerabilities are eliminated for each source separately.
Software info	Data from KICS for Networks is always recorded (if available). For other sources, the first value is selected according to the following priority: • Received from Kaspersky Security Center. • Manually defined.
Hardware info	The first value from the sources is selected according to the following priority: • Received from Kaspersky Security Center. • Defined via the API.

The updated data is displayed in the asset details. You can view asset details in OSMP Console.

This data may be overwritten when new assets are added. If the data used to generate asset information is not updated from sources for more than 30 days, the asset is deleted. The next time you add an asset from the same sources, a new asset is created.

If you are using OSMP Console to edit asset information that was received from Kaspersky Security Center or KICS for Networks, you can edit the following asset data:

- Name.
- Category.

If asset information was added manually, you can edit the following asset data when editing these assets in OSMP Console:

- Name
- Name of the tenant that owns the asset.
- IP address.
- Fully qualified domain name.
- MAC address.
- Owner.
- Category.
- Operating system.
- Hardware info.

Asset data cannot be edited via the REST API. When importing from the REST API, the data is updated according to the rules for merging asset details provided above.

Adding asset information in OSMP

To add an asset in OSMP:

1. In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**, and then click **Add**.

   The **Add asset** details area opens in the right part of the window.

2. Enter the asset parameters:

   - **Asset name** (required)
   - **Tenant** (required)
   - **IP address** and/or **FQDN** (required) You can specify multiple FQDNs by clicking **Add FQDN**.

- **MAC address.**
- **Owner.**

3. If necessary, manage the settings on the following tabs:
   - The **Additional** tab contains information about the owner, category, and operating system of the asset.
   - The **Hardware** tab contains information about the hardware of the asset.
4. Click **Add**.

   The asset is created and displayed in the assets table in the category assigned to it or in the **Uncategorized assets** category.

Importing asset information from Kaspersky Security Center

All assets that are protected by this program are registered in Kaspersky Security Center. Information about assets protected by Kaspersky Security Center can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

KUMA imports the following device information received from Kaspersky Security Center Network Agents:

- Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
- Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

To import information about the Kaspersky Security Center assets:

1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Click **Import**, and then select one of the following actions:
   - To import information about the basic attributes of assets, click **Import KSC assets**.

     This opens the **Import KSC assets** window.
   - To import information about other attributes of assets, click **Import KSC assets attributes**.

     This opens the **Import KSC assets attributes** window.
3. In the drop-down list, select the tenant for which you want to perform the import.

   In this case, the program downloads information about all assets of all Kaspersky Security Center servers that have been configured to connect to the selected tenant.

   If you want to import information about all assets of all Kaspersky Security Center servers for all tenants, select **All**.
4. Click the **Import** button.

   The asset information will be imported.

Also, in a tenant properties window, you can schedule regular import of asset information or run import manually.

Importing asset information from KICS for Networks

Information about assets protected by KICS for Networks can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

After configuring KICS for Networks integration, tasks to obtain data about KICS for Networks assets are created automatically. This occurs:

- Immediately after creating a new integration.
- Immediately after changing the settings of an existing integration.
- According to a regular schedule every several hours. Every 12 hours by default. The schedule can be changed.

Account data update tasks can be created manually.

To configure a task to update KICS for Networks asset data for a tenant:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant into which you want to import KICS/KATA assets.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Assets settings**.
4. On the **KICS/KATA import** tab, make sure that the **State** toggle switch is turned on.
5. Configure the asset data import:
   - To schedule regular import, in the **Import interval (hours)** field, specify the time interval at which OSMP updates data about KICS/KATA assets.
   - To run import manually, click the **Import** button.

A **task** to receive account data from the selected tenant is added to the Task manager section of OSMP Console.

Examples of asset field comparison during import

Each imported asset is compared to the matching OSMP asset.

Checking for two-field value match in the IP, MAC, and FQDN fields

Compared assets	Compared fields		
	FQDN	IP	MAC
KUMA asset	Yes	Filled in	Empty
Imported asset 1	Yes, matching	Filled in, matching	Filled in
Imported asset 2	Filled in, matching	Filled in, matching	Empty
Imported asset 3	Yes, matching	Empty	Filled in
Imported asset 4	Empty	Filled in, matching	Filled in
Imported asset 5	Filled in, matching	Empty	Empty
Imported asset 6	Empty	Empty	Filled in

Comparison results:

- Imported asset 1 and OSMP asset: the FQDN and IP fields are filled in and match, no conflict in the MAC fields between the two assets. The assets are merged.
- Imported asset 2 and OSMP asset: the FQDN and IP fields are filled in and match. The assets are merged.
- Imported asset 3 and OSMP asset: the FQDN and MAC fields are filled in and match, no conflict in the IP fields between the two assets. The assets are merged.
- Imported asset 4 and OSMP asset: the IP fields are filled in and match, no conflict in the FQDN and MAC fields between the two assets. The assets are merged.
- Imported asset 5 and OSMP asset: the FQDN fields are filled in and match, no conflict in the IP and MAC fields between the two assets. The assets are merged.
- Imported asset 6 and OSMP asset: no matching fields. The assets are not merged.

Checking for single-field value match in the IP, MAC, and FQDN fields

Compared assets	Compared fields		
	FQDN	IP	MAC
OSMP asset	Empty	Filled in	Empty
Imported asset 1	Filled in	Filled in, matching	Filled in
Imported asset 2	Filled in	Filled in, matching	Empty
Imported asset 3	Filled in	Empty	Filled in
Imported asset 4	Empty	Empty	Filled in

Comparison results:

- Imported asset 1 and OSMP asset: the IP fields are filled in and match, no conflict in the FQDN and MAC fields between the two assets. The assets are merged.
- Imported asset 2 and OSMP asset: the IP fields are filled in and match, no conflict in the FQDN and MAC fields between the two assets. The assets are merged.
- Imported asset 3 and OSMP asset: no matching fields. The assets are not merged.
- Imported asset 4 and OSMP asset: no matching fields. The assets are not merged.

Assigning a category to an asset

Assign a category to one asset in the properties of the asset

This method is not suitable for assigning a category to KSC or KICS assets. Follow the instructions to assign a category to one or more assets.

To assign a category to one asset:

1. In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Click the **Show navigation** button and select the tenant and the category that includes the assets that you need.

   The assets table is displayed.
3. Select an asset and in the menu, select **Show more**.
4. In the opened window, click the **Edit** button.
5. On the **Additional** tab, in the **Categories** field, select a category.

   If you want to move an asset to the **Uncategorized assets** section, you must delete the existing categories for the asset by clicking the × button.
6. Click **Save**.

The category will be assigned.

Assigning a category to one or more assets

To assign a category to one or more assets:

1. In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Click the **Show navigation** button and select the tenant and the category that includes the assets that you need.

   The assets table is displayed.
3. Select the check boxes next to the assets for which you want to change the category.
4. Click the **Link to category** button.
5. In the opened window, select a category.
6. Click the **Bind** button.

The category will be assigned.

Do not assign the `Categorized assets` category to assets.

Linking a group of assets to a category

To link a group of assets to a category:

1. In the **Asset management** section, select the check box in the header of the table of assets.
2. Select all assets visible on the page or all assets that match the selection condition.

   The **Link to category** button becomes active and opens the available categories.
3. Click the **Link to category** button and select one or more categories to link to.
4. Click **OK**.

   Assets are linked to the selected categories or folder.

Unlinking a group of assets from a category

To unlink a group of assets from a category:

1. Select one category (tenant) in the navigation pane.

   The list of assets in that category is displayed.

   The **Clean category** button is added to the folder properties.

2. In the context menu of the category, select **Clean category**.

   A dialog box is displayed with a confirmation prompt and the number of assets that will be unlinked.

   This option lets you unlink all assets in the selected category, not only those that are visible on the page. Assets in child categories are not unlinked.

3. In the dialog box, click **OK**.

   All selected assets are unlinked from the selected category.

Editing the parameters of assets

In OSMP, you can edit asset parameters. All the parameters of manually added assets can be edited. For assets imported from Kaspersky Security Center, you can only change the name of the asset and its category.

To change the parameters of an asset:

1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.

2. Select the category with the relevant assets.

   The assets table is displayed.

3. Select an asset, and then click **Details**.

4. In the opened window, click the **Edit** button.

   The **Edit asset** window opens.

5. Make the changes you need in the available fields:

   - **Asset name** (required) This is the only field available for editing if the asset was imported from Kaspersky Security Center or KICS for Networks.
   - **IP address** and/or **FQDN** (required) You can specify multiple FQDNs separated by commas.
   - **MAC address.**
   - **Owner.**
   - **Software info**:
     - **OS name**
     - **OS build**
   - **Hardware info**:

     Hardware parameters

     You can add information about asset hardware to the **Hardware info** section:

Available fields for describing the asset CPU:

- **CPU name**
- **CPU frequency**
- **CPU core count**

  You can add CPUs to the asset by using the **Add CPU** button.

Available fields for describing the asset disk:

- **Disk free bytes**
- **Disk volume**

  You can add disks to the asset by using the **Add disk** button.

Available fields for describing the asset RAM:

- **RAM frequency**
- **RAM total bytes**

Available fields for describing the asset network card:

- **Network card name**
- **Network card manufacture**
- **Network card driver version**

  You can add network cards to the asset by using the **Add network card** button.

- Custom fields.
- CII category.

6. On the **Additional** tab, in the **Categories** field, select a category.

> You can also select the asset and then drag and drop it into the relevant category. This category will be added to the list of asset categories.

> Do not assign the `Categorized assets` category to assets.

7. Click **Save**.

Asset parameters have been changed.

Archiving assets

In OSMP, the archival functionality is available for the following types of assets:

- For assets imported from Kaspersky Security Center and KICS.

  If OSMP could not receive information about the asset after attempting import ten times, the asset is automatically archived and is stored in the database for the time that you can specify in the **TTL for archived assets (days)** setting. The default setting is 0 days. This means that archived assets are stored indefinitely. An archived asset becomes active if OSMP receives information about the asset from the source before the retention period for archived assets expires.

- Combined assets

  When importing, OSMP performs a check for uniqueness among assets imported from Kaspersky Security Center and KICS, and among manually added assets. If the fields of an imported asset and a manually added asset match, the assets are combined into a single asset, which is considered imported and can become archived.

- Assets added manually in the console or using the API are archived and stored in the database for the time specified in the **TTL for archived assets (days)** setting. The default setting is 0 days. This means that archived assets are stored indefinitely. You can use the **Unarchive assets** option if you want to make the asset active before the retention period for archived assets expires.

An asset becomes archived under the following conditions:

- You use the **Archive assets** option for the assets created manually in the console or using the API.

- OSMP could not fetch information about the asset from Kaspersky Security Center or KICS for Networks after attempting import ten times.

- Disabled integration with Kaspersky Security Center.

  If you disable integration with Kaspersky Security Center, the asset is considered active for 30 days. After 30 days, the asset is automatically archived and is stored in the database for the time specified in the **TTL for archived assets (days)** field.

An asset is not updated in the following cases:

- Information about the Kaspersky Security Center asset has not been updated for more than the retention period of archived assets.

- Information about the asset does not exist in Kaspersky Security Center or KICS for Networks.

- Connection with the Kaspersky Security Center Server has not been established for more than 30 days.

To change the archive status for an asset or a group of assets created manually:

1. In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**.

   This opens the table of assets.

2. On the table of assets select the check boxes next to the assets created manually for which you want to change the archive status.

3. On the toolbar in the upper part of the assets table, click one of the following buttons:

   - Archive assets to archive selected assets.
   - **Unarchive assets** to restore the selected archived assets.

   The archive status of the asset is changed. You can filter assets out by their archive status in the assets table in the **Archived** column drop-down list by selecting one of the options: **Yes** to display only archived assets and **No** to display only active assets.

To configure the archived assets retention period:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant for which you want to change the archived assets retention period.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Assets settings**.
4. On the **General** tab, enter the new value in the **TTL for archived assets (days)** field.

   The default setting is 30 days. Enter 0 to retain archived assets indefinitely.
5. Click **Save**.

The retention period for archived assets is configured.

Information about the archived asset remains available for viewing in the alert and incident card.

To view an archived asset card:

1. In the main menu, under **Monitoring**, select the **Alerts** or **Incidents** section.

   A list of alerts or incidents is displayed.
2. Open the alert or incident card linked to the archived asset.

   You can view the information in the archived asset card.

Deleting assets

You can delete assets on the **Administration and protection** tab. On the **Analysis and response** tab, OSMP deletes only archived assets and only automatically. You cannot delete the assets manually. OSMP deletes an archived asset if the information about the asset has not been updated for longer than the retention period of archived assets.

Deleting an asset category

Category deletion is performed in two stages: archiving and permanent deletion. Archiving allows you to verify whether the category is still referenced by any resources before it is permanently removed from the system.

When a category is archived on a parent OSMP instance, the corresponding category on all child OSMP instances is also archived. The system then checks whether any resources still reference the archived category. If no references remain, the category is permanently deleted.

To delete an asset category:

1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. In the category tree, click the (⋮) icon next to the category you want to delete.
3. In the context menu, select **Archive**.
4. In the **Delete category?** dialog box, click **OK** to confirm.

If resources are still linked to the category, the category remains archived until all references are removed.

Archived categories do not appear in the category list, but may remain available in filters that reference the category. Category properties remain available for viewing, and resource associations can be removed. Modification of category properties is prohibited, except for the category name.

Additional restrictions apply to categories that contain child categories:

- A parent category cannot be archived or deleted while it has at least one non-archived child category.
- All child categories must be archived or permanently deleted before the parent category can be removed.
- Once all child categories are archived, the parent category follows the standard archiving and deletion process.

A category is permanently deleted only when all references to the category have been removed and all hierarchy constraints are satisfied.

Bulk deletion of assets

In the OSMP web interface, you can select multiple assets using a filter and delete all selected assets.

To delete assets, you must have rights to delete assets.

Bulk deletion of assets

To delete all selected assets:

1. In the main window of the application, go to the **Asset management** section and select an asset category.

   A table of assets is displayed.
2. Select the check box in the heading of the table of assets.

   You can delete all assets or all assets currently displayed on the page.
3. Click **Select all in page** or **Select all**.

   The **Delete** button becomes active.

4. Click the **Delete** button.

   This opens a window prompting you to confirm deletion and telling you that deleted assets will not be available in alerts, incidents, and widgets.

   In the lower part of the page, the number of assets selected for deletion is displayed.

5. Click **OK**.

   If you clicked **Select all**, you must enter the displayed generated string into the text box in the window to confirm deletion.

All selected assets are deleted.

Deleting asset folders

To delete a folder, you can either unlink all assets from the folder (which unlinks the assets but not does not delete them) and then delete the folder itself, or delete all assets and then delete the folder.

Updating third-party applications and fixing vulnerabilities on Kaspersky Security Center assets

You can update third-party applications (including Microsoft applications) that are installed on Kaspersky Security Center assets, and fix vulnerabilities in these applications.

First you need to create the *Install required updates and fix vulnerabilities* task on the selected Kaspersky Security Center Administration Server with the following settings:

- Application—Kaspersky Security Center.
- Task type—*Install required updates and fix vulnerabilities*.
- Devices to which the task will be assigned—you need to assign the task to the root administration group.
- Rules for installing updates:
  - Install approved updates only.
  - Fix vulnerabilities with a severity level equal to or higher than (optional setting).

    If this setting is enabled, updates fix only those vulnerabilities for which the severity level set by Kaspersky is equal to or higher than the value selected in the list (*Medium*, *High*, or *Critical*). Vulnerabilities with a severity level lower than the selected value are not fixed.
- Scheduled start—the task run schedule.

For details on how to create a task, please refer to the *Kaspersky Security Center Help Guide*.

The *Install required updates and fix vulnerabilities* task is available with a Vulnerability and Patch Management license.

Next, you need to install updates for third-party applications and fix vulnerabilities on assets in OSMP.

To install updates and fix vulnerabilities in third-party applications on an asset in OSMP:

1. Open the asset details window in one of the following ways:

   - In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**, select a category with the relevant assets, then select an asset, and then click **Details**.

   - In the main menu, go to **Monitoring** → **Threat hunting**. Search and filter events. Then select the event that you need and follow the link in one of the following fields: SourceAssetID, DestinationAssetID, or DeviceAssetID.

2. In the asset details window, expand the list of **Kaspersky Security Center vulnerabilities**.

3. Select the check boxes next to the applications that you want to update.

4. Click the **Upload updates** link.

5. In the opened window, select the check box next to the ID of the vulnerability that you want to fix.

6. If **No** is displayed in the **EULA accepted** column for the selected ID, click the **Approve updates** button.

7. Click the link in the **EULA URL** column and carefully read the text of the End User License Agreement.

8. If you agree to it, click **Accept selected EULAs**.

   The ID of the vulnerability for which the EULA was accepted shows **Yes** in the **EULA accepted successfully** column.

9. Repeat steps 7–10 for each required vulnerability ID.

10. Click **OK**.

    Updates will be uploaded and installed on the assets managed by the Administration Server where the task was started, and on the assets of all secondary Administration Servers.

> The terms of the End User License Agreement for updates and vulnerability patches must be accepted on each secondary Administration Server separately.

Updates are installed on assets where the vulnerability was detected.

You can update the list of vulnerabilities for an asset in the asset details window by clicking the **Update** link.

Moving assets to a selected administration group

You can move assets to a selected administration group of Kaspersky Security Center. In this case, the group policies and tasks will be applied to the assets. For more details on Kaspersky Security Center tasks and policies, please refer to the *Kaspersky Security Center Help Guide*.

Administration groups are added to OSMP when the hierarchy is loaded during **import of assets from Kaspersky Security Center**. First, you need to configure OSMP integration with Kaspersky Security Center.

All assets that are protected by this program are registered in Kaspersky Security Center. Information about assets protected by Kaspersky Security Center can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

KUMA imports the following device information received from Kaspersky Security Center Network Agents:

- Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
- Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

To import information about the Kaspersky Security Center assets:

1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Click **Import**, and then select one of the following actions:
   - To import information about the basic attributes of assets, click **Import KSC assets**.

     This opens the **Import KSC assets** window.
   - To import information about other attributes of assets, click **Import KSC assets attributes**.

     This opens the **Import KSC assets attributes** window.
3. In the drop-down list, select the tenant for which you want to perform the import.

   In this case, the program downloads information about all assets of all Kaspersky Security Center servers that have been configured to connect to the selected tenant.

   If you want to import information about all assets of all Kaspersky Security Center servers for all tenants, select **All**.
4. Click the **Import** button.

The asset information will be imported.

Also, in a tenant properties window, you can schedule regular import of asset information or run import manually.

To move an asset to a selected administration group:

1. Open the asset details window in one of the following ways:
   - In the main menu, go to **Asset management** → **Assets (Devices)** → **Analysis and response**, select a category with the relevant assets, then select an asset, and then click **Details**.
   - In the main menu, go to **Monitoring** → **Alerts**, click the link with the relevant alert, and then select the asset in the **Assets** section, and then click **View properties**.
2. In the asset details window, click **Response** → **Move to group**.

3. Select the group in the opened window.

   The selected group must be owned by the same tenant as the asset.

4. Click **Save**.

   The selected asset will be moved.

To move multiple assets to a selected administration group:

1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Select the category with the relevant assets.
3. Select the check boxes next to the assets that you want to move to the group.
4. Click click **Response** → **Move to group**.

   The button is active if all selected assets belong to the same Administration Server.

5. Select the group in the opened window.
6. Click **Save**.

   The selected assets will be moved.

The specific group of an asset is displayed in the asset details.

Kaspersky Security Center assets information is updated in OSMP when information about assets is imported from Kaspersky Security Center. This means that a situation may arise when assets have been moved between administration groups in Kaspersky Security Center, but this information is not yet displayed in OSMP. When an attempt is made to move such an asset to an administration group in which it is already located, OSMP returns the **Failed to move assets to another KSC group** error.

Assets audit

OSMP can be configured to generate asset audit events under the following conditions:

- Asset was added to OSMP. The application monitors manual asset creation, as well as creation during import via the REST API and during import from **Kaspersky Security Center** or KICS for Networks.

  All assets that are protected by this program are registered in Kaspersky Security Center. Information about assets protected by Kaspersky Security Center can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

KUMA imports the following device information received from Kaspersky Security Center Network Agents:

- Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
- Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

To import information about the Kaspersky Security Center assets:

1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
2. Click **Import**, and then select one of the following actions:
   - To import information about the basic attributes of assets, click **Import KSC assets**.

     This opens the **Import KSC assets** window.
   - To import information about other attributes of assets, click **Import KSC assets attributes**.

     This opens the **Import KSC assets attributes** window.
3. In the drop-down list, select the tenant for which you want to perform the import.

   In this case, the program downloads information about all assets of all Kaspersky Security Center servers that have been configured to connect to the selected tenant.

   If you want to import information about all assets of all Kaspersky Security Center servers for all tenants, select **All**.
4. Click the **Import** button.

The asset information will be imported.

Also, in a tenant properties window, you can schedule regular import of asset information or run import manually.

- Asset parameters have been changed. A change in the value of the following asset fields is monitored:
  - Name
  - Single IP address.
  - MAC address.
  - FQDN
  - System

  Fields may be changed when an asset is updated during import.
- Asset was deleted from OSMP. The program monitors manual deletion of assets, as well as automatic deletion of assets imported from Kaspersky Security Center and KICS for Networks, whose data is no longer being received.
- Vulnerability info was added to the asset. The program monitors the appearance of new vulnerability data for assets. Information about vulnerabilities can be added to an asset, for example, when importing assets from Kaspersky Security Center or KICS for Networks.

- Asset vulnerability was resolved. The application monitors the removal of vulnerability information from an asset. A vulnerability is considered to be resolved if data about this vulnerability is no longer received from any sources from which information about its occurrence was previously obtained.
- Asset was added to a category. The application monitors the assignment of an asset category to an asset.
- Asset was removed from a category. The application monitors the deletion of an asset from an asset category.

By default, if asset audit is enabled, under the conditions described above, OSMP creates not only audit events (`Type = 4`), but also base events (`Type = 1`).

Asset audit events can be sent to storage or to correlators, for example.

Configuring an asset audit

To configure an asset audit:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant for which you want to configure an asset audit.

   This opens the tenant properties window.

   If you want to configure an asset audit for a new tenant, then first create the tenant.
3. On the **Settings** tab, click **Assets audit**.
4. For each condition for generating asset audit events, select the destination to where the created events will be sent:

   a. In the settings block of the relevant type of asset audit events, use the **Add destination** drop-down list to select the type of destination to which the created events should be sent:

   - Select **Storage** if you want events to be sent to storage.
   - Select **Correlator** if you want events to be sent to the correlator.
   - Select **Other** if you want to select a different destination.

     > This type of resource includes correlator and storage services that were created in previous versions of the program.

   In the **Add destination** window that opens you must define the settings for event forwarding.

   b. Use the **Destination** drop-down list to select an existing destination or select **Create** if you want to create a new destination.

   If you are creating a new destination, fill in the settings as indicated in the destination description.

   c. Click **Save**.

A destination has been added to the condition for generating asset audit events. Multiple destinations can be added for each condition.

5. Click **Save**.

The asset audit has been configured. Asset audit events will be generated for those conditions for which destinations have been added. Click **Save**.

Storing and searching asset audit events

Asset audit events are considered to be base events and do not replace audit events. Asset audit events can be searched based on the following parameters:

Event field	Value
DeviceVendor	`"Kaspersky"`
DeviceProduct	`KUMA`
DeviceEventCategory	`Audit assets`

Enabling and disabling an asset audit

You can enable or disable asset audit for a tenant.

To enable or disable an asset audit for a tenant:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant for which you want to enable or disable an asset audit.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Assets audit**.
4. Turn on or turn off the **Audit events collection** toggle switch.
5. Click **Save**.

By default, when asset audit is enabled, when an audit condition occurs, two types of events are simultaneously created: a base event and an audit event.

You can disable the generation of base events with audit events.

To enable or disable the creation of base events for an individual condition:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant for which you want to enable or disable a condition for generating asset audit events.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Assets audit**.

4. Click a condition action name to enable or disable creation of the corresponding base events.

5. Click **Save**.

For disabled conditions, only audit events are created, and base events are not created.

Custom asset fields

In addition to the existing fields of the asset data model, you can create custom asset fields. Data from the custom asset fields is displayed when you view information about the asset. You can put data in custom fields either manually or using the API.

You can create or edit the custom fields in OSMP in the **Assets** section, in the **Custom fields** table. The table has the following columns:

- **Name** – the name of the custom field that is displayed when you view information about the asset.
- **Default value** – the value that is written to the custom field when an asset is added to KUMA.
- **Mask** – a regular expression to which the value in the custom field must match.

To create a custom asset field:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant for which you want to change the archived assets retention period.

   This opens the tenant properties window.
3. On the **Settings** tab, click **Assets settings**.
4. On the **General** tab, under **Custom fields** field, click **Add** button.

   An empty row is added to the **Custom fields** table. You can add multiple rows with the custom field settings at once.
5. Fill in the columns with the settings of the custom field:
   - **Name** (required)–from 1 to 128 characters in Unicode encoding.
   - **Default value**–from 1 to 1,024 Unicode characters.
   - **Mask**–from 1 to 1,024 Unicode characters.
6. Click **Save**.

A custom field is added to the asset data model.

To delete or edit a custom asset field:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the tenant for which you want to change the archived assets retention period.

   This opens the tenant properties window.

3. On the **Settings** tab, click **Assets settings**.

4. On the **General** tab, make the necessary changes in the **Custom fields** table:

   - To delete a custom field, select the check box next to the required field, and then click the **Delete** button. Deleting a field also deletes the data written in this field for all assets.

   - You can change the values of the field settings. Changing the default value does not affect the data written in the asset fields before.

   - To change the display order of the fields, use the **Move up** and **Move down** buttons.

5. Click **Save**.

   The changes are made.

Critical information infrastructure assets

In OSMP, you can tag assets related to the critical information infrastructure (CII) of the Russian Federation. This allows you to restrict the OSMP users capabilities to handle alerts and incidents, which are associated with the assets related to the CII objects.

> You can assign the CII category to assets if the license with the GosSOPKA module is active in OSMP.

Main administrators and users with the **Access to CII facilities** check box selected in their profiles can assign the CII category to an asset. If none of these conditions are met, the following restrictions apply to the user:

- The **CII category** group of settings is not displayed in the **Asset details** and **Edit asset** windows. You cannot view or change the CII category of an asset.

- Alerts and incidents associated with the assets of the CII category are not available for viewing. You cannot perform any actions on such alerts and incidents; they are not displayed in the table of alerts and incidents.

- The **CII** column is not displayed in the alert and incident tables.

- Alerts cannot be searched or closed using the REST API.

The CII category of an asset is displayed in the **Asset details** window in the **CII category** group of settings.

To change the CII category of an asset:

1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.

2. Select the category with the relevant assets.

   The assets table is displayed.

3. Select an asset, and then click **Details**.

   The **Asset details** window opens.

4. Click the **Edit** button and select one of the available values in the drop-down list:

   - **Information resource is not a CII object** – default value, indicating that the asset does not have a CII category. The users with the **Access to CII facilities** check box cleared in their profiles can work with such assets and the alerts and incidents related to these assets.
   - **CII object without a significance category**.
   - **CII object of the third category of significance**.
   - **CII object of the second category of significance**.
   - **CII object of the first category of significance**.

5. Click **Save**.

Deploying Kaspersky applications

This section describes Kaspersky applications deployment on client devices in your organization by means of OSMP Console.

Scenario: Kaspersky applications deployment

This scenario explains how to deploy Kaspersky applications through OSMP Console. You can use the Protection deployment wizard, or you can complete all necessary steps manually.

Stages

Kaspersky applications deployment proceeds in stages:

1. **Downloading and creating installation packages**

   Download the package manually.

   If you cannot install Kaspersky applications by means of Kaspersky EDR Expert on some devices, for example, on remote employees' devices, you can create stand-alone installation packages for applications. If you use stand-alone packages to install Kaspersky applications, you do not have to create and run a remote installation task, nor create and configure tasks for Kaspersky Endpoint Security for Windows.

   Alternatively, you can download the distribution packages for Network Agent and security applications from the Kaspersky website. If the remote installation of the applications is not possible for some reason, you can use the downloaded distribution packages to install the applications locally.

2. **Creating, configuring, and running the remote installation task**

   This step is part of the Protection deployment wizard. If you choose not to run the Protection deployment wizard, you must create this task manually and configure it manually.

   You also can manually create several remote installation tasks for different administration groups or different device selections. You can deploy different versions of one application in these tasks.

Make sure that all the devices on your network are discovered; then run the remote installation task (or tasks).

If you want to install Network Agent on devices with the SUSE Linux Enterprise Server 15 operating system, install the insserv-compat package first to configure Network Agent.

3. **Creating and configuring tasks**

   The *Update* task of Kaspersky Endpoint Security must be configured.

   Create this task manually and configure it manually. Make sure that the schedule for the task meets your requirements. (By default, the scheduled start for the task is set to **Manually**, but you might want to choose another option.)

4. **Creating policies**

   Create the policy for Kaspersky Endpoint Security manually. You can use the default policy settings. You can also modify the default settings of the policy in accordance with your needs at any time.

5. **Verifying the results**

   Make sure that deployment was completed successfully: you have policies and tasks for each application, and these applications are installed on the managed devices.

Results

Completion of the scenario yields the following:

- All required policies and tasks for the selected applications are created.
- The schedules of tasks are configured according to your needs.
- The selected applications are deployed, or scheduled to be deployed, on the selected client devices.

Protection deployment wizard

To install Kaspersky applications, you can use the Protection deployment wizard. The Protection deployment wizard enables remote installation of applications either through specially created installation packages or directly from a distribution package.

The Protection deployment wizard performs the following actions:

- Downloads an installation package for application installation (if it was not created earlier). The installation package is located at **Software management** → **Installation packages**. You can use this installation package for the application installation in the future.
- Creates and runs a remote installation task for specific devices or for an administration group. The newly created remote installation task is stored in the **Tasks** section. You can later start this task manually. The task type is **Install application remotely**.

If you want to install Network Agent on devices with the SUSE Linux Enterprise Server 15 operating system, install the insserv-compat package first to configure Network Agent.

Step 1. Starting Protection deployment wizard

You can start the Protection deployment wizard manually at any time.

To start the Protection deployment wizard manually,

In the main menu, go to **Discovery & deployment** → **Deployment & assignment** → **Protection deployment wizard**.

The Protection deployment wizard starts. Proceed through the wizard by using the **Next** button.

Step 2. Selecting the installation package

Select the installation package of the application that you want to install.

If the installation package of the required application is not listed, click the **Add** button and then select the application from the list.

Step 3. Selecting a method for distribution of key file or activation code

Select a method for the distribution of the key file or the activation code:

- **Do not add license key to installation package**

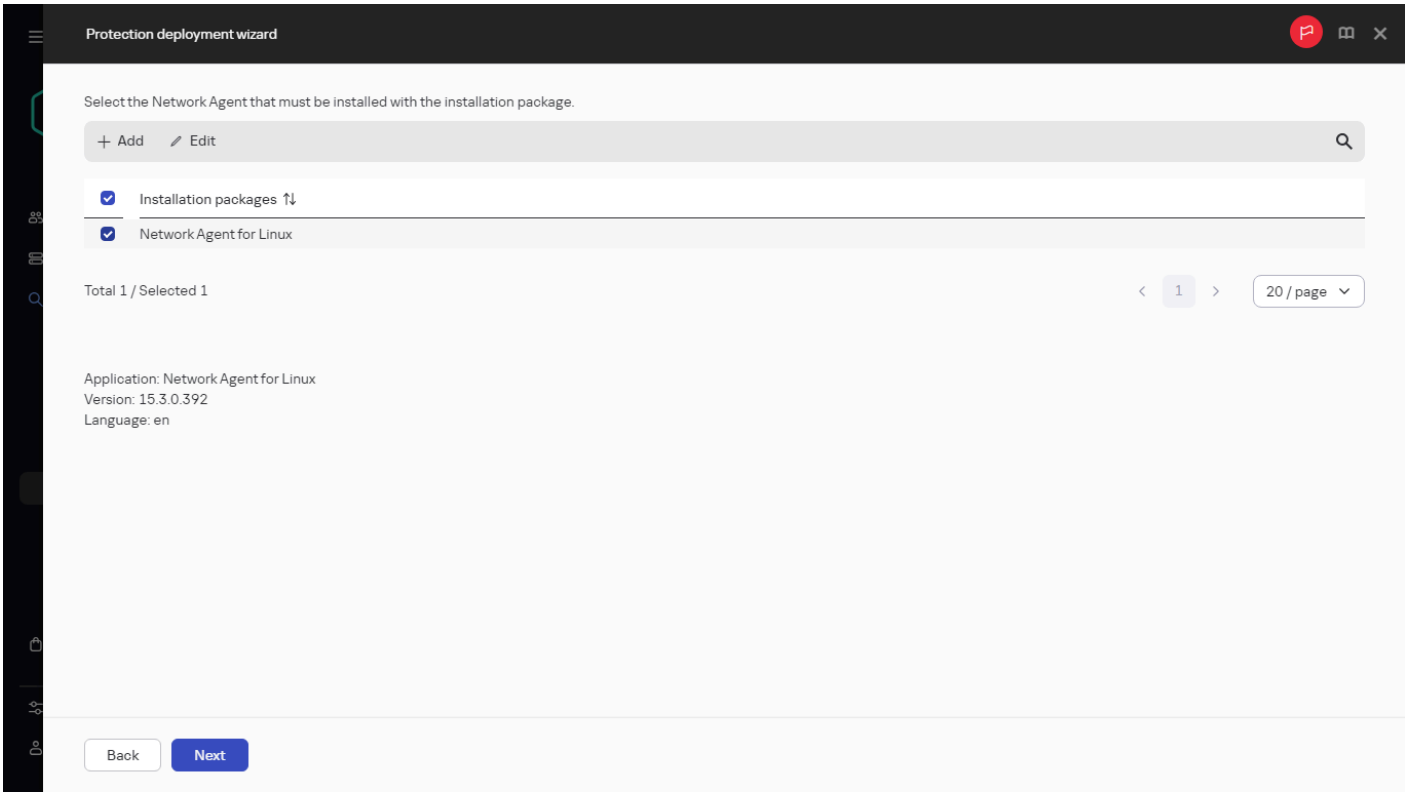
  The key is automatically distributed to all devices with which it is compatible:
  - If automatic distribution has been enabled in the key properties.
  - If the **Add key** task has been created.

- **Add license key to installation package**

  The key is distributed to devices together with the installation package.

  > We do not recommend that you distribute the key using this method because the shared Read access rights are enabled to the repository of installation packages.

If the installation package already includes a key file or an activation code, this window is displayed, but it only contains the license key information.



Selecting a method for distribution of key file or activation code

Step 4. Selecting the Network Agent version

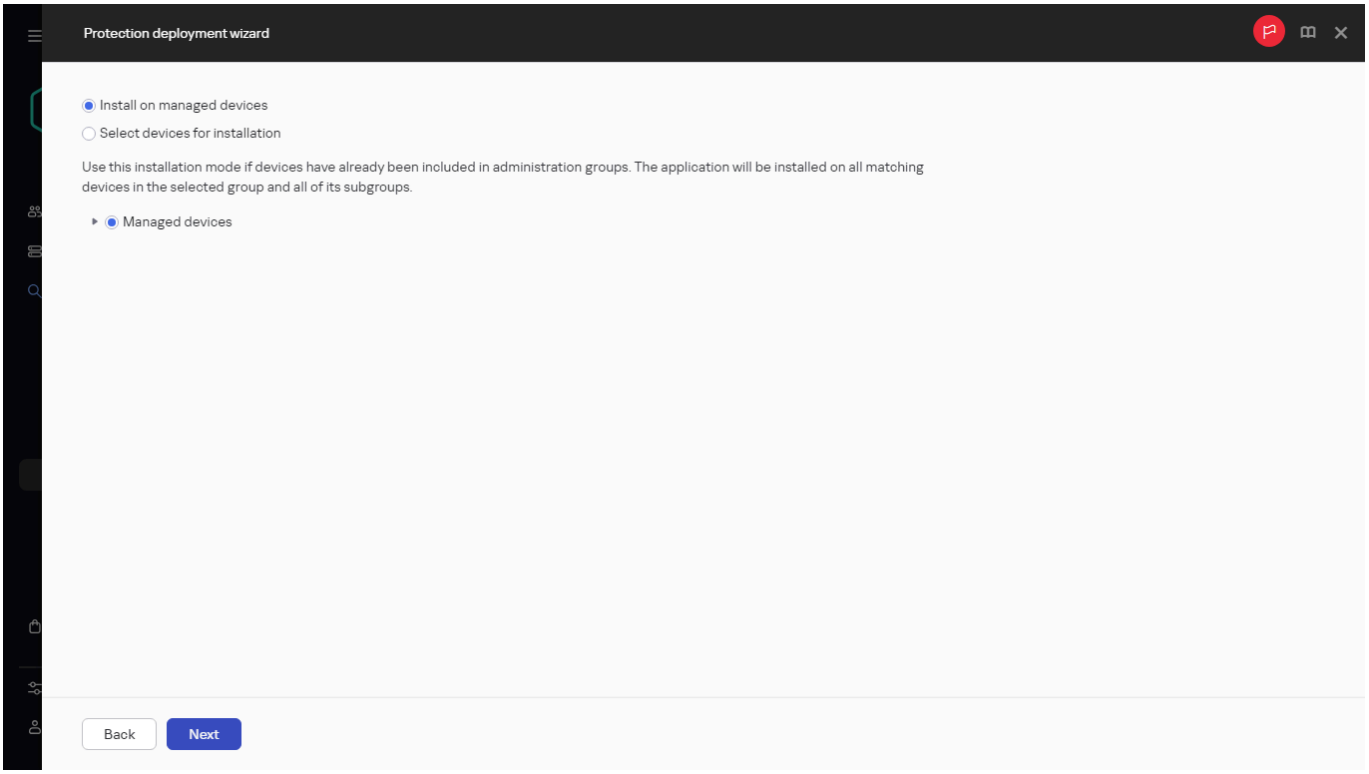
If you selected the installation package of an application other than Network Agent, you also have to install Network Agent, which connects the application with Administration Server.

Select the latest version of Network Agent.

Selecting the Network Agent version

Step 5. Selecting devices

Specify a list of devices on which the application will be installed:



- **Install on managed devices**

  If this option is selected, the remote installation task is created for a group of devices.

- **Select devices for installation**

  The task is assigned to devices included in a device selection. You can specify one of the existing selections.

For example, you may want to use this option to run a task on devices with a specific operating system version.

Specifying the list of devices on which the application will be installed

Step 6. Specifying the remote installation task settings

On the **Remote installation task settings** page, specify the settings for remote installation of the application.

In the **Force installation package download** settings group, specify how files that are required for the application installation are distributed to client devices:

- **Using Network Agent**

  If this option is enabled, installation packages are delivered to client devices by Network Agent installed on those client devices.

  If this option is disabled, installation packages are delivered using the operating system tools of client devices.

  We recommend that you enable this option if the task has been assigned to devices with Network Agents installed.

  By default, the option is enabled.

- **Using operating system resources through distribution points**

  If this option is enabled, installation packages are transmitted to client devices using operating system tools through distribution points. You can select this option if there is at least one distribution point on the network.

  If the **Using Network Agent** option is enabled, the files are delivered using operating system tools only if Network Agent tools are unavailable.

  By default, this option is enabled for remote installation tasks that have been created on a virtual Administration Server.

The only way to install an application for Windows (including Network Agent for Windows) on a device that does not have Network Agent installed is by using a Windows-based distribution point. Therefore, when you install a Windows application:

- Select this option.
- Ensure that a distribution point is assigned for the target client devices.
- Ensure the distribution point is Windows-based.

- **Using operating system resources through Administration Server**

  If this option is enabled, files are transmitted to client devices by using operating system tools of client devices through the Administration Server. You can enable this option if no Network Agent is installed on the client device, but the client device is in the same network as the Administration Server.

  By default, the option is enabled.

Define the additional setting:

- **Do not re-install application if it is already installed**

  If this option is enabled, the selected application will not be re-installed if it has already been installed on this client device.

  If this option is disabled, the application will be installed anyway.

  By default, the option is enabled.

- **Assign package installation in Active Directory group policies**

  If this option is enabled, an installation package is installed by using the Active Directory group policies.

  This option is available if the Network Agent installation package is selected.

  By default, this option is disabled.

Specifying the remote installation task settings

Step 7. Restart management

Specify the action to be performed if the operating system must be restarted when you install the application:

- **Do not restart the device**

  Client devices are not restarted automatically after the operation. To complete the operation, you must restart a device (for example, manually or through a device management task). Information about the required restart is saved in the task results and in the device status. This option is suitable for tasks on servers and other devices where continuous operation is critical.

- **Restart the device**

  Client devices are always restarted automatically if a restart is required for completion of the operation. This option is useful for tasks on devices that provide for regular pauses in their operation (shutdown or restart).

- **Prompt user for action**

  The restart reminder is displayed on the screen of the client device, prompting the user to restart it manually. Some advanced settings can be defined for this option: text of the message for the user, the message display frequency, and the time interval after which a restart will be forced (without the user's confirmation). This option is most suitable for workstations where users must be able to select the most convenient time for a restart.

  By default, this option is selected.

  - **Repeat prompt every (min)**

    If this option is enabled, the application prompts the user to restart the operating system with the specified frequency.

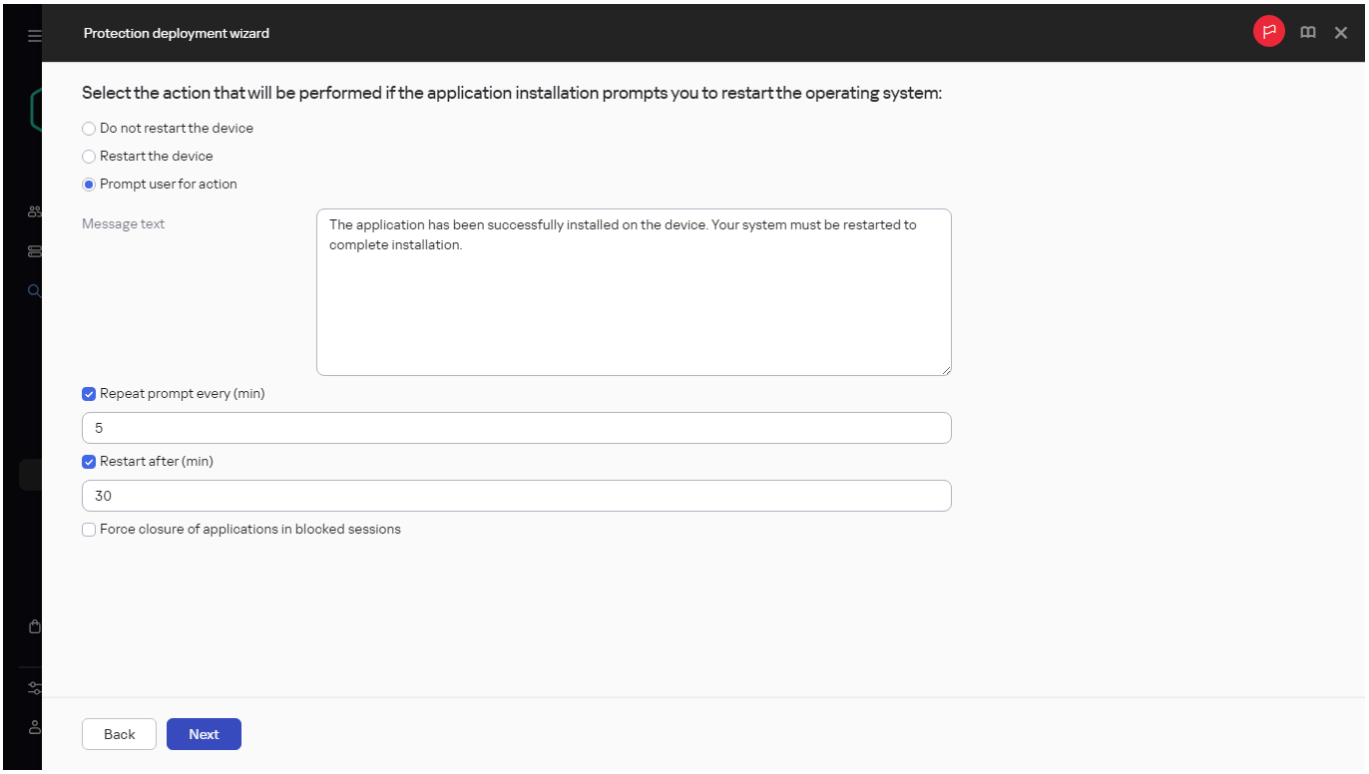
    By default, the option is enabled. The default interval is 5 minutes. Available values are between 1 and 1440 minutes.

    If this option is disabled, the prompt is displayed only once.

  - **Restart after (min)**

    After prompting the user, the application forces restart of the operating system upon expiration of the specified time interval.

    By default, the option is enabled. The default delay is 30 minutes. Available values are between 1 and 1440 minutes.



- **Force closure of applications in blocked sessions**

  Running applications may prevent a restart of the client device. For example, if a document is being edited in a word processing application and is not saved, the application does not allow the device to restart.

  If this option is enabled, such applications on a locked device are forced to close before the device restart. As a result, users may lose their unsaved changes.

  If this option is disabled, a locked device is not restarted. The task status on this device states that a device restart is required. Users have to manually close all applications running on locked devices and restart these devices.

By default, this option is disabled.

Selecting the operating system restart option

Step 8. Removing incompatible applications before installation

This step is only present if the application that you deploy is known to be incompatible with some other applications.

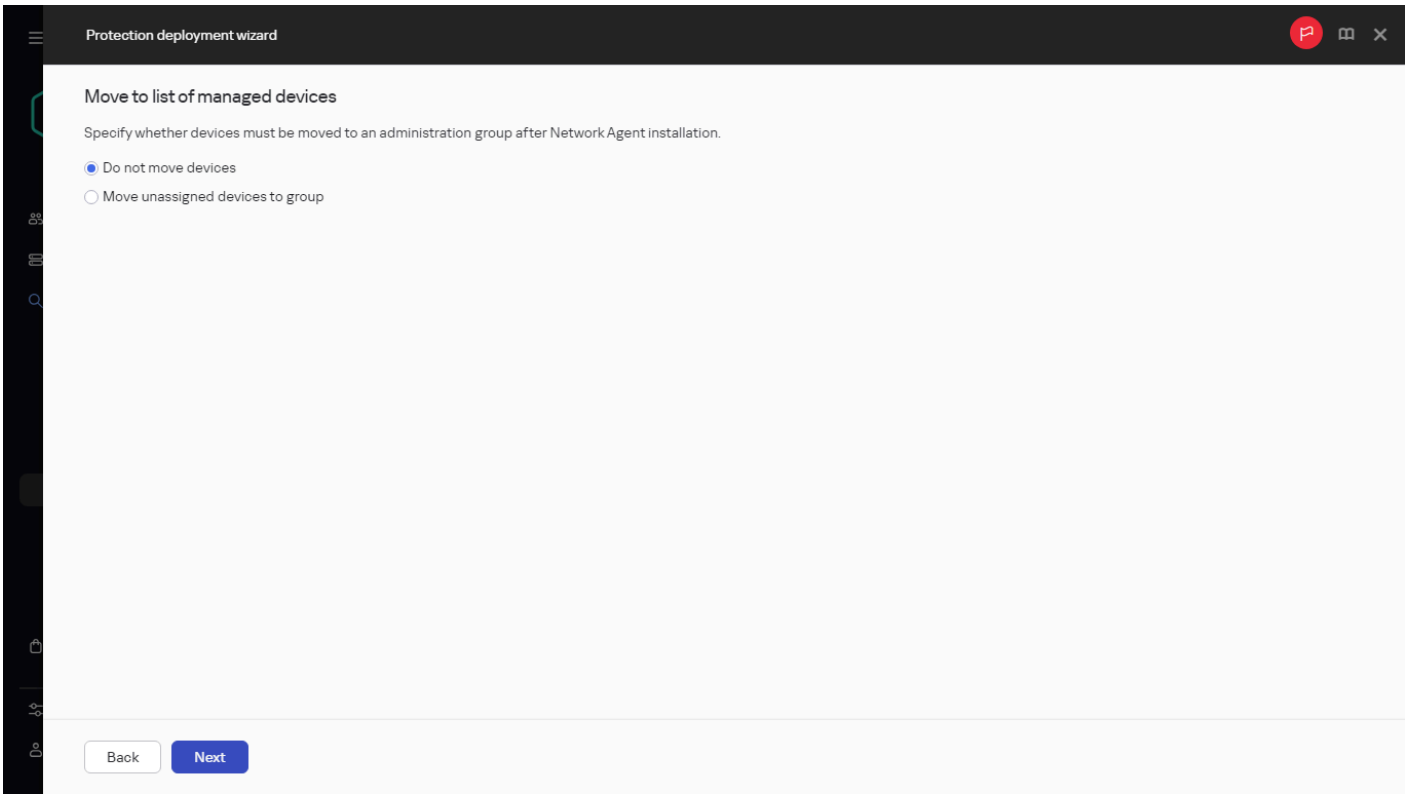
Select the option if you want Kaspersky EDR Expert to automatically remove applications that are incompatible with the application you deploy.

The list of incompatible applications is also displayed.

If you do not select this option, the application will only be installed on devices that have no incompatible applications.

Step 9. Moving devices to Managed devices

Specify whether devices must be moved to an administration group after Network Agent installation.



- **Do not move devices**

  The devices remain in the groups in which they are currently located. The devices that have not been placed in any group remain unassigned.

- **Move unassigned devices to group**

  The devices are moved to the administration group that you select.

The **Do not move devices** option is selected by default. For security reasons, you might want to move the devices manually.

Selecting an option to move devices to an administration group

Step 10. Selecting accounts to access devices

If necessary, add the accounts that will be used to start the remote installation task:

- **No account required (Network Agent installed)**

  If this option is selected, you do not have to specify the account under which the application installer will be run. The task will run under the account under which the Administration Server service is running.

  If Network Agent has not been installed on client devices, this option is not available.

- **Account required (Network Agent is not used)**

  Select this option if Network Agent is not installed on the devices for which you assign the remote installation task. In this case, you can specify a user account or an SSH certificate to install the application.

  - **Local or domain account**. If this option is selected, specify the user account under which the application installer will be run. Click the **Add** button, select **Local or domain account**, and then specify the user account credentials.

    You can specify multiple user accounts if, for example, none of them have all the required rights on all devices for which you assign the task. In this case, all added accounts are used for running the task, in consecutive order, top-down.

  - **SSH certificate**. If you want to install an application on a Linux-based client device, you can specify an SSH certificate instead of a user account. Click the **Add** button, select **SSH certificate**, and then specify the private and public keys of the certificate.

To generate a private key, you can use the ssh-keygen utility. Note that Open Single Management Platform supports the PEM format of private keys, but the ssh-keygen utility generates SSH keys in the OPENSSH format by default. The OPENSSH format is not supported by Open Single Management Platform. To create a private key in the supported PEM format, add the -m PEM option in the ssh-keygen command. For example:

```
ssh-keygen -m PEM -t rsa -b 4096 -C "<user email>"
```

Selecting accounts to access devices

Step 11. Starting installation

This page is the final step of the wizard. At this step, the **Remote installation task** has been successfully created and configured.

By default, the **Run the task after the wizard finishes** option is not selected. If you select this option, the **Remote installation task** will start immediately after you complete the wizard. If you do not select this option, the **Remote installation task** will not start. You can later start this task manually.

Click **OK** to complete the final step of the Protection deployment wizard.

Adding management plug-ins for Kaspersky applications

For remote administration of Kaspersky applications by using OSMP Console, you must use management web plug-ins. Management web plug-ins are installed automatically after you deploy Kaspersky EDR Expert.

If you need to reinstall a management web plug-in manually, contact Kaspersky Technical Support to receive the archive with the required management plug-in.

To reinstall a management web plug-in for a Kaspersky application:

1. Move the management web plug-in archive to the administrator host on which the KDT utility is located.
2. If necessary, on the administrator host, export the current version of the configuration file.

   You do not need to export the configuration file if the installation parameters are not added or modified.
3. Run the following command to install the plug-in:

   ```
   ./kdt apply -k <path_to_plugin_archive> -i <path_to_configuration_file>
   ```

   In the command, specify the path to the plug-in archive and the path to the current configuration file. You do not need to specify the path to the configuration file in the command if the installation parameters are not added or modified.

The management web plug-in is reinstalled. Reload OSMP Console to update the plug-in.

You can view the list of components related to OSMP (including management web plug-ins) by using KDT. Also, you can view OSMP Console version and the list of installed management web plug-ins. To do this, in the upper pane of OSMP Console, go to your account menu, and then select **About**.

Removing management web plug-ins

You can remove the management web plug-ins of Kaspersky applications that provide additional functionality for Kaspersky EDR Expert. The Kaspersky EDR Expert services plug-ins are used for the correct function of Kaspersky EDR Expert and cannot be removed (for example, the plug-in of Incident Response Platform).

To remove a management web plug-in:

1. If needed, run the following command to obtain the name of the plug-in that you want to remove:

   ```
   ./kdt state
   ```

   The list of components is displayed.
2. On the administrator host, run the following command. Specify the name of the plug-in that you want to remove:

   ```
   ./kdt remove --cnab <plug-in_name>
   ```

The specified management web plug-in is removed by KDT.

Viewing the list of components integrated in Open Single Management Platform

You can view the list of components integrated in OSMP (including management web plug-ins) by using KDT.

To view the list of components,

On the administrator host on which KDT is located, run the following command:

```
./kdt state
```

The list of components integrated in OSMP (including management web plug-ins) is displayed in the command line window.

Viewing names, parameters, and custom actions of Kaspersky EDR Expert components

KDT allows you to view the list of the Kaspersky EDR Expert components that are contained in the transport archive, as well as the list of installed components. Also, you can view the parameter list and the custom action list of a Kaspersky EDR Expert component. If custom actions are available for the component, you can also view the description and parameters of the specified custom action by using KDT.

Custom action is an action that allows you to perform additional operations specific to the Kaspersky EDR Expert component. For example, recovering Administration Server data and increasing the amount of disk space used for Administration Server and its logs are performed by using custom actions.

A custom action is run by using KDT as follows:

```
./kdt invoke <component_name> --action <custom_action> --param
<custom_action_parameter>
```

To view the list of Kaspersky EDR Expert components included in the transport archive,

On the administrator host where the KDT utility is located, run the following command. In the command, specify the path to the transport archive and its name:

```
./kdt describe -k <transport_archive_name_with_path>
```

To view the list of Kaspersky EDR Expert components,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt describe
```

The lists of Kaspersky EDR Expert components are displayed.

To view the parameter list and the custom action list of the Kaspersky EDR Expert component,

On the administrator host where the KDT utility is located, run the following command and specify the name of the Kaspersky EDR Expert component:

```
./kdt describe <component_name>
```

The lists of the parameters and custom actions available for the specified component are displayed.

To view the description and the parameter list of the custom action,

On the administrator host where the KDT utility is located, run the following command and specify the Kaspersky EDR Expert component name and its command:

```
./kdt describe <component_name> <custom_action>
```

The description and the parameter list of the specified component custom action are displayed.

Downloading and creating installation packages for Kaspersky applications

You can create installation packages for Kaspersky applications from Kaspersky web servers if your Administration Server has access to the internet.

To download and create installation package for Kaspersky application:

1. In the main menu, go to **Software management** → **Installation packages**.

   You can also view notifications about new packages for Kaspersky applications in the list of onscreen notifications. If there are notifications about a new package, you can click the link next to the notification and proceed to the list of available installation packages.

   A list of installation packages available on Administration Server is displayed.

2. Click **Add**.

   The New package wizard starts. Proceed through the wizard by using the **Next** button.

3. Select **Create an installation package for a Kaspersky application**.

   A list of available installation packages on Kaspersky web servers appears. The list contains installation packages only for those applications that are compatible with the current version of Open Single Management Platform. By default, the list only shows applications with the language that matches the interface language. To display other languages, click **Filter** and configure the filter settings.

4. Click the name of an installation package, for example, Kaspersky Endpoint Security for Linux.

   A window opens with information about the installation package.

   > You can download and use an installation package which includes cryptographic tools that implement strong encryption, if it complies with applicable laws and regulations. To download the installation package of Kaspersky Endpoint Security for Windows valid for the needs of your organization, consult the legislation of the country where the client devices of your organization are located.

5. Read the information and click the **Download and create installation package** button.

   If a distribution package can not be converted to an installation package, the **Download and create installation package** button instead of the **Download distribution package** is displayed.

   The downloading of the installation package to Administration Server starts. You can close the wizard's window. In this case, the download process will continue in background mode. You can track the installation package download status as well as filter and sort the statuses in the **Package status** column.

If the download process stops and the download status switches to **Accept EULA**, then click the installation package name, and then proceed to step 6 of the instruction. By default, the installation packages with **In progress** and **Accept EULA** statuses are placed in the beginning of the list.

If the size of data contained in the selected distribution package exceeds the current limit, an error message is displayed. You can change the limit value and then proceed with the installation package creation.

6. For some Kaspersky applications, during the download process the **Show EULA** button is displayed. If it is displayed, do the following:

   a. Click the **Show EULA** button to read the End User License Agreement (EULA).

   b. Read the EULA that is displayed on the screen, and click **Accept**.

   The downloading continues after you accept the EULA. If you click **Decline**, the download is stopped.

7. When the downloading is complete, click the **Close** button.

The installation package is displayed in the list of installation packages.

Creating installation packages from a file

You can use custom installation packages to do the following:

- To install any application (such as a text editor) on a client device, for example, by means of a task.
- To create a stand-alone installation package.

A custom installation package is a folder with a set of files. The source to create a custom installation package is an *archive file*. The archive file contains a file or files that must be included in the custom installation package.

While creating a custom installation package, you can specify command-line parameters, for example, to install the application in silent mode.

To create a custom installation package:

1. In the main menu, go to **Software management** → **Installation packages**.

   A list of installation packages available on Administration Server is displayed.

2. Click **Add**.

   The New package wizard starts. Proceed through the wizard by using the **Next** button.

3. Select **Create an installation package from a file**.

4. Specify the package name and click the **Browse** button.

5. In the window that opens, choose an archive file located on the available disks.

   You can upload a ZIP, CAB, TAR, or TAR.GZ archive file. It is not possible to create an installation package from an SFX (self-extracting archive) file.

   File upload to the Administration Server starts.

6. If you specified a file of a Kaspersky application, you may be prompted to read and accept the End User License Agreement (EULA) for the application. To continue, you must accept the EULA. Select the **Accept the terms and conditions of this End User License Agreement** option only if you have fully read, understand and accept the terms of the EULA.

   Additionally, you may be prompted to read and accept the Privacy Policy. To continue, you must accept the Privacy Policy. Select the **I accept the Privacy Policy** option only if you understand and agree that your data will be handled and transmitted (including to third countries) as described in the Privacy Policy.

7. Select a file (from the list of files that are extracted from the chosen archive file) and specify the command-line parameters of an executable file.

   You can specify command-line parameters to install the application from the installation package in a silent mode. Specifying command-line parameters is optional.

   The process to create the installation package is started.

   The wizard informs you when the process is finished.

   If the installation package is not created, an appropriate message is displayed.

8. Click the **Finish** button to close the wizard.

The installation package appears in the list of installation packages.

In the list of installation packages available on Administration Server, by clicking the link with the name of a custom installation package, you can:

- View the following properties of an installation package:
  - **Name**. Custom installation package name.
  - **Package status**. Installation package download status.
  - **Source**. Application vendor name.
  - **Application**. Application name packed into the custom installation package.
  - **Version**. Application version.
  - **Language**. Language of the application packed into the custom installation package.
  - **Size (MB)**. Size of the installation package.
  - **OS**. Type of the operating system for which the installation package is intended.
  - **Created**. Installation package creation date.
  - **Modified**. Installation package modification date.
  - **Type**. Type of the installation package.
- Change the command-line parameters.

Creating stand-alone installation packages

You and device users in your organization can use stand-alone installation packages to install applications on devices manually.

A stand-alone installation package is an executable file that you can store on the Web Server or in the shared folder, send by email, or transfer to a client device by another method. On the client device, the user can run the received file locally to install an application without involving Kaspersky EDR Expert. You can create stand-alone installation packages for Kaspersky applications and for third-party applications. To create a stand-alone installation package for a third-party application you must create a custom installation package.

If the Administration Server has access to Internet, the **Download updates to the Administration Server repository** task is used to download dependencies required for creating Network Agent stand-alone installation packages. If the Administration Server does not have access to Internet, perform the following steps:

1. Execute the following command to create the RIUtilsArchiveDirUsed flag:

   ```
   /opt/kaspersky/ksc64/sbin/klscflag -fset -pv klserver -n RIUtilsArchiveDirUsed -t d -v 1
   ```

2. Execute the following command to restart the Administration Server service:

   ```
   systemctl restart kladminserver_srv.service
   ```

3. Download the following archives from the Kaspersky website and place the archives in the /var/opt/kaspersky/klnagent_srv/1093/.working/ri_utils_archives folder:

   - ri_utils_win32.zip
   - ri_utils_arm64.zip

   Do not rename the archives.

   The Administration Server now has the required dependencies.

Be sure that stand-alone installation package is not available for third persons.

To create a stand-alone installation package:

1. In the main menu, go to **Software management** → **Installation packages**.

   A list of installation packages available on Administration Server is displayed.

2. In the list of installation packages, select an installation package and, above the list, click the **Deploy** button.

3. Select the **Using a stand-alone package** option.

   The Stand-alone installation package creation wizard starts. Proceed through the wizard by using the **Next** button.

4. Make sure that the **Install Network Agent together with this application** option is enabled if you want to install Network Agent together with the selected application.

The option is displayed depending on the application for which you create a stand-alone installation package.

By default, the option is enabled. It is recommended to enable this option if you are not sure whether Network Agent is installed on the device. If Network Agent is already installed on the device, after the stand-alone installation package with Network Agent installed Network Agent will be updated to the newer version.

If you disable this option, Network Agent will not be installed on the device and the device will be unmanaged.

If a stand-alone installation package for the selected application already exists on Administration Server, the wizard informs you about this fact. In this case, you must select one of the following actions:

- **Create stand-alone installation package**. Select this option, for example, if you want to create a stand-alone installation package for a new application version and also want to retain a stand-alone installation package that you created for a previous application version. The new stand-alone installation package is placed in another folder.
- **Use existing stand-alone installation package**. Select this option if you want to use an existing stand-alone installation package. The process of package creation will not be started.
- **Rebuild existing stand-alone installation package**. Select this option if you want to create a stand-alone installation package for the same application again. The stand-alone installation package is placed in the same folder.

5. On the **Move to list of managed devices** step, the **Do not move devices** option is selected by default. If you do not want to move the client device to any administration group after Network Agent installation, do not change choice of option.

   If you want to move client device after Network Agent installation, select the **Move unassigned devices to this group** option and specify an administration group to which you want to move the client device. By default, the device is moved to the **Managed devices** group.

6. When the process of the stand-alone installation package creation is finished, click the **FINISH** button.

   The Stand-alone Installation Package Creation Wizard closes.

The stand-alone installation package is created and placed on the Web Server. You can view the list of stand-alone packages by clicking the **View the list of stand-alone packages** button above the list of installation packages.

Changing the limit on the size of custom installation package data

The total size of data unpacked during creation of a custom installation package is limited. The default limit is 1 GB.

If you attempt to upload an archive file that contains data exceeding the current limit, an error message is displayed. You might have to increase this limit value when creating installation packages from large distribution packages.

To change the limit value for the custom installation package size,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke ksc --action klscflag --param klscflag_param=' -fset -pv klserver -n
MaxArchivePkgSize -t d -v <number of bytes>'
```

Where <number of bytes> is a number of bytes in hexadecimal or decimal format.

For example, if the required limit is 2 GB, you can specify the decimal value 2147483648 or the hexadecimal value 0x80000000. In this case, for a local installation of Administration Server, you can use the following command:

```
./kdt invoke ksc --action klscflag --param klscflag_param=' -fset -pv klserver -n
MaxArchivePkgSize -t d -v 2147483648'
```

The limit on the size of custom installation package data is changed.

Installing Network Agent for Linux in silent mode (with an answer file)

You can install Network Agent on Linux devices by using an answer file—a text file that contains a custom set of installation parameters: variables and their respective values. Using this answer file allows you to run an installation in silent mode, that is, without user participation.

Before installing Network Agent on a Linux-based device, you must complete the general preparatory steps that are required to all Linux-based devices.

After completing the general steps, you can follow the additional instructions specific to your operating system:

- Preparing a device running SUSE Linux Enterprise Server 15
- Preparing a device running Astra Linux in the closed software environment mode
- Preparing a device running Ubuntu Server/Desktop version 10.04 and 16.04
- Preparing a device running a Linux operating system with glibc 2.5

To perform installation of Network Agent for Linux in silent mode:

1. Read the End User License Agreement. Follow the steps below only if you understand and accept the terms of the End User License Agreement.
2. Create the answer file (in TXT format). Add to the answer file a list of variables in the VARIABLE_NAME=variable_value format, each variable on a separate line.

   For correct usage of the answer file, you must include in it a minimum set of the three required variables:

   - KLNAGENT_SERVER
   - KLNAGENT_AUTOINSTALL
   - EULA_ACCEPTED

   You can also add any optional variables to use more specific parameters of your remote installation. The following table lists all of the variables that can be included in the answer file:

   Variables of the answer file used as parameters of Network Agent for Linux installation in silent mode

Variables of the answer file used as parameters of Network Agent for Linux installation in silent mode

Variable name	Required	Description	Possible values
KLNAGENT_SERVER	Yes	Contains the Administration Server name presented as fully qualified domain name (FQDN) or IP address.	DNS name or IP address.
KLNAGENT_AUTOINSTALL	Yes	Defines whether silent installation mode is enabled.	1—Silent mode is enabled; the user is not prompted for any actions during installation. Other—Silent mode is disabled; the user may be prompted for actions during installation.
EULA_ACCEPTED	Yes	Defines whether the user accepts the End User License Agreement (EULA) of Network Agent; when missing, can be interpreted as non-acceptance of the EULA.	1—I confirm that I have fully read, understand, and accept the terms and conditions of this End User License Agreement. Other or not specified—I do not accept the terms of the License Agreement (installation is not performed).
KLNAGENT_PROXY_USE	No	Defines whether connection with the Administration Server will use proxy settings. The default value is 0.	1—Proxy settings are used. Other—Proxy settings are not used.
KLNAGENT_PROXY_ADDR	No	Defines the address of the proxy server used for connection with the Administration Server.	DNS name or IP address.
KLNAGENT_PROXY_LOGIN	No	Defines the user name used for login to the proxy server.	Any existing user name.
KLNAGENT_PROXY_PASSWORD	No	Defines the user password used for login to the proxy server.	Any set of alphanumeric characters allowed by the password format in the operating system.
KLNAGENT_VM_VDI	No	Defines whether Network Agent is installed on an image for creation of dynamic virtual machines.	1—Network Agent is installed on an image, which is subsequently used for creation of dynamic virtual machines. Other—No image is used during installation.
KLNAGENT_VM_OPTIMIZE	No	Defines whether the Network Agent settings are optimal for hypervisor.	1—The default local settings of Network Agent are modified so that they allow optimized usage on hypervisor.
KLNAGENT_TAGS	No	Lists the tags assigned to the Network Agent instance.	One or multiple tag names separated with semicolon.
KLNAGENT_UDP_PORT	No	Defines the UDP port used by Network Agent. The default value is 15000.	Any existing port number.
KLNAGENT_PORT	No	Defines the non-TLS port used by Network Agent. The default value is 14000.	Any existing port number.
KLNAGENT_SSLPORT	No	Defines the TLS port used by Network Agent. The default value is 13000.	Any existing port number.
KLNAGENT_USESSL	No	Defines whether Transport Layer Security (TLS) is used for connection.	1 (default)—TLS is used. Other—TLS is not used.

KLNAGENT_GW_MODE	No	Defines whether connection gateway is used.	1 (default)—The current settings are not modified (at the first call, no connection gateway is specified). 2—No connection gateway is used. 3—Connection gateway is used. KLNAGENT_GW_ADDRESS is required. 4—The Network Agent instance is used as connection gateway in demilitarized zone (DMZ). Server certificate is required.
KLNAGENT_GW_ADDRESS	No	Defines the address of the connection gateway. The value is applicable only if KLNAGENT_GW_MODE=3.	DNS name or IP address.
KLNAGENT_DEVICEOWNER_REGISTRATION_START	No	Allows to run the user registration as a device owner utility after Network Agent installation. If turned off, then the registration as a device owner is not available to a user.	1—The user registration as a device owner utility will run after Network Agent installation. Other—Turned off.
PTCH_ALLOW_APPLY_NONAPROVED_PATCHES	No	Defines whether to install the downloaded updates automatically for Network Agent with the *Undefined* status.	true (default)—Updates are installed automatically. false—Updates are not installed automatically.

3. Run the Network Agent installation. The KLAUTOANSWERS environment variable, which specifies the path to the answer file, is passed to the installation command. Run one of the following command:

   - To install Network Agent from an RPM package to a 32-bit operating system, execute the following command:
     `sudo KLAUTOANSWERS=<path to answer file> yum install ./klnagent-<build number>.i386.rpm`

   - To install Network Agent from an RPM package to a 64-bit operating system, execute the following command:
     `sudo KLAUTOANSWERS=<path to answer file> yum install ./klnagent64-<build number>.x86_64.rpm`

   - To install Network Agent from an RPM package on a 64-bit operating system for the Arm architecture, execute the following command:
     `sudo KLAUTOANSWERS=<path to answer file> yum install ./klnagent64-<build number>.aarch64.rpm`

   - To install Network Agent from a DEB package to a 32-bit operating system, execute the following command:
     `sudo KLAUTOANSWERS=<path to answer file> apt install ./klnagent_<build number>_i386.deb`

   - To install Network Agent from a DEB package to a 64-bit operating system, execute the following command:
     `sudo KLAUTOANSWERS=<path to answer file> apt install ./klnagent64_<build number>_amd64.deb`

   - To install Network Agent from a DEB package on a 64-bit operating system for the Arm architecture, execute the following command:
     `sudo KLAUTOANSWERS=<path to answer file> apt install ./klnagent64_<build number>_arm64.deb`

Depending on the operating system configuration, you can also use the rpm, dpkg, or dnf package managers to install Network Agent.

Installation of Network Agent for Linux starts in silent mode; the user is not prompted for any actions during the process.

Preparing a device running Astra Linux in the closed software environment mode for installation of Network Agent

Prior to the installation of Network Agent on a device running Astra Linux in the closed software environment mode, you must perform two preparation procedures—the one in the instructions below and general preparation steps for any Linux device.

Run the commands provided in this instruction under an account with root privileges.

To prepare a device running Astra Linux in the closed software environment mode for installation of Network Agent:

1. Open the `/etc/digsig/digsig_initramfs.conf` file, and then specify the following setting:

   ```
   DIGSIG_ELF_MODE=1
   ```

2. In the command line, run the following command to install the compatibility package:

   ```
   apt install astra-digsig-oldkeys
   ```

3. Create a directory for the application key:

   ```
   mkdir -p /etc/digsig/keys/legacy/kaspersky/
   ```

4. Place the application key /opt/kaspersky/klnagent64/share/kaspersky_astra_pub_key.gpg in the directory created in the previous step:

   ```
   cp kaspersky_astra_pub_key.gpg /etc/digsig/keys/legacy/kaspersky/
   ```

   If the Open Single Management Platform distribution kit does not include the kaspersky_astra_pub_key.gpg application key, you can download it by clicking the link: https://media.kaspersky.com/utilities/CorporateUtilities/kaspersky_astra_pub_key.gpg.

5. Update the RAM disks:

   ```
   update-initramfs -u -k all
   ```

   Reboot the system.

The Linux device is ready for installation of Network Agent. You can install Network Agent remotely, in interactive mode, or in silent mode.

Viewing the list of stand-alone installation packages

You can view the list of stand-alone installation packages and properties of each stand-alone installation package.

To view the list of stand-alone installation packages for all installation packages:

Above the list, click the **View the list of stand-alone packages** button.

In the list of stand-alone installation packages, their properties are displayed as follows:

- **Package name**. Stand-alone installation package name that is automatically formed as the application name included in the package and the application version.
- **Application name**. Application name included in the stand-alone installation package.
- **Application version**.
- **Network Agent installation package name**. The property is displayed only if Network Agent is included in the stand-alone installation package.
- **Network Agent version**. The property is displayed only if Network Agent is included in the stand-alone installation package.
- **Size**. File size in MB.
- **Group**. Name of the group to which the client device is moved after Network Agent installation.
- **Created**. Date and time of the stand-alone installation package creation.
- **Modified**. Date and time of the stand-alone installation package modification.
- **Path**. Full path to the folder where the stand-alone installation package is located.
- **Web address**. Web address of the stand-alone installation package location.
- **File hash**. The property is used to certify that the stand-alone installation package was not changed by third-party persons and a user has the same file you have created and transferred to the user.

Information about the size, file hash, and path is not available in the list of installation packages for the Network Agent stand-alone package or for any packages created on virtual Administration Servers. These stand-alone packages are generated at the time of download.

To view the list of stand-alone installation packages for specific installation package:

Select the installation package in the list and, above the list, click the **View the list of stand-alone packages** button.

In the list of stand-alone installation packages, you can do the following:

- Publish a stand-alone installation package on the Web Server by clicking the **Publish** button. Published stand-alone installation package is available for downloading for users whom you sent the link to the stand-alone installation package.
- Cancel publication of a stand-alone installation package on the Web Server by clicking the **Unpublish** button. Unpublished stand-alone installation package is available for downloading only for you and other administrators.
- Download a stand-alone installation package to your device by clicking the **Download** button.

- Send email with the link to a stand-alone installation package by clicking the **Send by email** button.
- Remove a stand-alone installation package by clicking the **Remove** button.

Distributing installation packages to secondary Administration Servers

Open Single Management Platform allows you to create installation packages for Kaspersky applications and for third-party applications, as well as distribute installation packages to client devices and install applications from the packages. To optimize the load on the primary Administration Server, you can distribute installation packages to secondary Administration Servers. After that, the secondary Servers transmit the packages to client devices, and then you can perform the remote installation of the applications on your client devices.

To distribute installation packages to secondary Administration Servers:

1. Make sure that the secondary Administration Servers are connected to the primary Administration Server.
2. In the main menu, go to **Tasks**.

   The list of tasks is displayed.
3. Click the **Add** button.

   The New task wizard starts. Follow the instructions of the wizard.
4. On the **New task settings** page, from the **Application** drop-down list, select **Kaspersky Security Center**. Then, from the **Task type** drop-down list, select **Distribute installation package**, and then specify the task name.
5. On the **Task scope** page, select the devices to which the task is assigned in one of the following ways:
   - If you want to create a task for all secondary Administration Servers in a specific administration group, select this group, and then create a group task for it.
   - If you want to create a task for specific secondary Administration Servers, select these Servers, and then create a task for them.
6. On the **Distributed installation packages** page, select the installation packages that are to be copied to the secondary Administration Servers.
7. Specify an account to run the *Distribute installation package* task under this account. You can use your account and keep the **Default account** option enabled. Alternatively, you can specify that the task should be run under another account that has the necessary access rights. To do this, select the **Specify account** option, and then enter the credentials of that account.
8. On the **Finish task creation** page, you can enable the **Open task details when creation is complete** option to open the task properties window, and then modify the default task settings. Otherwise, you can configure the task settings later, at any time.

9. Click the **Finish** button.

   The task created for distributing installation packages to the secondary Administration Servers is displayed in the task list.

10. Run the task manually or wait for it to launch according to the schedule that you specified in the task settings.

After the task is completed, the selected installation packages are copied to the specified secondary Administration Servers.

Preparing a Linux device for installation of Network Agent

Prior to the installation of Network Agent on a Linux device, you must perform preparation steps that are required for any Linux device.

To prepare a device running Linux for remote installation of Network Agent:

1. Make sure that the device on which you want to install Network Agent for Linux is running one of the supported Linux distributions.

2. If you want to install Network Agent on AltOS in the closed software environment mode, disable the closed software environment mode until the installation is finished.

3. Download the Network Agent installation package by using the Web Console interface or from the Kaspersky website.

   If you need to install Network Agent on a device running a Linux operating system with glibc 2.5, you must download the *Kaspersky Network Agent for Linux Legacy* installation package by using the Web Console interface or from the Kaspersky website.

4. Make sure that the following software is installed on the target Linux device:

   - Sudo (for Ubuntu 10.04, Sudo version is 1.7.2p1 or later)
   - Perl language interpreter version 5.10 or later
   - ps utility

5. Test the device configuration:

   a. Check whether you can connect to the device through an SSH client (such as PuTTY).

      If you cannot connect to the device, open the `/etc/ssh/sshd_config` file and make sure that the following settings have the respective values listed below:

      ```
      PasswordAuthentication no
      ChallengeResponseAuthentication yes
      ```

      Do not modify the /etc/ssh/sshd_config file if you can connect to the device with no issues; otherwise, you may encounter SSH authentication failure when running a remote installation task.

      Save the file (if necessary) and restart the SSH service by using the `sudo service ssh restart` command.

b. Ensure that port TCP 22 is open and accessible on a Linux-based unassigned device.

TCP port 22 must be available for successful installation of Network Agent for Linux.

c. Disable the sudo password for the user account under which the device is to be connected.

d. Use the `visudo` command in sudo to open the sudoers configuration file.

In the file you have opened, add the following line to the end of the file: `<username> ALL = (ALL) NOPASSWD: ALL`. In this case, `<username>` is the user account which is to be used for the device connection using SSH. If you are using the Astra Linux operating system, in the /etc/sudoers file, add the last line with the following text: `%astra-admin ALL=(ALL:ALL) NOPASSWD: ALL`

e. Save the sudoers file and then close it.

f. Connect to the device again through SSH and make sure that the Sudo service does not prompt you to enter a password; you can do this using the `sudo whoami` command.

6. If you want to install Network Agent remotely on devices running operating system with the systemd initialization system, open the `/etc/systemd/logind.conf` file, and then do one of the following:

- Specify `no` as a value for the `KillUserProcesses` setting: `KillUserProcesses=no`.
- For the `KillExcludeUsers` setting, type the user name of the account under which the remote installation is to be performed, for example, `KillExcludeUsers=root`.

Astra Linux target device

If the target device is running Astra Linux, add `export PATH=/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin` string in the `/home/<username>/.bashrc` file, where `<username>` is the user account which is to be used for the device connection using SSH.

OSnova target device

If the target device is running OSnova, do the following:

a. Open the `/usr/lib/systemd/logind.conf/10-enable-kill-user-processes.conf` file, and then comment out the `#KillUserProcess=yes` line.

b. Open the `/usr/lib/NESS/pam-user-session` file, and then comment out the `#loginctl terminate-session "$XDG_SESSION_ID"` line.

To apply the changed setting, restart the Linux device or execute the following command:

```
sudo systemctl restart systemd-logind.service
```

7. If you want to install Network Agent on devices with the SUSE Linux Enterprise Server 15 operating system, install the insserv-compat package first to configure Network Agent.

8. If you want to install Network Agent on devices that have the Astra Linux operating system running in the closed software environment mode, perform additional steps to prepare Astra Linux devices.

9. If you want to install Network Agent on devices running Ubuntu Server or Ubuntu Desktop version 10.04, perform additional steps to prepare these devices.

10. If you want to install Network Agent on a device running a Linux operating system with glibc 2.5, perform additional steps to prepare the target devices.

11. If you're installing Network Agent on AltOS in the closed software environment mode, re-enable the closed software environment mode.

12. If you want to install Network Agent on devices that use the operating system RED OS 7.3.4 or later or MSVSPHERE 9.2 or later, install the libxcrypt-compat package for the correct function of Network Agent.

The Linux device is ready for installation of Network Agent. You can install Network Agent remotely, in interactive mode, or in silent mode.

Installing applications using a remote installation task

Kaspersky EDR Expert allows you to install applications on devices remotely, using remote installation tasks. Those tasks are created and assigned to devices through a dedicated wizard. To assign a task more quickly and easily, you can specify devices (up to 1000 devices) in the wizard window in one of the following ways:

- **Assign task to an administration group**. In this case, the task is assigned to devices included in an administration group created earlier.

- **Specify device addresses manually or import addresses from list**. You can specify DNS names, IP addresses, and IP subnets of devices to which you want to assign the task.

- **Assign task to a device selection**. In this case, the task is assigned to devices included in a selection created earlier. You can specify the default selection or a custom one that you created. You can only select up to 1000 devices.

To avoid issues that may occur during installation of the application on a client device without Network Agent installed, you must proceed as described in forced deployment through the remote installation task of Open Single Management Platform.

Installing an application remotely

This section contains information on how to remotely install an application on devices in an administration group, devices with specific addresses, or a selection of devices.

To install an application on specific devices:

1. In the main menu, go to **Asset management** → **Tasks**.

2. Click the **Add** button.

   The New task wizard starts.

3. In the **Task type** field, select **Install application remotely**.

4. Choose one of the following options:

   - **Assign task to an administration group**

     The task is assigned to devices included in an administration group. You can specify one of the existing groups or create a new one.

     For example, you may want to use this option to run a task of sending a message to users if the message is specific for devices included in a specific administration group.

If a task is assigned to an administration group, the **Security** tab is not displayed in the task properties window because group tasks are subject to the security settings of the groups to which they apply.

- **Specify device addresses manually or import addresses from a list**

  You can specify DNS names, IP addresses, and IP subnets of devices to which you want to assign the task.

  You may want to use this option to execute a task for a specific subnet. For example, you may want to install a certain application on devices of accountants or to scan devices in a subnet that is probably infected.

- **Assign task to a device selection**

  The task is assigned to devices included in a device selection. You can specify one of the existing selections.

  For example, you may want to use this option to run a task on devices with a specific operating system version.

The *Install application remotely* task is created for the specified devices. If you selected the **Assign task to an administration group** option, the task is a group one.

Creating the Install application remotely task

5. At the **Task scope** step, specify an administration group, devices with specific addresses, or a device selection.

   The available settings depend on the option selected at the previous step.

6. At the **Installation packages** step, specify the following settings:

   - In the **Select installation package** field, select the installation package of an application that you want to install.

   - In the **Force installation package download** settings group, specify how files that are required for the application installation are distributed to client devices:

     - **Using Network Agent**

       If this option is enabled, installation packages are delivered to client devices by Network Agent installed on those client devices.

If this option is disabled, installation packages are delivered using the operating system tools of client devices.

We recommend that you enable this option if the task has been assigned to devices with Network Agents installed.

By default, the option is enabled.

- **Using operating system resources through distribution points**

  If this option is enabled, installation packages are transmitted to client devices using operating system tools through distribution points. You can select this option if there is at least one distribution point on the network.

  If the **Using Network Agent** option is enabled, the files are delivered using operating system tools only if Network Agent tools are unavailable.

  By default, this option is enabled for remote installation tasks that have been created on a virtual Administration Server.

  The only way to install an application for Windows (including Network Agent for Windows) on a device that does not have Network Agent installed is by using a Windows-based distribution point. Therefore, when you install a Windows application:

  - Select this option.
  - Ensure that a distribution point is assigned for the target client devices.
  - Ensure the distribution point is Windows-based.

- **Using operating system resources through Administration Server**

  If this option is enabled, files are transmitted to client devices by using operating system tools of client devices through the Administration Server. You can enable this option if no Network Agent is installed on the client device, but the client device is in the same network as the Administration Server.

  By default, the option is enabled.

- In the **Maximum number of concurrent downloads** field, specify the maximum allowed number of client devices to which Administration Server can simultaneously transmit the files.

- In the **Maximum number of installation attempts** field, specify the maximum allowed number of installer runs.

  If the number of attempts specified in the parameter is exceeded, Open Single Management Platform does not start the installer on the device anymore. To restart the *Install application remotely* task, increase the value of the **Maximum number of installation attempts** parameter and start the task. Alternatively, you can create a new *Install application remotely* task.

- If you migrate from one Kaspersky application to another and your current application is password-protected, enter the password in the **Password to uninstall the current Kaspersky application** field. Note that during the migration, your current Kaspersky application will be uninstalled.

  The **Password to uninstall the current Kaspersky application** field is only available if you have selected the **Using Network Agent** option in the **Force installation package download** settings group.

You can use the uninstall password only for the Kaspersky Security for Windows Server to Kaspersky Endpoint Security for Windows migration scenario when installing Kaspersky Endpoint Security for Windows by using the Install application remotely task. Using the uninstall password when installing other components may cause installation errors.

To complete the migration scenario successfully, make sure that the following prerequisites are met:

- You are using Kaspersky Security Center Network Agent 15.1 for Windows or later.
- You are installing the application on devices running Windows.

- Define the additional setting:
  - **Do not re-install the application if it is already installed**

    If this option is enabled, the selected application will not be re-installed if it has already been installed on this client device.

    If this option is disabled, the application will be installed anyway.

    By default, the option is enabled.

  - **Verify operating system type before downloading**

    Before transmitting the files to client devices, Open Single Management Platform checks if the Installation utility settings are applicable to the operating system of the client device. If the settings are not applicable, Open Single Management Platform does not transmit the files and does not attempt to install the application. For example, to install some application to devices of an administration group that includes devices running various operating systems, you can assign the installation task to the administration group, and then enable this option to skip devices that run an operating system other than the required one.

    When you remotely install Network Agent on unassigned devices, Open Single Management Platform or a distribution point automatically determines the device's operating system type, regardless of the **Verify operating system type before downloading** setting.

  - **Assign package installation in Active Directory group policies**

    If this option is enabled, an installation package is installed by using the Active Directory group policies.

    This option is available if the Network Agent installation package is selected.

    By default, this option is disabled.

  - **Prompt users to close running applications**

    Running applications may prevent a restart of the client device. For example, if a document is being edited in a word processing application and is not saved, the application does not allow the device to restart.

    If this option is enabled, such applications on a locked device are forced to close before the device restart. As a result, users may lose their unsaved changes.

    If this option is disabled, a locked device is not restarted. The task status on this device states that a device restart is required. Users have to manually close all applications running on locked devices and restart these devices.

    By default, this option is disabled.

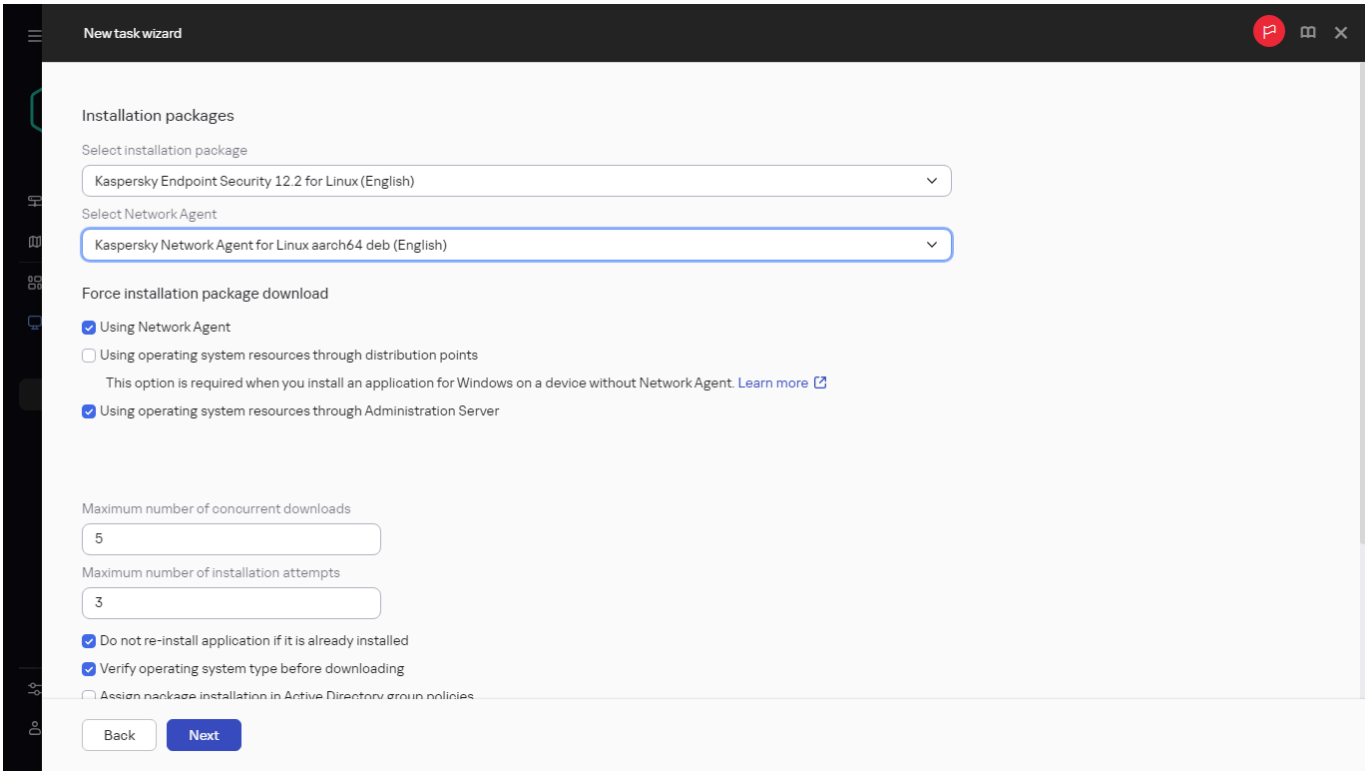
- Select on which devices you want to install the application:
  - **Install on all devices**

    The application will be installed even on devices managed by other Administration Servers.

    This option is selected by default. You do not have to change this setting if you have only one Administration Server in your network.

  - **Install only on devices managed through this Administration Server**

    The application will be installed only on devices managed by this Administration Server. Select this option if you have more than one Administration Server in your network and want to avoid conflicts between them.



- Specify whether devices must be moved to an administration group after installation:
  - **Do not move devices**

    The devices remain in the groups in which they are currently located. The devices that have not been placed in any group remain unassigned.

  - **Move unassigned devices to the selected group (only a single group can be selected)**

    The devices are moved to the administration group that you select.

  Note that the **Do not move devices** option is selected by default. For security reasons, you might want to move the devices manually.

Specifying the task settings

7. At the this step of the wizard, specify whether the devices must be restarted during installation of applications:

- **Do not restart the device**

  If this option is selected, the device will not be restarted after the security application installation.

- **Restart the device**

  If this option is selected, the device will be restarted after the security application installation.

8. If necessary, at the **Select accounts to access devices** step, add the accounts that will be used to start the *Install application remotely* task:

   - **No account required (Network Agent installed)**

     If this option is selected, you do not have to specify the account under which the application installer will be run. The task will run under the account under which the Administration Server service is running.

     If Network Agent has not been installed on client devices, this option is not available.

   - **Account required (Network Agent is not used)**

     Select this option if Network Agent is not installed on the devices for which you assign the remote installation task. In this case, you can specify a user account or an SSH certificate to install the application.

     - **Local or domain account**. If this option is selected, specify the user account under which the application installer will be run. Click the **Add** button, select **Local or domain account**, and then specify the user account credentials.

       You can specify multiple user accounts if, for example, none of them have all the required rights on all devices for which you assign the task. In this case, all added accounts are used for running the task, in consecutive order, top-down.

     - **SSH certificate**. If you want to install an application on a Linux-based client device, you can specify an SSH certificate instead of a user account. Click the **Add** button, select **SSH certificate**, and then specify the private and public keys of the certificate.

       To generate a private key, you can use the ssh-keygen utility. Note that Open Single Management Platform supports the PEM format of private keys, but the ssh-keygen utility generates SSH keys in the OPENSSH format by default. The OPENSSH format is not supported by Open Single Management Platform. To create a private key in the supported PEM format, add the -m PEM option in the ssh-keygen command. For example:

       ```
       ssh-keygen -m PEM -t rsa -b 4096 -C "<user email>"
       ```

9. At the **Finish task creation** step, click the **Finish** button to create the task and close the wizard.

   If you enabled the **Open task details when creation is complete** option, the task settings window opens. In this window, you can check the task parameters, modify them, or configure a task start schedule, if necessary.

10. In the task list, select the task you created, and then click **Start**.

    Alternatively, wait for the task to launch according to the schedule that you specified in the task settings.

When the remote installation task is completed, the selected application is installed on the specified devices.

Installing applications on secondary Administration Servers

If your Administration Server version is 15.4 or later, you can install applications on a secondary Administration Server only if its version is 15.4 or later.

To install an application on secondary Administration Servers:

1. Establish a connection with the Administration Server that controls the relevant secondary Administration Servers.
2. Make sure that the installation package corresponding to the application being installed is available on each of the selected secondary Administration Servers. If you cannot find the installation package on any of the secondary Servers, distribute it. For this purpose, create a task with the **Distribute installation package** task type.
3. Create a task for a remote application installation on secondary Administration Servers. Select the **Install application on secondary Administration Server remotely** task type.

   The New task wizard creates a task for remote installation of the application selected in the wizard on specific secondary Administration Servers.
4. Run the task manually or wait for it to launch according to the schedule that you specified in the task settings.

When the remote installation task is complete, the selected application is installed on the secondary Administration Servers.

Specifying settings for remote installation on Unix devices

When you install an application on a Unix device by using a remote installation task, you can specify Unix-specific settings for the task. These settings are available in the task properties after the task is created.

To specify Unix-specific settings for a remote installation task:

1. In the main menu, go to **Tasks**.
2. Click the name of the remote installation task for which you want to specify the Unix-specific settings.

   The task properties window opens.
3. Go to **Application settings** → **Unix-specific settings**.
4. Specify the following parameters:

   Set a password for the root account (only for deployment through SSH)

   If the `sudo` command cannot be used on the target device without specifying the password, select this option, and then specify the password for the root account. Kaspersky EDR Expert transmits the password in an encrypted form to the target device, decrypts the password, and then starts the installation procedure on behalf of the root account with the specified password.

   Kaspersky EDR Expert does not use the account or the specified password to create an SSH connection.

   Specify the path to a temporary folder with Execute permissions on the target device (only for deployment through SSH)

   If the /tmp directory on the target device does not have the execute permission, select this option, and then specify the path to the directory with the execute permission. Kaspersky EDR Expert uses the specified directory as a temporary directory to access via SSH. The application places the installation package in the directory and runs the installation procedure.

5. Click the **Save** button.

   The specified task settings are saved.

Starting and stopping Kaspersky applications

You can use the *Start or stop application* task for starting and stopping Kaspersky applications on managed devices.

To create the Start or stop application task:

1. In the main menu, go to **Tasks**.
2. Click **Add**.

   The New task wizard starts. Proceed through the wizard by using the **Next** button.
3. In the **Application** drop-down list, select the application for which you want to create the task.
4. In the **Task type** list, select the **Start or stop application** task.
5. In the **Task name** field, specify the name of the new task.

   The task name cannot be more than 100 characters long and cannot include any special characters ("*<>?\:|).
6. Select devices to which the task will be assigned.
7. In the **Applications** window, do the following:
   - Select the check boxes next to the names of applications for which you want to create the task.
   - Select the **Start application** or the **Stop application** option.
8. If you want to modify the default task settings, enable the **Open task details when creation is complete** option at the **Finish task creation** step. If you do not enable this option, the task is created with the default settings. You can change the default settings later, at any time.
9. Click the **Finish** button.

   The task is created and displayed in the list of tasks.
10. Click the name of the created task to open the task properties window.
11. In the task properties window, specify the general task settings according to your needs, and then save the settings.

    The task is created and configured.

To run the task, select it in the task list, and then click the **Start** button.

Replacing third-party security applications

Installation of Kaspersky security applications through Kaspersky EDR Expert may require removal of third-party software that is incompatible with the application being installed. Open Single Management Platform provides several ways of removing the third-party applications.

Removing incompatible applications when configuring remote installation of an application

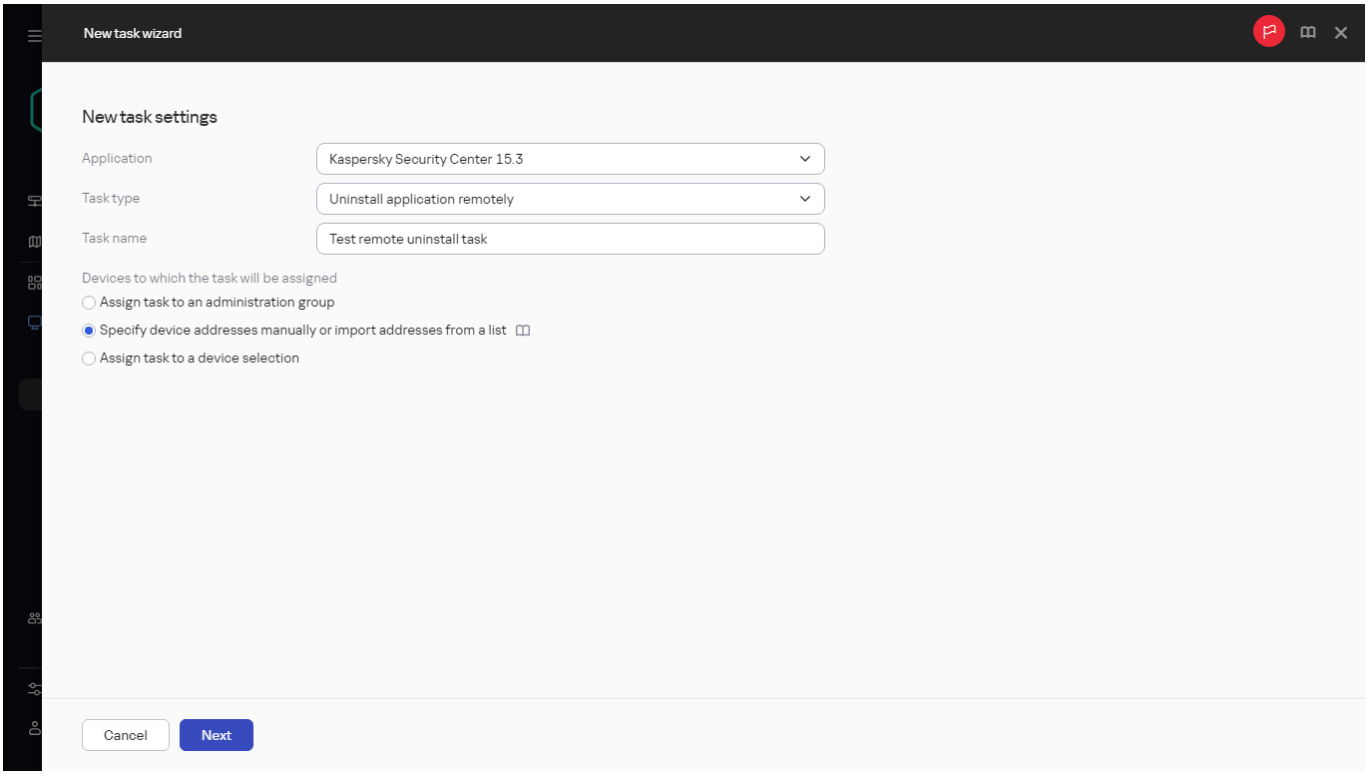
You can enable the **Uninstall incompatible applications automatically** option when you configure remote installation of a security application in the Protection deployment wizard. When this option is enabled, Open Single Management Platform removes incompatible applications before installing a security application on a managed device.

Removing incompatible applications through a dedicated task

To remove incompatible applications through a task, use the *Uninstall application remotely* task. This task should be run on devices before the security application installation task. For example, in the installation task you can select **On completing another task** as the schedule type where the other task is *Uninstall application remotely*.

This method of uninstallation is useful when the security application installer cannot properly remove an incompatible application.

Removing applications or software updates remotely

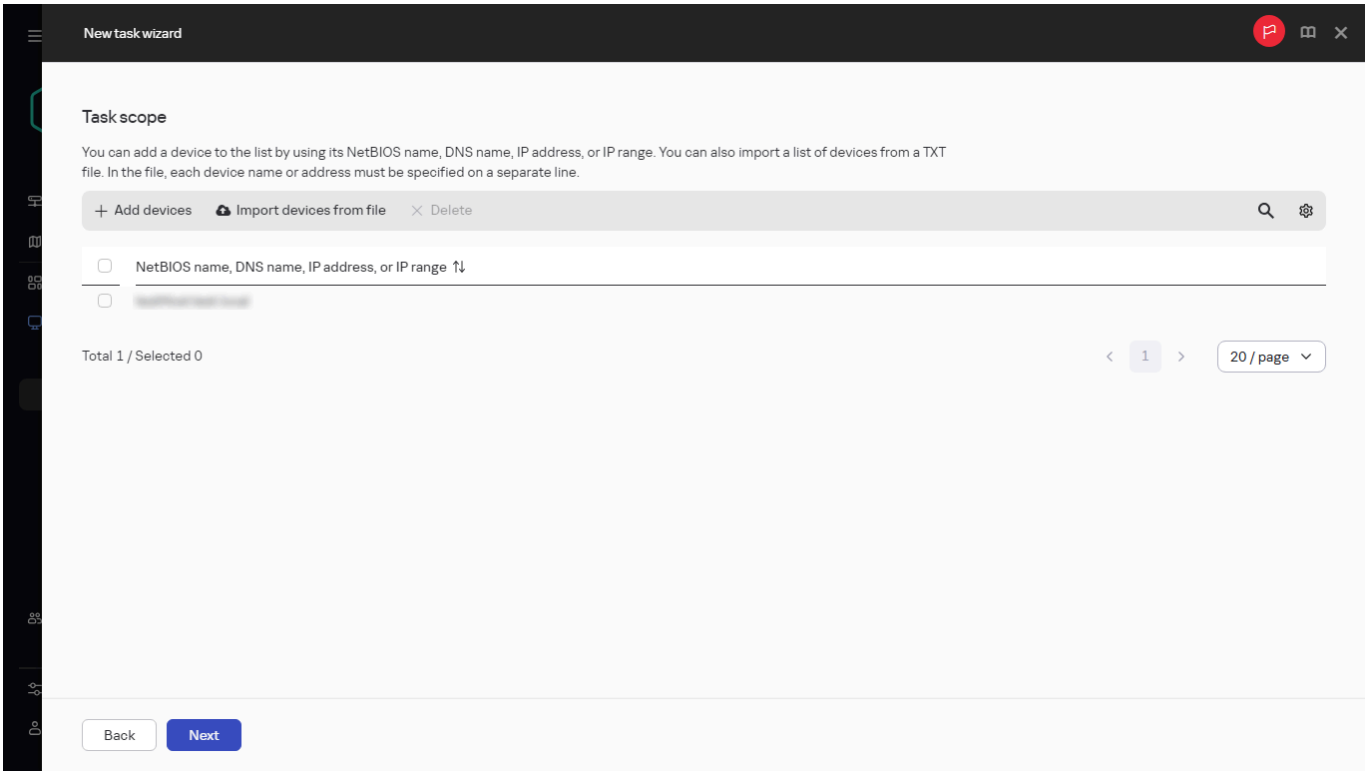


You can remove applications or software updates on managed devices that run Linux remotely only by using Network Agent.

To remove applications or software updates remotely from selected devices:

1. In the main menu, go to **Tasks**.
2. Click the **Add** button.

   The New task wizard starts. Proceed through the wizard by using the **Next** button.
3. In the **Application** drop-down list, select Kaspersky EDR Expert.
4. In the **Task type** list, select the **Uninstall application remotely** task type.
5. In the **Task name** field, specify the name of the new task.



The task name cannot be more than 100 characters long and cannot include any special characters ("*<>?\:|).

Creating the Uninstall application remotely task

6. Select devices to which the task will be assigned.

   Go to the next step of the wizard.

Specifying the task scope

7. Select what kind of software you want to remove, and then select specific applications, updates, or patches that you want to remove:

   Uninstall managed application

   A list of Kaspersky applications is displayed. Select the application that you want to remove.

Verify that the **Use uninstallation password** policy setting is disabled for the managed application.

Uninstall incompatible application

A list of applications incompatible with Kaspersky security applications or Open Single Management Platform is displayed. Select the check boxes next to the applications that you want to remove.

Uninstall application from applications registry

By default, Network Agents send the Administration Server information about the applications installed on the managed devices. The list of installed applications is stored in the applications registry.

To select an application from the applications registry:

a. Click the **Application to uninstall** field, and then select the application that you want to remove.

> If you select Kaspersky Security Center Network Agent, when you run the task, the status *Completed successfully* shows that the process of removing started. If Kaspersky Security Center Network Agent is removed, the status does not change. If the task fails, the status changes to *Failed.*

b. Specify the uninstallation options:

- **Uninstallation mode**

  Select how you want to remove the application:

  - **Define uninstallation command automatically**

    If the application has an uninstallation command defined by the application vendor, Open Single Management Platform uses this command. We recommend that you select this option.

  - **Specify uninstallation command**

    Select this option if you want to specify your own command for the application uninstallation.

    > We recommend that you first try to remove the application by using the **Define uninstallation command automatically** option. If the uninstallation through the automatically defined command fails, then use your own command.

    Type an installation command into the field, and then specify the following option:

    Use this command for uninstallation only if the default command was not autodetected

    Open Single Management Platform checks whether or not the selected application has an uninstallation command defined by the application vendor. If the command is found, Open Single Management Platform will use it instead of the command specified in the **Command for application uninstallation** field.

    We recommend that you enable this option.

- **Perform restart after successful application uninstallation**

  If the application requires the operating system to be restarted on the managed device after successful uninstallation, the operating system is restarted automatically.

Uninstall the specified application update, patch, or third-party application

A list of updates, patches, and third-party applications is displayed. Select the item that you want to remove.

The displayed list is a general list of applications and updates, and it does not correspond to the applications and updates installed on the managed devices. Before selecting an item, we recommend that you ensure that the application or update is installed on the devices defined in the task scope. You can view the list of devices on which the application or update is installed, via the properties window.

To view the list of devices:

a. Click the name of the application or update.

The properties window opens.

b. Open the **Devices** section.

You can also view the list of installed applications and updates in the device properties window.

8. Specify how client devices will download the Uninstallation utility:

Using Network Agent

The files are delivered to client devices by Network Agent installed on those client devices.

If this option is disabled, the files are delivered using the Linux operating system tools.

We recommend that you enable this option if the task has been assigned to devices with Network Agents installed.

Using operating system resources through Administration Server

The option is obsolete. Use the **Using Network Agent** or **Using operating system resources through distribution points** option instead.

The files are transmitted to client devices by using the Administration Server operating system tools. You can enable this option if no Network Agent is installed on the client device, but the client device is in the same network as the Administration Server.

Using operating system resources through distribution points

The files are transmitted to client devices by using operating system tools through distribution points. You can enable this option if there is at least one distribution point on the network.

If the **Using Network Agent** option is enabled, the files are delivered by using operating system tools only if Network Agent tools are unavailable.

Maximum number of concurrent downloads

The maximum allowed number of client devices to which Administration Server can simultaneously transmit the files. The larger this number, the faster the application will be uninstalled, but the load on Administration Server is higher.

Maximum number of uninstallation attempts

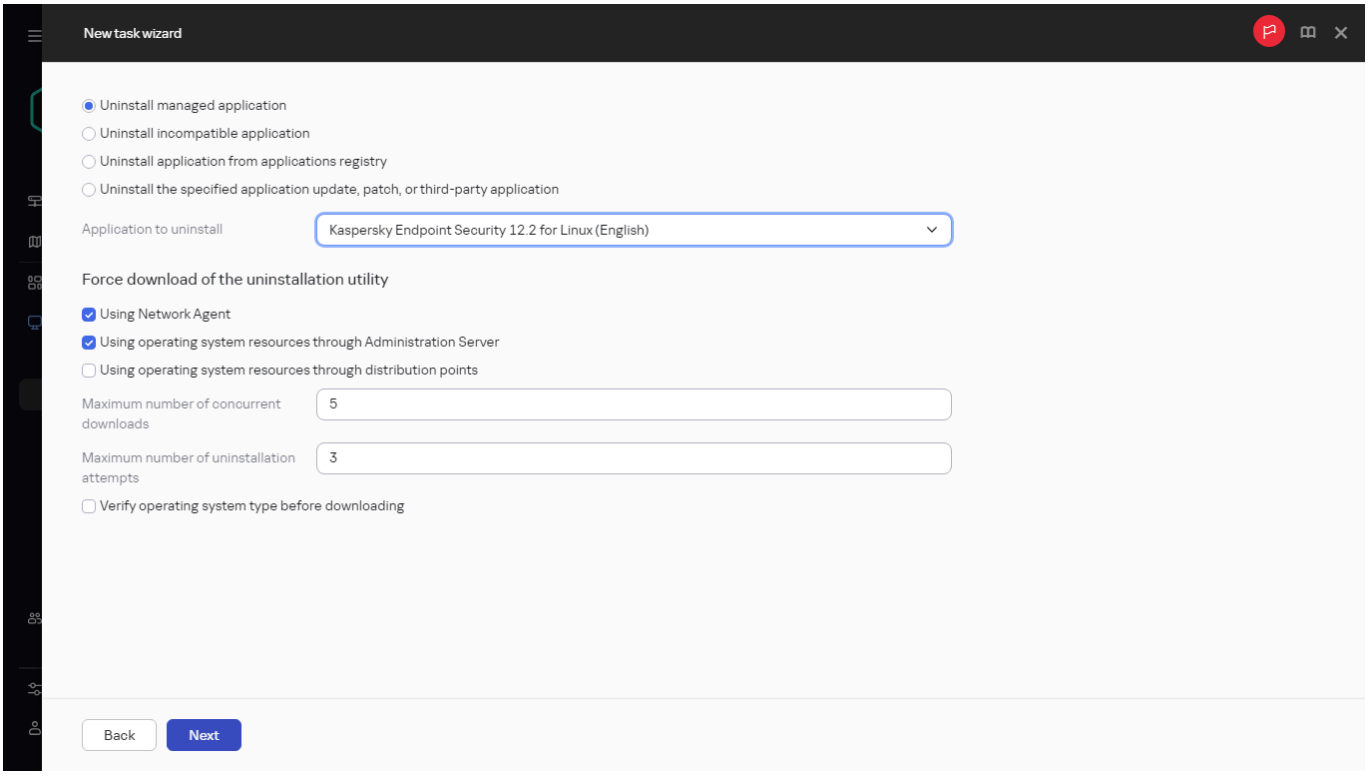
If, when running the *Uninstall application remotely* task, Open Single Management Platform fails to uninstall an application on a managed device within the number of installer runs specified by the parameter, Open Single Management Platform stops delivering the Uninstallation utility to this managed device and does not start the installer on the device anymore.

The **Maximum number of uninstallation attempts** parameter allows you to save the resources of the managed device, as well as reduce traffic (uninstallation, MSI file run, and error messages).

Recurring task start attempts may indicate a problem on the device and which prevents uninstallation. The administrator should resolve the problem within the specified number of uninstallation attempts and then restart the task (manually or by a schedule).

If uninstallation is not achieved eventually, the problem is considered unresolvable and any further task starts are seen as costly in terms of unnecessary consumption of resources and traffic.

When the task is created, the attempts counter is set to `0`. Each run of the installer that returns an error on the device increments the counter reading.



If the number of attempts specified in the parameter has been exceeded and the device is ready for application uninstallation, you can increase the value of the **Maximum number of uninstallation attempts** parameter and start the task to uninstall the application. Alternatively, you can create a new *Uninstall application remotely* task.

Verify operating system type before downloading

Before transmitting the files to client devices, Open Single Management Platform checks if the Installation utility settings are applicable to the operating system of the client device. If the settings are not applicable, Open Single Management Platform does not transmit the files and does not attempt to install the application. For example, to install some application to devices of an administration group that includes devices running various operating systems, you can assign the installation task to the administration group, and then enable this option to skip devices that run an operating system other than the required one.

When you remotely install Network Agent on unassigned devices, Open Single Management Platform or a distribution point automatically determines the device's operating system type, regardless of the **Verify operating system type before downloading** setting.

Go to the next step of the wizard.

Specifying the task settings

9. Specify the operating system restart settings:

Do not restart the device

Client devices are not restarted automatically after the operation. To complete the operation, you must restart a device (for example, manually or through a device management task). Information about the required restart is saved in the task results and in the device status. This option is suitable for tasks on servers and other devices where continuous operation is critical.

Restart the device

Client devices are always restarted automatically if a restart is required for completion of the operation. This option is useful for tasks on devices that provide for regular pauses in their operation (shutdown or restart).

Prompt user for action

The restart reminder is displayed on the screen of the client device, prompting the user to restart it manually. Some advanced settings can be defined for this option: text of the message for the user, the message display frequency, and the time interval after which a restart will be forced (without the user's confirmation). This option is most suitable for workstations where users must be able to select the most convenient time for a restart.

By default, this option is selected.

- **Repeat prompt every (min)**
- **Restart after (min)**

Force closure of applications in blocked sessions

Running applications may prevent a restart of the client device. For example, if a document is being edited in a word processing application and is not saved, the application does not allow the device to restart.

If this option is enabled, such applications on a locked device are forced to close before the device restart. As a result, users may lose their unsaved changes.

If this option is disabled, a locked device is not restarted. The task status on this device states that a device restart is required. Users have to manually close all applications running on locked devices and restart these devices.

By default, this option is disabled.

Go to the next step of the wizard.

10. If necessary, add the accounts that will be used to start the remote uninstallation task:

No account required (Network Agent installed)

If this option is selected, you do not have to specify the account under which the application installer will be run. The task will run under the account under which the Administration Server service is running.

If Network Agent has not been installed on client devices, this option is not available.

Account required (Network Agent is not used)

Select this option if Network Agent is not installed on the devices for which you assign the *Uninstall application remotely* task. In this case, you can specify a user account or an SSH certificate to uninstall the application.

- **Local or domain account**. If this option is selected, specify the user account under which the application installer will be run. Click the **Add** button, select **Local or domain account**, and then specify the user account credentials.

  You can specify multiple user accounts if, for example, none of them have all the required rights on all devices for which you assign the task. In this case, all added accounts are used for running the task, in consecutive order, top-down.

- **SSH certificate**. If you want to uninstall an application from a Linux-based client device, you can specify an SSH certificate instead of a user account. Click the **Add** button, select **SSH certificate**, and then specify the private and public keys of the certificate.

  To generate a private key, you can use the ssh-keygen utility. Note that Open Single Management Platform supports the PEM format of private keys, but the ssh-keygen utility generates SSH keys in the OPENSSH format by default. The OPENSSH format is not supported by Open Single Management Platform. To create a private key in the supported PEM format, add the -m PEM option in the ssh-keygen command.

  For example:

  ```
  ssh-keygen -m PEM -t rsa -b 4096 -C "<user email>"
  ```

11. If at the **Finish task creation** step of the wizard, you enable the **Open task details when creation is complete** option, you can edit the default settings of the task.

    If you do not enable this option, the task is created with the default settings. You can modify the default settings later.

12. Click the **Finish** button.

    The wizard creates the task. If you enabled the **Open task details when creation is complete** option, the task properties window automatically opens. In this window, you can specify the general task settings and, if required, change the settings specified during task creation.

    > You can also open the task properties window by clicking the name of the created task in the list of tasks.

    The task is created, configured, and displayed in the list of tasks at **Tasks**.

13. To run the task, select it in the task list, and then click the **Start** button.

    You can also set a task start schedule on the **Schedule** tab of the task properties window.

    For a detailed description of scheduled start settings, refer to the general task settings.

After the task is completed, the selected application is removed from the selected devices.

Remote uninstallation issues

Sometimes remote uninstallation of third-party applications may finish with the following warning: "Remote uninstallation has finished on this device with warnings: Application for removal is not installed." This issue occurs when the application to be uninstalled has already been uninstalled or was installed only for an individual user. Applications installed for an individual user (also referred to as per-user applications) become invisible and cannot be uninstalled remotely if the user is not logged in.

This behavior differs from applications intended for use by multiple users on the same device (also referred to as per-device applications). Per-device applications are visible and accessible to all users of the device.

Therefore, per-user applications must be uninstalled only when the user is logged in.

Source of information about installed applications

The Network Agent retrieves information about software installed on Windows devices from the following registry keys:

- HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Uninstall

  Contains information about applications installed for all users.

- HKEY_LOCAL_MACHINE\Software\Wow6432Node\Microsoft\Windows\CurrentVersion\Uninstall

  Contains information about applications installed for all users.

- HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Uninstall

  Contains information about applications installed for the current user.

- HKEY_USER<...>\Software\Microsoft\Windows\CurrentVersion\Uninstall

  Contains information about applications installed for specific users.

Preparing a device running SUSE Linux Enterprise Server 15 for installation of Network Agent

Prior to the installation of Network Agent on a device running SUSE Linux Enterprise Server 15, you must perform two preparation procedures—the one in the instructions below and general preparation steps for any Linux device.

To install Network Agent on a device with the SUSE Linux Enterprise Server 15 operating system:

Before the Network Agent installation, run the following command:

```
sudo zypper install insserv-compat
```

This enables you to install the insserv-compat package and configure Network Agent properly.

Run the `rpm -q insserv-compat` command to check whether the package is already installed.

If your network includes a lot of devices running SUSE Linux Enterprise Server 15, you can use the special software for configuring and managing the company infrastructure. By using this software, you can automatically install the insserv-compat package on all necessary devices at once. For example, you can use Puppet, Ansible, Chef, you can make your own script—use any method that is convenient for you.

If the device does not have the GPG signing keys for SUSE Linux Enterprise, you may encounter the following warning: `Package header is not signed!` Select the `i` option to ignore the warning.

After preparing the Linux device, you can install Network Agent remotely, in interactive mode, or in silent mode.

Preparing a Windows device for remote installation

Remote installation of the application on the client device may return an error for the following reasons:

- The task has already been successfully performed on this device.

  In this case, the task does not have to be performed again.

- When a task was started, the device was shut down.

  In this case, turn on the device, and then restart the task.

- There is no connection between the Administration Server and the Network Agent installed on the client device.

  To determine the cause of the problem, use the utility designed for remote diagnostics of client devices (klactgui).

- If Network Agent is not installed on the device, the following issues may occur during remote installation:
  - Network errors
  - Misconfigured operating system
  - Incorrectly configured account rights in the remote installation task

  To avoid issues that may occur during installation of the application on a client device without Network Agent installed, you must force the installation of selected installation packages by using the remote installation task of Open Single Management Platform—provided that each device has a user account with local administrator rights.

Previously, the riprep utility was used to prepare a Windows device for remote installation. This is now considered an outdated method for configuring operating systems. The riprep utility is not recommended for use on operating systems newer than Windows XP and Windows Server 2003 R2.

Forced installation can also be applied if devices cannot be directly accessed by Administration Server. For example, if the devices are on isolated networks or on a local network, while Administration Server is in the DMZ. In such cases, a distribution point is required for deployment to such devices.

Using distribution points as local installation centers may also be useful when performing installation on devices in subnets communicating with Administration Server via a low-capacity channel while a broader channel is available between devices in the same subnet.

In case of initial deployment, Network Agent is not installed. Therefore, in the settings of the remote installation task, you cannot select distribution of files required for application installation by using Network Agent. You can only choose to distribute files by using operating system resources through Administration Server or distribution points.

You should specify an account that has access to the admin$ share in the settings of the remote installation task.

You can specify target devices either explicitly (with a list), by selecting the Open Single Management Platform administration group to which they belong, or by creating a selection of devices based upon a specific criterion. The installation start time is defined by the task schedule. If the **Run missed tasks** setting is enabled in the task properties, the task can be run either immediately after target devices are turned on or when they are moved to the target administration group.

Forced installation consists of delivering installation packages to target devices, subsequent copying of files to the admin$ resource on each of the target devices, and remote registration of supporting services on those devices. Delivery of installation packages to target devices is performed through the Open Single Management Platform feature that ensures network interaction. The following conditions must be met in this case:

- Target devices are accessible from the distribution point with the Windows operating system, from which remote installation to client devices is to be carried out and this distribution point is selected for the target devices.
- Name resolution for target devices functions properly on the network.
- The administrative shares (admin$) remain enabled on target devices.
- The following system services are running on target devices:
  - Server (LanmanServer)

    By default, this service is running.

- DCOM Server Process Launcher (DcomLaunch)
- RPC Endpoint Mapper (RpcEptMapper)
- Remote Procedure Call (RpcSs)

- Port TCP 445 is open on target devices, to enable remote access through Windows tools.

  TCP 139, UDP 137, and UDP 138 are used by older protocols and are no longer necessary for current applications.

  Dynamic outbound access ports must be allowed on the firewall, for connections from distribution points to target devices.

- The Active Directory domain policy security settings are allowed to provide the operation of the NTLM protocol during the deployment of Network Agent.
- On target devices running Microsoft Windows XP, Simple File Sharing mode is disabled.
- On target devices, the access sharing and security model are set as *Classic – local users authenticate as themselves*. It can in no way be *Guest only – local users authenticate as Guest*.
- Target devices are members of the domain, or uniform accounts with administrator rights are created on target devices in advance.

To deploy Network Agent or other applications successfully to a device that is not joined to a Windows Server 2003 or later Active Directory domain, you must disable remote UAC on that device. Remote UAC is one of the reasons that prevent local administrative accounts from accessing admin$, which is necessary for forced deployment of Network Agent or other applications. Disabling remote UAC does not affect local UAC.

During installation on new devices that have not yet been allocated to any of the Open Single Management Platform administration groups, you can open the remote installation task properties and specify the administration group to which devices will be moved after Network Agent installation.

When creating a group task, keep in mind that each group task affects all devices in all nested groups within a selected group. Therefore, you must avoid duplicating installation tasks in subgroups.

A simplified way to create tasks for forced installation of applications is automatic installation. To do this, you must open the administration group properties, open the list of installation packages, and then select the ones that must be installed on devices in this group. As a result, the selected installation packages will be automatically installed on all devices in this group and all of its subgroups. The time interval over which the packages will be installed depends on the network throughput and the total number of networked devices.

You can use several distribution points to reduce the load during the delivery of installation packages to target devices. Note that this installation method places a significant load on devices acting as distribution points. If you use distribution points, you have to make sure that they are present in each of the isolated subnets hosting target devices.

The free disk space in the partition with the %ALLUSERSPROFILE%\Application Data\KasperskyLab\adminkit folder must exceed, by many times, the total size of the distribution packages of installed applications.

Configuring Kaspersky applications

This section contains information about manual configuration of policies and tasks, about user roles, about building an administration group structure and hierarchy of tasks.

Scenario: Configuring network protection

Create and configure policies and tasks required for your network.

Prerequisites

Before you start, make sure that you have done the following:

- Installed Administration Server
- Installed OSMP Console
- Completed the Open Single Management Platform main installation scenario

Configuring network protection proceeds in stages:

1. **Setup and propagation of Kaspersky application policies and policy profiles**

   To configure and propagate settings for Kaspersky applications installed on the managed devices, you can use two different security management approaches—device-centric or user-centric. These two approaches can also be combined.

2. **Configuring tasks for remote management of Kaspersky applications**

   Manually create and configure the following policies and tasks in the **Managed devices** administration group:

   - Policy of Kaspersky Endpoint Security
   - Group task for updating Kaspersky Endpoint Security
   - Policy of Network Agent

   How-to instructions: Setting up the group task for updating Kaspersky Endpoint Security.

   If necessary, create additional tasks to manage the Kaspersky applications installed on the client devices.

3. **Evaluating and limiting the event load on the database**

   Information about events that occur during operation of managed applications is transferred from a client device and registered in the Administration Server database. To reduce the load on the Administration Server, evaluate and limit the maximum number of events that can be stored in the database.

   How-to instructions: Setting the maximum number of events.

Results

Upon completion of this scenario, your network will be protected by configuration of Kaspersky applications, tasks, and events received by the Administration Server:

- The Kaspersky applications are configured according to the policies and policy profiles.
- The applications are managed through a set of tasks.
- The maximum number of events that can be stored in the database is set.

When the network protection configuration is complete, you can proceed to configuring regular updates to Kaspersky databases and applications.

About device-centric and user-centric security management approaches

You can manage security settings from the standpoint of device features and from the standpoint of user roles. The first approach is called *device-centric security management* and the second is called *user-centric security management*. To apply different application settings to different devices, you can use either or both types of management in combination.

Device-centric security management enables you to apply different security application settings to managed devices depending on device-specific features. For example, you can apply different settings to devices allocated in different administration groups.

User-centric security management enables you to apply different security application settings to different user roles. You can create several user roles, assign an appropriate user role to each user, and define different application settings to the devices owned by users with different roles. For example, you may want to apply different application settings to devices of accountants and human resources (HR) specialists. As a result, when user-centric security management is implemented, each department—accounts department and HR department—has its own settings configuration for Kaspersky applications. A settings configuration defines which application settings can be changed by users and which are forcibly set and locked by the administrator.

By using user-centric security management, you can apply specific application settings to individual users. This may be required when an employee has a unique role in the company or when you want to monitor security issues related to devices of a specific person. Depending on the role of this employee in the company, you can expand or limit the rights of this person to change application settings. For example, you might want to expand the rights of a system administrator who manages client devices in a local office.

You can also combine the device-centric and user-centric security management approaches. For example, you can configure a specific application policy for each administration group, and then create policy profiles for one or several user roles of your enterprise. In this case, the policies and policy profiles are applied in the following order:

1. The policies created for device-centric security management are applied.
2. They are modified by the policy profiles according to the policy profile priorities.
3. The policies are modified by the policy profiles associated with user roles.

Policy setup and propagation: Device-centric approach

When you complete this scenario, the applications will be configured on all of the managed devices in accordance with the application policies and policy profiles that you define.

Prerequisites

Before you start, make sure that you have installed Administration Server and OSMP Console. You might also want to consider user-centric security management as an alternative or additional option to the device-centric approach. Learn more about two management approaches.

Stages

The scenario of device-centric management of Kaspersky applications consists of the following steps:

1. **Configuring application policies**

   Configure settings for Kaspersky applications installed on the managed devices by creating a policy for each application. The set of policies will be propagated to the client devices.

   If you have a hierarchical structure of several Administration Servers and/or administration groups, the secondary Administration Servers and child administration groups inherit the policies from the primary Administration Server by default. You can force the inheritance by the child groups and secondary Administration Servers to prohibit any modifications of the settings configured in the upstream policy. If you want only part of the settings to be forcibly inherited, you can lock them in the upstream policy. The rest unlocked settings will be available for modification in the downstream policies. The created hierarchy of policies will allow you to effectively manage devices in the administration groups.

   How-to instructions: Creating a policy

2. **Creating policy profiles (optional)**

   If you want devices within a single administration group to run under different policy settings, create policy profiles for those devices. A policy profile is a named subset of policy settings. This subset is distributed on target devices together with the policy, supplementing it under a specific condition called the *profile activation condition*. Profiles only contain settings that differ from the "basic" policy, which is active on the managed device.

   By using profile activation conditions, you can apply different policy profiles, for example, to the devices having a specific hardware configuration or marked with specific tags. Use tags to filter devices that meet specific criteria. For example, you can create a tag called *CentOS*, mark all devices running CentOS operating system with this tag, and then specify this tag as an activation condition for a policy profile. As a result, Kaspersky applications installed on all devices running CentOS will be managed by their own policy profile.

   How-to instructions:

   - Creating a policy profile
   - Creating a policy profile activation rule

3. **Propagating policies and policy profiles to the managed devices**

By default, the Administration Server automatically synchronizes with managed devices every 15 minutes. During the synchronization, the new or changed policies and policy profiles are propagated to the managed devices. You can circumvent auto-synchronization and run the synchronization manually by using the Force synchronization command. When synchronization is complete, the policies and policy profiles are delivered and applied to the installed Kaspersky applications.

You can check whether the policies and policy profiles were delivered to a device. Open Single Management Platform specifies the delivery date and time in the properties of the device.

How-to instructions: Forced synchronization

Results

When the device-centric scenario is complete, the Kaspersky applications are configured according to the settings specified and propagated through the hierarchy of policies.

The configured application policies and policy profiles will be applied automatically to the new devices added to the administration groups.

Policy setup and propagation: User-centric approach

This section describes the scenario of user-centric approach to the centralized configuration of Kaspersky applications installed on the managed devices. When you complete this scenario, the applications will be configured on all of the managed devices in accordance with the application policies and policy profiles that you define.

Prerequisites

Before you start, make sure that you have successfully installed Administration Server and OSMP Console, and completed the main deployment scenario. You might also want to consider device-centric security management as an alternative or additional option to the user-centric approach. Learn more about two management approaches.

Process

The scenario of user-centric management of Kaspersky applications consists of the following steps:

1. **Configuring application policies**

   Configure settings for Kaspersky applications installed on the managed devices by creating a policy for each application. The set of policies will be propagated to the client devices.

If you have a hierarchical structure of several Administration Servers and/or administration groups, the secondary Administration Servers and child administration groups inherit the policies from the primary Administration Server by default. You can force the inheritance by the child groups and secondary Administration Servers to prohibit any modifications of the settings configured in the upstream policy. If you want only part of the settings to be forcibly inherited, you can lock them in the upstream policy. The rest unlocked settings will be available for modification in the downstream policies. The created hierarchy of policies will allow you to effectively manage devices in the administration groups.

How-to instructions: Creating a policy

2. **Specifying owners of the devices**

   Assign the managed devices to the corresponding users.

   How-to instructions: Assigning a user as a device owner

3. **Defining user roles typical for your enterprise**

   Think about different kinds of work that the employees of your enterprise typically perform. You must divide all employees in accordance with their roles. For example, you can divide them by departments, professions, or positions. After that you will need to create a user role for each group. Keep in mind that each user role will have its own policy profile containing application settings specific for this role.

4. **Creating user roles**

   Create and configure a user role for each group of employees that you defined on the previous step or use the predefined user roles. The user roles will contain set of rights of access to the application features.

   How-to instructions: Creating a user role

5. **Defining the scope of each user role**

   For each of the created user roles, define users and/or security groups and administration groups. Settings associated with a user role apply only to devices that belong to users who have this role, and only if these devices belong to groups associated with this role, including child groups.

   How-to instructions: Editing the scope of a user role

6. **Creating policy profiles**

   Create a policy profile for each user role in your enterprise. The policy profiles define which settings will be applied to the applications installed on users' devices depending on the role of each user.

   How-to instructions: Creating a policy profile

7. **Associating policy profiles with the user roles**

   Associate the created policy profiles with the user roles. After that: the policy profile becomes active for a user that has the specified role. The settings configured in the policy profile will be applied to the Kaspersky applications installed on the user's devices.

   How-to instructions: Associating policy profiles with roles

8. **Propagating policies and policy profiles to the managed devices**

   By default, Open Single Management Platform automatically synchronizes the Administration Server with the managed devices every 15 minutes. During the synchronization, the new or changed policies and policy profiles are propagated to the managed devices. You can circumvent auto-synchronization and run the synchronization manually by using the Force synchronization command. When synchronization is complete, the policies and policy profiles are delivered and applied to the installed Kaspersky applications.

   You can check whether the policies and policy profiles were delivered to a device. Open Single Management Platform specifies the delivery date and time in the properties of the device.

   How-to instructions: Forced synchronization

Results

When the user-centric scenario is complete, the Kaspersky applications are configured according to the settings specified and propagated through the hierarchy of policies and policy profiles.

For a new user, you will have to create a new account, assign the user one of the created user roles, and assign the devices to the user. The configured application policies and policy profiles will be automatically applied to the devices of this user.

About switching Network Agent to other Administration Servers

Kaspersky EDR Expert provides the option of switching Network Agent on a client device to other Administration Servers if the following settings of the network have been changed:

- **Condition for DHCP server address**—The IP address of the network Dynamic Host Configuration Protocol (DHCP) server has changed.

  > The **Condition for DHCP server address** setting is currently not available.

- **Condition for default connection gateway address**—The address of the main network gateway has changed.
- **Condition for DNS domain**—The DNS suffix of the subnet has changed.
- **Condition for DNS server address**—The IP address of the network DNS server has changed.
- **Condition for WINS server address**—The IP address of the network WINS server has changed. This setting is available only for devices running Windows.
- **Condition for name resolvability**—The DNS or NetBIOS name of the client device has changed.
- **Condition for subnet**—Changes the subnet address and mask.
- **Condition for Windows domain accessibility**—Changes the status of the Windows domain to which the client device is connected. This setting is available only for devices running Windows.
- **Condition for SSL connection address accessibility**—The client device can or cannot (depending on the option that you select) establish an SSL connection with a specified server (name:port). You must use a dedicated server with software capable of handling high load and frequent Network Agent requests for the connection. Do not specify the Administration Server's port. For each server, you can additionally specify an SSL certificate. In this case, the Network Agent verifies the server certificate in addition to checking the capability of an SSL connection. If the certificate does not match, the connection fails.

The initial settings of the Network Agent connection to Administration Server are defined when installing the Network Agent. Afterwards, if rules for switching the Network Agent to other Administration Servers have been created, the Network Agent responds to changes in the network settings as follows:

- If the network settings comply with one of the rules created, Network Agent connects to the Administration Server specified in this rule. Applications installed on client devices switch to out-of-office policies, provided such behavior is enabled by a rule.
- If none of the rules apply, Network Agent reverts to the default settings of connection to the Administration Server specified during the installation. Applications installed on client devices switch back to active policies.
- If the Administration Server is not accessible, Network Agent uses out-of-office policies.

Network Agent switches to the out-of-office policy only if the **Enable out-of-office mode when Administration Server is not available** option is enabled in the Network Agent policy settings.

The settings of Network Agent connection to Administration Server are saved in a connection profile. In the connection profile, you can create rules for switching client devices to out-of-office policies, and you can configure the profile so that it could only be used for downloading updates.

Creating a connection profile for out-of-office users

To create a profile for connecting Network Agent to Administration Server for out-of-office users:

1. If you want to create a connection profile for a group of managed devices, open the Network Agent policy of this group. To do this, do the following:

   a. In the main menu, go to **Asset management** → **Policies**.

   b. Select the administration group for which the connection profile is to be created:

      - For the root group, you can proceed to the next step.
      - For a subgroup, click the **Show hierarchy** button at the top of the page, and then in the window that opens, click the name of the required subgroup.

      The path to the selected group is displayed at the top of the page. If necessary, you can click a link with the administration group name to go to the group. By default, the last link in the path is inactive. Also, you can close the hierarchy window by clicking the **Hide hierarchy** button.

   c. Add the Network Agent policy for the group of managed devices. If you have already created it, click the Network Agent policy name to open the policy properties.

2. If you want to create a connection profile for a specific managed device, do the following:

   a. In the main menu, go to **Asset management** → **Assets (Devices)**.

   b. Click the name of the managed device.

   c. In the managed device properties window that opens, go to the **Applications** tab.

   d. Click the name of the Network Agent policy to which only the selected managed device applies.

3. In the properties window that opens, go to **Application settings → Connectivity → Connection profiles.**

4. In the **Administration Server connection profiles** section, click the **Add** button.

   By default, the list of connection profiles contains the <Offline mode> and <Home Administration Server> profiles. Profiles cannot be edited or removed.

   The <Offline mode> profile does not specify any Server for connection. Therefore, Network Agent, when switched to that profile, does not attempt to connect to any Administration Server while applications installed on client devices run under out-of-office policies. The <Offline mode> profile can be used if devices are disconnected from the network.

   The <Home Administration Server> profile specifies the connection for the Administration Server that was selected during Network Agent installation. The <Home Administration Server> profile is applied when a device is reconnected to the home Administration Server after it was running on an external network for some time.

5. In the **Configure profile** window that opens, configure the connection profile:

   - **Profile name**

     In the entry field you can view or change the connection profile name.

   - **Administration Server address**

     Address of the Administration Server to which the client device must connect during profile activation.

   - **Port number**

     Port number that is used for connection.

   - **SSL port**

     Port number for connection if using the SSL protocol.

   - **Use SSL connection**

     If this option is enabled, the connection is established through a secure port, by using SSL protocol.

     By default, the option is enabled. We recommend that you do not disable this option so your connection remains secured.

   - Select the **Use proxy server** option if you want to use a proxy server when connecting to the internet. If this option is selected, fields are available for entering settings. Specify the following settings for a proxy server connection:

     - **Address**

       Address of the proxy server used for Kaspersky EDR Expert connection to the internet.

     - **Port number**

       Number of the port through which Kaspersky EDR Expert proxy connection will be established.

     - **Proxy server authentication**

       If this check box is selected, in the entry fields you can specify the credentials for proxy server authentication.

- **User name**

  User account under which connection to the proxy server is established (this field is available if the **Proxy server authentication** check box is selected).

- **Password**

  Password set by the user under whose account the proxy server connection is established (this field is available if the **Proxy server authentication** check box is selected).

  To see the entered password, click and hold the **Show** button for as long as you require.

- **Connection gateway address**

  Address of the gateway through which client devices connect to the Administration Server.

- **Enable out-of-office mode when Administration Server is not available**

  Select this check box to allow the applications installed on a client device to use policy profiles for devices in out-of-office mode, as well as out-of-office policies, at any connection attempt if the Administration Server is not available. If no out-of-office policy has been defined for the application, the active policy will be used.

  If this option is disabled, applications will use active policies.

  This check box is cleared by default.

- **Use to receive updates only**

  If this option is enabled, the profile will only be used for downloading updates by applications installed on the client device. For other operations, connection to the Administration Server will be established with the initial connection settings defined during Network Agent installation.

  By default, the option is enabled.

- **Synchronize connection settings with Administration Server settings specified in this profile**

  If this option is enabled, Network Agent connects to Administration Server using the settings specified in the profile properties.

  If this option is disabled, Network Agent connects to Administration Server using the original settings that have been specified during installation.

  This option is available if the **Use to receive updates only** option is disabled.

  By default, this option is disabled.

A profile for connecting Network Agent to Administration Server is created for out-of-office users. When Network Agent connects to Administration Server by using this profile, applications installed on the client device will use policies for devices in out-of-office mode or out-of-office policies.

Policies and policy profiles

In OSMP Console, you can create policies for Kaspersky applications. This section describes policies and policy profiles, and provides instructions for creating and modifying them.

About policies and policy profiles

A *policy* is a set of Kaspersky application settings that are applied to an administration group and its subgroups. You can install several Kaspersky applications on the devices of an administration group. Kaspersky EDR Expert provides a single policy for each Kaspersky application in an administration group. A policy has one of the following statuses:

The status of the policy

State	Description
Active	The current policy that is applied to the device. Only one policy may be active for a Kaspersky application in each administration group. Devices apply the settings values of an active policy for a Kaspersky application.
Inactive	A policy that is not currently applied to a device.
Out-of-office	If this option is selected, the policy becomes active when the device leaves the corporate network.

Policies function according to the following rules:

- Multiple policies with different values can be configured for a single application.
- Only one policy can be active for the current application.
- A policy can have child policies.

Generally, you can use policies as preparations for emergency situations, such as a virus attack. For example, if there is an attack via flash drives, you can activate a policy that blocks access to flash drives. In this case, the current active policy automatically becomes inactive.

In order to prevent maintaining multiple policies, for example, when different occasions assume changing of several settings only, you may use policy profiles.

A *policy profile* is a named subset of policy settings values that replaces the settings values of a policy. A policy profile affects the effective settings formation on a managed device. *Effective settings* are a set of policy settings, policy profile settings, and local application settings that are currently applied for the device.

Policy profiles function according to the following rules:

- A policy profile takes effect when a specific activation condition occurs.
- Policy profiles contain values of settings that differ from the policy settings.
- Activation of a policy profile changes the effective settings of the managed device.
- A policy can include a maximum of 100 policy profiles.

About lock and locked settings

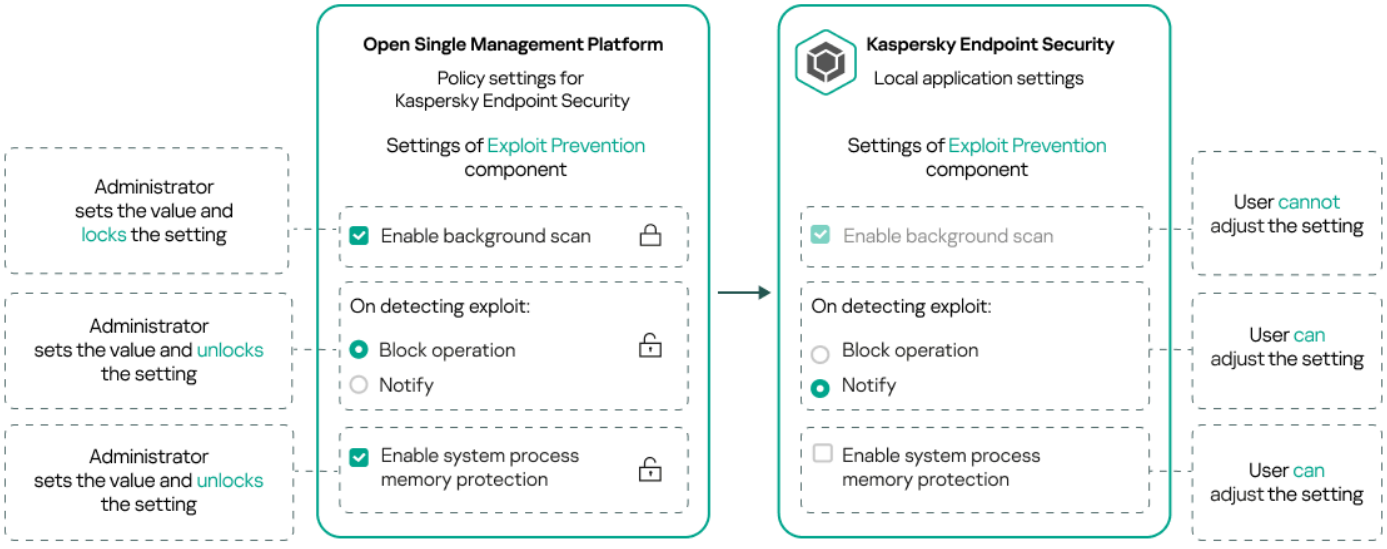
Each policy setting has a lock button icon (). The table below shows lock button statuses:

Lock button statuses

State	Description
Undefined	If an open lock is displayed next to a setting and the toggle button is disabled, the setting is not specified in the policy. A user can change these settings in the managed application interface. These type of settings are called *unlocked*.
Enforce	If a closed lock is displayed next to a setting and the toggle button is enabled, the setting is applied to the devices where the policy is enforced. A user cannot modify the values of these settings in the managed application interface. These type of settings are called *locked*.

We highly recommend that you close locks for the policy settings that you want to apply on the managed devices. The unlocked policy settings can be reassigned by Kaspersky application settings on a managed device.

You can use a lock button for performing the following actions:



- Locking settings for an administration subgroup policy
- Locking settings of a Kaspersky application on a managed device

Thus, a locked setting is used for implementing effective settings on a managed device.

A process of effective settings implementation includes the following actions:

- Managed device applies settings values of Kaspersky application.
- Managed device applies locked settings values of a policy.

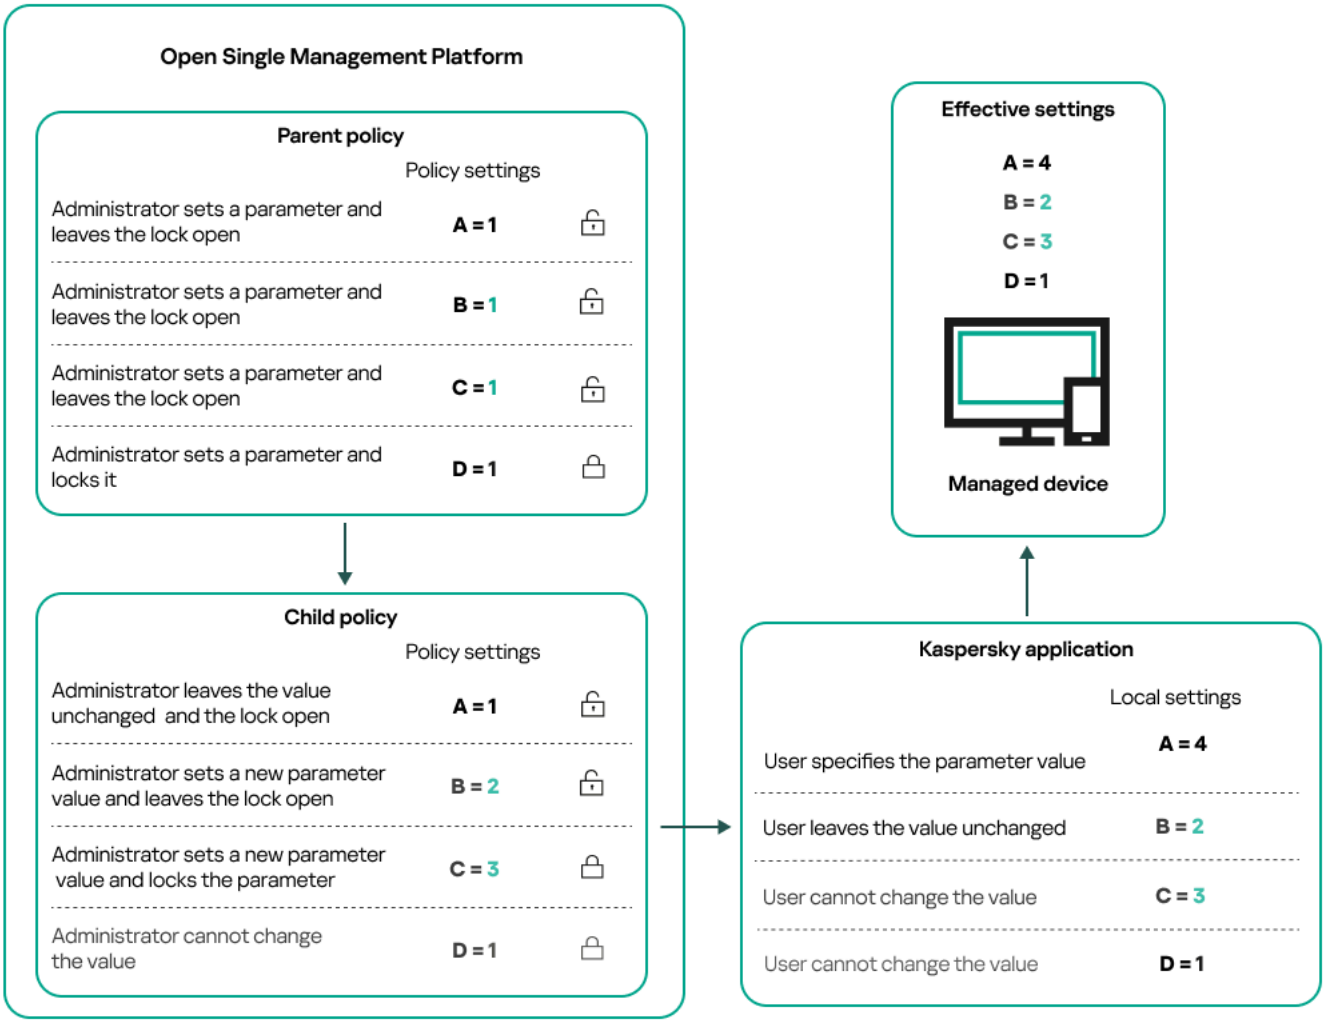
A policy and managed Kaspersky application contain the same set of settings. When you configure policy settings, the Kaspersky application settings change values on a managed device. You cannot adjust locked settings on a managed device (see the figure below):

Locks and Kaspersky application settings

Inheritance of policies and policy profiles

This section provides information about the hierarchy and inheritance of policies and policy profiles.

Hierarchy of policies



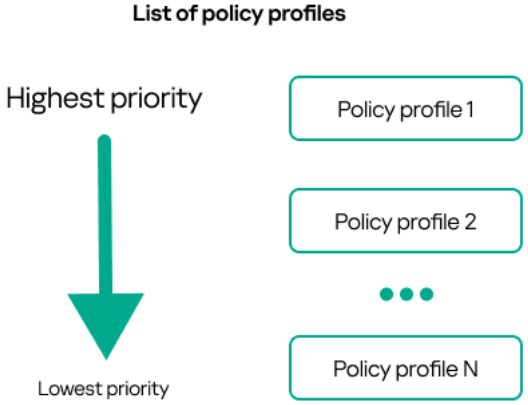
If different devices need different settings, you can organize devices into administration groups.

You can specify a policy for a single administration group. Policy settings can be *inherited*. Inheritance means receiving policy settings values in subgroups (child groups) from a policy of a higher-level (parent) administration group.

Hereinafter, a policy for a parent group is also referred to as a *parent policy*. A policy for a subgroup (child group) is also referred to as a *child policy*.

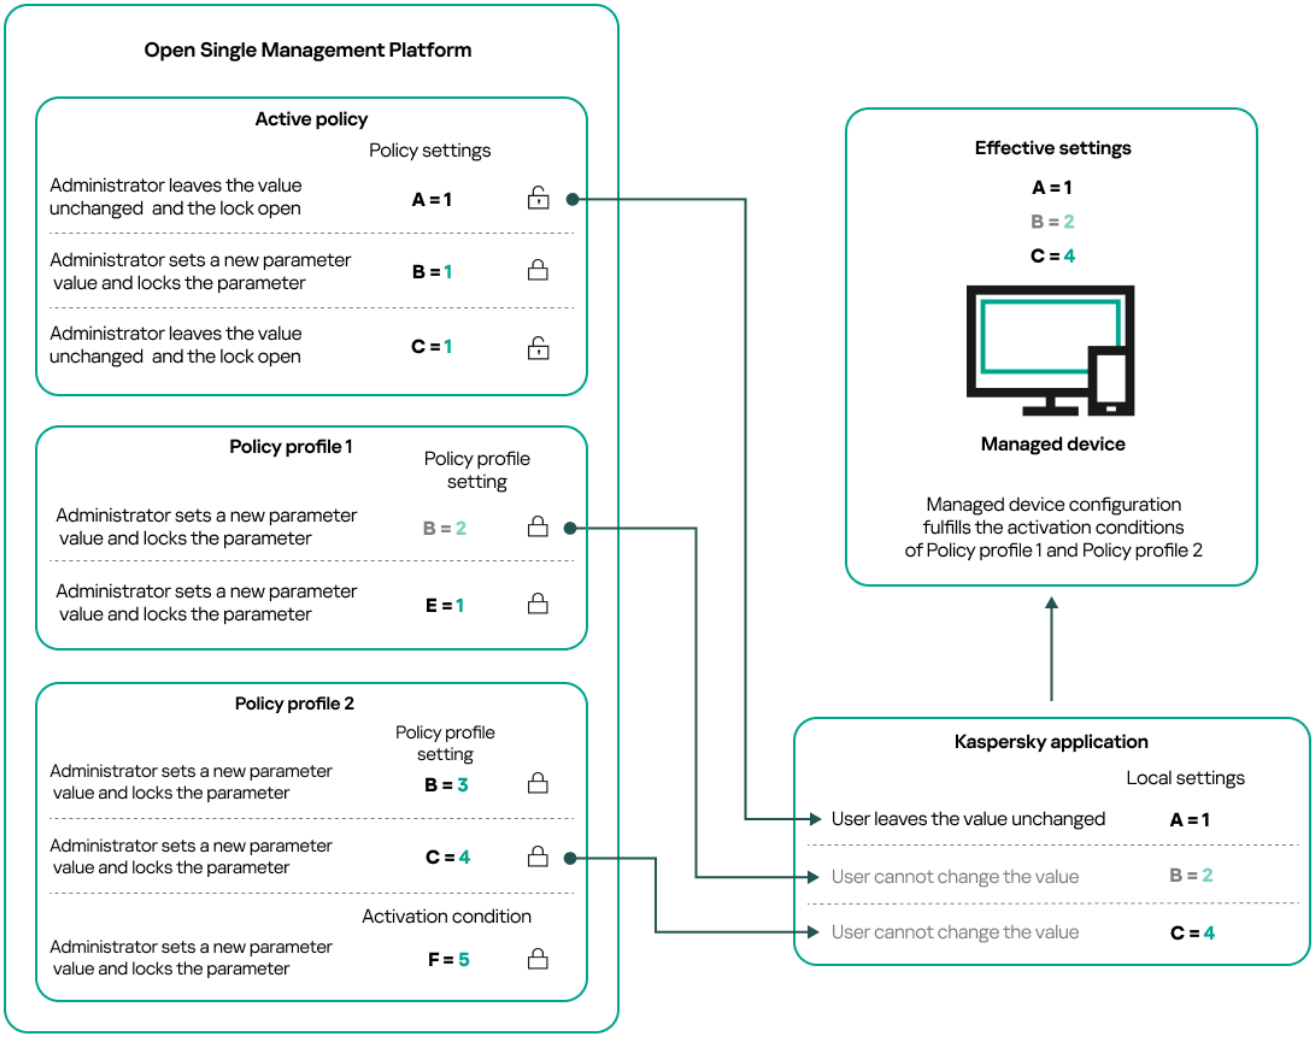
By default, at least one managed devices group exists on Administration Server. If you want to create custom groups, they are created as subgroups (child groups) within the managed devices group.

Policies of the same application act on each other, according to a hierarchy of administration groups. Locked settings from a policy of a higher-level (parent) administration group will reassign policy settings values of a subgroup (see the figure below).



Hierarchy of policies

Policy profiles in a hierarchy of policies

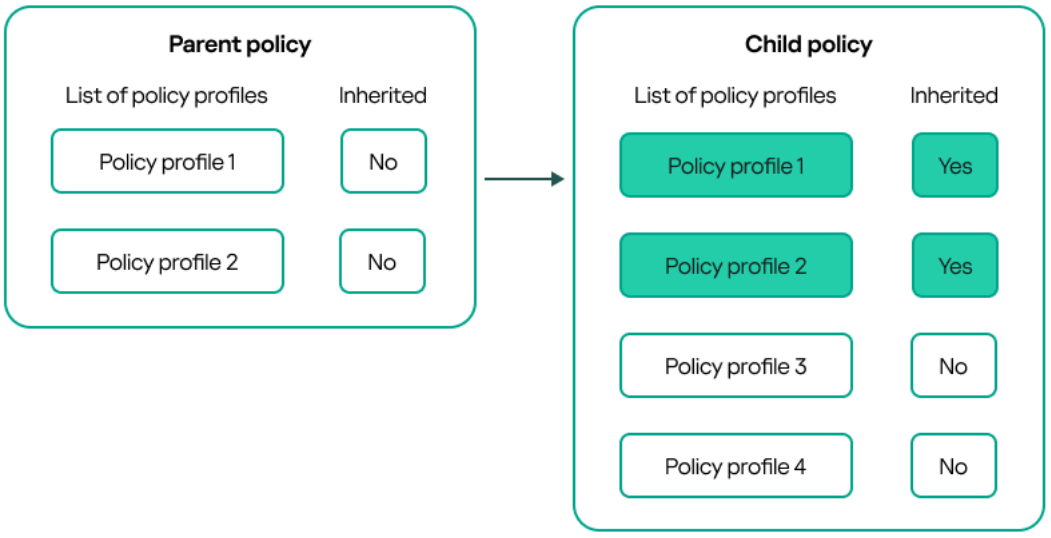


Policy profiles have the following priority assignment conditions:

- A profile's position in a policy profile list indicates its priority. You can change a policy profile priority. The highest position in a list indicates the highest priority (see the figure below).

Priority definition of a policy profile

- Activation conditions of policy profiles do not depend on each other. Several policy profiles can be activated simultaneously. If several policy profiles affect the same setting, the device takes the setting value from the policy profile with the highest priority (see the figure below).

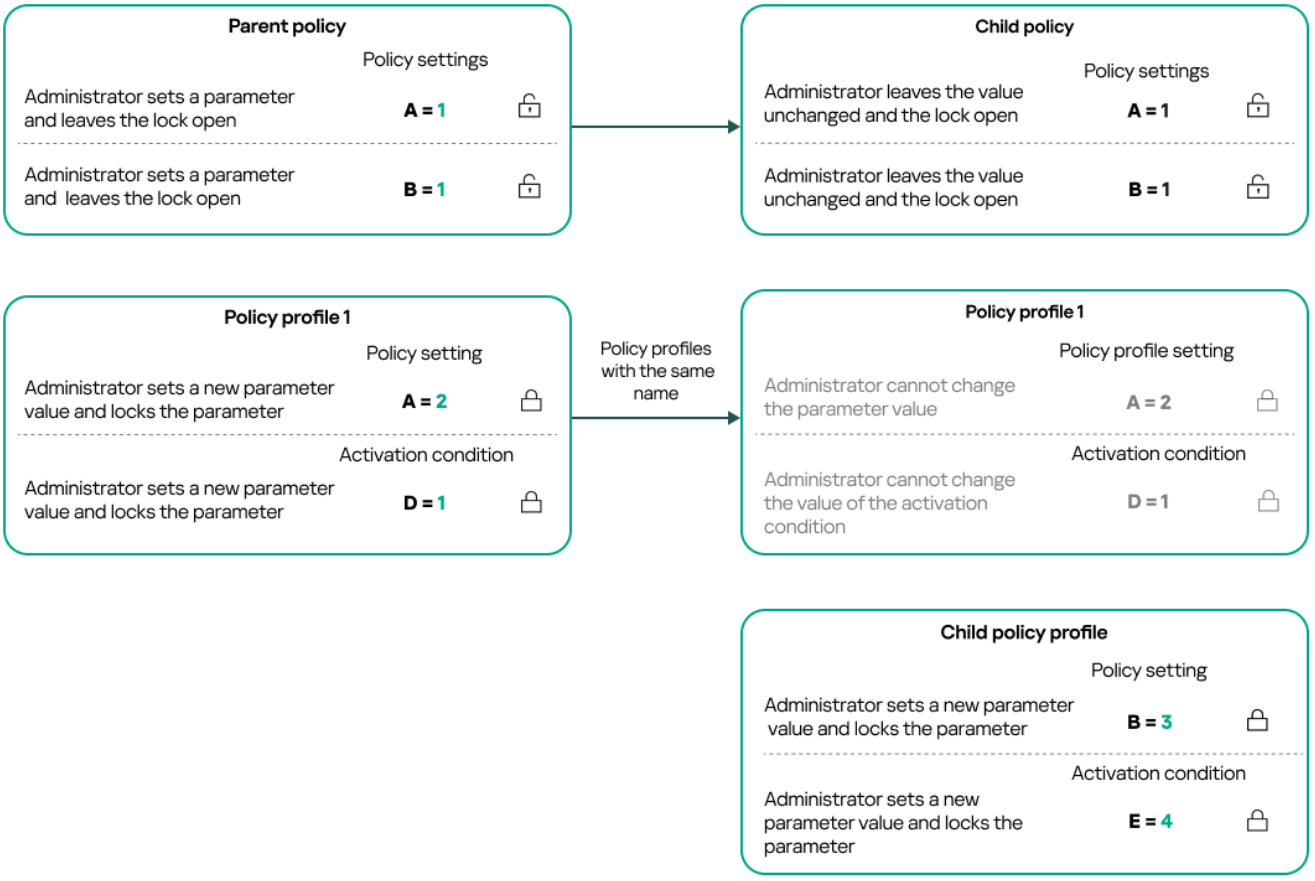


Managed device configuration fulfills activation conditions of several policy profiles

Policy profiles in a hierarchy of inheritance

Policy profiles from different hierarchy level policies comply with the following conditions:

- A lower-level policy inherits policy profiles from a higher-level policy. A policy profile inherited from a higher-level policy obtains higher priority than the original policy profile's level.
- You cannot change a priority of an inherited policy profile (see the figure below).



Inheritance of policy profiles

Policy profiles with the same name

If there are two policies with the same names in different hierarchy levels, these policies function according to the following rules:

- Locked settings and the profile activation condition of a higher-level policy profile changes the settings and profile activation condition of a lower-level policy profile (see the figure below).

Child profile inherits settings values from a parent policy profile

- Unlocked settings and the profile activation condition of a higher-level policy profile do not change the settings and profile activation condition of a lower-level policy profile.

How settings are implemented on a managed device

Implementation of effective settings on a managed device can be described as follows:

- The values of all settings that have not been locked are taken from the policy.
- Then they are overwritten with the values of managed application settings.
- And then the locked settings values from the effective policy are applied. Locked settings values change the values of unlocked effective settings.

Managing policies

This section describes managing policies and provides information about viewing the list of policies, creating a policy, modifying a policy, copying a policy, moving a policy, forced synchronization, viewing the policy distribution status chart, and deleting a policy.

Viewing the list of policies

You can view lists of policies created for the Administration Server or for any administration group.

To view a list of policies:

1. In the main menu, go to **Asset management** → **Hierarchy of groups**.
2. In the administration group structure, select the administration group for which you want to view the list of policies.

The list of policies appears in tabular format. If there are no policies, the table is empty. You can show or hide the columns of the table, change their order, view only lines that contain a value that you specify, or use search.

Creating a new policy

You can create policies; you can also modify and delete existing policies.

To create a policy:

1. In the main menu, go to **Asset management** → **Policies**.
2. Select the administration group for which the policy is to be created:
   - For the root group.

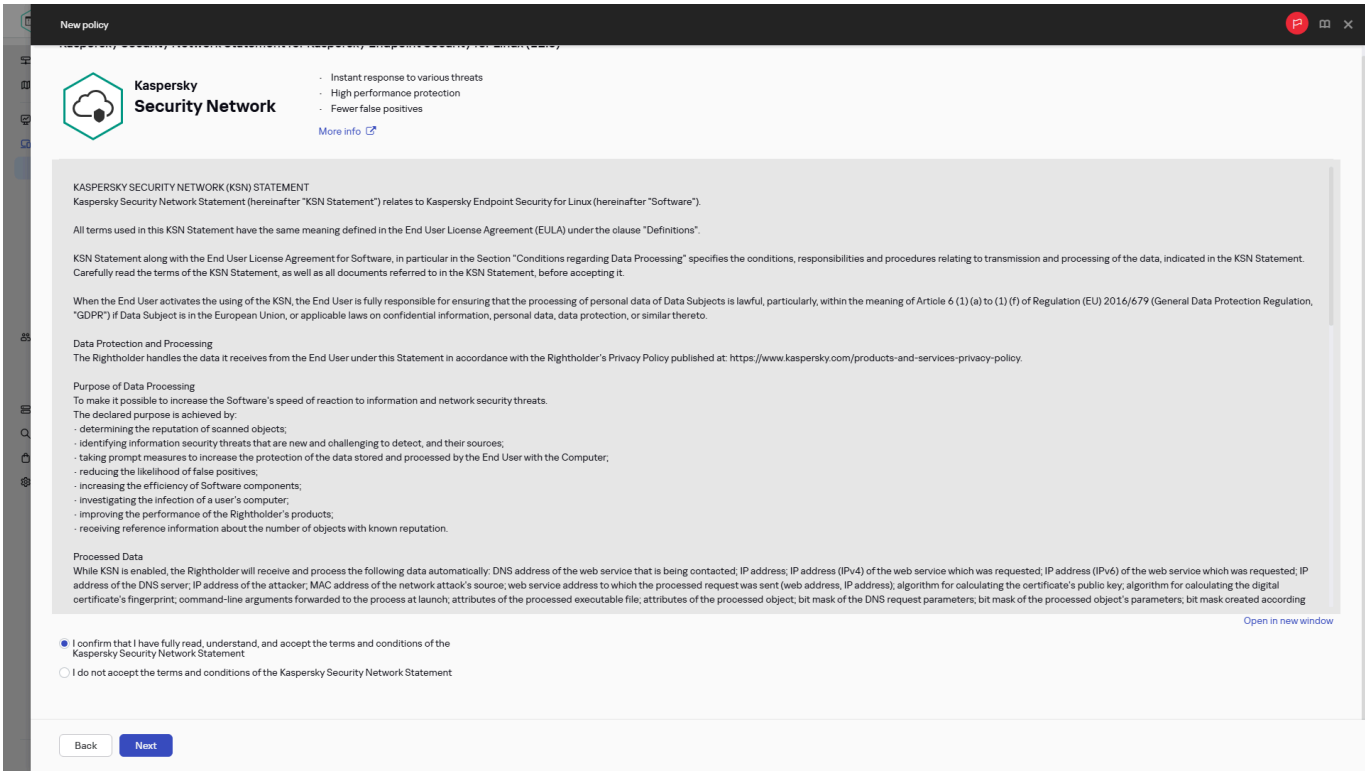
     In this case you can proceed to the next step.
   - For a subgroup:

     a. Click the **Show hierarchy** button at the top of the page.

     b. The button name changes to **Hide hierarchy**.

     c. In the window that opens, click the name of the required subgroup.

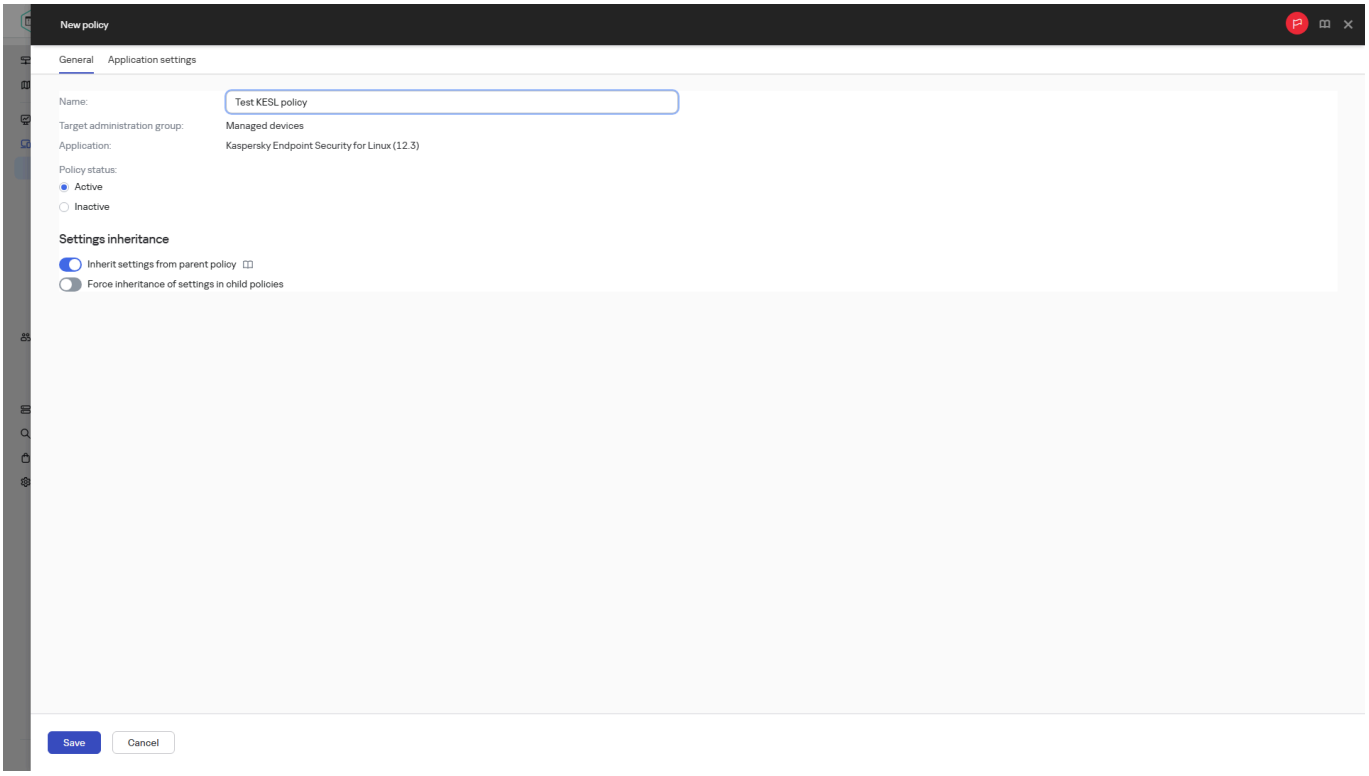
     The path to the selected group is displayed at the top of the page. If necessary, you can click a link with the administration group name to go to the group. By default, the last link in the path is inactive. Also, you can close the hierarchy window by clicking the **Hide hierarchy** button.
3. Click **Add**.



The **Select application** window opens.

Creating a new policy

4. Select the application for which you want to create a policy.



5. If Kaspersky Security Network is supported by the Kaspersky application, for which you are creating a policy, you will be prompted to accept the KSN Statement. If you want to use Kaspersky Security Network, accept the KSN Statement.

Accepting the KSN Statement

6. Click **Next**.

The new policy settings window opens with the **General** tab selected. If you want, change the default name, default status, and default inheritance settings of the policy.

The new policy settings window

7. Select the **Application settings** tab.

   Or, you can click **Save** and exit. The policy will appear in the list of policies, and you can edit its settings later.

8. On the **Application settings** tab, in the left pane select the category that you want and in the results' pane on the right, edit the settings of the policy. You can edit policy settings in each category (section).

   The set of settings depends on the application for which you create a policy. For details, refer to the following:

   - Configuring Administration Server
   - Network Agent policy settings
   - Kaspersky Endpoint Security for Linux Help
   - Kaspersky Endpoint Security for Windows Help

   For details about settings of other security applications, refer to the documentation for the corresponding application.

   When editing the settings, you can click **Cancel** to cancel the last operation.

9. Click **Save** to save the policy.

   A notification is displayed with the following message: **The policy is being saved and distributed through the hierarchy of Administration Servers**.

   If the policy passes validation, the following notification is displayed: **Policy has been saved**.

   If the policy fails validation, the following notification is displayed: **Failed to save and distribute the policy through the Administration Servers hierarchy. Contact Technical Support**. You can review and revise the policy settings, and then try again. If the issue persists, contact Technical Support.

The policy will appear in the list of policies. Once the policy is created, policy change events are exported to SIEM system, if this option is enabled.

General policy settings

General

In the **General** tab, you can modify the policy status and specify the inheritance of policy settings:

- In the **Policy status** block, you can select one of the policy modes:

  Active

  If this option is selected, the policy becomes active.

  By default, this option is selected.

  Out-of-office

  If this option is selected, the policy becomes active when the device leaves the corporate network.

  Inactive

  If this option is selected, the policy becomes inactive, but it is still stored in the **Policies** folder. If required, the policy can be activated.

- In the **Settings inheritance** settings group, you can configure the policy inheritance:

  Inherit settings from parent policy

  If this option is enabled, the policy setting values are inherited from the upper-level group policy and, therefore, are locked.

  By default, the option is enabled.

  Force inheritance of settings in child policies

  If this option is enabled, after policy changes are applied, the following actions will be performed:

  - The values of the policy settings will be propagated to the policies of administration subgroups, that is, to the child policies.
  - In the **Settings inheritance** block of the **General** section in the properties window of each child policy, the **Inherit settings from parent policy** option will be automatically enabled.

  If this option is enabled, the child policies settings are locked.

  By default, this option is disabled.

Event configuration

The **Event configuration** tab allows you to configure event logging and event notification. Events are distributed by importance level on the following tabs:

- **Critical**

  The **Critical** section is not displayed in the Network Agent policy properties.

- **Functional failure**

- **Warning**
- **Info**

In each section, the list shows the types of events and the default event storage period on the Administration Server (in days). Clicking an event type lets you specify the following settings:

- **Event registration**

  You can specify how many days to store the event and select where to store the event:

  - **Export to SIEM system by using Syslog**
  - **Store in the OS event log on device**
  - **Store in the OS event log on Administration Server**

- **Event notifications**

  You can select if you want to be notified about the event in one of the following ways:

  - **Notify by email**
  - **Notify by SMS**
  - **Notify by running an executable file or script**
  - **Notify by SNMP**

  By default, the notification settings specified on the Administration Server properties tab (such as recipient address) are used. If you want, you can change these settings in the **Email**, **SMS**, and **Executable file to be run** tabs.

Also, the **Event configuration** tab displays a notification when new event types are added (for example, in a new version of the application), and enables you to apply the new settings by clicking the **Save** or **Save and close** button.

Revision history

The **Revision history** tab allows you to view the list of the policy revisions, compare the policy revisions, and roll back changes made to the policy, if necessary.

Modifying a policy

To modify a policy:

1. In the main menu, go to **Asset management** → **Policies**.
2. Click the policy that you want to modify.

   The policy settings window opens.

3. Specify the general settings and settings of the application for which you create a policy. For details, refer to the following:

   - Configuring Administration Server
   - Network Agent policy settings
   - Kaspersky Endpoint Security for Windows documentation

   For details about settings of other security applications, refer to the documentation for that application.

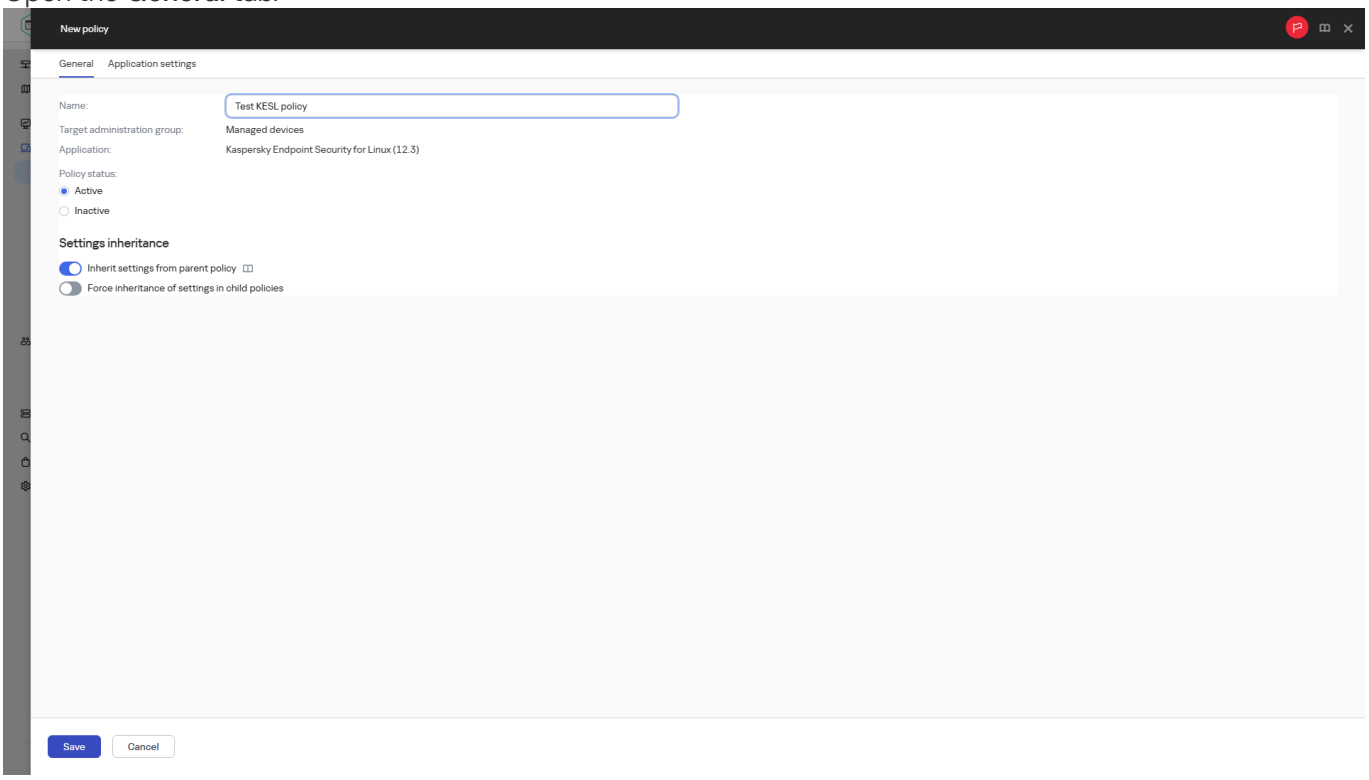
4. Click the **Save** button.

   A notification is displayed with the following message: **The policy is being saved and distributed through the hierarchy of Administration Servers**.

   If the policy passes validation, the following notification is displayed: **Policy has been saved**.

   If the policy fails validation, the following notification is displayed: **Failed to save and distribute the policy through the Administration Servers hierarchy. Contact Technical Support**. You can review and revise the policy settings, and then try again. If the issue persists, contact Technical Support.

The changes made to the policy will be saved in the policy properties, and will appear in the **Revision history** section. Once the policy is modified, policy change events are exported to SIEM system, if this option is enabled.

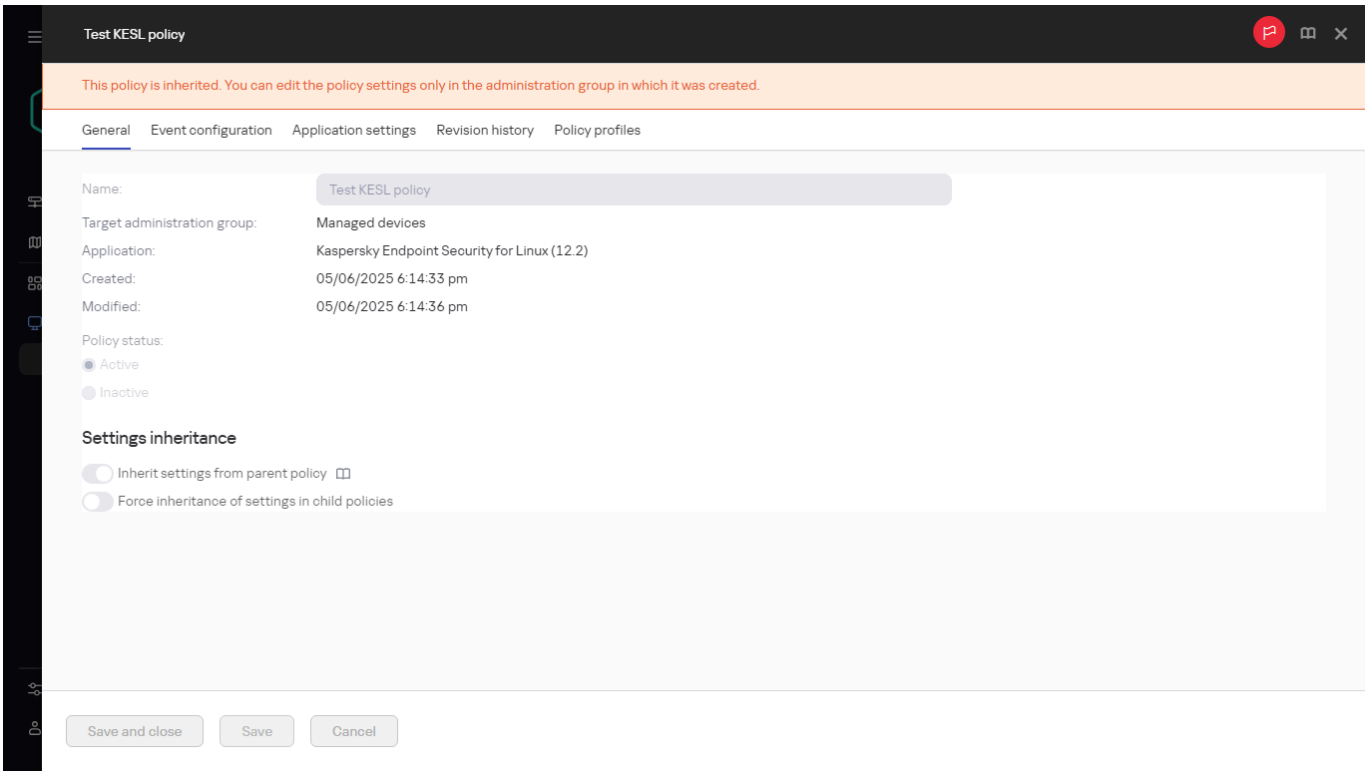


If necessary, you can compare policy revisions. The option is available for the policies of Administration Server, Network Agent, Kaspersky Endpoint Security for Windows (starting from 14.0 web plug-in version), and Kaspersky Endpoint Security for Mac (starting from 12.2.1 Patch A web plug-in version).

Enabling and disabling a policy inheritance option

To enable or disable the inheritance option in a policy:

1. Open the required policy.



2. Open the **General** tab.

Creating a new policy

3. Enable or disable policy inheritance:

   - If you enable **Inherit settings from parent policy** in a child policy and an administrator locks some settings in the parent policy, then you cannot change these settings in the child policy.
   - If you disable **Inherit settings from parent policy** in a child policy, then you can change all of the settings in the child policy, even if some settings are locked in the parent policy.
   - If you enable **Force inheritance of settings in child policies** in the parent group, this enables the **Inherit settings from parent policy** option for each child policy. In this case, you cannot disable this option for any child policy. All of the settings that are locked in the parent policy are forcibly inherited in the child groups, and you cannot change these settings in the child groups.

Locked policy settings

4. Click the **Save** button to save changes or click the **Cancel** button to reject changes.

By default, the **Inherit settings from parent policy** option is enabled for a new policy.

If a policy has profiles, all of the child policies inherit these profiles.

Copying a policy

You can copy policies from one administration group to another.

To copy a policy to another administration group:

1. In the main menu, go to **Asset management** → **Policies**.
2. Select the check box next to the policy (or policies) that you want to copy.
3. Click **Copy**.

   On the right side of the screen, the tree of the administration groups appears.

4. In the tree, select the target group, that is, the group to which you want to copy the policy (or policies).

5. Click the **Copy** button at the bottom of the screen.

6. Click **OK** to confirm the operation.

The policy (policies) will be copied to the target group with all its profiles. The status of each copied policy in the target group will be **Inactive**. You can change the status to **Active** at any time.

If a policy with the name identical to that of the newly moved policy already exists in the target group, the name of the newly moved policy is expanded with the (<next sequence number>) index, for example: (1).

Moving a policy

You can move policies from one administration group to another. For example, you want to delete a group, but you want to use its policies for another group. In this case, you may want move the policy from the old group to the new one before deleting the old group.

When moving a policy to another administration group, the revision history of the policy is cleared. The **Revision history** tab displays information about the latest change only.

To move a policy to another administration group:

1. In the main menu, go to **Asset management** → **Policies**.

2. Select the check box next to the policy (or policies) that you want to move.

3. Click the **Move** button.

   On the right side of the screen, the tree of the administration groups appears.

4. In the tree, select the target group, that is, the group to which you want to move the policy (or policies).

5. Click the **Move** button at the bottom of the screen.

6. Click **OK** to confirm the operation.

   If a policy is not inherited from the source group, it is moved to the target group with all its profiles. The status of the policy in the target group is **Inactive**. You can change the status to **Active** at any time.

   If a policy is inherited from the source group, it remains in the source group. It is copied to the target group with all its profiles. The status of the policy in the target group is **Inactive**. You can change the status to **Active** at any time.

If a policy with the name identical to that of the newly moved policy already exists in the target group, the name of the newly moved policy is expanded with the (<next sequence number>) index, for example: (1).

Exporting a policy

Open Single Management Platform allows you to save a policy, its settings, and the policy profiles to a KLP file. You can use this KLP file to import the saved policy both to Kaspersky Security Center Windows and Kaspersky Security Center Linux.

To export a policy:

1. In the main menu, go to **Asset management** → **Policies**.
2. Select the check box next to the policy that you want to export.

   You cannot export multiple policies at the same time. If you select more than one policy, the **Export** button will be disabled.
3. Click the **Export** button.
4. In the opened **Save as** window, specify the policy file name and path. Click **Save**.

   The **Save as** window is displayed only if you use Google Chrome, Microsoft Edge, or Opera. If you use another browser, the policy file is automatically saved in the **Downloads** folder.

Importing a policy

Open Single Management Platform allows you to import a policy from a KLP file. The KLP file contains the exported policy, its settings, and the policy profiles.

To import a policy:

1. In the main menu, go to **Asset management** → **Policies**.
2. Click the **Import** button.
3. Click the **Browse** button to choose a policy file that you want to import.
4. In the opened window, specify the path to the KLP policy file, and then click the **Open** button. Note that you can select only one policy file.

   The policy processing starts.
5. After the policy is processed successfully, select the administration group to which you want to apply the policy.
6. Click the **Complete** button to finish the policy import.

The notification with the import results appears. If the policy is imported successfully, you can click the **Details** link to view the policy properties.

After a successful import, the policy is displayed in the policy list. The settings and profiles of the policy are also imported. Regardless of the policy status that was selected during the export, the imported policy is inactive. You can change the policy status in the policy properties.

If the newly imported policy has a name identical to that of an existing policy, the name of the imported policy is expanded with the **(<next sequence number>)** index, for example: **(1)**, **(2)**.

Forced synchronization

Although Kaspersky EDR Expert automatically synchronizes the status, settings, tasks, and policies for managed devices, in some cases the administrator must know for certain, at a given moment, whether synchronization has already been performed for a specified device.

Synchronizing a single device

To force synchronization between the Administration Server and a managed device:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.
2. Click the name of the device that you want to synchronize with the Administration Server.

   A property window opens with the **General** section selected.
3. Click the **Force synchronization** button.

The application synchronizes the selected device with the Administration Server.

Synchronizing multiple devices

To force synchronization between the Administration Server and multiple managed devices:

1. Open the device list of an administration group or a device selection:
   - Run a device selection to view the device list.
   - In the main menu, go to **Asset management** → **Assets (Devices)**, and then select the administration group that contains devices to synchronize:
     - For the root group, you can proceed to the next step.
     - For a subgroup, click the **Show hierarchy** button at the top of the page, and then in the window that opens, click the name of the subgroup.

       The path to the selected group is displayed at the top of the page. If necessary, you can click a link with the administration group name to go to the group. By default, the last link in the path is inactive. Also, you can close the hierarchy window by clicking the **Hide hierarchy** button.
2. Select the check boxes next to the devices that you want to synchronize with the Administration Server.

3. Above the list of managed devices, click the ellipsis button (...), then click the **Force synchronization** button.

   The application synchronizes the selected devices with the Administration Server.

4. In the device list, check that the time of last connection to the Administration Server has changed, for the selected devices, to the current time. If the time has not changed, update the page content by clicking the **Refresh** button.

The selected devices are synchronized with the Administration Server.

Viewing the time of a policy delivery

After changing a policy for a Kaspersky application on the Administration Server, the administrator can check whether the changed policy has been delivered to a specific managed device. A policy can be delivered during a regular synchronization or a forced synchronization.

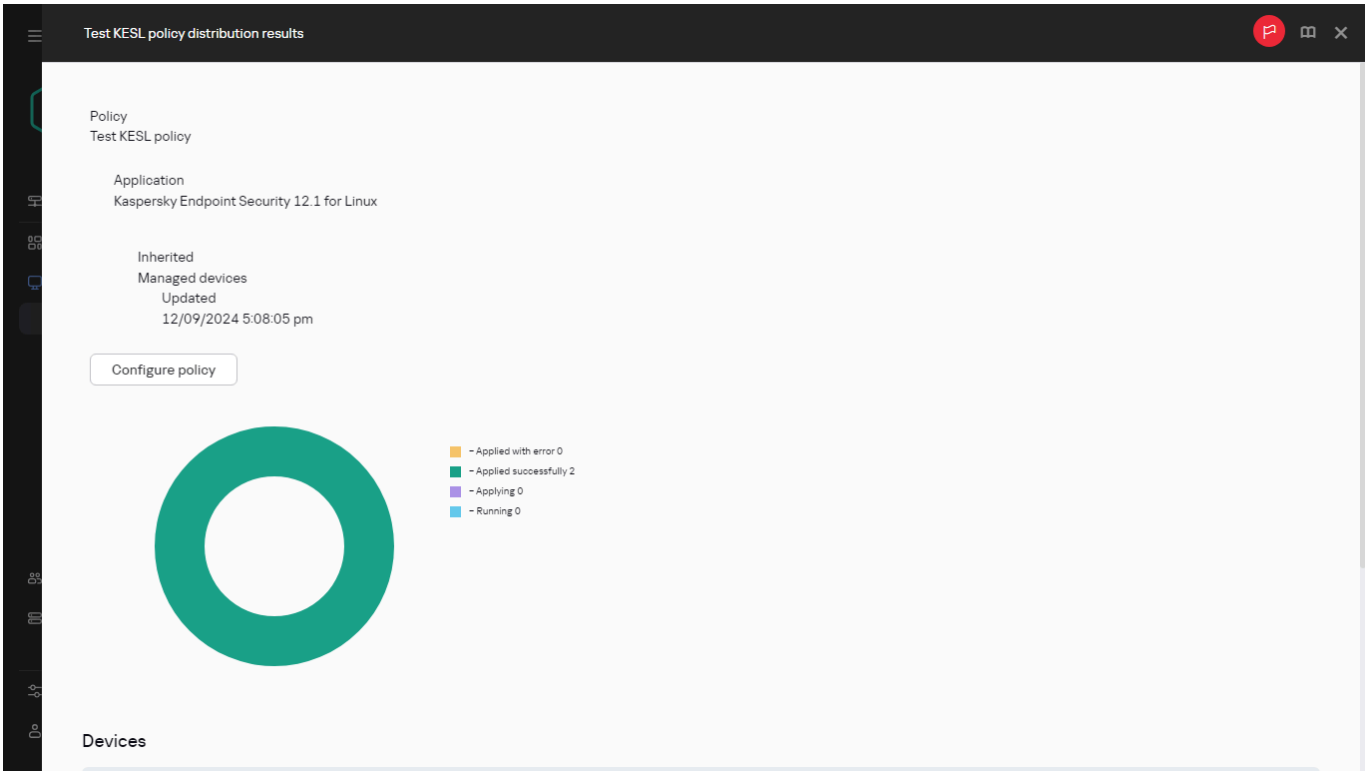
To view the date and time that an application policy was delivered to a managed device:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.
2. Click the name of the device that you want to synchronize with the Administration Server.

   A property window opens with the **General** section selected.

3. Click the **Applications** tab.
4. Select the application for which you want to view the policy synchronization date.

   The application policy window opens with the **General** section selected and the policy delivery date and time displayed.



Viewing the policy distribution status chart

In Open Single Management Platform, you can view the status of policy application on each device in a policy distribution status chart.

To view the policy distribution status on each device:

1. In the main menu, go to **Asset management** → **Policies**.
2. Select check box next to the name of the policy for which you want to view the distribution status on devices.
3. In the menu that appears, select the **Distribution** link.

The **<Policy name> distribution results** window opens.

Policy distribution status chart

4. In the **<Policy name> distribution results** window that opens, the **Status description** of the policy is displayed.

You can change number of results displayed in the list with policy distribution. The maximum number of devices is 100,000.

To change the number of devices displayed in the list with policy distribution results:

1. In the main menu, go to **Settings** → **Interface options**.
2. In the **Limit of devices displayed in policy distribution results**, enter the number of devices (up to 100,000).

   By default, the number is 5000.
3. Click the **Save** button.

   The settings are saved and applied.

Activating a policy automatically at the Virus outbreak event

To make a policy perform automatic activation at a Virus outbreak event:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens, with the **General** tab selected.
2. Select the **Virus outbreak** section.
3. In the right pane, click the **Configure policies to activate when a virus outbreak event occurs** link.

   The **Policy activation** window opens.

4. In the section relating to the component that detects a virus outbreak—Anti-Virus for workstations and file servers, Anti-Virus for mail servers, or Anti-Virus for perimeter defense—select the option button next to the entry you want, and then click **Add**.

   A window opens with the **Managed devices** administration group.

5. Click the chevron icon (>) next to **Managed devices**.

   A hierarchy of administration groups and their policies is displayed.

6. In the hierarchy of administration groups and their policies, click the name of a policy or policies that are activated when a virus outbreak is detected.

   To select all policies in the list or in a group, select the check box next to the required name.

7. Click the **Save** button.

   The window with the hierarchy of administration groups and their policies is closed.

The selected policies are added to the list of policies that are activated when a virus outbreak is detected. The selected policies are activated at the virus outbreak, independent whether they are active or inactive.

If a policy has been activated on the Virus outbreak event, you can return to the previous policy only by using the manual mode.

Deleting a policy

You can delete a policy if you do not need it anymore. You can delete only a policy that is not inherited in the specified administration group. If a policy is inherited, you can only delete it in the upper-level group for which it was created.

To delete a policy:

1. In the main menu, go to **Asset management** → **Policies**.

2. Select the check box next to the policy that you want to delete, and click **Delete**.

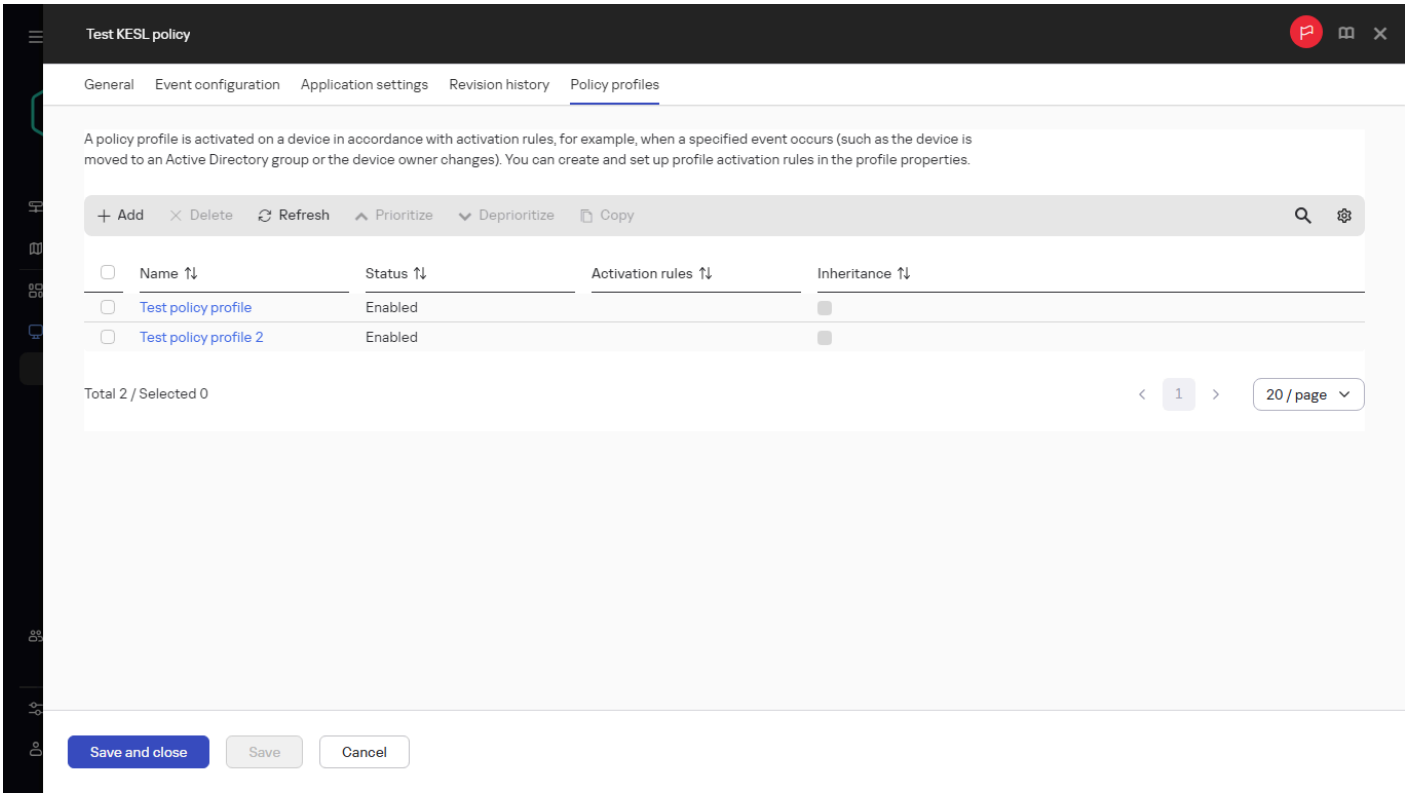
   The **Delete** button becomes unavailable (dimmed) if you select an inherited policy.

3. Click **OK** to confirm the operation.

The policy is deleted together with all its profiles. Once the policy is deleted, policy change events are exported to SIEM system, if this option is enabled.

Managing policy profiles

This section describes managing policy profiles and provides information about viewing the profiles of a policy, changing a policy profile priority, creating a policy profile, copying a policy profile, creating a policy profile activation rule, deleting, exporting and importing a policy profile.



Viewing the profiles of a policy

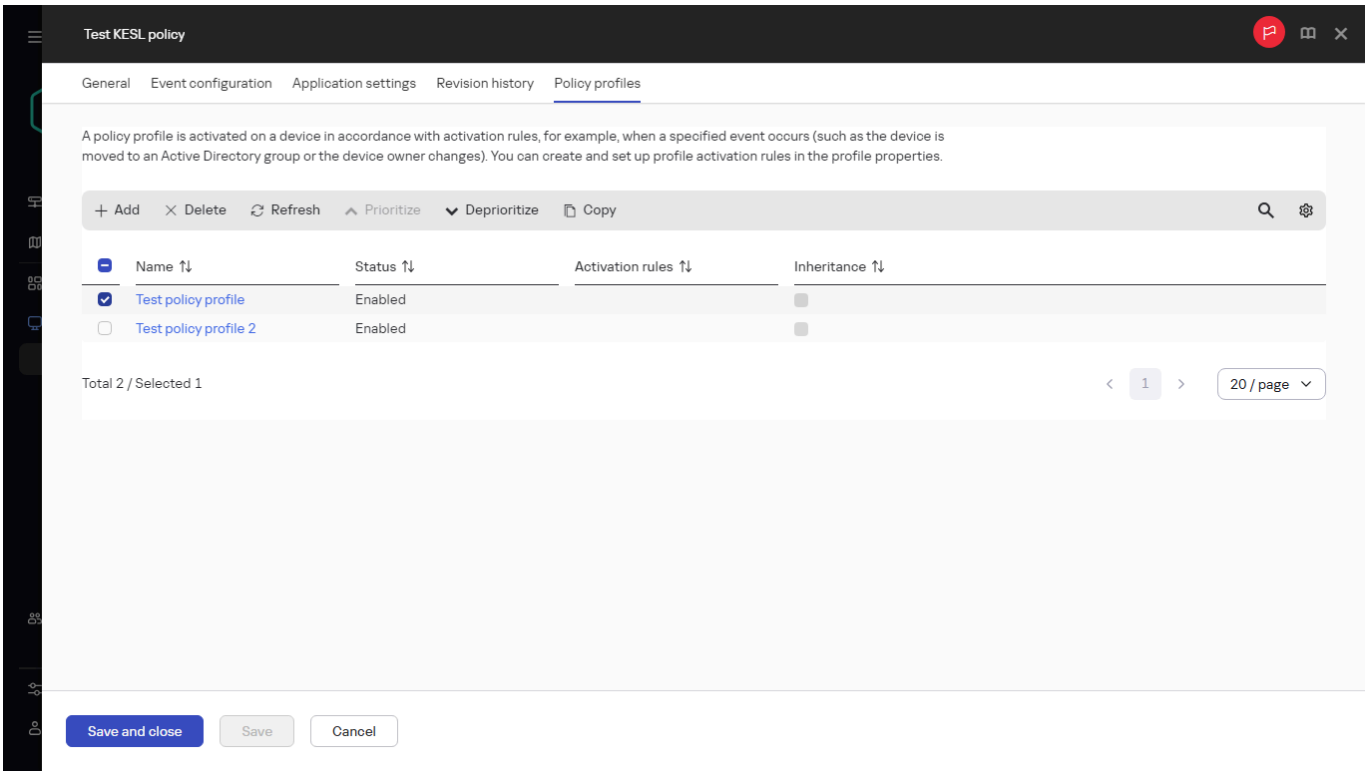
To view profiles of a policy:

1. In the main menu, go to **Asset management** → **Policies**.
2. Click the name of the policy whose profiles you want to view.

   The policy properties window opens with the **General** tab selected.
3. Open the **Policy profiles** tab.

The list of policy profiles appears in tabular format. If the policy does not have profiles, an empty table appears.

The list of policy profiles



Changing a policy profile priority

To change a policy profile priority:

1. Proceed to the list of profiles of the policy that you want.

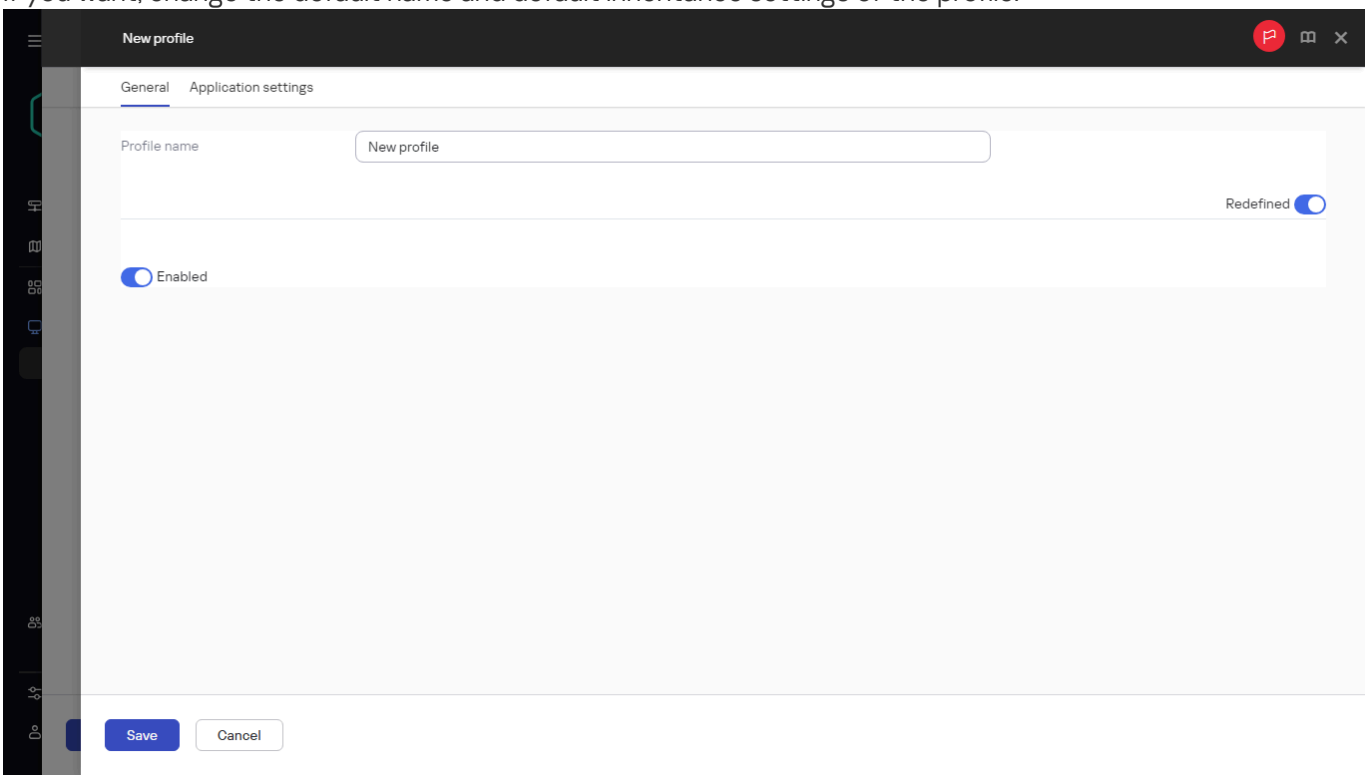
   The list of policy profiles appears.
2. On the **Policy profiles** tab, select the check box next to the policy profile for which you want to change priority.
3. Set a new position of the policy profile in the list by clicking **Prioritize** or **Deprioritize**.

   The higher a policy profile is located in the list, the higher its priority.

4. Click the **Save** button.

   Priority of the selected policy profile is changed and applied.

Creating a policy profile



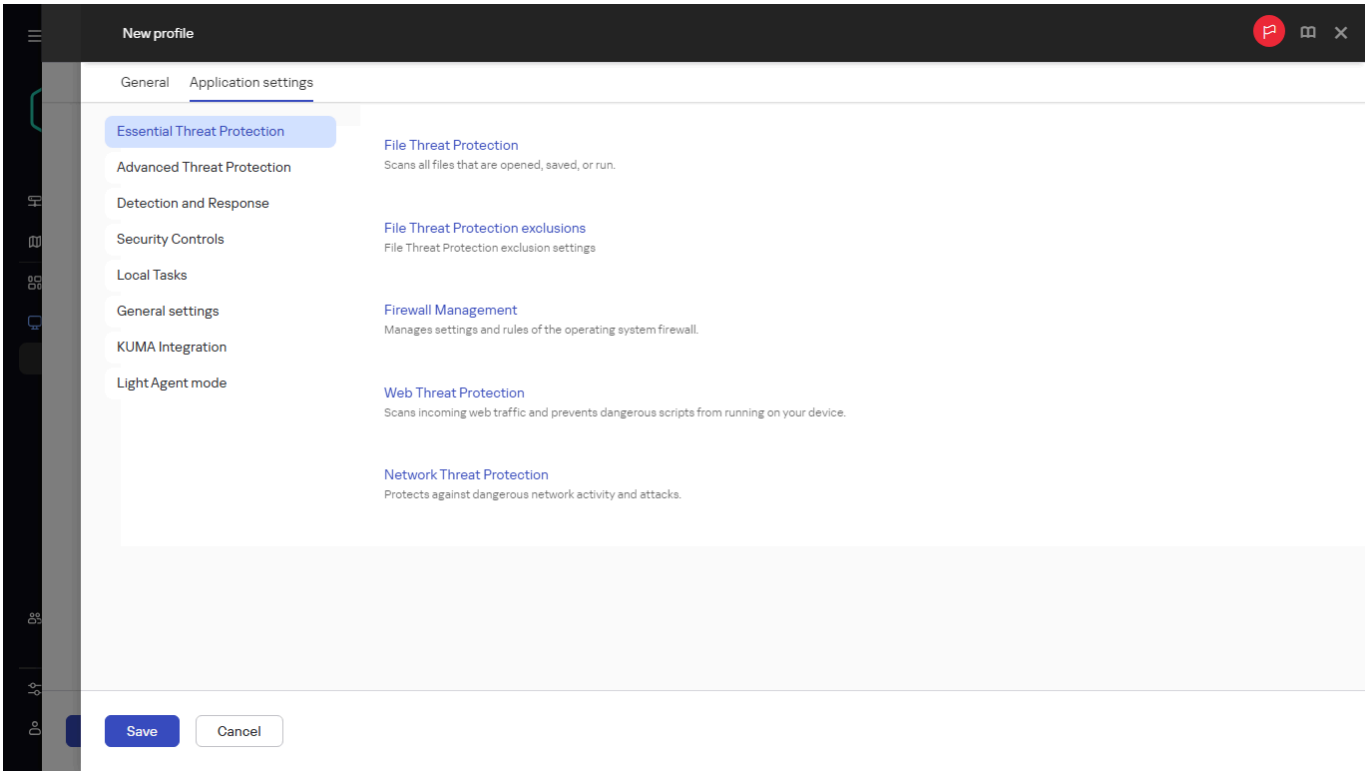
To create a policy profile:

1. Proceed to the list of profiles of a policy that you want.

   The list of policy profiles appears. If the policy does not have profiles, an empty table appears.

2. Click **Add**.

3. If you want, change the default name and default inheritance settings of the profile.



Creating a policy profile

4. Select the **Application settings** tab.

   Alternatively, you can click **Save** and exit. The profile that you have created appears in the list of policy profiles, and you can edit its settings later.

5. On the **Application settings** tab, in the left pane, select the category that you want and in the results pane on the right, edit the settings for the profile. You can edit policy profile settings in each category (section).

When editing the settings, you can click **Cancel** to cancel the last operation.

Specifying the policy profile settings

6. Click **Save** to save the profile.

The profile will appear in the list of policy profiles.

Copying a policy profile

You can copy a policy profile to the current policy or to another, for example, if you want to have identical profiles for different policies. You can also use copying if you want to have two or more profiles that differ in only a small number of settings.

To copy a policy profile:

1. Proceed to the list of profiles of the policy that you want.

   The list of policy profiles appears. If the policy does not have profiles, an empty table appears.

2. On the **Policy profiles** tab, select the policy profile that you want to copy.

3. Click the **Copy** button.

4. In the window that opens, select the policy to which you want to copy the profile.

   You can copy a policy profile to the same policy or to a policy that you specify.

5. Click the **Copy** button.

The policy profile is copied to the policy that you selected. The newly copied profile gets the lowest priority. If you copy the profile to the same policy, the name of the newly copied profile will be expanded with the () index, for example: (1), (2).

You can later change the settings of the policy profile, including its name and priority. In this case, the original policy profile is not changed.

Creating a policy profile activation rule

To create a policy profile activation rule:

1. Proceed to the list of profiles of the policy that you want.

   The list of policy profiles appears.

2. On the **Policy profiles** tab, click the policy profile for which you need to create an activation rule.

   If the list of policy profiles is empty, you can create a policy profile.

3. On the **Activation rules** tab, click the **Add** button.

   The window with policy profile activation rules opens.

4. Specify a name for the rule.

5. Select the check boxes next to the conditions that must affect activation of the policy profile that you are creating:

   General rules for policy profile activation

   Select this check box to set up policy profile activation rules on the device depending on the status of the device offline mode, rule for connection to Administration Server, and tags assigned to the device.

   For this option, specify at the next step:

   Device status

   Defines the condition for device presence on the network:

   - **Online**—The device is on the network, and so the Administration Server is available.
   - **Offline**—The device is on an external network, which means that the Administration Server is not available.
   - **N/A**—The criterion will not be applied.

   Network location of the device

   Choose the condition of policy profile activation (whether the rule is executed or not) and select the rule name.

   The rule defines the network location of the device for connection to the Administration Server, whose conditions must be met (or must not be met) for activation of the policy profile.

   A network location description of devices for connection to an Administration Server can be created or configured in a Network Agent switching rule.

   - **Rules for specific device owner**

     For this option, specify at the next step:

     Device owner

Enable this option to configure and enable the rule for profile activation on the device according to its owner. In the drop-down list under the check box, you can select a criterion for the profile activation:

- The device belongs to the specified owner ("=" sign).
- The device does not belong to the specified owner ("#" sign).

  If this option is enabled, the profile is activated on the device in accordance with the criterion configured. You can specify the device owner when the option is enabled. If this option is disabled, the profile activation criterion is not applied. By default, this option is disabled.

Device owner is included in an internal security group

Enable this option to configure and enable the rule of profile activation on the device by the owner's membership in an internal security group of Kaspersky EDR Expert. In the drop-down list under the check box, you can select a criterion for the profile activation:

- The device owner is a member of the specified security group ("=" sign).
- The device owner is not a member of the specified security group ("#" sign).

  If this option is enabled, the profile is activated on the device in accordance with the criterion configured. You can specify a security group of Kaspersky EDR Expert. If this option is disabled, the profile activation criterion is not applied. By default, this option is disabled.

- **Rules for hardware specifications**

  Select this check box to set up rules for policy profile activation on the device depending on the memory volume and the number of logical processors.

  For this option, specify at the next step:

  RAM size, in MB

  Enable this option to configure and enable the rule of profile activation on the device by the RAM volume available on that device. In the drop-down list under the check box, you can select a criterion for the profile activation:

  - The device RAM size is less than the specified value ("<" sign).
  - The device RAM size is greater than the specified value (">" sign).

  If this option is enabled, the profile is activated on the device in accordance with the criterion configured. You can specify the RAM volume on the device. If this option is disabled, the profile activation criterion is not applied. By default, this option is disabled.

  Number of logical processors

  Enable this option to configure and enable the rule of profile activation on the device by the number of logical processors on that device. In the drop-down list under the check box, you can select a criterion for the profile activation:

  - The number of logical processors on the device is less than or equal to the specified value ("<" sign).
  - The number of logical processors on the device is greater than or equal to the specified value (">" sign).

  If this option is enabled, the profile is activated on the device in accordance with the criterion configured. You can specify the number of logical processors on the device. If this option is disabled, the profile activation criterion is not applied. By default, this option is disabled.

- **Rules for role assignment**

  For this option, specify at the next step:

Activate policy profile by specific role of device owner

Select this option to configure and enable the rule of profile activation on the device depending on the owner's role. Add the role manually from the list of existing roles.

If this option is enabled, the profile is activated on the device in accordance with the criterion configured.

- **Rules for tag usage**

  Select this check box to set up rules for policy profile activation on the device depending on the tags assigned to the device. You can activate the policy profile to the devices that either have the selected tags or do not have them.

  For this option, specify at the next step:

  Tag list

  In the list of tags, specify the rule for device inclusion in the policy profile by selecting the check boxes next to the relevant tags.

  You can add new tags to the list by entering them in the field over the list and clicking the **Add** button.

  The policy profile includes devices with descriptions containing all the selected tags. If check boxes are cleared, the criterion is not applied. By default, these check boxes are cleared.

  Apply to devices without the specified tags

  Enable this option if you have to invert your selection of tags.

  If this option is enabled, the policy profile includes devices with descriptions that contain none of the selected tags. If this option is disabled, the criterion is not applied.

  By default, this option is disabled.

- **Rules for Active Directory usage**

  Select this check box to set up rules for policy profile activation on the device depending on the presence of the device in an Active Directory organizational unit (OU), or on membership of the device (or its owner) in an Active Directory security group.

  For this option, specify at the next step:

  Device owner's membership in an Active Directory security group

  If this option is enabled, the policy profile is activated on the device whose owner is a member of the specified security group. If this option is disabled, the profile activation criterion is not applied. By default, this option is disabled.

  Device membership in Active Directory security group

  If this option is enabled, the policy profile is activated on the device. If this option is disabled, the profile activation criterion is not applied. By default, this option is disabled.

  Device allocation in Active Directory organizational unit

  If this option is enabled, the policy profile is activated on the device which is included in the specified Active Directory organizational unit (OU). If this option is disabled, the profile activation criterion is not applied.

  By default, this option is disabled.

The number of additional pages of the wizard depends on the settings that you select at the first step. You can modify policy profile activation rules later.

Creating a policy profile activation rule

6. Check the list of the configured parameters. If the list is correct, click **Create**.

   The profile will be saved. The profile will be activated on the device when activation rules are triggered.

Policy profile activation rules created for the profile are displayed in the policy profile properties on the **Activation rules** tab. You can modify or remove any policy profile activation rule.

Multiple activation rules can be triggered simultaneously.

Deleting a policy profile

To delete a policy profile:

1. Proceed to the list of profiles of the policy that you want.

   The list of policy profiles appears.

2. On the **Policy profiles** tab, select the check box next to the policy profile that you want to delete, and click **Delete**.

3. In the window that opens, click **Delete** again.

   The policy profile is deleted. If the policy is inherited by a lower-level group, the profile remains in that group, but becomes the policy profile of that group. This is done to eliminate significant change in settings of the managed applications installed on the devices of lower-level groups.

Exporting and importing a policy profile

You can save a policy profile to a KLPROF file without exporting a policy, and then use this KLPROF file to import the saved profile to the policy.

This allows you to restore the policy profile settings quickly, instead of configuring them again.

A policy profile is imported to the policy of the same version of the application from which you exported the profile. For applications that support backward compatibility of policies (for example, Kaspersky Endpoint Security for Windows), you can import policy profiles to different versions of the policy.

To export a policy profile:

1. Proceed to the list of profiles of a policy that you want.

   The list of policy profiles appears.

2. On the **Policy profiles** tab, click the policy profile that you want to export.

3. In the toolbar, click the **Export** button.

4. In the window that opens, specify the directory to which you want to save the file with the policy profile.

   You can change the file name, if necessary.

5. Click **Save**.

If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

To import a policy profile:

1. Proceed to the list of profiles of the policy that you want.

   The list of policy profiles appears.

2. In the toolbar, click the **Import** button.

3. In the window that opens, select the KLPROF file with the required policy profile, and then click the **Open** button.

   The maximum size of the imported file is 4 MB.

If the operation is completed successfully, an appropriate message is displayed on the screen. Otherwise, an error message is displayed.

The policy profile is imported with the name it had when you exported it, not with the name of the KLPROF file. The file is imported with the **Disabled** status and the lowest priority, regardless of the priority the policy profile had before the export.

You cannot perform the import:

- If the policy already has a profile with the same name.
- If the number of profiles in the policy is 100.

Network Agent policy settings

To configure the Network Agent policy:

1. In the main menu of the application, go to **Asset management** → **Policies**.
2. Click the name of the Network Agent policy.

   The properties window of the Network Agent policy opens. The properties window contains the tabs and settings described below.

See the comparison table detailing how the settings below apply, depending on the type of operating system used.

Common

On this tab, you can modify the policy name, policy status, and specify the inheritance of policy settings:

- In the **Name** field, you can modify the policy name.
- In the **Policy status** block, you can select one of the policy modes:

  Active

  If this option is selected, the policy becomes active.

  By default, this option is selected.

  Inactive

  If this option is selected, the policy becomes inactive, but it is still stored in the **Policies** folder. If required, the policy can be activated.

- In the **Settings inheritance** settings group, you can configure the policy inheritance:

  Inherit settings from parent policy

  If this option is enabled, the policy setting values are inherited from the upper-level group policy and, therefore, are locked.

  By default, the option is enabled.

  Force inheritance of settings in child policies

If this option is enabled, after policy changes are applied, the following actions will be performed:

- The values of the policy settings will be propagated to the policies of administration subgroups, that is, to the child policies.
- In the **Settings inheritance** block of the **General** section in the properties window of each child policy, the **Inherit settings from parent policy** option will be automatically enabled.

If this option is enabled, the child policies settings are locked.

By default, this option is disabled.

Event configuration

On this tab, you can configure event logging and event notification. Events are distributed according to importance level in the following sections:

- **Functional failure**
- **Warning**
- **Info**

In each section, the list shows the types of events and the default event storage period on the Administration Server (in days). After you click the event type, you can specify the settings of event logging and notifications about events selected in the list. By default, common notification settings specified for the entire Administration Server are used for all event types. However, you can change specific settings for the required event types.

For example, in the **Warning** section, you can configure the **Incident has occurred** event type. Such events may happen, for instance, when the free disk space of a distribution point is less than 2 GB (at least 4 GB are required to install applications and download updates remotely). To configure the **Incident has occurred** event, click it and specify where to store the occurred events and how to notify about them.

If the Network Agent detects a security issue, you can manage this issue by using the settings of a managed device.

Application settings

Settings

In the **Settings** section, you can configure the Network Agent policy:

Distribute files through distribution points only

If this option is enabled, Network Agents on managed devices retrieve updates from distribution points only.

If this option is disabled, Network Agents on managed devices retrieve updates from distribution points or from Administration Server.

> Note that the security applications on managed devices retrieve updates from the source set in the update task for each security application. If you enable the **Distribute files through distribution points only** option, make sure that Open Single Management Platform is set as an update source in the update tasks.

By default, this option is disabled.

Maximum size of event queue, in MB

In this field you can specify the maximum space on the drive that an event queue can occupy.

The default setting is 2 MB.

Application is allowed to retrieve policy's extended data on device

Network Agent installed on a managed device transfers information about the applied security application policy to the security application (for example, Kaspersky Endpoint Security for Linux). You can view the transferred information in the security application interface.

Network Agent transfers the following information:

- Time of the policy delivery to the managed device.
- Name of the active policy at the moment of the policy delivery to the managed device.
- Name of the out-of-office policy at the moment of the policy delivery to the managed device (not available for the Network Agent for Linux).
- Name and full path to the administration group that contained the managed device at the moment of the policy delivery to the managed device.
- List of active policy profiles with their names and priorities at the moment of the policy delivery to the managed device.

You can use the information to ensure the correct policy is applied to the device and for troubleshooting purposes. By default, this option is disabled.

Protect the Network Agent service against unauthorized removal or termination, and prevent changes to the settings

When this option is enabled, after Network Agent is installed on a managed device, the component cannot be removed or reconfigured without required privileges. The Network Agent service cannot be stopped. This option has no effect on domain controllers.

Enable this option to protect Network Agent on workstations operated with local administrator rights.

By default, this option is disabled.

Use uninstallation password

If this option is enabled, by clicking the **Modify** button you can specify the password for the klmover utility.

By default, this option is disabled.

Disable this option to uninstall Network Agent remotely.

Repositories

In the **Repositories** section, you can select the types of objects whose details will be sent from Network Agent to Administration Server:

Details of installed applications

If this option is enabled, information about applications installed on client devices is sent to the Administration Server.

By default, the option is enabled.

Include information about patches

Information about patches of applications installed on client devices is sent to the Administration Server. Enabling this option may increase the load on the Administration Server and DBMS, as well as cause increased volume of the database.

By default, the option is enabled. It is available only for Windows.

Details of Windows Update updates

If this option is enabled, information about mandatory Microsoft Windows Update updates that must be installed on client devices is sent to the Administration Server.

By default, the option is enabled. It is available only for Windows.

Information about optional Microsoft Windows updates is not being sent to the Administration Server.

Details of software vulnerabilities and corresponding updates

If this option is enabled, information about vulnerabilities in third-party software (including Microsoft software), detected on managed devices, and about software updates to fix third-party vulnerabilities (not including Microsoft software) is sent to the Administration Server.

Selecting this option (**Details of software vulnerabilities**) increases the network load, Administration Server disk load, and Network Agent resource consumption.

By default, the option is enabled. It is available only for Windows.

To manage software updates of Microsoft software, use the **Details of Windows Update updates** option.

Hardware registry details

Network Agent installed on a device sends information about the device hardware to the Administration Server. You can view the hardware details in the device properties.

Ensure that the lshw utility is installed on Linux devices from which you want to fetch hardware details. Hardware details fetched from virtual machines may be incomplete depending on the hypervisor used.

If modification of some settings in this section is prohibited by the Network Agent policy, you cannot modify these settings.

Software updates and vulnerabilities

In the **Software updates and vulnerabilities** section, you can enable scanning of executable files for vulnerabilities:

Scan executable files for vulnerabilities when running them

If this option is enabled, executable files are scanned for vulnerabilities when they are run.

By default, the option is enabled.

Restart management

In the **Restart management** section, you can specify the action to be performed if the operating system of a managed device has to be restarted for correct use, installation, or uninstallation of an application:

Do not restart the operating system

Client devices are not restarted automatically after the operation. To complete the operation, you must restart a device (for example, manually or through a device management task). Information about the required restart is saved in the task results and in the device status. This option is suitable for tasks on servers and other devices where continuous operation is critical.

Restart the operating system automatically, if necessary

Client devices are always restarted automatically if a restart is required for completion of the operation. This option is useful for tasks on devices that provide for regular pauses in their operation (shutdown or restart).

Prompt user for action

The restart reminder is displayed on the screen of the client device, prompting the user to restart it manually. Some advanced settings can be defined for this option: text of the message for the user, the message display frequency, and the time interval after which a restart will be forced (without the user's confirmation). This option is most suitable for workstations where users must be able to select the most convenient time for a restart.

By default, this option is selected.

Repeat the prompt every (min)

If this option is enabled, the application prompts the user to restart the operating system with the specified frequency.

By default, the option is enabled. The default interval is 5 minutes. Available values are between 1 and 1440 minutes.

If this option is disabled, the prompt is displayed only once.

Force restart after (min)

After prompting the user, the application forces restart of the operating system upon expiration of the specified time interval.

By default, the option is enabled. The default delay is 30 minutes. Available values are between 1 and 1440 minutes.

Force closure of applications in blocked sessions

Running applications may prevent a restart of the client device. For example, if a document is being edited in a word processing application and is not saved, the application does not allow the device to restart.

If this option is enabled, such applications on a locked device are forced to close before the device restart. As a result, users may lose their unsaved changes.

If this option is disabled, a locked device is not restarted. The task status on this device states that a device restart is required. Users have to manually close all applications running on locked devices and restart these devices.

By default, this option is disabled.

Manage patches and updates

In the Manage patches and updates section, you can configure the download and distribution of updates, as well as the installation of patches, on managed devices:

Automatically install applicable updates and patches for components that have the Undefined status

If this option is enabled, Kaspersky patches that have the *Undefined* approval status are automatically installed on managed devices immediately after they are downloaded from update servers.

If this option is disabled, Kaspersky patches that have been downloaded and tagged with the *Undefined* status will be installed only after you change their status to *Approved*.

By default, the option is enabled.

Download updates and anti-virus databases from Administration Server in advance (recommended)

If this option is enabled, the offline model of update download is used. When the Administration Server receives updates, it notifies Network Agent (on devices where it is installed) of the updates that will be required for managed applications. When Network Agent receives information about these updates, it downloads the relevant files from the Administration Server in advance. At the first connection with Network Agent, the Administration Server initiates an update download. After Network Agent downloads all the updates to a client device, the updates become available for applications on that device.

When a managed application on a client device attempts to access Network Agent for updates, Network Agent checks whether it has all required updates. If the updates are received from the Administration Server not more than 25 hours before they were requested by the managed application, Network Agent does not connect to the Administration Server but supplies the managed application with updates from the local cache instead. Connection with the Administration Server may not be established when Network Agent provides updates to applications on client devices, but connection is not required for updating.

If this option is disabled, the offline model of update download is not used. Updates are distributed according to the schedule of the update download task.

By default, the option is enabled.

Connectivity

The **Connectivity** section includes three subsections:

- **Network**
- **Connection profiles**
- **Connection schedule**

In the **Network** subsection, you can configure the connection to Administration Server, enable the use of a UDP port, and specify the UDP port number.

- In the **Connect to Administration Server** settings group, you can configure connection to the Administration Server and specify the time interval for synchronization between client devices and the Administration Server:

  Synchronization interval (min)

  Network Agent synchronizes the managed device with the Administration Server. We recommend that you set the synchronization interval (also referred to as the heartbeat) to 15 minutes per 10,000 managed devices.

  Compress network traffic

  If this option is enabled, the speed of data transfer by Network Agent is increased by means of a decrease in the amount of information being transferred and a consequent decreased load on the Administration Server.

  > The workload on the CPU of the client computer may increase.

  By default, this check box is enabled.

  Open Network Agent ports in Microsoft Windows Firewall

  If this option is enabled, the ports, necessary for the work of Network Agent, are added to the Microsoft Windows Firewall exclusion list.

  By default, the option is enabled.

  Use SSL connection

  If this option is enabled, connection to the Administration Server is established through a secure port via SSL.

  By default, the option is enabled.

  Use the connection gateway on a distribution point (if available), under the default connection settings

  If this option is enabled, the connection gateway on the distribution point is used under the settings specified in the administration group properties.

  By default, the option is enabled.

- **Use UDP port**

  If you need Network Agent to connect to Administration Server through a UDP port, enable the **Use UDP port** option and specify a **UDP port number**. By default, the option is enabled. The default UDP port to connect to Administration Server is 15000.

- **UDP port number**

  In this field you can enter the UDP port number. The default port number is 15000.

  The decimal system is used for records.

- **Use the distribution point to force a connection to the Administration Server**

  Select this option if you selected the **Use this distribution point as a push server** option in the distribution point settings window. Otherwise, the distribution point will not act as a push server.

In the **Connection profiles** subsection, you can specify the network location settings and enable out-of-office mode when Administration Server is not available:

Network location settings

Network location settings define the characteristics of the network to which the client device is connected and specify rules for Network Agent switching from one Administration Server connection profile to another when those network characteristics are altered.

Administration Server connection profiles

You can view and add profiles for Network Agent connection to the Administration Server. In this section, you can also create rules for switching Network Agent to different Administration Servers when the following events occur:

- When the client device connects to a different local network
- When the device loses connection with the local network of the organization
- When the connection gateway address is changed or the DNS server address is modified

Enable out-of-office mode when Administration Server is not available

If this option is enabled, in case of connection through this profile, applications installed on the client device use policy profiles for devices in out-of-office mode, as well as out-of-office policies. If no out-of-office policy has been defined for the application, the active policy will be used.

If this option is disabled, applications will use active policies.

By default, this option is disabled.

In the **Connection schedule** subsection, you can specify the time intervals during which Network Agent sends data to the Administration Server:

Connect when necessary

If this option is selected, the connection is established when Network Agent has to send data to the Administration Server.

By default, this option is selected.

Connect at specified time intervals

If this option is selected, Network Agent connects to the Administration Server at a specified time. You can add several connection time periods.

Network polling by distribution points

In the **Network polling by distribution points** section, you can configure automatic polling of the network. You can use the following options to enable the polling and set its frequency:

Windows network

The option is available only for Windows-based distribution points.

If the option is enabled, the Administration Server automatically polls the network according to the schedule that you configured by clicking the **Set quick poll schedule** and **Set full poll schedule** links.

If this option is disabled, the Administration Server polls the network with the interval specified in the **Frequency of network polls (min)** field.

The device discovery interval for Network Agent versions can be configured in the **Frequency of polls from Windows domains (min)** (for quick Windows network poll) and **Frequency of network polls (min)** (for full Windows network poll) fields.

By default, this option is disabled.

IP ranges

If the option is enabled, the distribution point automatically polls IP ranges according to the schedule that you configured by clicking the **Set polling schedule** button.

If this option is disabled, the distribution point does not poll IP ranges.

The frequency of IP range polling for Network Agent versions prior to 10.2 can be configured in the **Poll interval (min)** field. The field is available if the option is enabled.

By default, this option is disabled.

Zeroconf

If this option is enabled, the distribution point automatically polls the network with IPv6 devices by using zero-configuration networking (also referred to as *Zeroconf*). In this case, the enabled IP range polling is ignored, because the distribution point polls the whole network.

To start to use Zeroconf, the following conditions must be fulfilled:

- The distribution point must run Linux.
- You must install the avahi-browse utility on the distribution point.

If this option is disabled, the distribution point does not poll networks with IPv6 devices.

By default, this option is disabled.

Domain controllers

If the option is enabled, the distribution point automatically polls domain controllers according to the schedule that you configured by clicking the **Set polling schedule** button.

If this option is disabled, the distribution point does not poll domain controllers.

The frequency of domain controller polling for Network Agent versions prior to 10.2 can be configured in the **Poll interval (min)** field. The field is available if this option is enabled.

By default, this option is disabled.

Network settings for distribution points

In the **Network settings for distribution points** section, you can specify the internet access settings:

- **Use proxy server**

  If this option is enabled, an internet proxy server is used to connect distribution points to Kaspersky update servers.

- **Address**
- **Port number**

- **Bypass proxy server for local addresses**

  If this option is enabled, no proxy server is used to connect to devices on the local network.

  By default, this option is disabled.

- **Proxy server authentication**

  If this check box is selected, in the entry fields you can specify the credentials for proxy server authentication.

  This check box is cleared by default.

KSN Proxy (distribution points)

In the **KSN Proxy (distribution points)** section, you can configure the application to use the distribution point to forward Kaspersky Security Network (KSN) requests from the managed devices:

Enable KSN Proxy on the distribution point side

The KSN proxy service is run on the device that is used as a distribution point. Use this feature to redistribute and optimize traffic on the network.

The distribution point sends the KSN statistics, which are listed in the Kaspersky Security Network statement, to Kaspersky.

By default, this option is disabled. Enabling this option takes effect only if the **Use Administration Server as a proxy server** and **I agree to use Kaspersky Security Network** options are enabled in the Administration Server properties window.

You can assign a node of an active-passive cluster to a distribution point and enable KSN proxy server on this node.

Forward KSN requests to Administration Server

The distribution point forwards KSN requests from the managed devices to the Administration Server.

By default, the option is enabled.

Access KSN Cloud/KPSN directly over the internet

The distribution point forwards KSN requests from managed devices to the KSN Cloud or KPSN. The KSN requests generated on the distribution point itself are also sent directly to the KSN Cloud or KPSN.

TCP port

The number of the TCP port that the managed devices will use to connect to KSN proxy server. The default port number is 13111.

UDP port

If you need Network Agent to connect to Administration Server through a UDP port, enable the **Use UDP port** option and specify a **UDP port number**. By default, the option is enabled. The default UDP port to connect to Administration Server is 15000.

HTTPS port

If you need the managed devices to connect to the KSN proxy server through an HTTPS port, enable the **Use HTTPS** option, and then specify a port number in the **HTTPS port** field. By default, this option is disabled. The default HTTPS port to connect to the KSN proxy server is 17111.

Updates (distribution points)

In the **Updates (distribution points)** section, you can enable the downloading diff files feature, so distribution points take updates in the form of diff files from Kaspersky update servers.

Local account management (Linux only)

The **Local account management (Linux only)** section includes three subsections:

- **User certificates management**
- **Add or edit applicable local administrator groups**
- **Upload a reference file to protect the sudoers file on the user's device from changes**

In the **User certificates management** subsection, you can specify which root certificates to install. These certificates can be used, for example, to verify the authenticity of websites or web servers.

Install root certificates

If this option is enabled, certificates added to the table will be installed on the specified devices.

If this option is disabled, no certificates will be installed on the specified devices.

By default, this option is disabled.

Add

Clicking this button opens a window, in which where you can add a certificate.

The certificate must be less than 10 MB.

Kaspersky Security Center supports certificates with CER, CRT, CERT, PEM, and KEY extensions.

In the **Add or edit applicable local administrator groups** subsection, you can manage local administrator groups. These groups are used, for example, when revoking local administrator rights. You can also check the list of privileged user accounts using the **Report on privileged device users (Linux only)**.

Add

Clicking this button opens a window, where you can add a local administrator group.

Edit

Clicking this button opens a window, where you can edit the local administrator group.

This button is available if the check box next to the local administrator group is selected.

Delete

Clicking this button deletes the selected local administrator group from the table.

This button is available if the check box next to the local administrator group is selected.

In the **Upload a reference file to protect the sudoers file on the user's device from changes** subsection, you can configure control of the sudoers file. Privileged groups and device users are defined by the sudoers file on the device. The sudoers file is located at `/etc/sudoers`. You can upload a reference sudoers file to protect the sudoers file from changes. This will prevent unwanted changes to the sudoers file.

An invalid reference sudoers file may cause the user's device to malfunction.

Control sudoers file

If this option is enabled, the sudoers file will be replaced by the current reference sudoers file.

If this option is disabled, the sudoers file will remain unchanged.

By default, this option is disabled.

Reference sudoers file

This field displays the name of the uploaded reference sudoers file.

Upload

Clicking this button opens a window, where you can upload a reference sudoers file.

Current reference sudoers file

Clicking this button shows the contents of the current sudoers file.

Revision history

On the **Revision history** tab, you can:

- View and save the history of policy revisions.
- Roll back to a policy revision.
- Add and edit policy revision descriptions.
- Compare policy revisions.

Usage of Network Agent for Windows, Linux, and macOS: Comparison

The Network Agent usage varies depending on the operating system of the device. The Network Agent policy and installation package settings also differ depending on the operating system. The table below compares Network Agent features and usage scenarios available for Windows, Linux, and macOS operating systems.

Network Agent feature comparison

Network Agent feature	Windows	Linux	macOS
Installation			
Installing by cloning an image of the administrator's hard drive with the operating system and Network Agent using third-party tools	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓	✓
Installing with third-party tools for remote installation of applications	✓	✓	✓
Installing manually, by running application installers on devices	✓	✓	✓
Installing Network Agent in silent mode	✓	✓	✓
Manually connecting a client device to the Administration Server. klmover utility	✓	✓	✓
Automatic installing of updates and patches for Kaspersky EDR Expert components	✓	✓	–
Automatic distributing of a key	✓	✓	✓
Forced synchronization	✓	✓	✓ Except a push server
Distribution point			
Using as distribution point	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓	✓
Calculating the number and configuration of distribution points	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓ Without using Network Location Awareness (NLA).	✓ Without using Network Location Awareness (NLA).
Offline model of update download	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓	✓
Network polling	✓ • IP range polling • Domain controller polling (Microsoft Active Directory) Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓ IP range polling Zeroconf polling Domain controller polling (Microsoft Active Directory, Samba 4 Active Directory, FreeIPA, ALD Pro)	–

Network Agent feature	Windows	Linux	macOS
Running KSN proxy service on a distribution point side	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓	—
Downloading updates via Kaspersky update servers to the distribution points repositories that distribute updates to managed devices	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓	— (If one or more devices running Linux or macOS are within the scope of the Download updates to the repositories of distribution points task, the task completes with the Failed status, even if it has successfully completed on all Windows devices.)
Push installation of applications	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	Restricted: it is not possible to perform push installation on Windows devices by using Linux distribution points.	Restricted: it is not possible to perform push installation on Windows devices by using macOS distribution points.
Using as a push server	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓	—
Handling third-party applications			
Remote installing of applications on devices	✓	✓	✓ Refer to the following article for details: Remote installing of applications on macOS devices.
Configuring operating system updates in a Network Agent policy	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	—	—
Viewing information about software vulnerabilities	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	—	—
Scanning applications for vulnerabilities	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	—	—
Software updates	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	—	—
Inventory of software installed on devices	✓	✓	—
Virtual machines			
Installing Network Agent on a virtual machine	✓	✓	✓

Network Agent feature	Windows	Linux	macOS
Optimization settings for virtual desktop infrastructure (VDI)	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓	✓
Support of dynamic virtual machines	✓ Limitation: Not supported by Network Agent for Microsoft Windows on Arm.	✓	✓
Other			
Auditing actions on a remote client device by using Windows Desktop Sharing	✓	—	—
Monitoring the anti-virus protection status	✓	✓	✓
Managing device restarts	✓	—	—
Support of file system rollback	✓	✓	✓
Using a Network Agent as connection gateway	✓	✓	✓
Connection Manager	✓	✓	✓
Connection profiles for out-of-office users	✓	✓	✓
Network Agent switching from one Administration Server to another (automatically by network location)	✓	✓	✓
Checking the connection between a client device and the Administration Server. Klnagchk utility	✓	✓	✓
Remotely connecting to the desktop of a client device	✓	✓	✓ By using the Virtual Network Computing (VNC) system.
Downloading a stand-alone installation package through the Migration wizard	✓	✓	✓
Viewing information about the hardware of client devices	✓	✓ Information about the hardware of Linux devices sent to the Administration Server by Network Agent installed on these devices is limited to the information specified in the description of the managed device settings.	✓ Information about the hardware of macOS devices sent to the Administration Server by Network Agent installed on these devices is limited to the information specified in the description of the managed device settings.

Comparison of Network Agent settings by operating systems

The table below shows which Network Agent policy settings are available depending on the operating system of the managed device where Network Agent was installed.

Network Agent settings: comparison by operating systems

Settings section	Windows	Linux	macOS
General	✓	✓	✓
Event configuration	✓	✓	✓
Settings	✓	✓ The following options are available: • **Distribute files through distribution points only** • **Maximum size of event queue, in MB** • **Application is allowed to retrieve policy's extended data on device**	✓
Repositories	✓	✓ The following options are available: • **Details of installed applications** • **Hardware registry details**	✓ The **Hardware registry details** option is available.
Connectivity → Network	✓	✓ Except the **Open Network Agent ports in Microsoft Windows Firewall** option.	✓
Connectivity → Connection profiles	✓	✓	✓
Connectivity → Connection schedule	✓	✓	✓
Network polling by distribution points	✓ The following settings are available: • **Windows network** • **IP ranges** • **Domain controllers**	✓ The following settings are available: • **Zeroconf** • **IP ranges** • **Domain controllers**	—
Network settings for distribution points	✓	✓	✓
KSN Proxy (distribution points)	✓	✓	—
Updates (distribution points)	✓	✓	—

Configuring protection settings of managed applications

To configure the protection settings of managed Kaspersky applications, you can use policies.

For more information about configuring policies of Kaspersky Endpoint Security, see the corresponding Help:

- Kaspersky Endpoint Security for Windows Help
- Kaspersky Endpoint Security for Linux Help
- Kaspersky Endpoint Security for Mac Help

Manual setup of the group update task for Kaspersky Endpoint Security

The optimal and recommended schedule option for Kaspersky Endpoint Security is **When new updates are downloaded to the repository** when the **Use automatically randomized delay for task starts** check box is selected.

Kaspersky Security Network (KSN)

This section describes how to use an online service infrastructure named Kaspersky Security Network (KSN). The section provides the details on KSN, as well as instructions on how to enable KSN, configure access to KSN, and view the statistics of the use of KSN proxy server.

> Updates functionality (including providing anti-virus signature updates and codebase updates), as well as KSN functionality may not be available in the software in the U.S.

About KSN

Kaspersky Security Network (KSN) is an online service infrastructure that provides access to the online Knowledge Base of Kaspersky, which contains information about the reputation of files, web resources, and software. The use of data from Kaspersky Security Network ensures faster responses by Kaspersky applications to threats, improves the effectiveness of some protection components, and reduces the risk of false positives. KSN allows you to use Kaspersky reputation databases to retrieve information about applications installed on managed devices.

By participating in the Kaspersky Security Network, you agree to automatically provide Kaspersky with information about the operation of security applications installed on computers and mobile devices that are managed using the Open Single Management Platform. Information is transferred in accordance with the current KSN access settings.

Open Single Management Platform supports the following KSN infrastructure solutions:

- *Global KSN* is a solution that allows you to exchange information with Kaspersky Security Network. By participating in KSN, you agree to send to Kaspersky in automatic mode information about the operation of Kaspersky applications installed on client devices that are managed through Open Single Management Platform. Information is transferred in accordance with the current KSN access settings. Kaspersky analysts additionally analyze received information, and include it in the reputation and statistical databases of Kaspersky Security Network. Open Single Management Platform uses this solution by default.

- *Kaspersky Private Security Network (KPSN)* is a solution that allows users of devices with Kaspersky applications installed to obtain access to reputation databases of Kaspersky Security Network, and other statistical data, without sending data to KSN from their own computers. KPSN is designed for corporate customers who are unable to participate in Kaspersky Security Network for any of the following reasons:

  - User devices are not connected to the internet.

  - Transmission of any data outside the country or the corporate LAN is prohibited by law or corporate security policies.

  You can set up access settings of Kaspersky Private Security Network in the **KSN Proxy** section of the Administration Server properties window.

You can start or stop using KSN at any moment.

You use KSN in accordance with the KSN Statement that you read and accept when you enable KSN. If the KSN Statement is updated, it is displayed to you when you update or upgrade Administration Server. You can accept the updated KSN Statement or decline it. If you decline it, you keep using KSN in accordance with the previous version of KSN Statement that you accepted before.

When KSN is enabled, Open Single Management Platform checks if the KSN servers are accessible. If access to the servers using system DNS is not possible, the application uses public DNS servers. This is necessary to make sure the level of security is maintained for the managed devices.

Client devices managed by the Administration Server interact with KSN through KSN proxy server. KSN proxy server provides the following features:

- Client devices can send requests to KSN and transfer information to KSN even if they do not have direct access to the internet.

- The KSN proxy server caches processed data, thus reducing the load on the outbound channel and the time period spent for waiting for information requested by a client device.

You can configure the KSN proxy server in the **KSN Proxy** section of the Administration Server properties window.

Setting up access to KSN

You can set up access to Kaspersky Security Network (KSN) on the Administration Server and on a distribution point.

KSN functionality is only available with current Kaspersky EDR Expert license.

To set up Administration Server access to KSN:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **KSN Proxy** section.

3. Switch the toggle button to the **Enable KSN Proxy on Administration Server Enabled** position.

   Data is sent from client devices to KSN in accordance with the Kaspersky Endpoint Security policy, which is active on those client devices. If this check box is cleared, no data will be sent to KSN from the Administration Server and client devices through Kaspersky EDR Expert. However, client devices can send data to KSN directly (bypassing Kaspersky EDR Expert), in accordance with their respective settings. The Kaspersky Endpoint Security policy, which is active on client devices, determines which data will be sent directly (bypassing Kaspersky EDR Expert) from those devices to KSN.

4. Switch the toggle button to the **Use Kaspersky Security Network Enabled** position.

   If this option is enabled, client devices send patch installation results to Kaspersky. When enabling this option, make sure to read and accept the terms of the KSN Statement.

   If you are using KPSN, switch the toggle button to the **Use Kaspersky Private Security Network Enabled** position and click the **Select file with KSN Proxy settings** button to download the settings of KPSN (files with the extensions pkcs7 and pem). After the settings are downloaded, the interface displays the provider's name and contacts, as well as the creation date of the file with the settings of KPSN.

   When you switch the toggle button to the **Use Kaspersky Private Security Network Enabled** position, a message appears with details about KPSN.

   The following Kaspersky applications support KPSN:

   - Kaspersky EDR Expert
   - Kaspersky Endpoint Security for Linux
   - Kaspersky Endpoint Security for Windows

   If you enable KPSN in Kaspersky EDR Expert, these applications receive information about supporting KPSN. In the settings window of the application, in the **Kaspersky Security Network** subsection of the **Advanced Threat Protection** section, the information about selected KSN provider is displayed — KSN or KPSN.

   > Kaspersky EDR Expert does not send any statistical data to Kaspersky Security Network if KPSN is configured in the **KSN Proxy** section of the Administration Server properties window.

5. If you have the proxy server settings configured in the Administration Server properties, but your network architecture requires that you use KPSN directly, enable the **Ignore proxy server settings when connecting to KPSN** option. Otherwise, requests from the managed applications cannot reach KPSN.

6. Under **Connection settings**, configure the Administration Server connection to the KSN proxy service:

   - The TCP port 13111 is used for connecting to the KSN proxy server. For the root Administration Server, this port number cannot be changed.
   - If you want the Administration Server to connect to the KSN proxy server through a UDP port, enable the **Use UDP port** option. By default, this option is disabled, and TCP port is used. If this option is enabled, the UDP port 15111 is used by default. For the root Administration Server, this port number cannot be changed.

7. Switch the toggle button to the **Connect secondary Administration Servers to KSN through the primary Administration Server Enabled** position.

   If this option is enabled, secondary Administration Servers use the primary Administration Server as the KSN proxy server. If this option is disabled, secondary Administration Servers connect to KSN on their own. In this case, managed devices use secondary Administration Servers as KSN proxy servers.

   > Secondary Administration Servers use the primary Administration Server as a proxy server if in the right pane of the **KSN Proxy** section, in the properties of secondary Administration Servers the toggle button is switched to the **Enable KSN Proxy on Administration Server Enabled** position.

8. Click the **Save** button.

The KSN access settings will be saved.

You can also set up distribution point access to KSN, for example, if you want to reduce the load on the Administration Server. The distribution point that acts as a KSN proxy server sends KSN requests from managed devices to Kaspersky directly, without using the Administration Server.

To set up distribution point access to Kaspersky Security Network (KSN):

1. Make sure that the distribution point is assigned manually.
2. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.
3. On the **General** tab, select the **Distribution points** section.
4. Click the name of the distribution point to open its properties window.
5. In the distribution point properties window, in the **KSN Proxy** section, enable the **Enable KSN Proxy on the distribution point side** option, and then enable the **Access KSN Cloud/KPSN directly over the internet** option.
6. Click **OK**.

The distribution point will act as a KSN proxy server.

> Please note that the distribution point does not support managed device authentication by using the NTLM protocol.

Enabling and disabling the usage of KSN

You can enable the usage of KSN in the Administration Server settings. To enable the usage of KSN for integrated solutions, you must also enable it in the OSMP settings.

Enabling and disabling the usage of KSN in the Administration Server settings

To enable the usage of KSN:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **KSN Proxy** section.

3. Switch the toggle button to the **Enable KSN Proxy on Administration Server Enabled** position.

The KSN proxy server is enabled and sends data to KSN to increase the efficiency of Kaspersky EDR Expert components and improve the performance of Kaspersky applications.

1. Depending on the KSN infrastructure solution that you are using, enable the corresponding toggle buttons.

   - If you are using Global KSN, switch the toggle button to the **Use Kaspersky Security Network Enabled** position.

     Sending data to KSN is now available. When enabling this option, you have to read and accept the terms of the KSN Statement.

   - If you are using KPSN, switch the toggle button to the **Use Kaspersky Private Security Network ENABLED** position and click the **Select file with KSN Proxy settings** button to download the settings of KPSN (files with the extensions pkcs7 and pem). After the settings are downloaded, the interface displays the provider's name and contacts, as well as the creation date of the file with the settings of KPSN.

     When you switch the toggle button to the **Use Kaspersky Private Security Network ENABLED** position, a message with detailed information about KPSN is displayed.

2. Click the **Save** button.

To disable the usage of KSN:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **KSN Proxy** section.

3. Switch the toggle button to the **Enable KSN Proxy on Administration Server Disabled** position to disable the KSN proxy service.

4. Click the **Save** button.

Enabling and disabling the usage of KSN in the OSMP settings

Users with the following roles can view and edit the status of participation in KSN and KPSN in OSMP settings:

- Main administrator
- SOC administrator
- Tenant administrator (editing the status is available only for a root tenant, for other tenants in the hierarchy, settings are applied automatically)

Users with the Auditor role can only view the status of participation in KSN and KPSN.

To enable the usage of KSN in the OSMP settings:

1. In the main menu, go to **Settings** → **Kaspersky Security Network**.
2. In the **Kaspersky EDR Expert** section, select the **KSN** connection mode.
3. Switch the **Participate in KSN** toggle button on.
4. Carefully read the KSN Statement.
5. If you agree with the terms and conditions of the KSN Statement, select the **I confirm that I have fully read, understand, and accept the terms and conditions of KSN Statement** option and click **Accept**.

   The KSN is enabled and Open Single Management Platform sends statistics to KSN for analysis by Kaspersky specialists.
6. If you do not agree with the terms and conditions of the KSN Statement, click **Decline**.

   The KSN will not be enabled.

To enable the usage of KPSN in the OSMP settings:

1. In the main menu, go to **Settings** → **Kaspersky Security Network**.
2. In the **Kaspersky EDR Expert** section, select the **KPSN** connection mode.
3. Switch the **Participate in KPSN** toggle button on.
4. Click the **Upload** button, select the KPSN configuration file (file with the .pkcs7 or .pem extension) and click **Open**.

Participation in KPSN is enabled.

To disable the usage of KSN or KPSN in the OSMP settings:

1. In the main menu, go to **Settings** → **Kaspersky Security Network**.
2. If you want to disable participation in KSN, select the **KSN** connection mode, and switch the **Participate in KSN** toggle button off.

   Participation in KSN is disabled.
3. If you want to disable participation in KPSN, select the **KPSN** connection mode, and switch the **Participate in KPSN** toggle button off.

Participation in KPSN is disabled.

Viewing the accepted KSN Statement

When you enable Kaspersky Security Network (KSN), you must read and accept the KSN Statement. You can view the accepted KSN Statement at any time.

To view the accepted KSN Statement:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.
2. On the **General** tab, select the **KSN Proxy** section.
3. Click the **View Kaspersky Security Network Statement** link.

In the window that opens, you can view the text of the accepted KSN Statement.

Accepting an updated KSN Statement

You use KSN in accordance with the KSN Statement that you read and accept when you enable KSN. If the KSN Statement is updated, it is displayed to you when you upgrade a version of Administration Server. You can accept the updated KSN Statement or decline it. If you decline it, you will continue using KSN in accordance with the version of the KSN Statement that you previously accepted.

After upgrading a version of Administration Server, the updated KSN Statement is displayed automatically. If you decline the updated KSN Statement, you can still view and accept it later.

To view and then accept or decline an updated KSN Statement:

1. Click the **View notifications** link in the upper-right corner of the main application window.

   The **Notifications** window opens.
2. Click the **View the updated KSN Statement** link.

   The **Kaspersky Security Network Statement update** window opens.

3. Read the KSN Statement, and then make your decision by clicking one of the following buttons:

   - **I accept the updated KSN Statement**
   - **Use KSN under the old Statement**

   Depending on your choice, KSN keeps working in accordance with the terms of the current or updated KSN Statement. You can view the text of the accepted KSN Statement in the properties of Administration Server at any time.

Checking whether the distribution point works as KSN proxy server

On a managed device assigned to work as a distribution point, you can enable Kaspersky Security Network (KSN) Proxy. A managed device works as the KSN proxy server when the ksnproxy service is running on the device. You can check, turn on, or turn off this service on the device locally.

You can assign a Windows-based or a Linux-based device as a distribution point. The method of distribution point checking depends on the operating system of this distribution point.

To check whether the Linux-based distribution point works as KSN proxy server:

1. On the distribution point device, run the `ps aux` command to display the list of running processes.
2. In the list of running processes, check whether the `/opt/kaspersky/klnagent64/sbin/ksnproxy` process is running.

If `/opt/kaspersky/klnagent64/sbin/ksnproxy` process is running, then Network Agent on the device participates in Kaspersky Security Network and works as the KSN proxy server for the managed devices included in the scope of the distribution point.

To check whether the Windows-based distribution point works as KSN proxy server:

1. On the distribution point device, in Windows, open **Services** (**All Programs** → **Administrative Tools** → **Services**).
2. In the list of services, check whether the ksnproxy service is running.

   If the ksnproxy service is running, then Network Agent on the device participates in Kaspersky Security Network and works as KSN proxy server for the managed devices included in the scope of the distribution point.

   If you want, you may turn off the ksnproxy service. In this case, Network Agent on the distribution point stops participating in Kaspersky Security Network. This requires local administrator rights.

Viewing the statistics of KSN proxy server

OSMP Console allows you to view usage statistics of KSN proxy server.

Statistics includes the following parameters:

- Connection status to KSN
- Number of cache records

- Number of packages processed in cache
- Number of received packages

If you use KPSN as an infrastructure solution, usage statistics of KPSN will be displayed.

To view the statistics:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **KSN Proxy** section, and then open the **Statistics** tab.

   This tab displays the actual statistics of the use of the KSN proxy server. Statistics refreshes every 15 seconds.

You can copy statistics by clicking the **Copy to clipboard** button.

Managing endpoint protection tasks

This section describes tasks used by Open Single Management Platform.

About tasks

Open Single Management Platform manages Kaspersky security applications installed on devices by creating and running *tasks*. Tasks are required for installing, launching, and stopping applications, scanning files, updating databases and software modules, and performing other actions on applications.

Tasks for a specific application can be created using OSMP Console only if the management plug-in for that application is installed on OSMP Console Server.

Tasks can be performed on the Administration Server and on devices.

The tasks that are performed on the Administration Server include the following:

- Automatic distribution of reports
- Downloading of updates to the repository
- Backup of Administration Server data
- Maintenance of the database

The following types of tasks are performed on devices:

- *Local tasks*—Tasks that are performed on a specific device

  Local tasks can be modified either by the administrator, by using OSMP Console, or by the user of a remote device (for example, through the security application interface). If a local task has been modified simultaneously by the administrator and the user of a managed device, the changes made by the administrator will take effect because they have a higher priority.

- *Group tasks*—Tasks that are performed on all devices of a specific group

  Unless otherwise specified in the task properties, a group task also affects all subgroups of the selected group. A group task also affects (optionally) devices that have been connected to secondary and virtual Administration Servers deployed in the group or any of its subgroups.

- *Global tasks*—Tasks that are performed on a set of devices, regardless of whether they are included in any group

For each application, you can create any number of group tasks, global tasks, or local tasks.

You can make changes to the settings of tasks, view the progress of tasks, and copy, export, import, and delete tasks.

A task is started on a device only if the application for which the task was created is running.

Execution results of tasks are saved in the operating system event log on each device, in the operating system event log on the Administration Server, and in the Administration Server database.

Do not include private data in task settings. For example, avoid specifying the domain administrator password.

About task scope

The *scope of a task* is the set of devices on which the task is performed. The types of scope are as follows:

- For a *local task*, the scope is the device itself.
- For an *Administration Server task*, the scope is the Administration Server.
- For a *group task*, the scope is the list of devices included in the group.

When creating a *global task*, you can use the following methods to specify its scope:

- Specifying certain devices manually.

  You can use an IP address (or IP range) or DNS name as the device address. You can also select networked devices detected by Administration Server.

- Importing a list of devices from a .txt file with the device addresses to be added (each address must be placed on an individual line).

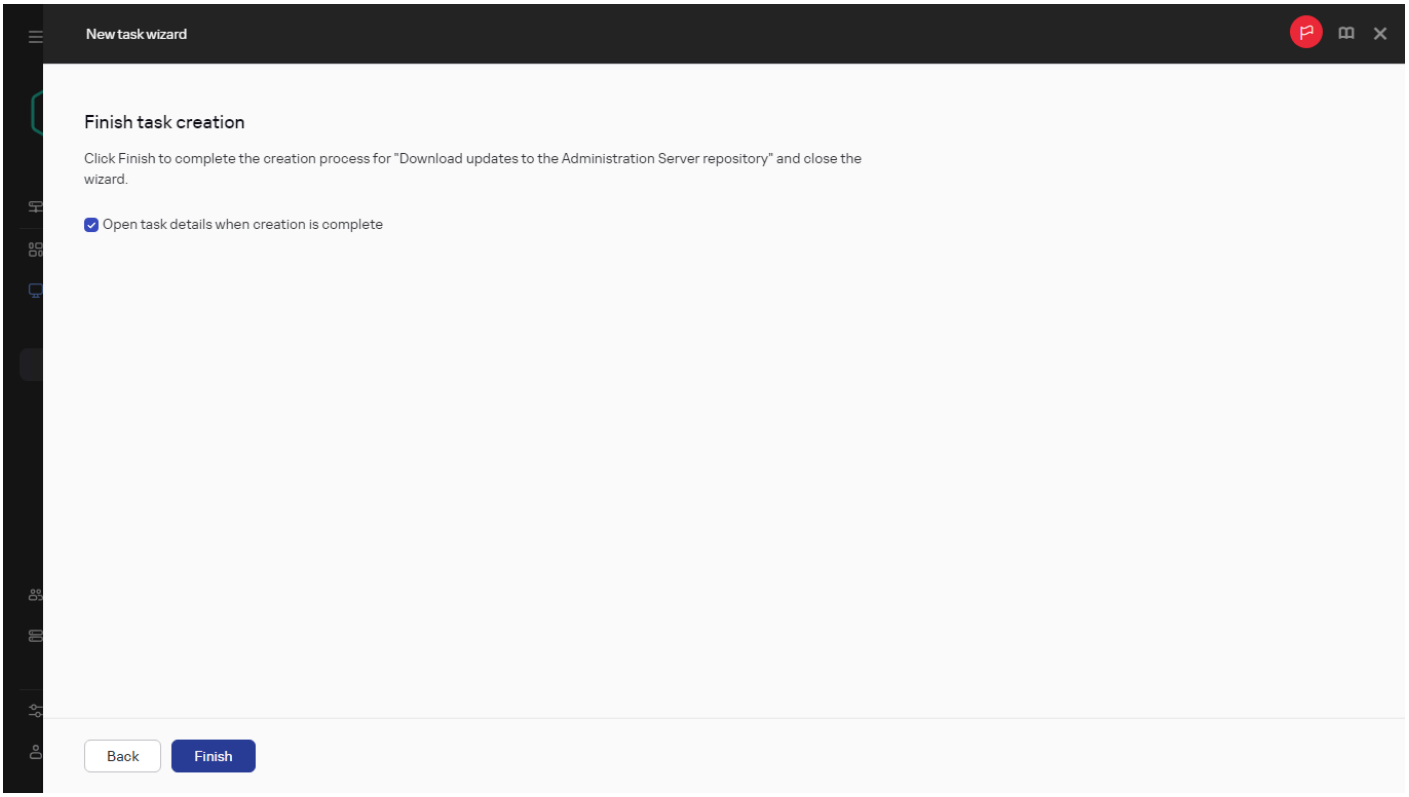
  If you import a list of devices from a file or create a list manually, and if devices are identified by their names, the list can only contain devices for which information has already been entered into the Administration Server database. Moreover, the information must have been entered when those devices were connected or during device discovery.

- Specifying a device selection.

  Over time, the scope of a task changes as the set of devices included in the selection change. A selection of devices can be made on the basis of device attributes, including software installed on a device, and on the basis of tags assigned to devices. Device selection is the most flexible way to specify the scope of a task.

Tasks for device selections are always run on a schedule by the Administration Server. These tasks cannot be run on devices that lack connection to the Administration Server. Tasks whose scope is specified by using other methods are run directly on devices and therefore do not depend on the device connection to the Administration Server.

Tasks for device selections are not run on the local time of a device; instead, they are run on the local time of the Administration Server. Tasks whose scope is specified by using other methods are run on the local time of a device.



Creating a task

To create a task:

1. In the main menu, go to **Tasks**.
2. Click the **Add** button.

   The New task wizard starts. Follow its instructions.
3. If you want to modify the default task settings, enable the **Open task details when creation is complete** option on the **Finish task creation** page. If you do not enable this option, the task is created with the default settings. You can change the default settings later, at any time.
4. Click the **Finish** button.

The task is created and displayed in the list of tasks.

Finishing task creation

To create a new task assigned to the selected devices:

1. In the main menu, go to **Asset management → Assets (Devices)**.

   The list of managed devices is displayed.

2. In the list of managed devices, select check boxes next to the devices to run the task for them. You can use the search and filter functions to find the devices you're looking for.

3. Click the **Run task** button, and then select **Add a new task**.

   The New task wizard starts.

   On the first step of the wizard, you can remove the devices selected to include in the task scope. Follow the wizard instructions.

4. Click the **Finish** button.

The task is created for the selected devices.

Starting a task manually

The application starts tasks according to the schedule settings specified in the properties of each task. You can start a task manually at any time from the task list. Alternatively, you can select devices in the **Assets (Devices)** list, and then start an existing task for them.

To start a task manually:

1. In the main menu, go to **Tasks**.

2. In the task list, select the check box next to the task that you want to start.

3. Click the **Start** button.

The task starts. You can check the task status in the **Status** column or by clicking the **Result** button.

Starting a task for selected devices

You can select one or more client devices in the list of devices, and then launch a previously created task for them. This allows you to run tasks created earlier for a specific set of devices.

This changes the list of devices to which the task is applied.
The old task scope is deleted and replaced with the selected scope.

To start a task for selected devices:

1. In the main menu, go to **Asset management** → **Assets (Devices)**. The list of managed devices is displayed.

2. In the list of managed devices, select check boxes for devices that you want to run the task for. You can use the search and filter functions to find the devices you're looking for.

3. Click the **Run task** button, and then select **Apply existing task**.

   The list of existing tasks is displayed.

4. The selected devices are displayed above the task list. If necessary, you can remove a device from this list. You can delete all but one device.

5. Select the desired task in the list. You can use the search box above the list to search for the desired task by name. Only one task can be selected.

6. Save changes by clicking one of the buttons:

   - **Run and close**

     The task is run for the selected devices.

   - **Run and open**

     The task is run for the selected devices and the task properties window is displayed, in which you can quickly review the task results.

The scheduled start settings in the task are not changed.

Viewing the task list

You can view the list of tasks that are created in Kaspersky EDR Expert.

To view the list of tasks,

In the main menu, go to **Tasks**.

The list of tasks is displayed. The tasks are grouped by the names of applications to which they are related. For example, the *Install application remotely* task is related to the Administration Server, and the *Update* task refers to Kaspersky Endpoint Security.

To view properties of a task,

Click the name of the task.

The task properties window is displayed with several named tabs. For example, the **Task type** is displayed on the **General** tab, and the task schedule—on the **Schedule** tab.

General task settings

This section contains the settings that you can view and configure for most of your tasks. The list of settings available depends on the task you are configuring.

Settings specified during task creation

You can specify the following settings when creating a task. Some of these settings can also be modified in the properties of the created task.

- Operating system restart settings:

  Do not restart the device

Client devices are not restarted automatically after the operation. To complete the operation, you must restart a device (for example, manually or through a device management task). Information about the required restart is saved in the task results and in the device status. This option is suitable for tasks on servers and other devices where continuous operation is critical.

Restart the device

Client devices are always restarted automatically if a restart is required for completion of the operation. This option is useful for tasks on devices that provide for regular pauses in their operation (shutdown or restart).

Force closure of applications in blocked sessions

Running applications may prevent a restart of the client device. For example, if a document is being edited in a word processing application and is not saved, the application does not allow the device to restart.

If this option is enabled, such applications on a locked device are forced to close before the device restart. As a result, users may lose their unsaved changes.

If this option is disabled, a locked device is not restarted. The task status on this device states that a device restart is required. Users have to manually close all applications running on locked devices and restart these devices.

By default, this option is disabled.

- Task scheduling settings:

  The types of schedule may vary depending on the task.

  Some types of schedule may be unavailable for other Kaspersky applications.

  - **Start task setting:**

    Every N hours

    The task runs regularly, with the specified interval in hours, starting from the specified date and time.

    By default, the task runs every 6 hours, starting from the current system date and time.

    Every N days

    The task runs regularly, with the specified interval in days. Additionally, you can specify a date and time of the first task run. These additional options become available, if they are supported by the application for which you create the task.

    By default, the task runs every day, starting from the current system date and time.

    Every N minutes

    The task runs regularly, with the specified interval in minutes, starting from the specified time on the day that the task is created.

    By default, the task runs every 30 minutes, starting from the current system time.

    By days of week

    The task runs regularly, on the specified days of the week, at the specified time.

    By default, the task runs every Friday at 6:00:00 PM.

    Monthly

    The task runs regularly, on the specified day of the month, at the specified time.

In months that lack the specified day, the task runs on the last day.

By default, the task runs on the first day of each month, at the current system time.

Manually

The task does not run automatically. You can only start it manually.

By default, this option is selected.

Once

The task runs once, on the specified date and time (by default, on the day when the task was created).

Immediately

The task runs immediately after its settings are saved.

Monthly on selected weekday

The task runs regularly, on the specified days of each month, at the specified time.

By default, the start time is 18:00, and no days of the month are selected.

> Note that you select neither a specific date in the month, nor the number of the week (first, second week of the month) but the sequence number of the weekday within a month. For example, if you set the cursor in the **Tu** cell of the **First** row, it means the task will run every first Tuesday of each new month.

You can select several days of week.

When new updates are downloaded to the repository

The task runs after updates are downloaded to the repository. For example, you may want to use this schedule for the *Update* task.

On completing another task

The current task starts after another task completes. This option only works if both tasks are assigned to the same devices. For example, you may want to run the *Manage devices* task with the **Turn on the device** option and, after it completes, run the *Virus scan* task as a triggering task.

You have to select the triggering task from the table and the status with which this task must complete (**Completed successfully** or **Failed**).

If necessary, you can search, sort, and filter the tasks in the table as follows:

- Enter the task name in the search field, to search the task by its name.
- Click the sort icon to sort the tasks by name.

  By default, the tasks are sorted in alphabetical ascending order.
- Click the filter icon, and in the window that opens, filter the tasks by group, and then click the **Apply** button.

If you are creating a task for a managed application, and the schedule of the task can be paused, such a task has the following schedule settings:

- **End time**

  The task schedule is stopped at 12:00 a.m. on the specified date. If the task itself is still running when the end time of the schedule arrives, the task is not terminated.

  For example, suppose a task runs at 11:00 p.m. every day. You specify that the schedule for this task is to be stopped on January 1. On December 31, the task starts at 11:00 p.m., and at 12:00 a.m. on January 1, its schedule is paused: the task continues to run until completion, but the schedule no longer triggers at 11:00 p.m. on January 1.

  This option is available for all schedule types except **Manually** and **Once**.

- **Pause task**

  If this option is enabled, you can specify a time interval during which a task previously started on schedule is to be paused. For example, from 10:00 a.m. to 11:00 a.m.

  This may be necessary during periods of peak device usage to minimize the impact of the managed application (such as Kaspersky Endpoint Security) on performance.

  This option is available for all schedule types.

- **Run missed tasks**

  This option determines the behavior of a task if a client device is not visible on the network when the task is about to start.

  If this option is enabled, the system attempts to start the task the next time the Kaspersky application is run on the client device. If the task schedule is **Manually**, **Once** or **Immediately**, the task is started immediately after the device becomes visible on the network or immediately after the device is included in the task scope.

  If this option is disabled, only scheduled tasks run on client devices. For **Manually**, **Once** and **Immediately** schedule, tasks run only on those client devices that are visible on the network. For example, you may want to disable this option for a resource-consuming task that you want to run only outside of business hours.

  By default, this option is enabled.

- **Use automatically randomized delay for task starts**

  If this option is enabled, the task is started on client devices randomly within a specified time interval, that is, *distributed task start*. A distributed task start helps to avoid a large number of simultaneous requests by client devices to the Administration Server when a scheduled task is running.

  The distributed start time is calculated automatically when a task is created, depending on the number of client devices to which the task is assigned. Later, the task is always started on the calculated start time. However, when task settings are edited or the task is started manually, the calculated value of the task start time changes.

  If this option is disabled, the task starts on client devices according to the schedule.

  By default, this option is enabled.

- **Use automatically randomized delay for task starts within an interval of**

  If this option is enabled, the task is started on client devices randomly within the specified time interval. A distributed task start helps to avoid a large number of simultaneous requests by client devices to the Administration Server when a scheduled task is running.

  If this option is disabled, the task starts on client devices according to the schedule.

  By default, this option is disabled. The default time interval is one minute.

- Devices to which the task will be assigned:

Select networked devices detected by Administration Server

The task is assigned to specific devices. The specific devices can include devices in administration groups as well as unassigned devices.

For example, you may want to use this option in a task of installing Network Agent on unassigned devices.

Specify device addresses manually or import addresses from list

You can specify DNS names, IP addresses, and IP subnets of devices to which you want to assign the task.

You may want to use this option to execute a task for a specific subnet. For example, you may want to install a certain application on devices of accountants or to scan devices in a subnet that is probably infected.

Assign task to a device selection

The task is assigned to devices included in a device selection. You can specify one of the existing selections.

For example, you may want to use this option to run a task on devices with a specific operating system version.

Assign task to an administration group

The task is assigned to devices included in an administration group. You can specify one of the existing groups or create a new one.

For example, you may want to use this option to run a task of sending a message to users if the message is specific for devices included in a specific administration group.

If a task is assigned to an administration group, the **Security** tab is not displayed in the task properties window because group tasks are subject to the security settings of the groups to which they apply.

- Account settings:

  Default account

  The task will be run under the same account as the application that performs this task.

  By default, this option is selected.

  Specify an account

  Fill in the **Account** and **Password** fields to specify the details of an account under which the task is run. The account must have sufficient rights for this task.

  Login.

  Account under which the task is run.

  Password

  Password of the account under which the task will be run.

Settings specified after task creation

You can specify the following settings only after a task is created.

- Group task settings:

  Distribute to subgroups

  This option is only available in the settings of the group tasks.

When this option is enabled, the task scope includes:

- The administration group that you selected while creating the task.
- The administration groups subordinate to the selected administration group at any level down by the group hierarchy.

When this option is disabled, the task scope includes only the administration group that you selected while creating the task.

By default, this option is enabled.

Distribute to secondary and virtual Administration Servers

When this option is enabled, the task that is effective on the primary Administration Server is also applied on the secondary Administration Servers (including virtual ones). If a task of the same type already exists on the secondary Administration Server, both tasks are applied on the secondary Administration Server—the existing one and the one that is inherited from the primary Administration Server.

This option is only available when the **Distribute to subgroups** option is enabled.

By default, this option is disabled.

- Advanced scheduling settings:

  Turn on devices by using the Wake-on-LAN function before starting the task

  The operating system on the device starts at the specified time before the task is started. The default time period is five minutes.

  Enable this option if you want the task to run on all of the client devices from the task scope, including those devices that are turned off when the task is about to start.

  If you want the device to be automatically turned off after the task is completed, enable the **Shut down device when task is complete** option. This option can be found in the same window.

  By default, this option is disabled.

  Shut down the devices after completing the task

  For example, you may want to enable this option for an install update task that installs updates to client devices each Friday after business hours, and then turns off these devices for the weekend.

  By default, this option is disabled.

  Stop the task if it runs longer than

  After the specified time period expires, the task is stopped automatically, whether it is completed or not.

  Enable this option if you want to interrupt (or stop) tasks that take too long to execute.

  By default, this option is disabled. The default task execution time is 120 minutes.

- Notification settings:

  - **Store task history** block:

    Store in the Administration Server database for (days)

    Application events related to execution of the task on all client devices from the task scope are stored on the Administration Server during the specified number of days. When this period elapses, the information is deleted from the Administration Server.

    By default, this option is enabled.

Store in the OS event log on device

Application events related to execution of the task are stored locally in the Syslog Event Log of each client device.

By default, this option is disabled.

Store in the OS event log on Administration Server

Application events related to execution of the task on all client devices from the task scope are stored centrally in the Syslog Event Log of the Administration Server operating system (OS).

By default, this option is disabled.

Save all events

If this option is selected, all events related to the task are saved to the event logs.

Save events related to task progress

If this option is selected, only events related to the task execution are saved to the event logs.

Save only task execution results

If this option is selected, only events related to the task results are saved to the event logs.

- **Notify administrator of task execution results**

  You can select the methods by which administrators receive notifications about task execution results: by email, by SMS, and by running an executable file. To configure notification, click the **Settings** link.

  By default, all notification methods are disabled.

- **Notify of errors only**

  If this option is enabled, administrators are only notified when a task execution completes with an error.

  If this option is disabled, administrators are notified after every task execution completion.

  By default, this option is enabled.

- Security settings.

- Task scope settings.

  Depending on how the task scope is determined, the following settings are present:

  Devices

  If the scope of a task is determined by an administration group, you can view this group. No changes are available here. However, you can set **Exclusions from task scope**.

  If the scope of a task is determined by a list of devices, you can modify this list by adding and removing devices.

  Device selection

  You can change the device selection to which the task is applied.

  Exclusions from task scope

You can specify groups of devices to which the task is not applied. Groups to be excluded can only be subgroups of the administration group to which the task is applied.

- **Revision history**.

Exporting a task

Open Single Management Platform allows you to save a task and its settings to a KLT file. You can use this KLT file to import the saved task both to Kaspersky Security Center Windows and Kaspersky Security Center Linux.

To export a task:

1. In the main menu, go to **Tasks**.
2. Select the check box next to the task that you want to export.

   You cannot export multiple tasks at the same time. If you select more than one task, the **Export** button will be disabled. Administration Server tasks are also unavailable for export.
3. Click the **Export** button.
4. In the opened **Save as** window, specify the task file name and path. Click **Save**.

   The **Save as** window is displayed only if you use Google Chrome, Microsoft Edge, or Opera. If you use another browser, the task file is automatically saved in the **Downloads** folder.

Importing a task

Open Single Management Platform allows you to import a task from a KLT file. The KLT file contains the exported task and its settings.

For correct import of the Kaspersky application task, you have to install the appropriate management plug-in.

To import a task:

1. In the main menu, go to **Tasks**.
2. Click the **Import** button.
3. Click the **Browse** button to choose a task file that you want to import.
4. In the opened window, specify the path to the KLT task file, and then click the **Open** button. Note that you can select only one task file.

   The task processing starts.
5. After the task is processed successfully, select the devices to which you want to assign the task. To do this, select one of the following options:

   Assign task to an administration group

   The task is assigned to devices included in an administration group. You can specify one of the existing groups or create a new one.

For example, you may want to use this option to run a task of sending a message to users if the message is specific for devices included in a specific administration group.

If a task is assigned to an administration group, the **Security** tab is not displayed in the task properties window because group tasks are subject to the security settings of the groups to which they apply.

Specify device addresses manually or import addresses from a list

You can specify DNS names, IP addresses, and IP subnets of devices to which you want to assign the task.

You may want to use this option to execute a task for a specific subnet. For example, you may want to install a certain application on devices of accountants or to scan devices in a subnet that is probably infected.

Assign task to a device selection

The task is assigned to devices included in a device selection. You can specify one of the existing selections.

For example, you may want to use this option to run a task on devices with a specific operating system version.

6. Specify the task scope.

7. Click the **Complete** button to finish the task import.

The notification with the import results appears. If the task is imported successfully, you can click the **Details** link to view the task properties.

After a successful import, the task is displayed in the task list. The task settings and schedule are also imported. The task will be started according to its schedule.

> If the newly imported task has an identical name to an existing task, the name of the imported task is expanded with the **(<next sequence number>)** index, for example: **(1)**, **(2)**.

Starting the Change tasks password wizard

For a non-local task, you can specify an account under which the task must be run. You can specify the account during task creation or in the properties of an existing task. If the specified account is used in accordance with security instructions of the organization, these instructions might require changing the account password from time to time. When the account password expires and you set a new one, the tasks will not start until you specify the new valid password in the task properties.

The Change tasks password wizard enables you to automatically replace the old password with the new one in all tasks in which the account is specified. Alternatively, you can change this password manually in the properties of each task.

To start the Change tasks password wizard:

1. In the main menu, go to **Tasks**.

2. Click **Manage credentials of accounts for starting tasks**.

Follow the steps of the wizard.

Step 1. Specifying credentials

Specify new credentials that are currently valid in your system. When you switch to the next step of the wizard, Open Single Management Platform checks if the specified account name matches the account name in the properties of each non-local task. If the account names match, the password in the task properties will be automatically replaced with the new one.

To specify the new account, select an option:

Use current account

The wizard uses the name of the account under which you are currently signed in to OSMP Console. Then manually specify the account password in the **Current password to use in tasks** field.

Specify a different account

Specify the name of the account under which the tasks must be started. Then specify the account password in the **Current password to use in tasks** field.

If you fill in the **Previous password (optional; if you want to replace it with the current one)** field, Open Single Management Platform replaces the password only for those tasks in which both the account name and the old password are found. The replacement is performed automatically. In all other cases you have to choose an action to take in the next step of the wizard.

Step 2. Selecting an action to take

If you did not specify the previous password in the first step of the wizard or if the specified old password has not matched the passwords in the task properties, you must choose an action to take for the tasks found.

To choose an action for a task:

1. Select the check box next to the task for which you want to choose an action.
2. Do one of the following:
   - To remove the password in the task properties, click **Delete credentials**.

     The task is switched to run under the default account.
   - To replace the password with a new one, click **Enforce the password change even if the old password is wrong or not provided**.
   - To cancel the password change, click **No action is selected**.

The chosen actions are applied after you move to the next step of the wizard.

Step 3. Viewing the results

On the last step of the wizard, view the results for each of the found tasks. To complete the wizard, click the **Finish** button.

Viewing task run results stored on the Administration Server

Kaspersky EDR Expert allows you to view the results for group tasks, tasks for specific devices, and Administration Server tasks.

To view the task results:

In the task properties window, go to the **Results** tab.

To view task results for a secondary Administration Server:

1. In the task properties window, select the **General** section.
2. Click the **Results** link to open the **Task results** window.
3. Click **Statistics from secondary Servers**.
4. Select the secondary Server for which you want to display the **Task results** window.

Manual setup of the group task for scanning a device with Kaspersky Endpoint Security

If the automatically specified schedule of the group scanning task is not appropriate for your organization, you must manually set up the most convenient schedule for this task based on the workplace rules adopted in the organization.

For example, the task is assigned a **Run on Fridays at 7:00 PM** schedule with automatic randomization, and the **Run missed tasks** check box is cleared. This means that if the devices in the organization are shut down on Fridays, for example, at 6:30 PM, the device scan task will never run. In this case you need to set up the group scanning task manually.

Managing detection and response tasks

When managing the program console, you can use tasks to perform various operations. For example, you can import assets or export KUMA event information to a TSV file.

Viewing the tasks table

The task table contains a list of created tasks and is located in the **Asset management** → **Tasks** → **Analysis and response** section of the program console window. You can view the tasks that were created by you (current user).

A user with the Main administrator role can view the tasks of all users.

The tasks table contains the following information:

- **State**—the state of the task. One of the following statuses can be assigned to a task:
  - *Green dot blinking*—the task is active.
  - **Completed**—the task is complete.
  - **Cancel**—the task was canceled by the user.
  - **Error**—the task was not completed because of an error. The error message is displayed if you hover the mouse over the exclamation mark icon.
- **Task**—the task type. The program provides the following types of tasks:
  - **Events export**—export events.
  - **Run query in the background**—runs an SQL query in the background.
  - **Threat Lookup**—request data from the Kaspersky Threat Intelligence Portal.
  - **Retroscan**—task for replaying events.
  - **OSMP assets import**—imports asset data from Kaspersky Security Center Servers.
  - **Accounts import**—imports user data from Active Directory.
  - **KICS for Networks assets import**—imports asset data from KICS for Networks.
  - **Repository update**—updates the KUMA repository to receive the resource packages from the source specified in settings.
  - **Partition backup** backs up partitions and saves the backup file at a specified path.
  - **Restoring partitions from backup** restores partitions from a backup copy.
  - **Importing partitions** imports partitions from an external KUMA installation.
- **Created by**—the user who created the task. If the task was created automatically, the column will show **Scheduled task**.

  This column is displayed only for users with the Main administrator and Tenant administrator roles.
- **Created**—task creation time.
- **Updated**—time when the task was last updated.
- **Tenant**—the name of the tenant in which the task was started.

The task date format depends on the localization language selected in the application settings. Possible date format options:

- English localization: YYYY-MM-DD.
- Russian localization: DD.MM.YYYY.

Viewing task run results

To view the results of a task:

1. In the main menu, go to **Asset management** → **Tasks** → **Analysis and response**.
   The tasks table is displayed.
2. Click the link containing the task type in the **Task** column.
   A list of the operations available for this task type will be displayed.
3. Select **Show results**.

The task results window opens.

Restarting a task

To restart a task:

1. In the main menu, go to **Asset management** → **Tasks** → **Analysis and response**.
   The tasks table is displayed.
2. Select the check box next to the task that you want to restart.
3. Click the **Restart** button.

The task will be restarted.

Application tags

Kaspersky EDR Expert enables you to tag the applications from applications registry. A tag is the label of an application that can be used for grouping or finding applications. A tag assigned to applications can serve as a condition in device selections.

For example, you can create the `[Browsers]` tag and assign it to all browsers such as Microsoft Internet Explorer, Google Chrome, Mozilla Firefox.

Creating an application tag

To create an application tag:

1. In the main menu, go to **Software management** → **Third-party applications** → **Application tags**.
2. Click **Add**.
   A new tag window opens.

3. Enter the tag name.
4. Click **OK** to save the changes.

The new tag appears in the list of application tags.

Renaming an application tag

To rename an application tag:

1. In the main menu, go to **Software management** → **Third-party applications** → **Application tags**.
2. Select the check box next to the tag that you want to rename, and then click **Edit**.

   A tag properties window opens.
3. Change the tag name.
4. Click **OK** to save the changes.

The updated tag appears in the list of application tags.

Assigning tags to an application

To assign one or several tags to an application:

1. In the main menu, go to **Software management** → **Third-party applications** → **Applications registry**.
2. Click the name of the application to which you want to assign tags.
3. Select the **Tags** tab.

   The tab displays all application tags that exist on the Administration Server. For tags assigned to the selected application, the check box in the **Tag assigned** column is selected.
4. For tags that you want to assign, select check boxes in the **Tag assigned** column.
5. Click **Save** to save changes.

The tags are assigned to the application.

Removing assigned tags from an application

To remove one or several tags from an application:

1. In the main menu, go to **Software management** → **Third-party applications** → **Applications registry**.
2. Click the name of the application from which you want to remove tags.

3. Select the **Tags** tab.

   The tab displays all application tags that exist on the Administration Server. For tags assigned to the selected application, the check box in the **Tag assigned** column is selected.

4. For tags that you want to remove, clear check boxes in the **Tag assigned** column.

5. Click **Save** to save changes.

The tags are removed from the application.

> The removed application tags are not deleted. If you want, you can delete them manually.

Deleting an application tag

To delete an application tag:

1. In the main menu, go to **Software management** → **Third-party applications** → **Application tags**.

2. In the list, select the application tag that you want to delete.

3. Next, click the **Delete** button.

4. In the window that opens, click **OK**.

The application tag is deleted. The deleted tag is automatically removed from all of the applications to which it was assigned.

Registering Kaspersky Industrial CyberSecurity for Networks application in OSMP Console

To start working with the Kaspersky Industrial CyberSecurity for Networks application via OSMP Console, you must first register it in OSMP Console.

To register the Kaspersky Industrial CyberSecurity for Networks application:

1. Make sure that the following is done:

   - You have downloaded and installed the Kaspersky Industrial CyberSecurity for Networks web plug-in.

     You can do it later while waiting for the Kaspersky Industrial CyberSecurity for Networks Server to synchronize with the Administration Server. After the plug-in is downloaded and installed, the **KICS for Networks** section is displayed in the OSMP Console main menu.

   - In the Kaspersky Industrial CyberSecurity for Networks web interface, interaction with Kaspersky EDR Expert is configured and enabled. For details, refer to the Kaspersky Industrial CyberSecurity for Networks Online Help.

2. Move the device where Kaspersky Industrial CyberSecurity for Networks Server is installed from the Unassigned devices group to the Managed devices group:

   a. In the main menu, go to **Asset management** → **Unassigned devices**.

   b. Select the check box next to the device where the Kaspersky Industrial CyberSecurity for Networks Server is installed.

   c. Click the **Move to group** button.

   d. In the hierarchy of administration groups, select the check box next to the **Managed devices** group.

   e. Click the **Move** button.

3. Open the properties window of the device where the Kaspersky Industrial CyberSecurity for Networks Server is installed.

4. On the device properties page, in the **General** section, select the **Do not disconnect from the Administration Server** option, and then click the **Save** button.

5. On the device properties page, select the **Applications** section.

6. In the **Applications** section, select Kaspersky Security Center Network Agent.

7. If the current status of the application is *Stopped*, wait until it changes to *Running*.

   This may take up to 15 minutes. If you have not yet installed the Kaspersky Industrial CyberSecurity for Networks web plug-in, you can do it now.

8. If you want to view the statistics of Kaspersky Industrial CyberSecurity for Networks, you may add widgets on the dashboard. To add the widgets, do the following:

   a. In the main menu, go to **Monitoring** → **Dashboard**.

   b. On the dashboard, click the **Add or restore web widget** button.

   c. In the widget menu that opens, select **Other**.

   d. Select the widgets that you want to add:

      - KICS for Networks deployment map
      - Information about KICS for Networks Servers
      - Up-to-date events of KICS for Networks
      - Devices with issues in KICS for Networks
      - Critical events in KICS for Networks
      - Statuses in KICS for Networks

9. To proceed to the Kaspersky Industrial CyberSecurity for Networks web interface, do the following:

   a. In the main menu, go to **KICS for Networks** → **Search**.

   b. Click the **Find events or devices** button.

   c. In the **Query parameters** window that opens, click the **Server** field.

   d. Select the Kaspersky Industrial CyberSecurity for Networks Server from the drop-down list of servers that are integrated with Kaspersky EDR Expert, and then click the **Find** button.

   e. Click the **Go to Server** link next to the name of the Kaspersky Industrial CyberSecurity for Networks Server.

   The Kaspersky Industrial CyberSecurity for Networks sign-in page is displayed.

   > To log in to the Kaspersky Industrial CyberSecurity for Networks web interface, you need to provide the application user account credentials.

Updating Kaspersky databases and applications

This section describes steps you must take to regularly update the following:

- Kaspersky databases and software modules
- Installed Kaspersky applications, including Open Single Management Platform components and security applications

> Updates functionality (including providing anti-virus signature updates and codebase updates), as well as KSN functionality may not be available in the software in the U.S.

Scenario: Regular updating Kaspersky databases and applications

This section provides a scenario for regular updating of Kaspersky databases, software modules, and applications. After you complete the Configuring network protection scenario, you must maintain the reliability of the protection system to make sure that the Administration Servers and managed devices are kept protected against various threats, including viruses, network attacks, and phishing attacks.

Network protection is kept up-to-date by regular updates of the following:

- Kaspersky databases and software modules
- Installed Kaspersky applications, including Kaspersky EDR Expert components and security applications

When you complete this scenario, you can be sure of the following:

- Your network is protected by the most recent Kaspersky software, including Kaspersky EDR Expert components and security applications.
- The anti-virus databases and other Kaspersky databases critical for the network safety are always up-to-date.

Prerequisites

The managed devices must have a connection to the Administration Server. If they do not have a connection, consider updating Kaspersky databases and software modules manually or directly from the Kaspersky update servers.

Administration Server must have a connection to the internet.

Before you start, make sure that you have done the following:

1. Deployed the Kaspersky security applications to the managed devices according to the scenario of deploying Kaspersky applications through OSMP Console.
2. Created and configured all required policies, policy profiles, and tasks according to the scenario of configuring network protection.
3. Assigned an appropriate amount of distribution points in accordance with the number of managed devices and the network topology.

Updating Kaspersky databases and applications proceeds in stages:

1. **Choosing an update scheme**

   There are several schemes that you can use to install updates to Open Single Management Platform components and security applications. Choose the scheme or several schemes that meet the requirements of your network best.

2. **Creating the task for downloading updates to the repository of the Administration Server**

   Create a *Download updates to the Administration Server repository* task manually.

   This task is required to download updates from Kaspersky update servers to the repository of the Administration Server, as well as to update Kaspersky databases and software modules for Open Single Management Platform. After the updates are downloaded, they can be propagated to the managed devices.

   If your network has assigned distribution points, the updates are automatically downloaded from the Administration Server repository to the repositories of the distribution points. In this case the managed devices included in the scope of a distribution point download the updates from the repository of the distribution point instead of the Administration Server repository.

   How-to instructions: Creating the task for downloading updates to the repository of the Administration Server

3. **Creating the task for downloading updates to the repositories of distribution points (optional)**

   By default, the updates are downloaded to the distribution points from the Administration server. You can configure Open Single Management Platform to download the updates to the distribution points directly from Kaspersky update servers. Download to the repositories of distribution points is preferable if the traffic between the Administration Server and the distribution points is more expensive than the traffic between the distribution points and Kaspersky update servers, or if your Administration Server does not have internet access.

When your network has assigned distribution points and the *Download updates to the repositories of distribution points* task is created, the distribution points download updates from Kaspersky update servers, and not from the Administration Server repository.

How-to instructions: Creating the task for downloading updates to the repositories of distribution points

4. **Configuring distribution points**

When your network has assigned distribution points, make sure that the **Enabled** option is enabled in the properties of all required distribution points. When this option is disabled for a distribution point, the devices included in the scope of the distribution point download updates from the repository of the Administration Server.

5. **Optimizing the update process by using the diff files (optional)**

You can optimize traffic between the Administration Server and the managed devices by using diff files. When this feature is enabled, the Administration Server or a distribution point downloads diff files instead of entire files of Kaspersky databases or software modules. A diff file describes the differences between two versions of a file of a database or software module. Therefore, a diff file occupies less space than an entire file. This results in decrease in the traffic between the Administration Server or distribution points and the managed devices. To use this feature, enable the **Download diff files** option in the properties of the *Download updates to the Administration Server repository* task and/or the *Download updates to the repositories of distribution points* task.

How-to instructions: Using diff files for updating Kaspersky databases and software modules

6. **Configuring automatic installation of updates for the security applications**

Create the *Update* tasks for the managed applications to provide timely updates to the software modules and Kaspersky databases, including anti-virus databases. To ensure timely updates, we recommend that you select the **When new updates are downloaded to the repository** option when configuring the task schedule.

If an update requires reviewing and accepting the terms of the End User License Agreement, then you first need to accept the terms. After that the update can be propagated to the managed devices.

7. **Approving and declining updates of managed Kaspersky applications**

By default, the downloaded software updates have the *Undefined* status. You can change the status to *Approved* or *Declined*. The approved updates are always installed. If an update of a managed Kaspersky application requires reviewing and accepting the terms of the End User License Agreement, then you first need to accept the terms. After that the update can be propagated to the managed devices. The updates for which you set *Declined* status will not be installed on devices. If a declined update for a managed application was previously installed, Open Single Management Platform will try to uninstall the update from all devices.

Approving and declining updates is available only for Network Agent and managed Kaspersky applications installed on Windows-based client devices. Seamless updating of Administration Server, OSMP Console, and management web plug-ins is not supported.

How-to instructions: Approving and declining software updates

Sometimes after Network Agent update you may be prompted to restart managed devices. If the notification about the required restart is displayed, click the **View devices** link in the notification, select the check boxes next to the devices to be restarted, and then click the **Restart** button to finish the Network Agent update.

Results

Upon completion of the scenario, Kaspersky EDR Expert is configured to update Kaspersky databases after the updates are downloaded to the repository of the Administration Server. You can then proceed to monitoring the network status.

About updating Kaspersky databases, software modules, and applications

To be sure that the protection of your Administration Servers and managed devices is up-to-date, you must provide timely updates of the following:

- Kaspersky databases and software modules

  Before downloading Kaspersky databases and software modules, Open Single Management Platform checks if Kaspersky servers are accessible. If access to the servers using system DNS is not possible, the application uses public DNS servers. This is necessary to make sure anti-virus databases are updated and the level of security is maintained for the managed devices.

- Installed Kaspersky applications, including Open Single Management Platform components and security applications

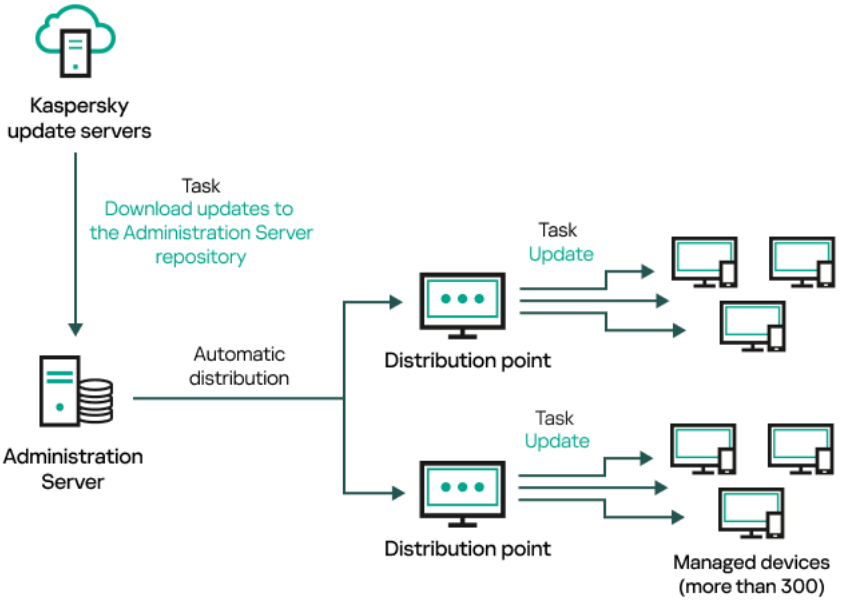
  Open Single Management Platform allows you to update Network Agent and Kaspersky applications installed on Windows-based client devices automatically. Seamless updating of Administration Server, OSMP Console, and management web plug-ins is not supported. To update these components, you have to download the latest versions from the Kaspersky website, and then install them manually.

Depending on the configuration of your network, you can use the following schemes of downloading and distributing the required updates to the managed devices:

- By using a single task: *Download updates to the Administration Server repository*
- By using two tasks:
  - The *Download updates to the Administration Server repository* task
  - The *Download updates to the repositories of distribution points* task
- Manually through a shared folder or an FTP server
- Directly from Kaspersky update servers to Kaspersky Endpoint Security on the managed devices
- Through a network folder if Administration Server has no internet connection

Using the Download updates to the Administration Server repository task

In this scheme, Open Single Management Platform downloads updates through the *Download updates to the Administration Server repository* task. In small networks that contain less than 300 managed devices in a single network segment or less than 10 managed devices in each network segment, the updates are distributed to the managed devices directly from the Administration Server repository (see figure below).



Updating by using the *Download updates to the Administration Server repository* task without distribution points

As a source of updates, you can use not only Kaspersky update servers, but also a network folder.

By default, the Administration Server communicates with Kaspersky update servers and downloads updates by using the HTTPS protocol. You can configure the Administration Server to use the HTTP protocol instead of HTTPS.

If your network contains 300 managed devices or more in a single network segment or if your network consists of several network segments with more than 9 managed devices in each network segment, we recommend that you use distribution points to propagate the updates to the managed devices (see figure below). Distribution points reduce the load on the Administration Server and optimize traffic between the Administration Server and the managed devices. You can calculate the number and configuration of distribution points required for your network.

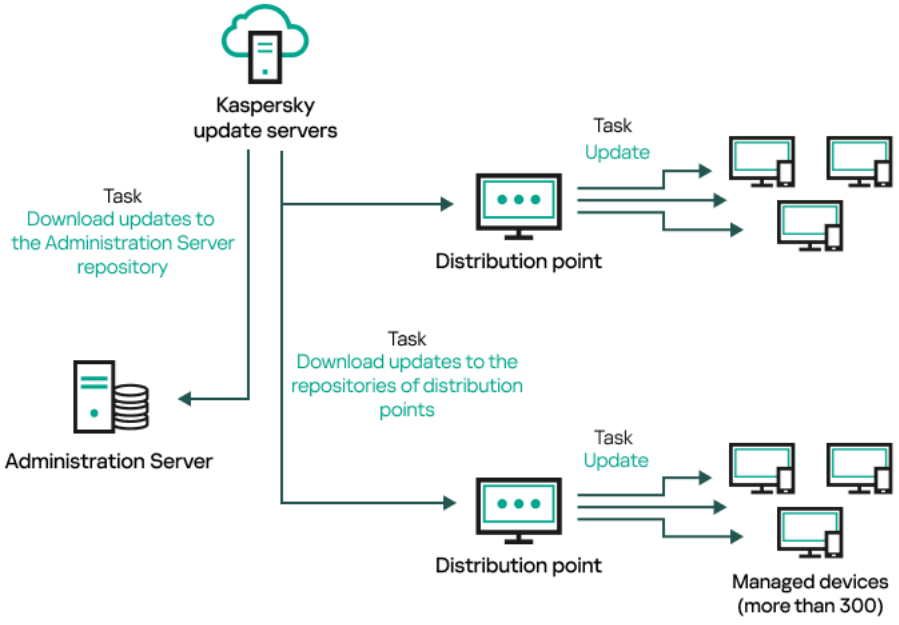
In this scheme, the updates are automatically downloaded from the Administration Server repository to the repositories of the distribution points. The managed devices included in the scope of a distribution point download the updates from the repository of the distribution point instead of the Administration Server repository.

Updating by using the *Download updates to the Administration Server repository* task with distribution points

When the *Download updates to the Administration Server repository* task is complete, the updates for Kaspersky databases and software modules for Kaspersky Endpoint Security are downloaded to the Administration Server repository. These updates are installed through the *Update* task for Kaspersky Endpoint Security.

The *Download updates to the repository of the Administration Server* task is not available on virtual Administration Servers. The repository of the virtual Administration Server displays updates downloaded to the primary Administration Server.

You can configure the updates to be verified for operability and errors on a set of test devices. If the verification is successful, the updates are distributed to other managed devices.



Each Kaspersky application requests required updates from Administration Server. Administration Server aggregates these requests and downloads only those updates that are requested by any application. This ensures that the same updates are not downloaded multiple times and that unnecessary updates are not downloaded at all. When running the *Download updates to the Administration Server repository* task, Administration Server sends the following information to Kaspersky update servers automatically in order to ensure the downloading of relevant versions of Kaspersky databases and software modules:

- Application ID and version
- Application setup ID
- Active key ID
- *Download updates to the repository of the Administration Server* task run ID

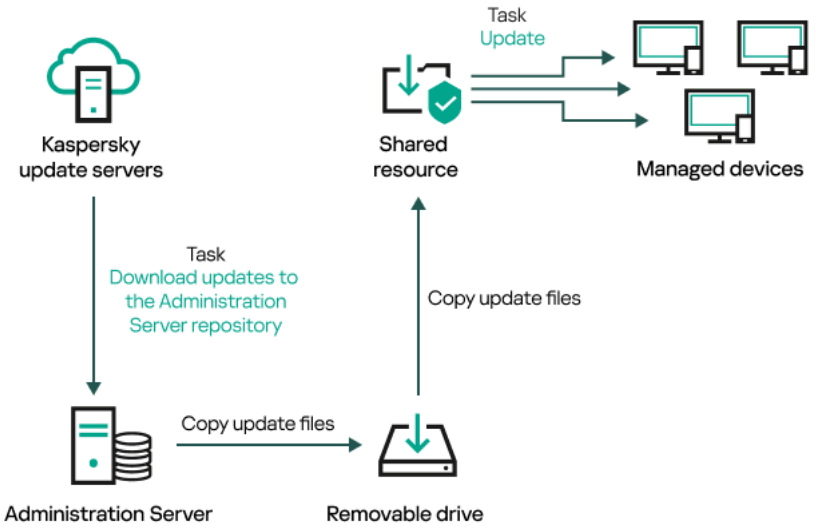
None of the transmitted information contains personal or other confidential data. AO Kaspersky Lab protects information in accordance with requirements established by law.

Using two tasks: the Download updates to the Administration Server repository task and the Download updates to the repositories of distribution points task

You can download updates to the repositories of distribution points directly from the Kaspersky update servers instead of the Administration Server repository, and then distribute the updates to the managed devices (see figure below). Download to the repositories of distribution points is preferable if the traffic between the Administration Server and the distribution points is more expensive than the traffic between the distribution points and Kaspersky update servers, or if your Administration Server does not have internet access.

Updating using the *Download updates to the Administration Server repository* and *Download updates to the repositories of distribution points* tasks

By default, the Administration Server and distribution points communicate with Kaspersky update servers and



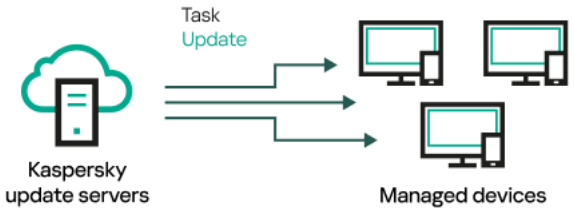
download updates by using the HTTPS protocol. You can configure the Administration Server and/or distribution points to use the HTTP protocol instead of HTTPS.

To implement this scheme, create the *Download updates to the repositories of distribution points* task in addition to the *Download updates to the Administration Server repository* task. After that the distribution points will download updates from Kaspersky update servers, and not from the Administration Server repository.

The *Download updates to the Administration Server repository* task is also required for this scheme, because this task is used to download Kaspersky databases and software modules for Open Single Management Platform.

Manually through a shared folder or an FTP server

If the client devices do not have a connection to the Administration Server, you can use a shared resource as a source for updating Kaspersky databases, software modules, and applications. In this scheme, you need to copy required updates from the Administration Server repository to a removable drive, then copy the updates to the shared resource specified as an update source in the settings of Kaspersky Endpoint Security (see figure below).



Updating through a shared folder or an FTP server

For more information about sources of updates in Kaspersky Endpoint Security, see the following Helps:

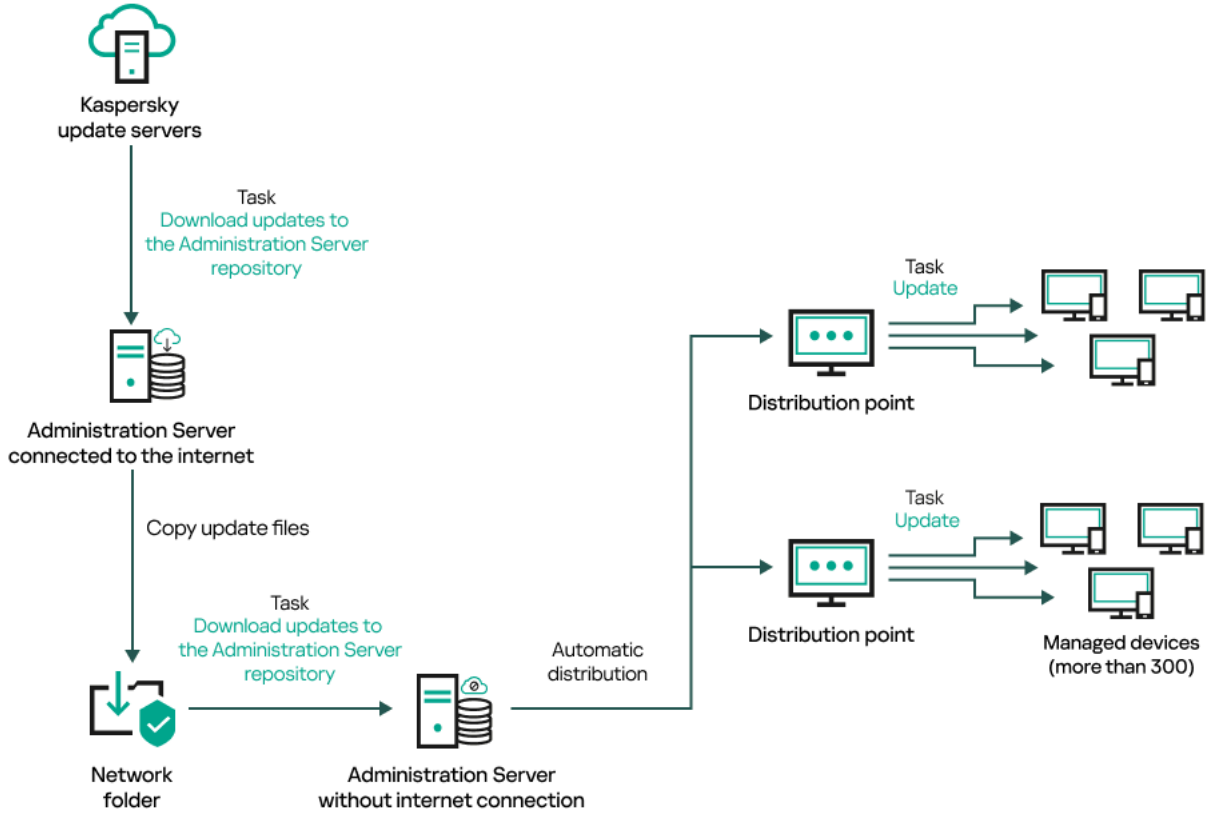
- Kaspersky Endpoint Security for Linux Help
- Kaspersky Endpoint Security for Windows Help

Directly from Kaspersky update servers to Kaspersky Endpoint Security on the managed devices

On the managed devices, you can configure Kaspersky Endpoint Security to receive updates directly from Kaspersky update servers (see figure below).

Updating security applications directly from Kaspersky update servers

In this scheme, the security application does not use the repository provided by Open Single Management Platform. To receive updates directly from Kaspersky update servers, specify Kaspersky update servers as an update source in the security application. For more information about these settings, see the following Helps:



- Kaspersky Endpoint Security for Linux Help
- Kaspersky Endpoint Security for Windows Help

Through a network folder if Administration Server has no internet connection

If Administration Server has no internet connection, you can configure the *Download updates to the Administration Server repository* task to download updates from a network folder. In this case, you must copy the required update files to the specified folder from time to time. For example, you can copy the required update files from one of the following sources:

- Administration Server that has an internet connection (see the figure below)

Because an Administration Server downloads only the updates that are requested by the security applications, the sets of security applications managed by the Administration Servers—the one that has an internet connection and the one that does not—must match.

Updating through a network folder if Administration Server has no internet connection

- Kaspersky Update Utility

  Because this utility uses the old scheme to download updates, open properties of the *Download updates to the Administration Server repository* task, and then enable the *Download updates by using the old scheme* option. If necessary, you can also configure the *Download the update request file automatically* option so that the Kaspersky Update Utility downloads only the required updates.

Creating the Download updates to the Administration Server repository task

The *Download updates to the Administration Server repository* task allows you to download updates of databases and software modules for Kaspersky security applications from Kaspersky update servers to the Administration Server repository. In the list of tasks, there can only be one *Download updates to the Administration Server repository* task.

After the *Download updates to the Administration Server repository* task is complete and the updates are downloaded, they can be propagated to the managed devices.

If you install Administration Server in a cluster, the *Download updates to the Administration Server repository* task is created automatically.

Before you distribute updates to the managed devices, you can run the *Update verification* task. This allows you to make sure that Administration Server installs the downloaded updates properly and a security level is not decreased because of the updates. To verify them before distributing, configure the **Run update verification** option in the *Download updates to the Administration Server repository* task settings.

To create a Download updates to the Administration Server repository task:

1. In the main menu, go to **Tasks**.
2. Click the **Add** button.

   The New task wizard starts. Follow the steps of the wizard.
3. For the Kaspersky EDR Expert application, select the **Download updates to the Administration Server repository** task type.
4. Specify the name for the task that you are creating. A task name cannot be more than 100 characters long and cannot include any special characters ("*<>?\:|).
5. On the **Finish task creation** page, you can enable the **Open task details when creation is complete** option to open the task properties window and modify the default task settings. Otherwise, you can configure the task settings later, at any time.
6. Click the **Finish** button.

   The task is created and displayed in the list of tasks.
7. Click the created task name to open the task properties window.
8. In the task properties window, on the **Application settings** tab, specify the following settings:

   - **Sources of updates**

     As a source of updates, you can use Kaspersky update servers or a network folder. If you are creating a task for a secondary or virtual Administration Server, you can also select a local directory or a primary Administration Server as the update source.

     In the *Download updates to the Administration Server repository* task and the *Download updates to the repositories of distribution points* task, user authentication does not work if you select a password-protected local or network folder as an update source. To resolve this issue, first mount the password-protected folder, and then specify the required credentials, for example, by means of the operating system. After that, you can select this folder as an update source in an update download task. Open Single Management Platform will not require that you enter the credentials.

   - **Folder for storing updates**

     The path to the specified folder for storing saved updates. You can copy the specified folder path to a clipboard. You cannot change the path to a specified folder for a group task.

- **Force update of secondary Administration Servers**

  If this option is enabled, the Administration Server starts update tasks on the secondary Administration Servers as soon as new updates are downloaded. Update tasks are started by using the source of update that is configured in the task properties on the secondary Administration Servers.

  If this option is disabled, the update tasks on the secondary Administration Servers start according to their schedules.

  By default, this option is disabled.

- **Copy downloaded updates to additional folders**

  After the Administration Server receives updates, it copies them to the specified folders. Use this option if you want to manually manage the distribution of updates on your network.

  For example, you may want to use this option in the following situation: the network of your organization consists of several independent subnets, and devices from each of the subnets do not have access to other subnets. However devices in all of the subnets have access to a common network share. In this case, you set Administration Server in one of the subnets to download updates from Kaspersky update servers, enable this option, and then specify this network share. In downloaded updates to the repository tasks for other Administration Servers, specify the same network share as the update source.

  If you select to copy the downloaded updates to a local folder, you must specify a folder on the device that has Administration Server installed. The path to the folder depends on the device's operating system. Since the local folder is located on Linux-based Administration Server, you have to specify the POSIX path, for example: /path/to/dir.

  When selecting a network folder that is located on Linux-based Administration Server, you must ensure access to the network folder in advance from the device with Administration Server installed by mounting the folder. Access to the folder is performed by using the SMB protocol.

  By default, this option is disabled.

- **Download diff files**

  This option enables the downloading diff files feature.

  By default, this option is disabled.

- **Download updates by using the old scheme**

  Open Single Management Platform downloads updates of databases and software modules by using the new scheme. For the application to download updates by using the new scheme, the update source must contain the update files with the metadata compatible with the new scheme. If the update source contains the update files with the metadata compatible with the old scheme only, enable the **Download updates by using the old scheme** option. Otherwise, the update download task will fail.

  For example, you must enable this option when a local or network folder is specified as an update source, and the update files in this folder were downloaded by Kaspersky Update Utility which downloads updates by using the old scheme.

  By default, this option is disabled.

- **Run update verification**

  Administration Server downloads updates from the source, saves them to a temporary repository, and runs the task defined in the **Update verification task** field. If the task completes successfully, the updates are copied from the temporary repository to a shared folder on the Administration Server and then distributed to all devices for which the Administration Server acts as the source of updates (tasks with the **When new updates are downloaded to the repository** schedule type are started). The task of downloading updates to the repository is finished only after completion of the *Update verification* task.

By default, this option is disabled.

- **Download the update request file automatically**

  If you want Kaspersky Update Utility to download only the required updates with suitable configuration, enable this option and specify the path where Kaspersky EDR Expert will create the update request file with information about the updates to be downloaded. The update request file contains the timestamp and the MD5 hash for version control.

  Make sure that the **Download updates by using the old scheme** option is disabled.

  Also, the update download in Kaspersky Update Utility must be configured.

  By default, the following path is specified: /var/opt/kaspersky/klnagent_srv/1093/.working/share_srv/retranslation_request.xml. If necessary, you can change the default name (retranslation_request) and path.

  > The request file can be placed at a local or shared folder. When using a shared folder, you have to ensure the access to this folder from the device with Administration Server installed. The ways to ensure the access and the tools used depend on your infrastructure.

  When performing the *Download updates to the Administration Server repository* task, Kaspersky EDR Expert creates the update request file in the XML format at the path that you have specified. Kaspersky Update Utility automatically obtains the information from the request file, and then downloads only the required updates. If Kaspersky Update Utility is unable to obtain the information automatically (for example, Kaspersky Update Utility does not have access to the folder where Kaspersky EDR Expert created the request file), you have to transmit the file by using third-party tools.

9. In the task properties window, on the **Schedule** tab, create a schedule for task start. If necessary, configure the following settings:

   - **Start task**:

     - **Manually** (selected by default)

       The task does not run automatically. You can only start it manually.

       By default, this option is selected.

     - **Every N minutes**

       The task runs regularly, with the specified interval in minutes, starting from the specified time on the day that the task is created.

       By default, the task runs every 30 minutes, starting from the current system time.

     - **Every N hours**

       The task runs regularly, with the specified interval in hours, starting from the specified date and time.

       By default, the task runs every 6 hours, starting from the current system date and time.

     - **Every N days**

       The task runs regularly, with the specified interval in days. Additionally, you can specify a date and time of the first task run. These additional options become available, if they are supported by the application for which you create the task.

By default, the task runs every day, starting from the current system date and time.

- **Every N weeks**

  The task runs regularly, with the specified interval in weeks, on the specified day of week and at the specified time.

  By default, the task runs every Friday at the current system time.

- **Daily (daylight saving time is not supported)**

  The task runs regularly, with the specified interval in days. This schedule does not support observance of daylight saving time (DST). It means that when clocks jump one hour forward or backward at the beginning or ending of DST, the actual task start time does not change.

  We do not recommend that you use this schedule. It is needed for backward compatibility of Kaspersky EDR Expert.

  By default, the task starts every day at the current system time.

- **Weekly**

  The task runs every week on the specified day and at the specified time.

- **By days of week**

  The task runs regularly, on the specified days of the week, at the specified time.

  By default, the task runs every Friday at 6:00:00 PM.

- **Monthly**

  The task runs regularly, on the specified day of the month, at the specified time.

  In months that lack the specified day, the task runs on the last day.

  By default, the task runs on the first day of each month, at the current system time.

- **Monthly on selected weekday**

  The task runs regularly, on the specified days of each month, at the specified time.

  By default, the start time is 18:00, and no days of the month are selected.

  > Note that you select neither a specific date in the month, nor the number of the week (first, second week of the month) but the sequence number of the weekday within a month. For example, if you set the cursor in the **Tu** cell of the **First** row, it means the task will run every first Tuesday of each new month.

  You can select several days of week.

- **On completing another task**

  The current task starts after another task completes. This option only works if both tasks are assigned to the same devices. For example, you may want to run the *Manage devices* task with the **Turn on the device** option and, after it completes, run the *Virus scan* task as a triggering task.

  You have to select the triggering task from the table and the status with which this task must complete (**Completed successfully** or **Failed**).

If necessary, you can search, sort, and filter the tasks in the table as follows:

- Enter the task name in the search field, to search the task by its name.
- Click the sort icon to sort the tasks by name.

  By default, the tasks are sorted in alphabetical ascending order.
- Click the filter icon, and in the window that opens, filter the tasks by group, and then click the **Apply** button.

- Additional task settings:

  - **Run missed tasks**

    This option determines the behavior of a task if a client device is not visible on the network when the task is about to start.

    If this option is enabled, the system attempts to start the task the next time the Kaspersky application is run on the client device. If the task schedule is **Manually**, **Once** or **Immediately**, the task is started immediately after the device becomes visible on the network or immediately after the device is included in the task scope.

    If this option is disabled, only scheduled tasks run on client devices. For **Manually**, **Once** and **Immediately** schedule, tasks run only on those client devices that are visible on the network. For example, you may want to disable this option for a resource-consuming task that you want to run only outside of business hours.

    By default, this option is enabled.

  - **Use automatically randomized delay for task starts**

    If this option is enabled, the task is started on client devices randomly within a specified time interval, that is, *distributed task start*. A distributed task start helps to avoid a large number of simultaneous requests by client devices to the Administration Server when a scheduled task is running.

    The distributed start time is calculated automatically when a task is created, depending on the number of client devices to which the task is assigned. Later, the task is always started on the calculated start time. However, when task settings are edited or the task is started manually, the calculated value of the task start time changes.

    If this option is disabled, the task starts on client devices according to the schedule.

    By default, this option is enabled.

  - **Use automatically randomized delay for task starts within an interval of**

    If this option is enabled, the task is started on client devices randomly within the specified time interval. A distributed task start helps to avoid a large number of simultaneous requests by client devices to the Administration Server when a scheduled task is running.

    If this option is disabled, the task starts on client devices according to the schedule.

    By default, this option is disabled. The default time interval is one minute.

  - **Stop the task if it runs longer than**

    After the specified time period expires, the task is stopped automatically, whether it is completed or not.

    Enable this option if you want to interrupt (or stop) tasks that take too long to execute.

    By default, this option is disabled. The default task execution time is 120 minutes.

10. Click the **Save** button.

The task is created and configured.

When Administration Server performs the *Download updates to the Administration Server repository* task, updates to databases and software modules are downloaded from the updates source and stored on Administration Server. If you create this task for an administration group, it will only be applied to Network Agents included in the specified administration group.

If you use a proxy server when connecting to the internet, you have to specify the proxy server address in the Administration Server properties. Otherwise, the *Download updates to the Administration Server repository* task will not work.

Viewing downloaded updates

When Administration Server performs the *Download updates to the Administration Server repository* task, updates to databases and software modules are downloaded from the updates source and stored on Administration Server. You can view the downloaded updates in the **Updates for Kaspersky databases and software modules** section.

To view the list of downloaded updates,

In the main menu, go to **Software management** → **Kaspersky applications** → **Updates for Kaspersky databases and software modules**.

A list of available updates appears.

Verifying downloaded updates

Before installing updates to the managed devices, you can first check the updates for operability and errors through the *Update verification* task. The *Update verification* task is performed automatically as part of the *Download updates to the Administration Server repository* task. The Administration Server downloads updates from the source, saves them in the temporary repository, and runs the *Update verification* task. If the task completes successfully, the updates are copied from the temporary repository to the Administration Server repository. They are distributed to all client devices for which the Administration Server is the source of updates.

If, as a result of the *Update verification* task, updates located in the temporary repository are incorrect or if the *Update verification* task completes with an error, such updates are not copied to the Administration Server repository. The Administration Server retains the previous set of updates. Also, the tasks that have the **When new updates are downloaded to the repository** schedule type are not started then. These operations are performed at the next start of the *Download updates to the Administration Server repository* task if scanning of the new updates completes successfully.

A set of updates is considered invalid if any of the following conditions is met on at least one test device:

- An update task error occurred.
- The real-time protection status of the security application changed after the updates were applied.

- An infected object was detected during running of the on-demand scan task.
- A runtime error of a Kaspersky application occurred.

If none of the listed conditions is true for any test device, the set of updates is considered valid, and the *Update verification* task is considered to have completed successfully.

Before you start to create the *Update verification* task, perform the prerequisites:

1. Create an administration group with several test devices. You will need this group to verify the updates.

   We recommend using devices with the most reliable protection and the most popular application configuration across the network. This approach increases the quality and probability of virus detection during scans, and minimizes the risk of false positives. If viruses are detected on test devices, the *Update verification* task is considered unsuccessful.

2. Create the update and malware scan tasks for an application supported by Open Single Management Platform, for example, Kaspersky Endpoint Security for Linux. When creating the update and malware scan tasks, specify the administration group with the test devices.

   The *Update verification* task sequentially runs the update and malware scan tasks on test devices to check that all updates are valid. In addition, when creating the *Update verification* task, you need to specify the update and malware scan tasks.

3. Create the *Download updates to the Administration Server repository* task.

To make Kaspersky EDR Expert verify downloaded updates before distributing them to client devices:

1. In the main menu, go to **Tasks**.
2. Click the **Download updates to the Administration Server repository** task.
3. In the task properties window that opens, go to the **Application settings** tab, and then enable the **Run update verification** option.
4. If the *Update verification* task exists, click the **Select task** button. In the window that opens, select the *Update verification* task in the administration group with test devices.
5. If you did not create the *Update verification* task earlier, do the following:

   a. Click the **New task** button.

   b. In the New task wizard that opens, specify the task name if you want to change the preset name.

   c. Select the administration group with test devices, which you created earlier.

   d. First, select the update task of a required application supported by Open Single Management Platform, and then select the malware scan task.

   After that, the following options appear. We recommend leaving them enabled:

   - **Restart the device after database update**

     After anti-virus databases are updated on a device, we recommend rebooting the device.

     By default, the option is enabled.

- **Check real-time protection status after database update and device restart**

  If this option is enabled, the *Update verification* task checks whether updates downloaded to the Administration Server repository are valid, and if the protection level decreased after the anti-virus database update and device restart.

  By default, the option is enabled.

e. Specify an account from which the *Update verification* task will be run. You can use your account and keep the **Default account** option enabled. Alternatively, you can specify that the task should be run under another account that has the necessary access rights. To do this, select the **Specify account** option, and then enter the credentials of that account.

6. Click **Save** to close the properties window of the *Download updates to the Administration Server repository* task.

The automatic update verification is enabled. Now, you can run the *Download updates to the Administration Server repository* task, and it will start from update verification.

Creating the task for downloading updates to the repositories of distribution points

You can create the *Download updates to the repositories of distribution points* task for an administration group. This task will run for distribution points included in the specified administration group.

You can use this task, for example, if traffic between the Administration Server and the distribution point(s) is more expensive than traffic between the distribution point(s) and Kaspersky update servers, or if your Administration Server does not have internet access.

This task is required to download updates from Kaspersky update servers to the repositories of distribution points. The list of updates includes:

- Updates to databases and software modules for Kaspersky security applications
- Updates to Kaspersky EDR Expert components
- Updates to Kaspersky security applications

After the updates are downloaded, they can be propagated to the managed devices.

*To create the **Download updates to the repositories of distribution points** task, for a selected administration group:*

1. In the main menu, go to **Tasks**.
2. Click the **Add** button.

   The New task wizard starts. Follow the instructions of the wizard.
3. For the Kaspersky EDR Expert application, in the **Task type** field select **Download updates to the repositories of distribution points**.
4. Specify the name for the task that you are creating. A task name cannot be more than 100 characters long and cannot include any special characters ("*<>?\:|).

5. Select an option button to specify the administration group, the device selection, or the devices to which the task applies.

6. At the **Finish task creation** step, if you want to modify the default task settings, enable the **Open task details when creation is complete** option. If you do not enable this option, the task will be created with the default settings. You can change the default settings later, at any time.

7. Click **Create**.

   The task is created and displayed in the list of tasks.

8. Click the name of the created task to open the task properties window.

9. On the **Application settings** tab of the task properties window, specify the following settings:

   - **Sources of updates**

     The following resources can be used as a source of updates for the distribution point:

     - Kaspersky update servers

       HTTP(S) servers at Kaspersky from which Kaspersky applications download database and application module updates.

       This option is selected by default.

     - Local or network folder

       A local or network folder that contains the latest updates. Only a mounted SMB share can be used as a network folder. When selecting a local folder, you must specify a folder on the device that has Administration Server installed.

       > In the *Download updates to the Administration Server repository* task and the *Download updates to the repositories of distribution points* task, user authentication does not work if you select a password-protected local or network folder as an update source. To resolve this issue, first mount the password-protected folder, and then specify the required credentials, for example, by means of the operating system. After that, you can select this folder as an update source in an update download task. Open Single Management Platform will not require that you enter the credentials.

   - **Folder for storing updates**

     The path to the specified folder for storing saved updates. You can copy the specified folder path to a clipboard. You cannot change the path to a specified folder for a group task.

   - **Download diff files**

     This option enables the downloading diff files feature.

     By default, this option is disabled.

   - **Download updates by using the old scheme**

     Open Single Management Platform downloads updates of databases and software modules by using the new scheme. For the application to download updates by using the new scheme, the update source must contain the update files with the metadata compatible with the new scheme. If the update source contains the update files with the metadata compatible with the old scheme only, enable the **Download updates by using the old scheme** option. Otherwise, the update download task will fail.

For example, you must enable this option when a local or network folder is specified as an update source, and the update files in this folder were downloaded by Kaspersky Update Utility which downloads updates by using the old scheme.

By default, this option is disabled.

10. Create a schedule for task start. If necessary, configure the following settings:

- **Start task**:
  - **Manually** (selected by default)

    The task does not run automatically. You can only start it manually.

    By default, this option is selected.

  - **Every N minutes**

    The task runs regularly, with the specified interval in minutes, starting from the specified time on the day that the task is created.

    By default, the task runs every 30 minutes, starting from the current system time.

  - **Every N hours**

    The task runs regularly, with the specified interval in hours, starting from the specified date and time.

    By default, the task runs every 6 hours, starting from the current system date and time.

  - **Every N days**

    The task runs regularly, with the specified interval in days. Additionally, you can specify a date and time of the first task run. These additional options become available, if they are supported by the application for which you create the task.

    By default, the task runs every day, starting from the current system date and time.

  - **Every N weeks**

    The task runs regularly, with the specified interval in weeks, on the specified day of week and at the specified time.

    By default, the task runs every Friday at the current system time.

  - **Daily (daylight saving time is not supported)**

    The task runs regularly, with the specified interval in days. This schedule does not support observance of daylight saving time (DST). It means that when clocks jump one hour forward or backward at the beginning or ending of DST, the actual task start time does not change.

    We do not recommend that you use this schedule. It is needed for backward compatibility of Kaspersky EDR Expert.

    By default, the task starts every day at the current system time.

  - **Weekly**

    The task runs every week on the specified day and at the specified time.

  - **By days of week**

    The task runs regularly, on the specified days of the week, at the specified time.

By default, the task runs every Friday at 6:00:00 PM.

- **Monthly**

  The task runs regularly, on the specified day of the month, at the specified time.

  In months that lack the specified day, the task runs on the last day.

  By default, the task runs on the first day of each month, at the current system time.

- **Monthly on selected weekday**

  The task runs regularly, on the specified days of each month, at the specified time.

  By default, the start time is 18:00, and no days of the month are selected.

  > Note that you select neither a specific date in the month, nor the number of the week (first, second week of the month) but the sequence number of the weekday within a month. For example, if you set the cursor in the **Tu** cell of the **First** row, it means the task will run every first Tuesday of each new month.

  You can select several days of week.

- **On virus outbreak**

  The task runs after a *Virus outbreak* event occurs. Select application types that will monitor virus outbreaks. The following application types are available:

  - Anti-virus for workstations and file servers
  - Anti-virus for perimeter defense
  - Anti-virus for mail systems

  By default, all application types are selected.

  You may want to run different tasks depending on the security application type that reports a virus outbreak. In this case, remove the selection of the application types that you do not need.

- **On completing another task**

  The current task starts after another task completes. This option only works if both tasks are assigned to the same devices. For example, you may want to run the *Manage devices* task with the **Turn on the device** option and, after it completes, run the *Virus scan* task as a triggering task.

  You have to select the triggering task from the table and the status with which this task must complete (**Completed successfully** or **Failed**).

  If necessary, you can search, sort, and filter the tasks in the table as follows:

  - Enter the task name in the search field, to search the task by its name.
  - Click the sort icon to sort the tasks by name.

    By default, the tasks are sorted in alphabetical ascending order.
  - Click the filter icon, and in the window that opens, filter the tasks by group, and then click the **Apply** button.

- **Run missed tasks**

  This option determines the behavior of a task if a client device is not visible on the network when the task is about to start.

  If this option is enabled, the system attempts to start the task the next time the Kaspersky application is run on the client device. If the task schedule is **Manually**, **Once** or **Immediately**, the task is started immediately after the device becomes visible on the network or immediately after the device is included in the task scope.

  If this option is disabled, only scheduled tasks run on client devices. For **Manually**, **Once** and **Immediately** schedule, tasks run only on those client devices that are visible on the network. For example, you may want to disable this option for a resource-consuming task that you want to run only outside of business hours.

  By default, this option is enabled.

- **Use automatically randomized delay for task starts**

  If this option is enabled, the task is started on client devices randomly within a specified time interval, that is, *distributed task start*. A distributed task start helps to avoid a large number of simultaneous requests by client devices to the Administration Server when a scheduled task is running.

  The distributed start time is calculated automatically when a task is created, depending on the number of client devices to which the task is assigned. Later, the task is always started on the calculated start time. However, when task settings are edited or the task is started manually, the calculated value of the task start time changes.

  If this option is disabled, the task starts on client devices according to the schedule.

  By default, this option is enabled.

- **Use automatically randomized delay for task starts within an interval of**

  If this option is enabled, the task is started on client devices randomly within the specified time interval. A distributed task start helps to avoid a large number of simultaneous requests by client devices to the Administration Server when a scheduled task is running.

  If this option is disabled, the task starts on client devices according to the schedule.

  By default, this option is disabled. The default time interval is one minute.

11. Click the **Save** button.

The task is created and configured.

In addition to the settings that you specify during task creation, you can change other properties of a created task.

When the *Download updates to the repositories of distribution points* task is performed, updates for databases and software modules are downloaded from the update source and stored in the distribution points repository. Downloaded updates will only be used by distribution points that are included in the specified administration group and that have no update download task explicitly set for them.

Adding sources of updates for the Download updates to the Administration Server repository task

When you create or use the task for downloading updates to the Administration Server repository, you can choose the following sources of updates:

- Kaspersky update servers
- Primary Administration Server

  This resource applies to tasks created for a secondary or virtual Administration Server.
- Local or network folder

  This resource applies to tasks created for a secondary or virtual Administration Server.
- Network folder

In the *Download updates to the Administration Server repository* task and the *Download updates to the repositories of distribution points* task, user authentication does not work if you select a password-protected local or network folder as an update source. To resolve this issue, first mount the password-protected folder, and then specify the required credentials, for example, by means of the operating system. After that, you can select this folder as an update source in an update download task. Open Single Management Platform will not require that you enter the credentials.

Kaspersky update servers are used by default, but you can also download updates from a local or network folder. You might want to use the folder if your network does not have access to the internet. In this case, you can manually download updates from Kaspersky update servers and put the downloaded files in the necessary folder.

You can specify only one path to a local or network folder. As a local folder, you must specify a folder on the device where the Administration Server is installed. As a network folder, you can use an FTP or HTTP server or an SMB share. If an SMB share requires authentication, it must be mounted in the system with the required credentials in advance. We recommend not using the SMB1 protocol since it is insecure.

If you add both Kaspersky update servers and the local or network folder, updates will be downloaded first from the folder. In the case of an error when downloading, Kaspersky update servers will be used.

In case a shared folder that contains updates is password-protected, enable the **Specify account for access to shared folder of the update source (if any)** option and enter the account credentials required for access.

To add the sources of updates:

1. In the main menu, go to **Tasks**.
2. Click **Download updates to the Administration Server repository**.
3. Go to the **Application settings** tab.
4. On the **Sources of updates** line, click the **Configure** button.
5. In the window that opens, click the **Add** button.

6. In the update source list, add the necessary sources. If you select the **Network folder** or **Local or network folder** check box, specify a path to the folder.

7. Click **OK**, and then close the update source properties window.

8. In the update source window, click **OK**.

9. Click the **Save** button in the task window.

Now updates are downloaded to the Administration Server repository from the specified sources.

Approving and declining software updates

The settings of an update installation task may require approval of updates that are to be installed. You can approve updates that must be installed and decline updates that must not be installed.

For example, you may want to first check the installation of updates in a test environment and make sure that they do not interfere with the operation of devices, and only then allow the installation of these updates on client devices.

> Approving and declining updates is available only for Network Agent and managed applications installed on the Windows-based client devices. Seamless updating of Administration Server, OSMP Console, and management web plug-ins is not supported. To update these components, you have to download the latest versions from the Kaspersky website, and then install them manually.

To approve or decline one or several updates:

1. In the main menu, go to **Software management** → **Kaspersky applications** → **Seamless updates**.

   A list of available updates appears.

   > Updates of managed applications may require a specific minimum version of Kaspersky Security Center to be installed. If this version is later than your current version, these updates are displayed but cannot be approved. Also, no installation packages can be created from such updates until you upgrade Kaspersky Security Center. You are prompted to upgrade your Kaspersky Security Center instance to the required minimum version.

2. If necessary, accept EULA by clicking the **View and accept License Agreements** button.

3. Select the updates that you want to approve or decline.

4. Click **Approve** to approve the selected updates or **Decline** to decline the selected updates.

   The default value is *Undefined*.

The updates to which you assign *Approved* status are placed in a queue for installation.

The updates to which you assign *Declined* status are uninstalled (if possible) from all devices on which they were previously installed. Also, they will not be installed on other devices in future.

Some updates for Kaspersky applications cannot be uninstalled. If you set *Declined* status for them, Kaspersky EDR Expert will not uninstall these updates from the devices on which they were previously installed. However, these updates will never be installed on other devices in future.

If you set *Declined* status for third-party software updates, these updates will not be installed on devices for which they were planned but have not yet been installed. Updates will remain on devices on which they were already installed. If you have to delete the updates, you can manually delete them locally.

Automatic installation of updates for Kaspersky Endpoint Security for Windows

You can configure automatic updates of databases and software modules of Kaspersky Endpoint Security for Windows on client devices.

To configure download and automatic installation of updates of Kaspersky Endpoint Security for Windows on devices:

1. In the main menu, go to **Tasks**.
2. Click the **Add** button.

   The New task wizard starts. Follow the instructions of the wizard.
3. For the Kaspersky Endpoint Security for Windows application, select **Update** as the task subtype.
4. Specify the name for the task that you are creating. A task name cannot be more than 100 characters long and cannot include any special characters ("*<>?\:|).
5. Choose the task scope.
6. Specify the administration group, the device selection, or the devices to which the task applies.
7. At the **Finish task creation** step, if you want to modify the default task settings, enable the **Open task details when creation is complete** option. If you do not enable this option, the task will be created with the default settings. You can change the default settings later, at any time.
8. Click **Create**.

   The task is created and displayed in the list of tasks.
9. Click the name of the created task to open the task properties window.

10. On the **Application settings** tab of the task properties window, define the update task settings in local or mobile mode:

    - **Local mode**: Connection is established between the device and the Administration Server.
    - **Mobile mode**: No connection is established between Kaspersky EDR Expert and the device (for example, when the device is not connected to the internet).

11. Enable the update sources that you want to use to update databases and application modules for Kaspersky Endpoint Security for Windows. If required, change positions of the sources in the list by using the **Move up** and **Move down** buttons. If several update sources are enabled, Kaspersky Endpoint Security for Windows tries to connect to them one after another, starting from the top of the list, and performs the update task by retrieving the update package from the first available source.

12. Enable the **Install approved application module updates** option to download and install software module updates together with the application databases.

    If the option is enabled, Kaspersky Endpoint Security for Windows notifies the user about available software module updates and includes software module updates in the update package when running the update task. Kaspersky Endpoint Security for Windows installs only those updates for which you have set the *Approved* status; they will be installed locally through the application interface or through Kaspersky EDR Expert.

    You can also enable the **Automatically install critical application module updates** option. If any updates are available for software modules, Kaspersky Endpoint Security for Windows automatically installs those that have *Critical* status; the remaining updates will be installed after you approve them.

    If updating the software module requires reviewing and accepting the terms of the License Agreement and Privacy Policy, the application installs updates after the terms of the License Agreement and Privacy Policy have been accepted by the user.

13. Select the **Copy updates to folder** check box in order for the application to save downloaded updates to a folder, and then specify the folder path.

14. Schedule the task. To ensure timely updates, we recommend that you select the **When new updates are downloaded to the repository** option.

15. Click the **Save** button.

When the **Update** task is running, the application sends requests to Kaspersky update servers.

Some updates require installation of the latest versions of management plug-ins.

About using diff files for updating Kaspersky databases and software modules

When Kaspersky EDR Expert downloads updates from Kaspersky update servers, it optimizes traffic by using diff files. You can also enable the usage of diff files by devices (Administration Servers, distribution points, and client devices) that take updates from other devices on your network.

About the Downloading diff files feature

A diff file describes the differences between two versions of a file of a database or software module. The usage of diff files saves traffic inside your company's network because diff files occupy less space than entire files of databases and software modules. If the *Downloading diff files* feature is enabled on Administration Server or a distribution point, the diff files are saved on this Administration Server or distribution point. As a result, devices that take updates from this Administration Server or distribution point can use the saved diff files to update their databases and software modules.

To optimize the usage of diff files, we recommend that you synchronize the update schedule of devices with the update schedule of the Administration Server or distribution point from which the devices take updates. However, the traffic can be saved even if devices are updated several times less often than are the Administration Server or distribution point from which the devices take updates.

Distribution points do not use IP multicasting for automatic distribution of diff files.

Enabling the Downloading diff files feature

Stages

1. **Enabling the feature on Administration Server**

   Enable the feature in the settings of a *Download updates to the repository of the Administration Server* task.

2. **Enabling the feature for a distribution point**

   Enable the feature for a distribution point that receives updates by means of a *Download updates to the repositories of distribution points* task.

   Then enable the feature in the Network Agent policy settings for a distribution point that receives updates from Administration Server.

   Then enable the feature for a distribution point that receives updates from Administration Server.

   The feature is enabled in the Network Agent policy settings and—if the distribution points are assigned manually and if you want to override policy settings—in the **Distribution points** section of the Administration Server properties.

To check that the Downloading diff files feature is successfully enabled, you can measure the internal traffic before and after you perform the scenario.

Downloading updates by distribution points

Kaspersky EDR Expert allows distribution points to receive updates from the Administration Server, Kaspersky servers, or from a local or network folder.

To configure update download for a distribution point:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Distribution points** section.

3. Click the name of the distribution point through which updates will be delivered to client devices in the group.

4. In the distribution point properties window, select the **Source of updates** section.

5. Select an update source for the distribution point:

   Source of updates

   Select an update source for the distribution point:

   - To allow the distribution point to receive updates from the Administration Server, select **Retrieve from Administration Server**.

   - To allow the distribution point to receive updates by using a task, select **Use update download task**, and then specify a *Download updates to the repositories of distribution points* task:

     - If such a task already exists on the device, select the task in the list.

     - If no such task yet exists on the device, click the **Create task** link to create a task. The New task wizard starts. Follow the steps of the wizard.

   Download diff files

   This option enables the downloading diff files feature.

   By default, the option is enabled.

The distribution point will receive updates from the specified source.

Updating Kaspersky databases and software modules on offline devices

Updating Kaspersky databases and software modules on managed devices is an important task for maintaining protection of the devices against viruses and other threats. Administrators usually configure regular updates through usage of the Administration Server repository.

When you need to update databases and software modules on a device (or a group of devices) that is not connected to the Administration Server (primary or secondary), a distribution point or the internet, you have to use alternative sources of updates, such as an FTP server or a local folder. In this case, you have to deliver the files of the required updates by using a mass storage device, such as a flash drive or an external hard drive.

You can copy the required updates from:

- The Administration Server.

  To be sure the Administration Server repository contains the updates required for the security application installed on an offline device, at least one of the managed online devices must have the same security application installed. This application must be configured to receive the updates from the Administration Server repository through the *Download updates to the Administration Server repository* task.

- Any device that has the same security application installed and configured to receive the updates from the Administration Server repository, a distribution point repository, or directly from the Kaspersky update servers.

Below is an example of configuring updates of databases and software modules by copying them from the Administration Server repository.

To update Kaspersky databases and software modules on offline devices:

1. Connect the removable drive to the device where the Administration Server is installed.

2. Copy the updates files to the removable drive.

   By default, the updates are located at: /var/opt/kaspersky/klnagent_srv/1093/.working/share_srv/Updates/.

   Alternatively, you can configure Open Single Management Platform to regularly copy the updates to the folder that you select. For this purpose, use the **Copy downloaded updates to additional folders** option in the properties of the *Download updates to the Administration Server repository* task. If you specify a folder located on a flash drive or an external hard drive as a destination folder for this option, this mass storage device will always contain the latest version of the updates.

3. On offline devices, configure Kaspersky Endpoint Security to receive updates from a local folder or a shared resource, such as an FTP server or a shared folder.

   How-to instructions:

   - Kaspersky Endpoint Security for Linux Help
   - Kaspersky Endpoint Security for Windows Help

4. Copy the updates files from the removable drive to the local folder or the shared resource that you want to use as an update source.

5. On the offline device that requires update installation, start the *Update* task of Kaspersky Endpoint Security for Linux or Kaspersky Endpoint Security for Windows, depending on the operating system of the offline device.

After the update task is complete, the Kaspersky databases and software modules are up-to-date on the device.

Remote diagnostics of client devices

You can use remote diagnostics for remote execution of the following operations on Windows-based and Linux-based client devices:

- Enabling and disabling tracing, changing the tracing level, and downloading the trace file

- Downloading system information and application settings

- Downloading event logs
- Generating a dump file for an application
- Starting diagnostics and downloading diagnostics reports
- Starting, stopping, and restarting applications

You can use event logs and diagnostics reports downloaded from a client device to troubleshoot problems on your own. Also, if you contact Kaspersky Technical Support, a Technical Support specialist might ask you to download trace files, dump files, event logs, and diagnostics reports from a client device for further analysis at Kaspersky.

Opening the remote diagnostics window

To perform remote diagnostics on Windows-based and Linux-based client devices, you first have to open the remote diagnostics window.

To open the remote diagnostics window:

1. To select the device for which you want to open the remote diagnostics window, perform one of the following:
   - If the device belongs to an administration group, in the main menu, go to **Asset management** → **Assets (Devices)**.
   - If the device belongs to the Unassigned devices group, in the main menu, go to **Asset management** → **Unassigned devices**.
2. Click the name of the required device.
3. In the device properties window that opens, select the **Advanced** tab.
4. On the **Advanced** tab, click **Remote diagnostics**.

   This opens the **Remote diagnostics** window of a client device. If connection between Administration Server and the client device is not established, the error message displays.

Alternatively, if you need to obtain all diagnostic information about a Linux-based client device at once, you can run the collect.sh script on this device.

Enabling and disabling tracing for applications

You can enable and disable tracing for applications, including Xperf tracing.

Enabling and disabling tracing

To enable or disable tracing on a remote device:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **Kaspersky applications** tab.

   In the **Application management** section, the list of Kaspersky applications installed on the device displays.
3. In the list of applications, select the application for which you want to enable or disable tracing.

   The list of remote diagnostics options opens.
4. If you want to enable tracing:

   a. In the **Tracing** section, click **Enable tracing**.

   b. In the **Modify tracing level** window that opens, we recommend that you keep the default values of the settings. When required, a Technical Support specialist will guide you through the configuration process. The following options are available:

   - **Tracing level**

     The tracing level defines the amount of detail that the trace file contains.

   - **Rotation-based tracing**

     The application overwrites the tracing information to prevent excessive increase in the size of the trace file. Specify the maximum number of files to be used to store the tracing information, and the maximum size of each file. If the maximum number of trace files of the maximum size are written, the oldest trace file is deleted so that a new trace file can be written.

     This setting is available for Kaspersky Endpoint Security only.

   c. Click the **Save** button.

   The tracing is enabled for the selected application. In some cases, the security application and its task must be restarted in order to enable tracing.

   > On Linux-based client devices, tracing for the Updater of Network Agent component is regulated by the Network Agent settings. Therefore, the **Enable tracing** and **Modify tracing level** options are disabled for this component on client devices running Linux.

5. If you want to disable tracing for the selected application, click the **Disable tracing** button.

   The tracing is disabled for the selected application.

Enabling Xperf tracing

For Kaspersky Endpoint Security, a Technical Support specialist may ask you to enable Xperf tracing for information about the system performance.

To enable and configure Xperf tracing or disable it:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **Kaspersky applications** tab.

   In the **Application management** section, the list of Kaspersky applications installed on the device displays.
3. In the list of applications, select Kaspersky Endpoint Security for Windows.

   The list of remote diagnostics options for Kaspersky Endpoint Security for Windows displays.
4. In the **Xperf tracing** section, click **Enable Xperf tracing**.

   If Xperf tracing is already enabled, the **Disable Xperf tracing** button is displayed instead. Click this button if you want to disable Xperf tracing for Kaspersky Endpoint Security for Windows.
5. In the **Change Xperf tracing level** window that opens, depending on the request from the Technical Support specialist, do the following:

   a. Select one of the following tracing levels:

   - **Light level**

     A trace file of this type contains the minimum amount of information about the system.

     By default, this option is selected.

   - **Deep level**

     A trace file of this type contains more detailed information than trace files of the *Light* type and may be requested by Technical Support specialists when a trace file of the *Light* type is not enough for the performance evaluation. A *Deep* trace file contains technical information about the system including information about hardware, operating system, list of started and finished processes and applications, events used for performance evaluation, and events from Windows System Assessment Tool.

   b. Select one of the following Xperf tracing types:

   - **Basic type**

     The tracing information is received during operation of the Kaspersky Endpoint Security application.

     By default, this option is selected.

   - **On-restart type**

     The tracing information is received when the operating system starts on the managed device. This tracing type is effective when the issue that affects the system performance occurs after the device is turned on and before Kaspersky Endpoint Security starts.

   You may also be asked to enable the **Rotation file size, in MB** option to prevent excessive increase in the size of the trace file. Then specify the maximum size of the trace file. When the file reaches the maximum size, the oldest tracing information is overwritten with new information.

c. Define the rotation file size.

d. Click the **Save** button.

Xperf tracing is enabled and configured.

6. If you want to disable Xperf tracing for Kaspersky Endpoint Security for Windows, click **Disable Xperf tracing** in the **Xperf tracing** section.

   Xperf tracing is disabled.

Downloading trace files of an application

To download a trace file of an application:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **Kaspersky applications** tab.

   In the **Application management** section, the list of Kaspersky applications installed on the device displays.
3. In the list of applications, select the application for which you want to download a trace file.
4. In the **Tracing** section, click the **Trace files** button.

   This opens the **Device tracing logs** window, where a list of trace files is displayed.
5. In the list of trace files, select the file that you want to download.
6. Do one of the following:

   - Download the selected file by clicking **Download**. You can select one or several files for downloading.
   - Download a portion of the selected file:

     a. Click **Download a portion**.

     You cannot download portions of several files at the same time. If you select more than one trace file, the **Download a portion** button will be disabled.

     b. In the window that opens, specify the name and the file portion to download, according to your needs.

     For Linux-based devices, editing the file portion name is not available.

     c. Click **Download**.

The selected file, or its portion, is downloaded to the location that you specify.

Deleting trace files

You can delete trace files that are no longer needed.

To delete a trace file:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window that opens, select the **Event logs** tab.
3. In the **Trace files** section, click **Windows Update logs** or **Remote installation logs**, depending on which trace files you want to delete.

   The **Windows Update logs** link is available only for Windows-based client devices.

   This opens the **Device tracing logs** window, where a list of trace files is displayed.
4. In the list of trace files, select one or several files that you want to delete.
5. Click the **Remove** button.

The selected trace files are deleted.

Downloading application settings

To download application settings from a client device:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **Kaspersky applications** tab.
3. In the **Application settings** section, click the **Download** button to download information about the settings of the applications installed on the client device.

The ZIP archive with information is downloaded to the specified location.

Downloading system information from a client device

To download system information from a client device:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **System information** tab.
3. Click the **Download** button to download the system information about the client device.

   If you obtain system information about a Linux-based device, a dump file for emergency terminated applications is added to the resulting file.

   The archive may contain sensitive data (for example, keys and passwords) in plain text. We recommend that you review the files in the archive and remove such data before sending it to Kaspersky Technical Support.

The file with information is downloaded to the specified location.

Downloading event logs

To download an event log from a remote device:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, on the **Event logs** tab, click **All device logs**.
3. In the **All device logs** window, select one or several relevant logs.
4. Do one of the following:
   - Download the selected log by clicking **Download entire file**.
   - Download a portion of the selected log:
     a. Click **Download a portion**.
     You cannot download portions of several logs at the same time. If you select more than one event log, the **Download a portion** button will be disabled.
     b. In the window that opens, specify the name and the log portion to download, according to your needs.
     For Linux-based devices, editing the log portion name is not available.
     c. Click **Download**.

The selected event log, or a portion of it, is downloaded to the specified location.

Starting, stopping, restarting the application

You can start, stop, and restart applications on a client device.

To start, stop, or restart an application:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **Kaspersky applications** tab.
   In the **Application management** section, the list of Kaspersky applications installed on the device displays.
3. In the list of applications, select the application that you want to start, stop, or restart.
4. Select an action by clicking one of the following buttons:
   - **Stop application**
     This button is available only if the application is currently running.
   - **Restart application**
     This button is available only if the application is currently running.

- **Start application**

  This button is available only if the application is not currently running.

Depending on the action that you have selected, the required application is started, stopped, or restarted on the client device.

If you restart the Network Agent, a message is displayed stating that the current connection of the device to the Administration Server will be lost.

Running the remote diagnostics of Kaspersky Security Center Network Agent and downloading the results

To start diagnostics for Kaspersky Security Center Network Agent on a remote device and download the results:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **Kaspersky applications** tab.

   In the **Application management** section, the list of Kaspersky applications installed on the device displays.
3. In the list of applications, select **Kaspersky Security Center Network Agent**.

   The list of remote diagnostics options opens.
4. In the **Diagnostics report** section, click the **Run diagnostics** button.

   This starts the remote diagnostics process and generates a diagnostics report. When the diagnostics process is complete, the **Download diagnostics report** button becomes available.
5. Click the **Download diagnostics report** button to download the report.

The report is downloaded to the specified location.

Running an application on a client device

You may have to run an application on the client device, if a Kaspersky support specialist requests it. You do not have to install the application on that device.

If you want to run a custom script on the client device, you can use the `KLACDT_SAVE_SETTING` environment variable to determine the path where the execution results will be saved. For example:

- For a Windows-based device:

  ```
  @echo some result > %KLACDT_SAVE_SETTING%\res.log
  ```

- For a Linux-based device:

  ```
  echo some result > $KLACDT_SAVE_SETTING/res.log
  ```

To run an application on the client device:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **Running a remote application** tab.

3. In the **Object type** field, select the type of object that you want to upload:

   - Select **File** to upload the executable file.
   - Select **Folder** to upload the folder containing the application that you want to run on the client device.

     If you select this object type, the **Name of the executable file to be run** field appears. In this field, specify the name of the executable file in the folder. You can also specify the relative path to the file.
   - Select **Archive** to upload the ZIP archive containing the application that you want to run on the client device.

     If you select this object type, the **Name of the executable file to be run** field appears. In this field, specify the name of the executable file in the folder. You can also specify the relative path to the file.

     > The ZIP archive must include the utility folder. This folder contains the executable file to be run on a remote device.

4. Upload the object by selecting it in the system window, or dragging it to the upload field.
5. If necessary, in the **Command line arguments** field, specify the command line arguments to be passed when running the executable file.
6. Click the **Upload and run** button to run the selected application on a client device.
7. After the application execution is completed successfully, download the execution results by clicking the **Download application execution results** button.

   > The application execution results are stored until you run a new diagnostic or close the window.

Remote diagnostics of the client device by using the application is completed.

Generating a dump file for an application

An application dump file allows you to view the parameters of the application running on a client device at a point in time. This file also contains information about modules that were loaded for an application.

> Obtaining dump files from Linux-based devices is not supported.

To obtain dump files through remote diagnostics, the kldumper utility is used. This utility is designed to obtain the dump files of processes of Kaspersky applications at the request of technical support specialists. Detailed information on the requirements for using the kldumper utility is provided in the Kaspersky Security Center Knowledge Base.

To create a dump file for an application:

1. Open the remote diagnostics window of a client device.
2. In the remote diagnostics window, select the **Running a remote application** tab.

3. In the **Generating the process dump file** section, specify the executable file of the application for which you want to generate a dump file.

4. Click the **Download dump file** button.

   An archive with the dump file for the specified application is downloaded.

   If the specified application is not running on the client device, the "result" folder contained in the downloaded archive will be empty.

   If the specified application is running, but the download fails with an error or the "result" folder contained in the downloaded archive is empty, refer to the Kaspersky Security Center Knowledge Base.

Running remote diagnostics on a Linux-based client device

Open Single Management Platform allows you to download the basic diagnostic information from a client device. Alternatively, you can obtain the diagnostic information about a Linux-based device by using the collect.sh script by Kaspersky. This script must be run on the Linux client device that needs to be diagnosed. A file is then created with diagnostic information, system information for the device, application trace files, device event logs and a dump file for crashes and terminated processes.

We recommend that you use the collect.sh script to obtain all diagnostic information about the Linux-based client device at once. If you download the diagnostic information remotely through Open Single Management Platform, you will need to go through all sections of the remote diagnostics interface. Also the diagnostic information for a Linux-based device will probably not be obtained completely.

If you need to send the generated file with the diagnostic information to the Kaspersky Technical Support, delete all confidential information before sending the file.

To download the diagnostic information from a Linux-based client device by using the collect.sh script:

1. Download the collect.sh script packed in the collect.tar.gz archive.

2. Copy the downloaded archive to the Linux-based client device that needs to be diagnosed.

3. Run the following command to unpack the collect.tar.gz archive:

   ```
   # tar -xzf collect.tar.gz
   ```

4. Run the following command to specify the script execution rights:

   ```
   # chmod +x collect.sh
   ```

5. Run the collect.sh script by using an account with administrator rights:

   ```
   # ./collect.sh
   ```

A file with the diagnostic information is generated and saved to the /tmp/$HOST_NAME-collect.tar.gz folder.

Managing third-party applications and executable files on client devices

This section describes the features of Kaspersky EDR Expert related to the management of third-party applications and executable files run on client devices.

Using Application Control to manage executable files

You can use the Application Control component to allow or block startup of executable files on user devices. The Application Control component supports Windows-based and Linux-based operating systems.

For Linux-based operating systems, Application Control component is available starting from Kaspersky Endpoint Security 11.2 for Linux.

Prerequisites

- Kaspersky EDR Expert is deployed in your organization.
- The policy of Kaspersky Endpoint Security for Linux or Kaspersky Endpoint Security for Windows is created and is active. The Application Control component is enabled in the policy.

Stages

The Application Control usage scenario proceeds in stages:

1. **Forming and viewing the list of executable files on client devices**

   This stage helps you find out what executable files are found on managed devices. View the list of executable files and compare it with the lists of allowed and prohibited executable files. The restrictions on executable files usage can be related to the information security polices in your organization.

   How-to instructions: Obtaining and viewing a list of executable files stored on client devices

2. **Creating categories for executable files used in your organization**

   Analyze the lists of executable files stored on managed devices. Based on the analysis, create categories for executable files. It is recommended to create a "Work applications" category that covers the standard set of executable files that are used at your organization. If different security groups use their own sets of executable files in their work, a separate category can be created for each security group.

Startup of executable files whose settings do not match any of the Application Control rules is regulated by the selected operating mode of the component:

- *Denylist*. The mode is used if you want to allow the startup of all executable files except those specified in block rules. This mode is selected by default.
- *Allowlist*. The mode is used if you want to block the startup of all executable files except those specified in allow rules.

The Application Control rules are implemented through categories for executable files. In Kaspersky EDR Expert there are three types of categories for executable files:

- Category with content added manually. You define conditions, for example, file metadata, file hashcode, file certificate, file path, to include executable files in the category.
- Category that includes executable files from selected devices. You specify a device whose executable files are automatically included in the category.
- Category that includes executable files from selected folder. You specify a folder from which executable files are automatically included in the category.

3. **Configuring Application Control in the Kaspersky Endpoint Security policy**

   Configure the Application Control component in Kaspersky Endpoint Security for Linux policy using the categories you have created on the previous stage.

   How-to instructions: Configuring Application Control in the Kaspersky Endpoint Security for Windows policy

4. **Turning on Application Control component in test mode**

   To ensure that Application Control rules do not block executable files required for user's work, it is recommended to enable testing of Application Control rules and analyze their operation after creating new rules. When testing is enabled, Kaspersky Endpoint Security for Windows will not block executable files whose startup is forbidden by Application Control rules, but will instead send notifications about their startup to the Administration Server.

   When testing Application Control rules, it is recommended to perform the following actions:

   - Determine the testing period. Testing period can vary from several days to two months.
   - Examine the events resulting from testing the operation of Application Control.

   How-to instructions for OSMP Console: Configuring Application Control component in the Kaspersky Endpoint Security for Windows policy Follow this instruction and enable the **Test Mode** option in configuration process.

5. **Changing the settings of Application Control component**

   If necessary, make changes to the Application Control settings. Based on the test results, you can add executable files related to events of the Application Control component to a category with content added manually.

   How-to instructions: OSMP Console: Adding event-related executable files to the application category

6. **Applying the rules of Application Control in operation mode**

   After Application Control rules are tested and configuration of categories is complete, you can apply the rules of Application Control in operation mode.

   How-to instructions for OSMP Console: Configuring Application Control component in the Kaspersky Endpoint Security for Windows policy. Follow this instruction and disable the **Test Mode** option in configuration process.

7. **Verifying Application Control configuration**

Be sure that you have done the following:

- Created categories for executable files.
- Configured Application Control using the categories.
- Applied the rules of Application Control in operation mode.

Results

When the scenario is complete, startup of executable files on managed devices is controlled. The users can run only those executable files that are allowed in your organization and cannot run executable files that are prohibited in your organization.

For detailed information about Application Control, refer to the Kaspersky Endpoint Security for Linux Help and Kaspersky Endpoint Security for Windows Help.

Application Control modes and categories

The Application Control component monitors users' attempts to start executable files. You can use Application Control rules to control the startup of executable files.

Application Control component is available for Kaspersky Endpoint Security 11.2 for Linux and later versions.

Startup of executable files whose settings do not match any of the Application Control rules is regulated by the selected operating mode of the component:

- *Denylist*. The mode is used if you want to allow the startup of all executable files except those specified in block rules. This mode is selected by default.
- *Allowlist*. The mode is used if you want to block the startup of all executable files except those specified in allow rules.

The Application Control rules are implemented through categories for executable files. In Kaspersky EDR Expert there are three types of categories:

- Category with content added manually. You define conditions, for example, file metadata, file hashcode, file certificate, file path, to include executable files in the category.
- Category that includes executable files from selected devices. You specify a device whose executable files are automatically included in the category.
- Category that includes executable files from selected folder. You specify a folder from which executable files are automatically included in the category.

For detailed information about Application Control, refer to the Kaspersky Endpoint Security for Linux Help and Kaspersky Endpoint Security for Windows Help.

Obtaining and viewing a list of applications installed on client devices

Kaspersky EDR Expert inventories all software installed on managed client devices running Linux and Windows.

Network Agent compiles a list of applications installed on a device, and then transmits this list to Administration Server. It takes about 10-15 minutes for the Network Agent to update the application list.

For Windows-based client devices, Network Agent receives most of the information about installed applications from the Windows registry. For Linux-based client devices, package managers provide information about installed applications to Network Agent.

To view the list of applications installed on managed devices:

1. In the main menu, go to **Software management** → **Third-party applications** → **Applications registry**.

   The page displays a table with the applications that are installed on managed devices. Select the application to view its properties, for example, vendor name, version number, list of executable files, list of devices on which the application is installed, list of available software updates, and list of detected software vulnerabilities.

2. You can group and filter the data of the table with installed applications as follows:

   - Click the settings icon (⚙) in the upper-right corner of the table.

     In the invoked **Table settings** menu, select the columns to be displayed in the table. To view the operating system type of the client devices on which the application is installed, select the **OS type** column.

   - Click the filter icon (▽) in the upper-right corner of the table, and then specify and apply the filter criterion in the invoked menu.

     The filtered table of installed applications is displayed.

To view the list of applications installed on a specific managed device,

In the main application window, go to the **Devices** → **Managed devices** → **device name** → **Advanced** → **Applications registry** section. In this menu, you can export the list of applications to a CSV file or TXT file.

For detailed information about Application Control, refer to the Kaspersky Endpoint Security for Linux Help and Kaspersky Endpoint Security for Windows Help.

Obtaining and viewing a list of executable files stored on client devices

You can obtain the list of executable files stored on client devices in one of the following ways:

- Enabling notifications about applications startup in Kaspersky Endpoint Security policy.
- Creating an inventory task.

Enabling notifications about applications startup in Kaspersky Endpoint Security policy

To enable notifications about applications startup:

1. Open the Kaspersky Endpoint Security policy settings, and then go to **General settings** → **Reports and Storage**.
2. In the **Data transfer to Administration Server** settings group, select the **About started applications** check box, and save the changes.

When a user attempts to start executable files, information about these files is added to the list of executable files on a client device. Kaspersky Endpoint Security sends this information to Network Agent, and then Network Agent sends it to Administration Server.

Creating an inventory task

For Kaspersky Endpoint Security for Linux, the feature of inventorying executable files is available since no earlier that version 11.2.

You can reduce load on the database while obtaining information about the installed applications. To save database space, run an inventory task on reference devices on which a standard set of software is installed. The preferable number of devices is 1-3.

To create an inventory task for executable files on client devices:

1. In the main menu, go to **Tasks**.

   The list of tasks is displayed.
2. Click the **Add** button.

   The New task wizard starts. Follow the instructions of the wizard.
3. On the **New task settings** page, from the **Application** drop-down list, select Kaspersky Endpoint Security for Linux or Kaspersky Endpoint Security for Windows, depending on the operating system of the client devices.
4. From the **Task type** drop-down list, select **Inventory**.
5. On the **Finish task creation** page, click the **Finish** button.

After the New task wizard has finished, the **Inventory** task is created and configured. If you want, you can change the settings for the created task. The newly created task is displayed in the list of tasks.

For a detailed description of the inventory task, see the Kaspersky Endpoint Security for Linux Help and the Kaspersky Endpoint Security for Windows Help.

After the **Inventory** task is performed, the list of executable files stored on managed devices is formed, and you can view the list.

During inventory, executable files in the following formats can be detected (depending on the option that you select in the inventory task properties): MZ, COM, PE, NE, SYS, CMD, BAT, PS1, JS, VBS, REG, MSI, CPL, DLL, JAR, and HTML.

Viewing the list of executable files stored on managed devices

To view the list of executable files stored on client devices:

In the main menu, go to **Software management** → **Third-party applications** → **Executable files**.

The page displays the list of executable files stored on client devices.

If necessary, you can send the executable file of the managed device to the device where your OSMP Console is open.

To send an executable file:

1. In the main menu, go to **Software management** → **Third-party applications** → **Executable files**.
2. Click the link of the executable file that you want to send.
3. In the window that opens, go to the **Devices** section, and then select the check box of the managed device from which you want to send the executable file.

   Before you send the executable file, make sure that the managed device has a direct connection to the Administration Server, by selecting the **Do not disconnect from the Administration Server** check box.

4. Click the **Send** button.

The selected executable file is downloaded for further sending to the device where your OSMP Console is open.

Creating an application category with content added manually

You can specify a set of criteria as a template of executable files for which you want to allow or block a start in your organization. On the basis of executable files corresponding to the criteria, you can create an application category and use it in the Application Control component configuration.

To create an application category with content added manually:

1. In the main menu, go to **Software management** → **Third-party applications** → **Application categories**.

   The page with a list of application categories is displayed.

2. Click the **Add** button.

   The New category wizard starts. Proceed through the wizard by using the **Next** button.

3. On the **Select category creation method** step, specify the application category name and select the **Category with content added manually. Data of executable files is manually added to the category** option.

4. On the **Conditions** step, click the **Add** button to add a condition criterion to include files in the creating category.

5. On the **Condition criteria** step, do the following:

   a. Select a rule type for the creation of the category:

   - **From KL category**

     If this option is selected, you can specify a Kaspersky application category as the condition of adding applications to the user category. The applications from the specified Kaspersky category will be added to the user application category.

   - **Select certificate from repository**

     If this option is selected, you can specify certificates from the repository. The category condition matches only the executable files signed by the specified certificate.

     Certificates are added to the repository if you created and started an inventory task or selected the **About started applications** check box in the Kaspersky Endpoint Security policy. You can perform both actions.

     > Information about certificates can be extracted only from executable files in PE format (.exe, .dll, .sys).

   - **Specify path to application (masks supported)**

     If this option is selected, you can specify the path to the folder on the client device containing the executable files that are to be added to the user application category.

   - **Removable drive**

     If this option is selected, you can specify the type of the medium (any drive or removable drive) on which the application is run. Applications that have been run on the selected drive type are added to the user application category.

   - **Hash, metadata, or certificate**:

     - **Select from list of executable files**

       If this option is selected, you can use the list of executable files on the client device to select and add applications to the category.

     - **Select from applications registry**

If this option is selected, application registry is displayed. After you select an application from the registry, the window opens with the parameters filled in with metadata from the application that you selected:

- Name of the file.
- File version. You can specify precise value of the version or describe a condition, for example "greater than 5.0".
- Application name.
- Application version. You can specify precise value of the version or describe a condition, for example "greater than 5.0".
- Vendor.

Note that only the launch of executable files that meet the specified parameters is blocked, not the launch of the application you select. If the selected application metadata matches the one of the executable file that is launched when you launch the application, then you can proceed to the next step. Otherwise, you have to change the values manually to match the metadata of the executable file.

- **Specify manually**

  If this option is selected, you must specify file hash, or metadata, or certificate as the condition of adding applications to the user category.

  File Hash

  Depending on the version of the security application installed on devices on your network, you should select an algorithm for hash value computing by Kaspersky EDR Expert for files in this category. Information about hash values computed by hash functions is stored in the Administration Server database.

  SHA256 is a cryptographic hash function: no vulnerabilities have been found in its algorithm, and so it is considered the most reliable cryptographic function nowadays. Kaspersky Endpoint Security for Linux supports SHA256 computing.

  Select either of the options of hash value computing by Kaspersky EDR Expert for files in the category:

  - If all instances of security applications installed on your network are Kaspersky Endpoint Security for Linux, select the **SHA256** check box.
  - Select the **MD5 hash** check box only if you use Kaspersky Endpoint Security for Windows. Kaspersky Endpoint Security for Linux does not support an MD5 hash function.

  Metadata

  If this option is selected, you can specify file metadata as file name, file version, vendor. The category condition matches only the executable files with the same metadata.

  Certificate

  If this option is selected, you can specify certificates from the repository. The category condition matches only the executable files signed by the specified certificate.

  Certificates are added to the repository if you created and started an inventory task or selected the **About started applications** check box in the Kaspersky Endpoint Security policy. You can perform both actions.

- **From archived folder**

If this option is selected, you can specify a file of an archived folder, and then select which condition you want to use to add applications to the user category. The archived folder is unpacked and the conditions that you select are applied to the files in the folder. As a condition, you can select one of the following criteria:

- **File Hash**

  You select which hash function (MD5 or SHA256) you want to use to calculate hash values. The applications that have the same hash value as the files in the archived folder are added to the user application category.

  Select an MD5 hash function only if you use Kaspersky Endpoint Security for Windows. Kaspersky Endpoint Security for Linux does not support an MD5 hash function.

- **Metadata**

  You select which metadata you want to use as criteria. Executable files that contain the same metadata will be added to the user application category.

- **Certificate**

  You select which certificate properties (certificate subject, fingerprint, or issuer) you want to use as criteria. Executable files that have been signed with the certificates that have the same properties will be added to the user category.

Metadata and **Certificate** criteria must be specified manually after uploading a file or an archived folder if you want to use these criteria.

If this option is selected, you can specify a file of an archived folder, and then select which condition you want to use to add applications to the user category. The archived folder is unpacked and the conditions that you select are applied to the files in the folder. As a condition, you can select one of the following criteria:

- **File Hash**

  You select which hash function (MD5 or SHA256) you want to use to calculate hash values. The applications that have the same hash value as the files in the archived folder are added to the user application category.

  Select an MD5 hash function only if you use Kaspersky Endpoint Security for Windows. Kaspersky Endpoint Security for Linux does not support an MD5 hash function.

- **Metadata**

  You select which metadata you want to use as criteria. Executable files that contain the same metadata will be added to the user application category.

- **Certificate**

  You select which certificate properties (certificate subject, fingerprint, or issuer) you want to use as criteria. Executable files that have been signed with the certificates that have the same properties will be added to the user category.

Metadata and **Certificate** criteria must be specified manually after uploading a file or an archived folder if you want to use these criteria.

b. If necessary, add a comment in the **Description** field. The number of symbols cannot exceed 1000.

Later you will be able to edit or delete the comment. To do so, in the application category properties, open the **Conditions** tab, then in the **Condition criterion** column, click the link with the condition for which you want to edit or delete the comment.

> When selecting the **From KL category** rule type, you can add one comment for all conditions to be created based on this rule type. You can edit or delete the comment for every condition separately.

The selected criterion is added to the list of conditions.

You can add as many criteria as you need for the application category that is being created.

6. On the **Exclusions** step, click the **Add** button to add an exclusive condition criterion to exclude files from the category that is being created.

   If necessary, you can add a comment in the **Description** field. The number of symbols cannot exceed 1000.

   Later, you can edit or delete the comment To do so, in the application category properties, open the **Exclusions** tab, then in the **Condition criterion** column, click the link with the condition for which you want to edit or delete the comment.

7. On the **Condition criteria** step, select a rule type from the list, in the same way that you selected a rule type for category creation.

When the wizard finishes, the application category is created and displayed in the list of application categories. You can use the created application category when you configure Application Control.

For detailed information about Application Control, refer to the Kaspersky Endpoint Security for Linux Help and Kaspersky Endpoint Security for Windows Help.

Creating an application category that includes executable files from selected devices

You can use executable files from selected devices as a template of executable files that you want to allow or block. Based on executable files from selected devices, you can create an application category and use it in the Application Control component configuration.

Make sure that the following prerequisites are met:

- The Application Control component is enabled in the Kaspersky Endpoint Security policy.
- A list of executable files stored on managed devices has been obtained.

To create application category that includes executable files from selected devices:

1. In the main menu, go to **Software management** → **Third-party applications** → **Application categories**.

   The page with a list of categories of executable files is displayed.

2. Click the **Add** button.

   The New category wizard starts. Proceed through the Wizard by using the **NEXT** button.

3. On the **Select category creation method** step, specify the category name and select the **Category that includes executable files from selected devices. These executable files are processed automatically and their metrics are added to the category** option.

4. Click the **Add** button.

5. In the window that opens, select a device or devices whose executable files will be used to create the application category.

6. Specify the following settings:

   - **Hash value computing algorithm**

     Depending on the version of the security application installed on devices on your network, you should select an algorithm for hash value computing by Kaspersky EDR Expert for files in this category. Information about hash values computed by hash functions is stored in the Administration Server database.

     SHA256 is a cryptographic hash function: no vulnerabilities have been found in its algorithm, and so it is considered the most reliable cryptographic function nowadays. Kaspersky Endpoint Security for Linux supports SHA256 computing.

     Select either of the options of hash value computing by Kaspersky EDR Expert for files in the category:

     - If all instances of security applications installed on your network are Kaspersky Endpoint Security for Linux, select the **SHA256** check box.

     Select the **MD5 hash** check box only if you use Kaspersky Endpoint Security for Windows. Kaspersky Endpoint Security for Linux does not support an MD5 hash function.

     The **Calculate SHA256 for files in this category (supported by Kaspersky Endpoint Security 10 Service Pack 2 for Windows and any later versions)** check box is selected by default.

     The **Calculate MD5 for files in this category (supported by versions earlier than Kaspersky Endpoint Security 10 Service Pack 2 for Windows)** is cleared by default.

   - **Synchronize data with Administration Server repository**

     Select this option if you want that Administration Server periodically to check changes in the specified folder (or folders).

     By default, this option is disabled.

     If you enable this option, specify the period (in hours) to check changes in the specified folder (folders). By default, scan interval is 24 hours.

   - **File type**

     In this section, you can specify file type that is used to create the application category.

     All files. All files are taken into consideration when creating the category. By default, this option is selected.

     Only files outside the application categories. Only files outside the application categories are taken into consideration when creating the category.

   - **Folders**

     In this section you can specify which folders from the selected device (devices) contain files that are used to create the application category.

     All folders. All folders are taken into consideration for the creating category. By default, this option is selected.

     Specified folder. Only specified folder is taken into consideration for the creating category. If you select this option you must specify path to the folder.

When the wizard finishes, the category of executable files is created. It is displayed in the list of categories. You can use the created category when you configure Application Control.

Creating an application category that includes executable files from selected folder

You can use executable files from a selected folder as a standard of executable files that you want to allow or block in your organization. On the basis of executable files from the selected folder, you can create an application category and use it in the Application Control component configuration.

To create a category that includes executable files from the selected folder:

1. In the main menu, go to **Software management** → **Third-party applications** → **Application categories**.

   The page with a list of categories is displayed.

2. Click the **Add** button.

   The New category wizard starts. Proceed through the wizard by using the **Next** button.

3. On the **Select category creation method** step, specify the category name and select the **Category that includes executable files from a specific folder. Executable files of applications copied to the specified folder are automatically processed and their metrics are added to the category** option.

4. Specify the folder whose executable files will be used to create the category.

5. Configure the following settings:

   - **Include dynamic-link libraries (DLL) in this category**

     The application category includes dynamic-link libraries (files in DLL format), and the Application Control component logs the actions of such libraries running in the system. Including DLL files in the category may lower the performance of Kaspersky EDR Expert.

     This check box is cleared by default.

   - **Include script data in this category**

     The application category includes data on scripts, and scripts are not blocked by Web Threat Protection. Including the script data in the category may lower the performance of Kaspersky EDR Expert.

     This check box is cleared by default.

   - **Hash value computing algorithm**: **Calculate SHA256 for files in this category (supported by Kaspersky Endpoint Security 10 Service Pack 2 for Windows and later versions)** / **Calculate MD5 for files in this category (supported by versions earlier than Kaspersky Endpoint Security 10 Service Pack 2 for Windows)**

     Depending on the version of the security application installed on devices on your network, you should select an algorithm for hash value computing by Kaspersky EDR Expert for files in this category. Information about hash values computed by hash functions is stored in the Administration Server database.

     SHA256 is a cryptographic hash function: no vulnerabilities have been found in its algorithm, and so it is considered the most reliable cryptographic function nowadays. Kaspersky Endpoint Security for Linux supports SHA256 computing.

     Select either of the options of hash value computing by Kaspersky EDR Expert for files in the category:

     - If all instances of security applications installed on your network are Kaspersky Endpoint Security for Linux, select the **SHA256** check box.

Select the **MD5 hash** check box only if you use Kaspersky Endpoint Security for Windows. Kaspersky Endpoint Security for Linux does not support an MD5 hash function.

The **Calculate SHA256 for files in this category (supported by Kaspersky Endpoint Security 10 Service Pack 2 for Windows and any later versions)** check box is selected by default.

The **Calculate MD5 for files in this category (supported by versions earlier than Kaspersky Endpoint Security 10 Service Pack 2 for Windows)** is cleared by default.

- **Force folder scan for changes**

  If this option is enabled, the application regularly checks the folder of category content addition for changes. You can specify the frequency of checks (in hours) in the entry field next to the check box. By default, the time interval between forced checks is 24 hours.

  If this option is disabled, the application does not force any checks of the folder. The Server attempts to access files if they have been modified, added, or deleted.

  By default, this option is disabled.

When the wizard finishes, the category of executable files is created. It is displayed in the list of categories. You can use the category at Application Control configuration.

For detailed information about Application Control, refer to the Kaspersky Endpoint Security for Linux Help and Kaspersky Endpoint Security for Windows Help.

Viewing the list of application categories

You can view the list of configured categories of executable files and the settings of each category.

To view the list of application categories,

In the main menu, go to **Software management → Third-party applications → Application categories**.

The page with a list of categories is displayed.

To view properties of an application category,

Click the name of the category.

The properties window of the category is displayed. The properties are grouped on several tabs.

Configuring Application Control in the Kaspersky Endpoint Security for Windows policy

After you create Application Control categories, you can use them for configuring Application Control in Kaspersky Endpoint Security for Windows policies.

To configure Application Control in the Kaspersky Endpoint Security for Windows policy:

1. In the main menu, go to **Asset management** → **Policies**.

   A page with a list of policies is displayed.

2. Click the **Kaspersky Endpoint Security for Windows** policy.

   The policy settings window opens.

3. Go to **Application settings** → **Security Controls** → **Application Control**.

   The **Application Control** window with Application Control settings is displayed.

4. The **Application Control** option is enabled by default. Switch the toggle button **Application Control DISABLED** to disable the option.

5. In the **Application Control Settings** block settings, enable the operation mode to apply the Application Control rules and allow Kaspersky Endpoint Security for Windows to block startup of applications.

   If you want to test the Application Control rules, in the **Application Control Settings** section, enable the test mode. In the test mode, Kaspersky Endpoint Security for Windows does not block startup of applications, but logs information about triggered rules in the report. Click the **View report** link to view this information.

6. Enable the **Control DLL modules load** option if you want Kaspersky Endpoint Security for Windows to monitor the loading of DLL modules when applications are started by users.

   Information about the module and the application that loaded the module will be saved to a report.

   Kaspersky Endpoint Security for Windows monitors only the DLL modules and drivers loaded after the **Control DLL modules load** option is selected. Restart the device after selecting the **Control DLL modules load** option if you want Kaspersky Endpoint Security for Windows to monitor all DLL modules and drivers, including those loaded before Kaspersky Endpoint Security for Windows is started.

7. (Optional) In the **Message templates** block, change the template of the message that is displayed when an application is blocked from starting and the template of the email message that is sent to you.

8. In the **Application Control Mode** block settings, select the **Denylist** or **Allowlist** mode.

   By default, the **Denylist** mode is selected.

9. Click the **Rules Lists Settings** link.

   The **Denylists and allowlists** window opens to let you add an application category. By default, the **Denylist** tab is selected if the **Denylist** mode is selected, and the **Allowlist** tab is selected if the **Allowlist** mode is selected.

10. In the **Denylists and allowlists** window, click the **Add** button.

    The **Application Control rule** window opens.

11. Click the **Please choose a category** link.

    The **Application Category** window opens.

12. Add the application category (or categories) that you created earlier.

    You can edit the settings of a created category by clicking the **Edit** button.

    You can create a new category by clicking the **Add** button.

    You can delete a category from the list by clicking the **Delete** button.

13. After the list of application categories is complete, click the **OK** button.

    The **Application Category** window closes.

14. In the **Application Control** rule window, in the **Subjects and their rights** section, create a list of users and groups of users to apply the Application Control rule.

15. Click the **OK** button to save the settings and to close the **Application Control rule** window.

16. Click the **OK** button to save the settings and to close the **Denylists and allowlists** window.

17. Click the **OK** button to save the settings and to close the **Application Control** window.

18. Close the window with the Kaspersky Endpoint Security for Windows policy settings.

    Application Control is configured. After the policy is propagated to the client devices, the startup of executable files is managed.

For detailed information about Application Control, refer to the Kaspersky Endpoint Security for Linux Help and Kaspersky Endpoint Security for Windows Help.

Adding event-related executable files to the application category

After you configure Application Control in the Kaspersky Endpoint Security policies, the following events will be displayed in the list of events:

- **Application startup prohibited** (*Critical* event). This event is displayed if you have configured Application Control to apply rules.
- **Application startup prohibited in test mode** (*Info* event). This event is displayed if you have configured Application Control to test rules.
- **Message to administrator about application startup prohibition** (*Warning* event). This event is displayed if you have configured Application Control to apply rules and a user has requested access to the application that is blocked at startup.

It is recommended to create event selections to view events related to Application Control operation.

You can add executable files related to Application Control events to an existing application category or to a new application category. You can add executable files only to an application category with content added manually.

To add executable files related to Application Control events to an application category:

1. In the main menu, go to **Monitoring → Event selections**.

   The list of event selections is displayed.

2. Select the event selection to view events related to Application Control and start this event selection.

   If you have not created event selection related to Application Control, you can select and start a predefined selection, for example, **Recent events**.

   The list of events is displayed.

3. Select the events whose associated executable files you want to add to the application category, and then click the **Assign to category** button.

   The New category wizard starts. Proceed through the Wizard by using the **NEXT** button.

4. On the wizard page, specify the relevant settings:

- In the **Action on executable file related to the event** section, select one of the following options:

  - **Add to a new application category**

    Select this option if you want to create a new application category based on event-related executable files.

    By default, this option is selected.

    If you have selected this option, specify a new category name.

  - **Add to an existing application category**

    Select this option if you want to add event-related executable files to an existing application category.

    By default, this option is not selected.

    If you have selected this option, select the application category with content added manually to which you want to add executable files.

- In the **Rule type** section, select one of the following options:

  - **Rules for adding to inclusions**

  - **Rules for adding to exclusions**

- In the **Parameter used as a condition** section, select one of the following options:

  - **Certificate details (or SHA256 hashes for files without a certificate)**

    Files may be signed with a certificate. Multiple files may be signed with the same certificate. For example, different versions of the same application may be signed with the same certificate, or several different applications from the same vendor may be signed with the same certificate. When you select a certificate, several versions of an application or several applications from the same vendor may end up in the category.

    Each file has its own unique SHA256 hash function. When you select an SHA256 hash function, only one corresponding file, for example, the defined application version, ends up in the category.

    Select this option if you want to add to the category rules the certificate details of an executable file (or the SHA256 hash function for files without a certificate).

    By default, this option is selected.

  - **Certificate details (files without a certificate will be skipped)**

    Files may be signed with a certificate. Multiple files may be signed with the same certificate. For example, different versions of the same application may be signed with the same certificate, or several different applications from the same vendor may be signed with the same certificate. When you select a certificate, several versions of an application or several applications from the same vendor may end up in the category.

    Select this option if you want to add the certificate details of an executable file to the category rules. If the executable file has no certificate, this file will be skipped. No information about this file will be added to the category.

  - **Only SHA256 (files without a hash will be skipped)**

    Each file has its own unique SHA256 hash function. When you select an SHA256 hash function, only one corresponding file, for example, the defined application version, ends up in the category.

    Select this option if you want to add only the details of the SHA256 hash function of the executable file.

- **Only MD5 (discontinued mode, only for Kaspersky Endpoint Security 10 Service Pack 1 version)**

  Select this option only if you use Kaspersky Endpoint Security for Windows. Kaspersky Endpoint Security for Linux does not support an MD5 hash function.

  Each file has its own unique MD5 hash function. When you select an MD5 hash function, only one corresponding file, for example, the defined application version, ends up in the category.

5. Click **OK**.

When the wizard finishes, executable files related to the Application Control events are added to the existing application category or to a new application category. You can view settings of the application category that you have modified or created.

For detailed information about Application Control, refer to the Kaspersky Endpoint Security for Linux Help and Kaspersky Endpoint Security for Windows Help.

Find vulnerabilities and required updates task settings

In addition to the general task settings, you can specify the following settings when creating the *Find vulnerabilities and required updates* task or later, when configuring the properties of the created task:

- **Search for vulnerabilities and updates listed by Microsoft**

  When searching for vulnerabilities and updates, Kaspersky EDR Expert uses the information about applicable Microsoft updates from the source of Microsoft updates, which are available at the present moment.

  For example, you may want to disable this option if you have different tasks with different settings for Microsoft updates and updates of third-party applications.

  By default, the option is enabled.

  Information about optional Microsoft Windows updates is not being sent to the Administration Server.

- **Connect to the update server to update data**

  Windows Update Agent on a managed device connects to the source of Microsoft updates. The following servers can act as a source of Microsoft updates:

  - Windows Server with Microsoft Windows Server Update Services (WSUS) deployed in your organization's network
  - Microsoft Updates servers

  If this option is enabled, Windows Update Agent on a managed device connects to the source of Microsoft updates to refresh the information about applicable Microsoft Windows updates.

  If this option is disabled, Windows Update Agent on a managed device uses the information about applicable Microsoft Windows updates that was received from the source of Microsoft updates earlier.

  Connecting to the source of Microsoft updates can be resource-consuming. You might want to disable this option if you set regular connection to this source of updates in another task or in the properties of Network Agent policy, in the section **Software updates and vulnerabilities**. If you do not want to disable this option, then, to reduce the Server overload, you can configure the task schedule to randomize delay for task starts within 360 minutes.

By default, the option is enabled.

Combination of the following options of the settings of Network Agent policy defines the mode of getting updates:

- The Windows Update Agent on a managed device connects to the update server to receive updates only if the **Connect to the update server to update data** setting is enabled in the properties of the *Find vulnerabilities and required updates* task and the **Windows update search mode** is set to **Active** in the Network Agent policy settings.

- If you do not need Network Agent to initiate a connection to the Microsoft Windows update source and download updates when performing the *Vulnerability scan* task, you can set the **Windows Update search mode** option to **Passive**, while the **Connect to the update server to update data** option must remain enabled. This allows for you to save resources and use previously received Windows updates to scan for vulnerabilities. You can use the passive mode if you configure receiving Microsoft Windows updates in a different way. If receiving Microsoft Windows updates is not configured in another way, do not set the **Windows Update search mode** option to **Passive**, because in this case, information about updates will never be received.

- Irrespective of the **Connect to the update server to update data** option's status (enabled or disabled), if the **Windows Update search mode** option is set to **Disabled**, Kaspersky EDR Expert does not request any information about updates.

If in the network of your organization the WSUS server is used (local WSUS server), and you want to use it together with Kaspersky Security Center Administration Server, you must first ensure that Kaspersky Security Center Administration Server is not used as a WSUS server, and then do the following:

1. On your managed devices running Windows, specify your local WSUS server for the Windows Update service. You can do it either manually in Windows Registry or by using a Windows group policy.

2. On your local WSUS server, specify the required classifications for updates and the applications on which the updates are to be distributed.

3. Synchronize your WSUS server with the upstream server (this can be either a Microsoft WSUS server or another local upstream WSUS server).

After the *Find vulnerabilities and required updates* task is run on the device, Network Agent uses the Windows Update service to initiate a request for Windows updates applicable to the device. The Windows Update service obtains the address of the external WSUS server from the registry and searches for updates directly from that external WSUS server. Then, the Windows Update service forwards this list to the Administration Server through Network Agent. Thus, Administration Server has an up-to-date base.

- **Search for third-party vulnerabilities and updates listed by Kaspersky**

  If this option is enabled, Kaspersky EDR Expert searches for vulnerabilities and required updates for third-party applications (applications made by software vendors other than Kaspersky and Microsoft) in Windows Registry and in the folders specified under **Specify paths for advanced search of applications in file system**. The full list of supported third-party applications is managed by Kaspersky.

  If this option is disabled, Kaspersky EDR Expert does not search for vulnerabilities and required updates for third-party applications. For example, you may want to disable this option if you have different tasks with different settings for Microsoft Windows updates and updates of third-party applications.

  By default, the option is enabled.

- **Specify paths for advanced search of applications across the file system**

  The folders in which Kaspersky EDR Expert searches for third-party applications that require vulnerability fix and update installation. You can use system variables.

  Specify the folders to which applications are installed. By default, the list contains system folders to which most of the applications are installed.

- **Enable advanced diagnostics**

  If this feature is enabled, Network Agent writes trace files even if writing trace files is disabled for Network Agent in Open Single Management Platform Remote Diagnostics Utility. Traces are written to two files in turn; the total size of both files is determined by the **Maximum size, in MB, of advanced diagnostics files** value. When both files are full, Network Agent starts writing to them again. The files with traces are stored in the %WINDIR%\Temp folder. These files are accessible in the remote diagnostics utility, you can download or delete them there.

  If this feature is disabled, Network Agent writes traces according to the settings in Open Single Management Platform Remote Diagnostics Utility. No additional traces are written.

  When creating a task, you do not have to enable advanced diagnostics. You may want to use this feature later if, for example, a task run fails on some of the devices and you want to get additional information during another task run.

  By default, this option is disabled.

- **Maximum size, in MB, of advanced diagnostics files**

  The default value is 100 MB, and available values are between 1 MB and 2048 MB. You may be asked to change the default value by Kaspersky Technical Support specialists when information in the advanced diagnostics files sent by you is not enough to troubleshoot the problem.

Recommendations on the task schedule

When scheduling the *Find vulnerabilities and required updates* task, make sure that two options—**Run missed tasks** and **Use automatically randomized delay for task starts**—are enabled.

By default, the *Find vulnerabilities and required updates* task is set to start manually. If the organization's workplace rules provide for shutting down all devices at this time, the *Find vulnerabilities and required updates* task will run after the devices are turned on again, that is, the following morning. Such activity may be undesirable because a vulnerability scan may increase the load on CPUs and disk subsystems. You must set up the most convenient schedule for the task based on the workplace rules adopted in the organization.

About the license

A *license* is a time-limited right to use Open Single Management Platform, granted under the terms of the signed License Contract (End User License Agreement).

The scope of services and validity period depend on the license under which the application is used.

The following license types are provided:

- *Trial*

A free license intended for trying out the application. A trial license usually has a short term.

When a trial license expires, all Open Single Management Platform features become disabled. To continue using the application, you need to purchase a commercial license.

You can use the application under a trial license for only one trial period.

- *Commercial*

  A paid license.

  When a commercial license expires, key features of the application become disabled. To continue using Open Single Management Platform, you must renew your commercial license. After the license expiration, you can no longer use the application and must delete it from your device.

  We recommend renewing your license before it expires, to ensure uninterrupted protection against all security threats.

OPENAPI REFERENCE GUIDE

This OpenAPI reference guide is designed to assist in the following tasks:

- Automation and customization. You can automate tasks that you might not want to handle manually. For example, as an administrator, you can use OpenAPI to create and run scripts that will facilitate developing the structure of administration groups and keep that structure up-to-date.
- Custom development. Using OpenAPI, you can develop a client application.

You can use the search field in the right part of the screen to locate the information you need in the OpenAPI reference guide.

OPENAPI REFERENCE GUIDE

Samples of scripts

The OpenAPI reference guide contains samples of the Python scripts listed in the table below. The samples show how you can call OpenAPI methods and automatically accomplish various tasks for protecting your network, for instance, create a "primary/secondary" hierarchy, run tasks in Open Single Management Platform, or assign distribution points. You can run the samples as is or create your own scripts based on the samples.

Matching between user scenarios and samples of OpenAPI methods

Example	Purpose of the sample	Scenario
Log KlAkParams	You can extract and process data by using the `KlAkParams` data structure. The sample shows how to work with this data structure. The sample output may be present in different ways. You can get the data to send an HTTP method or to use it in your code.	Monitoring and reporting
Create and delete a "primary/secondary" hierarchy	You can add a secondary Administration Server and establish a "primary/secondary" hierarchy. Alternately, you can disconnect the secondary Administration Server from the hierarchy.	Creating a hierarchy of Administration Servers, adding a secondary Administration Server, and deleting a hierarchy of Administration Servers

Example	Purpose of the sample	Scenario
Download network list files via connection gateway to the specified host	You can connect to Network Agent on the needed device by using a connection gateway, and then download a file with the network list to your device.	Adjustment of distribution points and connection gateways
Install a license key stored in the primary Administration Server repository onto the secondary Administration Servers	You can connect to the primary Administration Server, download a required license key from it, and transmit this key to all the secondary Administration Servers included in a hierarchy.	Licensing of managed applications
Create a report of effective user rights	You can create different reports. For instance, you can generate the report of effective user rights by using this sample. This report describes the rights that a user has, depending on his or her group and role. You can download the report in the HTML, PDF, or Excel format.	Generating and viewing a report
Start the device task	You can connect to Network Agent on the needed device by using a connection gateway, and then run the necessary task.	Starting a task manually
Register distribution points for devices in a group	You can assign managed devices as distribution points (previously known as update agents).	Updating Kaspersky databases and applications
Enumerate all groups	You can perform various actions with administration groups. The sample shows how to do the following: • Get an identifier of the "Managed devices" root group • Move through the group hierarchy • Retrieve the full, expanded hierarchy of groups, along with their names and nesting	Configuring Administration Server
Enumerate tasks, query task statistics, and run a task	You can find out the following information: • Task progress history • Current task status • Number of tasks in different statuses You can also run a task. By default, the sample runs a task after it outputs statistics.	Starting a task manually
Create and run a task	You can create a task. Specify the following task parameters in the sample: • Type • Method of run • Name. • Device group for which the task will be used By default, the sample creates a task with the "Show message" type. You can run this task for all managed devices of Administration Server. If necessary, you can specify your own task parameters.	Creating a task
Enumerate license keys	You can get a list of all the active license keys for Kaspersky applications installed on managed devices of Administration Server. The list contains detailed data about every license key, such as a name, type, or expiration date.	Licensing
Create a custom category	You can create the application category with the needed parameters.	Creating an application category with content added manually
Enumerate users by using SrvView	You can use the SrvView class to request detailed information from the Administration Server. For instance, you can get a list of users by using this sample.	Managing users and user roles

Applications interacting with Open Single Management Platform via OpenAPI

Some applications interact with Open Single Management Platform via OpenAPI. Such applications include, for example, Kaspersky Anti Targeted Attack Platform. This can also be a custom client application developed by you based on OpenAPI.

Applications interacting with Open Single Management Platform via OpenAPI connect to Administration Server. To find out whether the application that you use works by OpenAPI, see Help of this application.

Managing Endpoint Agents

Endpoint Agent is a Kaspersky EDR Expert component installed on workstations and servers in the IT infrastructure of an organization. Endpoint Agent continually monitor processes, active network connections, and files being modified. When integrated with Open Single Management Platform, Endpoint Agent sends the following information to Open Single Management Platform:

- telemetry
- threats detected by the application
- results of processing detected threats

Depending on the computer operating system, one of the following applications can be used as an Endpoint Agent:

- Kaspersky Endpoint Security for Windows
- Kaspersky Endpoint Security for Linux
- Kaspersky Endpoint Security for Mac

Managing Kaspersky Endpoint Security for Windows

For details about managing Kaspersky Endpoint Security for Windows, see Online Help:

- installing and uninstalling the application
- installing Windows Management Plug-in
- managing Quarantine
- managing the application by using the command line

Managing Kaspersky Endpoint Security for Linux

For details about managing Kaspersky Endpoint Security for Linux, see Online Help:

- installing, uninstalling, and upgrading the application
- managing the application by using the command line
- managing the application by using Kaspersky Security Center

Managing Kaspersky Endpoint Security for Mac

For details about managing Kaspersky Endpoint Security for Mac, see Online Help:

- installing and uninstalling the application
- managing the application by using the command line
- managing the application via Kaspersky Security Center Administration Console or Kaspersky Security Center Web Console and Cloud Console.

Monitoring, reporting, and audit

This section describes the monitoring and reporting capabilities of Kaspersky EDR Expert. These capabilities give you an overview of your infrastructure, protection statuses, and statistics.

After Kaspersky EDR Expert deployment or during the operation, you can configure the monitoring and reporting features to best suit your needs.

Scenario: Monitoring and reporting

This section provides a scenario for configuring the monitoring and reporting feature in Kaspersky EDR Expert.

Prerequisites

After you deploy Kaspersky EDR Expert in an organization's network, you can start to monitor it and generate reports on its functioning.

Monitoring and reporting in an organization's network proceeds in stages:

1. **Configuring the switching of device statuses**

   Get acquainted with the settings for device statuses depending on specific conditions. By changing these settings, you can change the number of events with *Critical* or *Warning* importance levels. When configuring the switching of device statuses, be sure of the following:

   - New settings do not conflict with the information security policies of your organization.
   - You are able to react to important security events in your organization's network in a timely manner.

2. **Configuring notifications about events on client devices**

   How-to instructions:

   Configure notification (by email, by SMS, or by running an executable file) of events on client devices

3. **Performing recommended actions for Critical and Warning notifications**

   How-to instructions:

   Perform recommended actions for your organization's network

4. **Reviewing the security status of your organization's network**

   How-to instructions:

   - Review the Protection status widget
   - Generate and review the Report on protection status
   - Generate and review the Report on errors

5. **Locating client devices that are not protected**

How-to instructions:

- Review the New devices widget
- Generate and review the Report on protection deployment

6. **Checking protection of client devices**

   How-to instructions:

   - Generate and review reports from the Protection status and Threat statistics categories
   - Start and review the Critical event selection

7. **Evaluating and limiting the event load on the database**

   Information about events that occur during operation of managed applications is transferred from a client device and registered in the Administration Server database. To reduce the load on the Administration Server, evaluate and limit the maximum number of events that can be stored in the database.

   How-to instructions:

   - Limiting the maximum number of events

8. **Reviewing license information**

   How-to instructions:

   - Add the License key usage widget to the dashboard and review it
   - Generate and review the Report on usage of license keys

Results

Upon completion of the scenario, you are informed about protection of your organization's network and, thus, can plan actions for further protection.

About types of monitoring and reporting

Information on security events in an organization's network is stored in the Administration Server database. Based on the events, OSMP Console provides the following types of monitoring and reporting in your organization's network:

- Dashboard
- Reports
- Event selections
- Notifications

Dashboard

The dashboard allows you to monitor security trends on your organization's network by providing you with a graphical display of information.

Reports

The Reports feature allows you to get detailed numerical information about the security of your organization's network, save this information to a file, send it by email, and print it.

Event selections

Event selections provide an onscreen view of named sets of events that are selected from the Administration Server database. These sets of events are grouped according to the following categories:

- By importance level—**Critical events**, **Functional failures**, **Warnings**, and **Informational messages**
- By time—**Recent events**
- By type—**User requests** and **Audit events**

You can create and view user-defined event selections based on the settings available, in the OSMP Console interface, for configuration.

Notifications

Notifications alert you about events and help you to speed up your responses to these events by performing recommended actions or actions you consider as appropriate.

Triggering of rules in Smart Training mode

This section provides information about the detections performed by the Adaptive Anomaly Control rules in Kaspersky Endpoint Security for Windows on client devices.

The rules detect anomalous behavior on client devices and may block it. If the rules work in Smart Training mode, they detect anomalous behavior and send reports about every such occurrence to Administration Server. You can view the reports about detected anomalous behavior in **Repositories** → **Rule triggers in Smart Training state**. You can confirm detections as correct or add them as exclusions, so that this type of behavior is not considered anomalous anymore.

Information about detections is stored in the event log on the Administration Server (along with other events) and in the Adaptive Anomaly Control report.

For more information about Adaptive Anomaly Control, the rules, their modes and statuses, refer to Kaspersky Endpoint Security for Windows Help.

Viewing and confirming detections performed using Adaptive Anomaly Control rules

To view the list of detections performed by Adaptive Anomaly Control rules:

1. In the main menu, go to **Repositories → Rule triggers in Smart Training state**.

   The list displays the following information about detections performed using Adaptive Anomaly Control rules:

   - **Administration group**

     The name of the administration group where the device belongs.

   - **Virtual Administration Server**

     Virtual Administration Server that manages the device.

   - **Device name**

     The name of the client device where the rule was applied.

   - **Name**

     The name of the rule that was applied.

   - **State**

     Excluding—If the Administrator processed this item and added it as an exclusion to the rules. This status remains till the next synchronization of the client device with the Administration Server; after the synchronization, the item disappears from the list.

     Confirming—If the Administrator processed this item and confirmed it. This status remains till the next synchronization of the client device with the Administration Server; after the synchronization, the item disappears from the list.

     Empty—If the Administrator did not process this item.

   - **Detections count**

     The number of detects within one heuristic rule, one process and one client device. This number is counted by Kaspersky Endpoint Security.

   - **User name**

     The name of the client device user who run the process that generated the detect.

   - **Source process path**

     Path to the source process, i.e. to the process that performs the action (for more information, refer to the Kaspersky Endpoint Security help).

   - **Source process hash**

     SHA256 hash of the source process file (for more information, refer to the Kaspersky Endpoint Security help).

- **Source object path**

  Path to the object that started the process (for more information, refer to the Kaspersky Endpoint Security help).

- **Source object hash**

  SHA256 hash of the source file (for more information, refer to the Kaspersky Endpoint Security help).

- **Target process path**

  Path to the target process (for more information, refer to the Kaspersky Endpoint Security help).

- **Target process hash**

  SHA256 hash of the target file (for more information, refer to the Kaspersky Endpoint Security help).

- **Target object path**

  Path to the target object (for more information, refer to the Kaspersky Endpoint Security help).

- **Target object hash**

  SHA256 hash of the target file (for more information, refer to the Kaspersky Endpoint Security help).

- **Processed**

  Date when the anomaly was detected.

To view the properties of a detection:

1. In the main menu, go to **Repositories** → **Rule triggers in Smart Training state**.
2. Do one of the following:

   - In the **Name** column, click the link with the name of the detection you want to view.
   - In the list of detections, select the check box next to the detection you want to view, and then click the **Properties** button.

   The properties window of the selected detection opens, displaying information about it.

You can confirm any detection from the list of detections of Adaptive Anomaly Control rules or from the properties window of a selected detection.

To confirm a detection:

- Select one or several detections in the list of detections, and then click the **Confirm** button.
- Open the properties window of a selected detection, and then click the **Confirm** button.

  The status of the detection is changed to **Confirming**. The detection disappears from the list of detections after the next synchronization of the client device with the Administration Server.

  Your confirmation will contribute to the statistics used by the rules. For more information, refer to Kaspersky Endpoint Security for Windows Help.

Adding exclusions from the Adaptive Anomaly Control rules

The Add to Adaptive Anomaly Control exclusions wizard allows you to add exclusions from the Adaptive Anomaly Control rules for Kaspersky Endpoint Security.

To add exclusions from the Adaptive Anomaly Control rules by using the wizard:

1. Start the wizard in one of the following ways:

   - In the main menu, go to **Repositories → Rule triggers in Smart Training state**, select one or several detections, and then click the **Exclude** button.

     You can add up to 1000 exclusions at a time.

     Before adding a detection to exclusions, you can view the properties of the detection by clicking the detection name or the **Properties** button. In the detection properties window that opens, you can also click the **Exclude** button.

   - In the main menu, go to the **Monitoring → Event selections**, click the link with the event selection you need, select the check box next to the detection you want to exclude, and then click the **Exclude from Adaptive Anomaly Control** button.

   The Add to Adaptive Anomaly Control exclusions wizard starts. Proceed through the wizard by using the **Next** button.

2. Select the policies and profiles to which you want to add exclusions.

   Inherited policies cannot be updated. If you do not have the rights to modify a policy, the policy will not be updated.

3. Click **Done** to close the wizard.

The status of the detection is changed to **Excluding**. The detection disappears from the list of detections after the next synchronization of the client device with the Administration Server. The exclusion from the Adaptive Anomaly Control rules is configured and applied.

Dashboard and widgets

This section contains information about the dashboard and the widgets that the dashboard provides. The section includes instructions on how to manage widgets and configure widget settings.

Using the dashboard

The dashboard allows you to monitor security trends on your organization's network by providing you with a graphical display of information.

The dashboard is available in the OSMP Console, in the **Monitoring → Dashboard** section.

The dashboard provides widgets that can be customized. You can choose a large number of different widgets, presented as pie charts or donut charts, tables, graphs, bar charts, and lists. The information displayed in the widgets is automatically updated, the update period is from one to two minutes. The interval between updates varies for different widgets. You can refresh data on a widget manually at any time by using the settings menu.

The dashboard includes the **Administration and protection** and **Analysis and response** tabs, to which you can add widgets.

The Administration and protection tab

The **Administration and protection** tab can contain widgets that display information about all events stored in the database of Administration Server.

In the **Administration and protection** tab, the widgets of the following groups are available:

- **Protection status**
- **Deployment**
- **Updating**
- **Threat statistics**
- **Other**

The Analysis and response tab

The **Analysis and response** tab can contain widgets that display information about detected and registered alerts and incidents, and the response actions to them. You can view data only for those tenants to which you have access.

In the **Analysis and response** tab, the widgets of the following groups are available:

- **Events**
- **Active lists**
- **Context tables**
- **Alerts**
- **Assets**
- **Incidents**
- **Playbooks**

- **Event sources**
- **Users**

Administration and protection widgets

When configuring the **Administration and protection** tab of the dashboard, you can add widgets, hide widgets, change the size or appearance of widgets, move widgets, and change their settings.

Some widgets have text information with links. You can view detailed information by clicking the link.

The following widget groups and widgets are available on the **Administration and protection** tab of the dashboard:

- **Protection status**

  The group includes the following widgets:

  - **History of software vulnerabilities**
  - **Number of vulnerable devices**
  - **Distribution of devices by severity level of vulnerabilities**
  - **Status of selected device**
  - **Protection status**

- **Deployment**

  This group includes the **New devices** widget.

- **Update**

  This group includes the following widgets:

  - **Statistics about Windows Update updates**
  - **Distribution of anti-virus databases**
  - **Active alerts**
  - **Statistics of update installation results by update category**
  - **Statistics of update installation statuses by update category**
  - **Statistics of update installation statuses**

- **Threat statistics**

  This group includes the following widgets:

  - **Detection of threats by a specified application component distributed by disinfection result**
  - **Detection of threats by application components**

- **Prohibited applications**
- **Types of network attacks**
- **Types of detected viruses and disinfection results**
- **Quarantine history**
- **History of detection of probably infected objects**
- **History of network attacks**
- **History of threat activity sorted by application type**
- **Threat activity**
- **Users of the 10 most heavily infected devices**
- **Most heavily infected devices**
- **Virtual Administration Servers infected most frequently**
- **Most frequent threats**
- **Windows domains infected most frequently**
- **Groups infected most frequently**
- **Alerts**

- **Other**

  This group includes the following widgets:

  - **License key usage**
  - **Notifications by selected severity level**
  - **Top 10 most frequent events in database**
  - **Current status of selected Administration Server task**
  - **Task history**

Adding widgets to the dashboard

To add widgets to the dashboard:

1. In the main menu, go to **Monitoring** → **Dashboard**.
2. Click the **Add or restore widget** button.

3. In the list of available widgets, select the widgets that you want to add to the dashboard.

   Widgets are grouped by category. To view the list of widgets included in a category, click the chevron icon (>) next to the category name.

4. Click the **Add** button.

The selected widgets are added at the end of the dashboard.

You can now edit the representation and parameters of the added widgets.

Hiding a widget from the dashboard

To hide a displayed widget from the dashboard:

1. In the main menu, go to the **Monitoring** → **Dashboard**.
2. Click the settings icon (⚙) next to the widget that you want to hide.
3. Select **Hide widget**.
4. In the **Warning** window that opens, click **OK**.

The selected widget is hidden. Later, you can add this widget to the dashboard again.

Moving a widget on the dashboard

To move a widget on the dashboard:

1. In the main menu, go to **Monitoring** → **Dashboard**.
2. Click the settings icon (⚙) next to the widget that you want to move.
3. Select **Move**.
4. Click the place to which you want to move the widget. You can select only another widget.

The places of the selected widgets are swapped.

Changing the widget size or appearance

For widgets that display a graph, you can change its representation—a bar chart or a line chart. For some widgets, you can change their size: compact, medium, or maximum.

To change the widget representation:

1. In the main menu, go to **Monitoring** → **Dashboard**.
2. Click the settings icon (⚙) next to the widget that you want to edit.

3. Do one of the following:

   - To display the widget as a bar chart, select **Chart type: Bars**.
   - To display the widget as a line chart, select **Chart type: Lines**.
   - To change the area occupied by the widget, select one of the values:
     - **Compact**
     - **Compact (bar only)**
     - **Medium (donut chart)**
     - **Medium (bar chart)**
     - **Maximum**

   The representation of the selected widget is changed.

Changing widget settings

To change settings of a widget:

1. In the main menu, go to **Monitoring** → **Dashboard**.
2. Click the settings icon (⚙) next to the widget that you want to change.
3. Select **Show settings**.
4. In the widget settings window that opens, change the widget settings as required.
5. Click **Save** to save changes.

   The settings of the selected widget are changed.

The set of settings depends on the specific widget. Below are some of the common settings:

- **Widget scope** (the set of objects for which the widget displays information)—for example, an administration group or device selection.
- **Select task** sets the task for which the widget displays information.
- **Time interval** (the time interval during which the information is displayed in the widget)—between the two specified dates; from the specified date to the current day; or from the current day minus the specified number of days to the current day.
- The **Set to Critical if the following settings are specified** and **Set to Warning if the following settings are specified** rules govern how colors are assigned on the status chart.

After you change the widget settings, you can refresh data on the widget manually.

To refresh data on a widget:

1. In the main menu, go to **Monitoring** → **Dashboard**.
2. Click the settings icon (⚙) next to the widget that you want to move.
3. Select **Refresh**.

   The data on the widget is refreshed.

Analysis and response widgets

On the **Analysis and response** tab, you can add, configure, and delete widgets.

A selection of widgets used in the **Analysis and response** tab is called a *layout*. All widgets must be placed in layouts. Kaspersky EDR Expert allows you to create, edit, and delete layouts. Preconfigured layouts are also available. You can edit widget settings in the preconfigured layouts as necessary. By default, the **Alerts Overview** layout is selected on the **Analysis and response** tab.

The widget displays data for the period selected in widget or layout settings only for the tenants that are selected in widget or layout settings.

By clicking the link with the name of the widget about events, alerts, incidents, or active lists, you can go to the corresponding section of the Kaspersky EDR Expert interface. Note that this option is not available for some widgets.

The following widget groups and widgets are available on the **Analysis and response** tab of the dashboard:

- **Events**. Widget for creating analytics based on events.
- **Active lists**. Widget for creating analytics based on active lists of correlators.
- **Alerts**. Group for analytics related to alerts. Includes information about alerts and incidents that is provided by Kaspersky EDR Expert.

  The group includes the following widgets:

  - **Active alerts**. Number of alerts that have not been closed.
  - **Active alerts by tenant**. Number of unclosed alerts for each tenant.
  - **Alerts by tenant**. Number of alerts of all statuses for each tenant.
  - **Unassigned alerts**. Number of alerts that have no assignee.
  - **Alerts by status**. Number of alerts that have the *New*, *Opened*, *Assigned*, or *Escalated* status. The grouping is by status.
  - **Latest alerts**. Table with information about the last 10 unclosed alerts belonging to the tenants selected in the layout.
  - **Alerts distribution**. Number of alerts created during the period configured for the widget.
  - **Alerts by users**. Number of alerts with the *Assigned* status. The grouping is by account name.

- **Alerts by groups**. Number of alerts assigned to each group and to analysts within each group. Alerts assigned to an analyst are counted in every group where that analyst is a member.
- **Alerts by severity**. Number of unclosed alerts grouped by their severity.
- **Alerts by rule**. Number of unclosed alerts grouped by correlation rule.
- **Alert statuses by period**. Number of alerts by status over the selected period.
- **Alerts by technology**. Names of protection technologies that generated the alert.
- **Alerts by hash**. Number of alerts grouped by the hashes of scanned objects. Supported hash types: MD5 and SHA256.
- **Alerts by detect source**. Number of alerts grouped by the detection source.
- **Alerts by file name**. Number of alerts grouped by scanned file name.

- **Assets**. Group for analytics related to assets from processed events. This group includes the following widgets:
  - **Affected assets in alerts**. Table with the names of assets and related tenants, and the number of unclosed alerts that are associated with these assets. The moving from the widget to the section with the asset list is not available.
  - **Affected asset categories**. Categories of assets linked to unclosed alerts.
  - **Number of assets**. Number of assets that were added to Kaspersky EDR Expert.
  - **Assets in incidents by tenant**. Number of assets associated with unclosed incidents. The grouping is by tenant.
  - **Assets in alerts by tenant**. Number of assets associated with unclosed alerts, grouped by tenant.
- Incidents. Group for analytics related to incidents.

  The group includes the following widgets:
  - **Active incidents**. Number of incidents that have not been closed.
  - **Unassigned incidents**. Number of incidents that have the *Opened* status.
  - **Incidents distribution**. Number of incidents created during the period configured for the widget.
  - **Incidents by status**. Number of incidents grouped by status.
  - **Incidents by type**. Number of incidents in any status grouped by type.
  - **Active incidents by tenant**. Number of unclosed incidents grouped by tenant available to the user account.
  - **All incidents**. Number of incidents of all statuses.
  - **All incidents by tenant**. Number of incidents of all statuses, grouped by tenant.
  - **Affected assets categories in incidents**. Asset categories associated with unclosed incidents.

- **Latest incidents**. Table with information about the last 10 unclosed incidents belonging to the tenants selected in the layout.
- **Incidents by user**. Number of incidents with the *Assigned* status. The grouping is by user account name.
- **Incidents by groups**. Number of incidents assigned to each group and to analysts within each group. Incidents assigned to an analyst are counted in every group where that analyst is a member.
- **Incidents by severity**. Number of unclosed incidents grouped by their severity.
- **Affected assets in incidents**. Number of assets associated with unclosed incidents. The moving from the widget to the section with the asset list is not available.
- **Affected users in incidents**. Users associated with incidents. The moving from the widget to the section with the user list is not available.

- **Event sources**. Group for analytics related to sources of events. The group includes the following widgets:
  - **Top event sources by alerts number**. Number of unclosed alerts grouped by event source.
  - **Top event sources by convention rate**. Number of events associated with unclosed alerts. The grouping is by event source.

    In some cases, the number of alerts generated by sources may be inaccurate. To obtain accurate statistics, it is recommended to specify the Device Product event field as unique in the correlation rule, and enable storage of all base events in a correlation event. However, correlation rules with these settings consume more resources.

- **Users**. Group for analytics related to users from processed events. The group includes the following widgets:
  - **Affected users in alerts**. Number of accounts related to unclosed alerts. The moving from the widget to the section with the user list is not available.
  - **Number of AD users**. Number of Active Directory accounts received via LDAP during the period configured for the widget.

    In the events table, in the event details area, in the alert window, and in the widgets, the names of assets, accounts, and services are displayed instead of the IDs as the values of the SourceAssetID, DestinationAssetID, DeviceAssetID, SourceAccountID, DestinationAccountID, and ServiceID fields. When exporting events to a file, the IDs are saved, but columns with names are added to the file. IDs are also displayed when you hover over the names of assets, user accounts, or services.
    You can search for fields with IDs only by IDs.

- **Playbooks**. Group for analytics related to playbooks.

  To view widgets in this group, you must have one of the following EDR roles: Main administrator, Tenant Administrator, SOC Administrator, SOC Manager, Tier 1 analyst, Tier 2 analyst, Approver, Auditor.

  The group includes the following widgets:

  - **Statistics MTTR**. Changes of the time to first response to alerts and incidents for the specified period of time (by default for 30 days). The widget displays a column chart.

The following configuration parameters of the **Statistics MTTR** widget are available:

- **MTTR type**:
  - **Mean**. Changes of the mean time to first response to alerts and incidents.
  - **Minimum**. Changes of the minimum time to first response to alerts and incidents.
  - **Maximum**. Changes of the maximum time to first response to alerts and incidents.
- **Response mode**:
  - **Manual**. Changes of the time only to manual first responses.
  - **Automatic**. Changes of the time only to automatic first responses.
  - **All**. Changes of the time to all first responses.
- **Scope**:
  - **Alerts**. Changes of the time to first response only to alerts.
  - **Incidents**. Changes of the time to first response only to incidents.
  - **All**. Changes of the time to first response to alerts and incidents.

- **Automatic and manual launches of playbooks**. The total number of automatic and manual launches of playbooks for a certain period. The widget displays a column chart.

  The **Launch type** parameter of the widget specifies whether to show only the number of automatic, only the number of manual, or the total number of playbook launches for a certain period.

  For the **Statistics MTTR** and **Automatic and manual launches of playbooks** widgets, you can also set the **Period segments length** parameter. This parameter specifies a time interval within which data will be grouped. You can group data for every hour, every 4 hours, or every 24 hours. On the column chart, the **Period segments length** parameter specifies the column width.

- **Coverage of alerts and incidents with playbooks**. Number of active alerts and incidents. You can select what components to display: incidents, alerts or all.

  The donut chart displays alerts/incidents in the following sectors:

  - Alerts/incidents for which a playbook in **Auto** operation mode was launched.
  - Alerts/incidents for which a playbook in **Training** operation mode was launched.
  - All other alerts/incidents.

- **Time saved by using playbooks**. Time saved by launching all the playbooks that have *Success* or *Warning* action status.

  The widget is not displayed by default.

You can view the full playbook list by clicking the name of any playbook widget.

- **IOA rules triggering Sandbox scan**. Top 10 IOA rules that most frequently cause Kaspersky Anti Targeted Attack Platform to submit files for scanning by the Sandbox component.

- **Top triggered IOA rules**. Top 10 IOA rules most frequently triggered in events detected by Targeted Attack Analyzer (TAA) technology.
- **Devices triggering IOA rules**. Top 10 devices on which IOA rules were triggered most frequently.

Basics of managing widgets

The principle of data display in the widget depends on the type of the graph. The following graph types are available in KUMA:

- Pie chart ( ).
- Counter ( ).
- Table ( ).
- Bar chart ( ).
- Date Histogram ( ).
- Line chart

Basics of general widget management

The name of the widget is displayed in the upper left corner of the widgets. By clicking the link with the name of the widget about events, alerts, incidents, or active lists, you can go to the corresponding section of OSMP Console.

A list of tenants for which data is displayed is located under the widget name.

In the upper right corner of the widget, the period for which data is displayed on the widget is indicated (for example, 30 days  . Data display period on the widget.). Keep in mind that the data displayed in the dashboard may lag behind real time because of caching. You can view the date and time of the last update by hovering over the period icon.

If the **Show data for previous period** option is enabled in the properties of the widget and the widget is displaying data for a relative period, the tooltip also displays the previous period. The previous period is calculated relative to the current period by subtracting the duration of the current period from the start and end times of the current period. For example, if data is updated daily and displayed for a month, but only the first 10 days of the month have passed, the previous period is taken to be the last 10 days of the previous month.

You can change the data display period for the widget by clicking the period icon and selecting an exact date or a relative period in the window that is displayed. If you want the widget to display data for the period selected for the layout, click the **Reset** button. Changing the displayed period on the layout also changes the period displayed in the widget.

> The time in the widget is displayed in the local time zone set in the browser.

The **CSV** button is located to the left of the period icon. You can download the data displayed on the widget in CSV format (UTF-8 encoding). The downloaded file name has the format <widget name>_<download date (YYYYMMDD)>_<download time (HHMMSS)>.CSV.

The widget displays data for the period selected in widget or layout settings only for the tenants that are selected in widget or layout settings.

If you have enabled the **Show total** toggle switch in the widget settings, the widget displays the **Total** value, but when you download the widget in CSV format, the **Total** value is not displayed. To display the **Total** value in the report, you can use Excel formulas or manually copy the total value from the widget.

Basics of managing Pie chart graphs

A pie chart with a legend is displayed below the list of tenants. The legend lists the names of the categories corresponding to the sectors of the diagram. You can left-click a category in the legend to go to the section of OSMP Console with the relevant data. The data in that section is sorted in accordance with the filters and/or search query specified in the widget.

When going from the legend of the widget to the events details section, pay attention to the text of the legend item that you click to go to the events section. Any \ or ' characters used in the text are escaped in the text of the SQL query. However, the / character is not escaped.

Under the period icon, the number of events, active lists, assets, alerts, or incidents grouped by the selected criteria for the data display period will be displayed.

Examples:

- In the **Alerts by status** widget, under the period icon, the number of alerts grouped by the **New**, **Open**, **Assigned**, or **Escalated** status is displayed.
  If you want to see the legend only for alerts with the **Opened** and **Assigned** status, you can clear the check boxes to the left of the **New** and **Escalated** statuses.
- In the **Events** widget, for which the SQL query `SELECT count(ID) AS `metric`, Name AS `value` FROM `events` GROUP BY Name ORDER BY `metric` DESC LIMIT 10` is specified, 10 events are displayed below the period icon, grouped by name and sorted in descending order.
  If you want to view events with specific names in the legend, you can clear the check boxes to the left of the names of events that you do not want to see in the legend.

Basics of managing Counter graphs

Graphs of this type display the sum total of selected data.

Example 1
The **Number of assets** widget displays the total number of assets added to KUMA.
Example 2
If you want to view trends to compare current data with data for a past period, you can create a widget that displays upward or downward trends. Trends can be configured in the following widgets:

- **Assets → Number of assets**.
- **Assets → Customized widget**.
- **Alerts → Active alerts**.
- **Alerts → Unassigned alerts**.
- **Incidents → Active incidents**.
- **Incidents → Unassigned incidents**.
- **Incidents → All incidents**.
- **Users -> Number of AD users**.
  To configure the display of trends, you need to enable the **Show data for previous period** toggle switch, and then select a trend on the Appearance tab. If the percentage value cannot be calculated, or if the values are equal, the (—) icon is displayed. If **Up is better** is selected, an uptrend is indicated by a green arrow on the chart, and a downtrend is indicated by a red arrow. If **Down is better** is selected, an uptrend is indicated by a red arrow on the chart, and a downtrend is indicated by a green arrow.
  You can click the value to change the display of data in the widget (for example, to display absolute values instead of percentages). This functionality is available when the widget is displayed on the dashboard and when the TV mode is on.

Basics of managing Table graphs

Graphs of this type display data in a table format.

Example:
In the **Events** widget, for which the SQL query `SELECT TenantID , Timestamp , Name , DeviceProduct , DeviceVendor FROM `events` LIMIT 10` is specified, displays an event table with **TenantID**, **Timestamp**, **Name**, **DeviceProduct**, and **DeviceVendor** columns. The table contains 10 rows.

You can customize the display of data in the table using two-color (red and green) or three-color (red, yellow, and green) gradient fill. After selecting the type of gradient, you can adjust the direction of the fill by clicking the toggle direction icon (⇆) and set thresholds. Two values must be specified for a two-color gradient, and three for a three-color gradient. These values are displayed in the legend and determine the color of the marker added to the cell of the selected column. The column is specified in the **Field for gradient indicator** drop-down list.

Basics of managing Bar chart graphs

A bar chart with a legend is displayed below the list of tenants. The legend lists the names of the categories corresponding to the bars of the diagram. By left-clicking a category in the legend, you can go to the section of OSMP Console with the corresponding data. The data in that section is sorted in accordance with the filters and/or search query specified in the widget.

When going from the legend of the widget to the events details section, pay attention to the text of the legend item that you click to go to the events section. Any \ or ' characters used in the text are escaped in the text of the SQL query. However, the / character is not escaped.

Example:
In the **a Netflow top internal IPs** widget for which the SQL query `SELECT sum(BytesIn) AS metric, DestinationAddress AS value FROM `events` WHERE (DeviceProduct = 'netflow' OR DeviceProduct = 'sflow') AND (inSubnet(DestinationAddress, '10.0.0.0/8') OR inSubnet(DestinationAddress, '172.16.0.0/12') OR inSubnet(DestinationAddress, '192.168.0.0/16')) GROUP BY DestinationAddress ORDER BY metric DESC LIMIT 10` is specified, the x-axis of the chart corresponds to the total traffic in bytes, and the y-axis corresponds to destination port addresses. The data is grouped by destination address in descending order of total traffic.

You can also customize the display of bars using two-color (red and green) or three-color (red, yellow, and green) gradient fill. After selecting the type of gradient, you can adjust the direction of the fill by clicking the toggle direction icon (⇆) and set thresholds. Two values must be specified for a two-color gradient, and three for a three-color gradient. These values are displayed in the legend and determine the coloring of the bars.

Basics of managing Date Histogram graphs

A Date Histogram with a legend is displayed below the list of tenants. The legend lists the names of the categories corresponding to the bars of the diagram. By left-clicking a category in the legend, you can go to the section of OSMP Console with the corresponding data. The data in that section is sorted in accordance with the filters and/or search query specified in the widget.

When going from the legend of the widget to the events details section, pay attention to the text of the legend item that you click to go to the events section. Any \ or ' characters used in the text are escaped in the text of the SQL query. However, the / character is not escaped.

If, when creating a widget with a **Date Histogram** type, the **Bar chart** view is selected, you can customize the display of the bars using two-color (red and green) or three-color (red, yellow, and green) gradient fill. After selecting the type of gradient, you can adjust the direction of the fill by clicking the toggle direction icon (⇆) and set thresholds. Two values must be specified for a two-color gradient, and three for a three-color gradient. These values are displayed in the legend and determine the coloring of the bars.

Example:

```
SELECT count(ID) AS `metric`, Timestamp AS `value`
FROM `events`
GROUP BY Timestamp
ORDER BY `metric` DESC
LIMIT 250
```

The X axis of the chart shows the date when the event was created, and the Y axis shows the number of events. The bars of the chart are arranged from left to right in descending order of the number of events.

If an additional field with the `category` alias is used in the SQL query, the bar chart is displayed as a stacked bar chart. In this case, gradient fill is not applied.

Example:

```
SELECT count(ID) AS `metric`, Timestamp AS `category`, Type AS `value`
FROM `events`
GROUP BY Timestamp, Type
ORDER BY metric DESC
LIMIT 250
```

The X axis indicates the time intervals, and the Y axis indicates the number of events. Each segment of the bar corresponds to a value of the field marked as **Type**.

If, when creating a widget with a **Date Histogram** type, the **Line chart** view is selected, there are two options for displaying the chart: single line (if only the `metric` and `value` fields are specified in the query) and multiple lines (if an additional field with the `category` alias is used). This lets you compare values for different groups, depending on which field is used for grouping in the query. For example, correlation rules, users, or hosts can be used. No gradient fill is applied to such charts.

Example:

```
SELECT count(ID) AS `metric`, Timestamp AS `category`, CorrelationRuleName AS `value`
FROM `events`
WHERE Type = 3
GROUP BY Timestamp, CorrelationRuleName
ORDER BY metric DESC
LIMIT 250
```

The chart displays the intervals on the X-axis (the field specified as the `category`). The Y-axis displays the number of times the correlation rules were triggered (the field marked as `metric`). Each line on the chart corresponds to a unique value in the `value` field (in this case, the name of the correlation rule).

You can use the following time fields for grouping in a Date Histogram:

- `Timestamp`
- `DeviceCustomDate1`
- `DeviceCustomDate2`
- `EndTime`
- `FileCreateTime`
- `FileModificationTime`
- `FlexDate1`
- `OldFileCreateTime`
- `OldFileModificationTime`
- `DeviceReceiptTime`
- `StartTime`

> For convenience, we recommend using supported ClickHouse functions to round the values in the time field (**Timestamp**), for example, to 1 hour or 1 day.

For a **Date Histogram** widget with the **Line chart** view, you can also configure the display of the average value. To do this, on the **Appearance** tab, for the **Regression** setting, select **LOESS**.

Basics of managing Line chart graphs

A line chart with a legend is displayed below the list of tenants. The legend displays the names of the categories corresponding to the lines on the chart. By left-clicking a category in the legend, you can go to the section of OSMP Console with the corresponding data. The data in that section is sorted in accordance with the filters and/or search query specified in the widget.

When going from the legend of the widget to the events details section, pay attention to the text of the legend item that you click to go to the events section. Any \ or ' characters used in the text are escaped in the text of the SQL query. However, the / character is not escaped.

Example:

In the **Events** widget, for which the SQL query `SELECT count(ID) AS `metric`, SourcePort AS `value` FROM `events` GROUP BY SourcePort ORDER BY `value` ASC LIMIT 250` is specified, the x-axis corresponds to the approximate port number, and the y-axis corresponds to the number of events. The data is grouped by port number in ascending order.

For a **Line chart** widget, you can also configure the display of the average value. To do this, on the **Appearance** tab, for the **Regression** setting, select **Linear**. If the chart displays multiple categories, the average is displayed for each category.

Basics of managing graphs of the Stacked bar chart type

A stacked bar chart with a legend is displayed below the list of tenants. The legend displays the names of the categories that make up parts of each bar. To the left of each category is a check box that lets you hide or show the category. The number of bars in the chart corresponds to the number of values in the selected grouping. The bars have captions. The color of the corresponding category in the bar is assigned automatically. When you hover over the zones of the bars, a tooltip is displayed with the value and a description of the value. You can left-click a category in the legend to go to the section of OSMP Console with the relevant data.

When going from the legend of the widget to the events details section, pay attention to the text of the legend item that you click to go to the events section. Any \ or ' characters used in the text are escaped in the text of the SQL query. However, the / character is not escaped.

The meaning of bar height depends on the **Format** setting:

- If the **Absolute values** format is configured, the height of the bars corresponds to the sum of the values of the measured figure.

- If the **Relative values, %** format is configured, all bars have the same height of 100%, and the relative heights of colored zones on the bars correspond to the ratios of the values.

If, when creating a custom widget based on the stacked bar chart, you selected the **Show data for previous period** option, and the standard `value`, `category`, `metric` aliases are used in the query, the chart displays previous-period data as separate bars. However, if instead of the standard `metric`, the query uses a custom metric calculation with non-standard aliases, the **Show data for previous period** is not taken into account when displaying the chart (see example queries below).

Examples:
When creating a custom widget of the **Stacked Bar chart** type based on an SQL query of an **Events** widget, the following rules apply:

- The field in the query that is marked as the `value` alias (required field) is used in the chart as the field by which the legend is created and the bars are divided into categories.
- The field in the query that is marked as the `category` alias (required field) is used in the chart as the field that defines the arrangement of bars along the X axis.
- The field in the query marked as the `metric` alias is used in the chart as the field that defines how bar areas are counted. In this case, the distribution is performed automatically.

However, you can manage the count by using standard aggregation functions (`sum`, `avg`, `min`, `max`, `count`) and your own arbitrarily named aliases as metrics instead of the standard `metric` alias (in this case, the display of data for the previous period is not supported).

Example 1:
For the **Events** widget, the following SQL query is specified with standard aliases, and the **Show data for previous period** option was selected when creating the widget:

```
SELECT count(ID) AS `metric`,

Type AS `value`,

TenantID AS `category`

FROM `events`

GROUP BY value, category

ORDER BY metric DESC
```

The X-axis stands for tenants (the field marked as the `category`), the Y-axis stands for the number of events of a certain type (the field marked as the value). Inside each bar, the quantity corresponding to a certain type is represented by a certain color. In the legend, the names of the event types by which the bars are divided are displayed as categories. Each category has an automatically assigned corresponding color on the bar. If you want to view only certain event types in the chart, you can clear or select the check boxes to the left of the corresponding event types in the legend.

Next to each bar, an additional bar is displayed with historical data, if such data was received in the query response.

Example 2:
For the **Events** widget, the following SQL query is marked with custom metrics marked as the `Base` and `Audit` aliases instead of the standard `metric` alias:

```
SELECT SUM(IF (Type = 1,1,0)) AS `Base`,

SUM(IF (Type = 4,1,0)) AS `Audit`,

TenantID as `category`

FROM `events`

GROUP BY category
```

The X-axis stands for tenants (the field marked as `category`), the Y-axis stands for the number of events of each type (custom metrics marked as the Base and Audit aliases). Inside each bar, the quantity corresponding to a certain metric is represented by a certain color. In the legend, the `Base` and `Audit` metrics by which the bars are divided into categories are displayed as category names. Each category has an automatically assigned corresponding color on the bar. If you want to view only event corresponding to a certain metric in the chart, you can clear or select the check boxes to the left of the relevant metric in the legend.

The additional bar with historical data is not displayed for a query with custom metrics, even if the Show data for previous period option was selected when creating the widget.

Example 3:
For the **Events** widget, the following SQL query is specified with standard aliases:

```
SELECT count(ID) AS `metric`,

TenantID as `value`,

Type as `category`

FROM events
```

```
GROUP BY value, category

ORDER BY metric DESC
```

In contrast to the similar query in example 1, in this case, the X-axis stands for the types of events (the field marked as the `category`), and the tenants (the field marked as the `value`) are represented by ranges of values in the bars (along the X axis) and the corresponding captions in the legend.

Example 4:
For the **Events** widget, the following SQL query is specified with standard aliases:

```
SELECT count(ID) AS `metric`,

CAST(fromUnixTimestamp64Milli(Timestamp) AS DATE) AS `category`,

Type as `value`

FROM `events`

GROUP BY category, value

ORDER BY category DESC
```

The chart displays the days of the month on the X axis (the field marked as the `category`). The Y axis displays the number of events of a particular type (the field marked as the `value`).

To create a similar chart with bars arranged by date and/or time, use a query with grouping and sorting by the following fields of the `timestamp` type:

- `Timestamp`
- `DeviceCustomDate1`
- `DeviceCustomDate2`
- `EndTime`
- `FileCreateTime`
- `FileModificationTime`
- `FlexDate1`
- `OldFileCreateTime`
- `OldFileModificationTime`
- `DeviceReceiptTime`
- `StartTime`

> We recommend using the **Date Histogram** to work with data that is arranged by date and/or time.

Basics of managing Speedometer charts

This type of chart displays the percentage of the number of objects of the selected category vs the total number of objects for a certain period. The **Speedometer chart** can be used for the following objects:

- Assets in a category that satisfy certain criteria vs the total number of assets in the same category or uncategorized assets
- Alerts that satisfy certain criteria vs the total number of alerts for a certain period

- Incidents that satisfy certain criteria vs the total number of incidents
- Events that satisfy certain criteria vs the total number of events for a certain period

The value on the chart is displayed as a percentage with a color matching the configured ranges of values. By default, the following ranges are specified: 0–30, 30–70, 70–100.

Example 1:
In the **Assets** customized widget, the user selects an asset category for comparing the number of assets in it with the total number of assets. The user can specify threshold values for the scale on the graph. Then, based on one or more conditions for the Y-axis, a calculation is performed with the existing asset database.

Example 2:
In the **Alerts** widget, you can select the **Speedometer chart** chart type for the **Active alerts** and **Unassigned alerts** categories. For alerts, a tenant and a period for analysis are selected. By default, these values match the values specified in the relevant dashboard. In the total number of alerts, you can also display data for the previous period.

The percentage value for the **Active incidents** and **Unassigned incidents** categories is calculated in the same way in the **Incidents** widget.

Example 3:
In the **Events** widget, for the **Speedometer chart** chart type, the user specifies a tenant, a period for analysis, and the event data storage. The SQL query is displayed as follows:

```
SELECT count(ID) AS `metric`, SourcePort AS `value` FROM `events` GROUP BY SourcePort ORDER BY value ASC LIMIT
250
```

Special considerations for displaying data in widgets

Limitations for the displayed data

For improved readability, KUMA has limitations on the data displayed in widgets depending on its type:

- Pie chart displays a maximum of 20 slices.
- Bar chart displays a maximum of 40 bars.
- Table displays a maximum of 500 entries.
- Date histogram displays a maximum of 365 days.

Data that exceeds the specified limitations is displayed in the widget in the **Other** category.

You can download the full data used for building analytics in the widget in CSV format.

Summing up the data

The format of displaying the total sum of data on date histogram, bar chart and pie chart depends on the locale:

- English locale: decades (every three digits) are separated by commas, the decimal part is separated by a period.
- Russian locale: decades (every three digits) are separated by spaces, the decimal part is separated by a comma.

Creating a widget

You can create a widget in a dashboard layout while creating or editing the layout.

To create a widget:

1. In the main menu, go to **Monitoring** → **Dashboard**, and the select the **Analysis and response** tab.
2. Create a layout or switch to editing mode for the selected layout.
3. Click **Add widget**.
4. Select a widget type from the drop-down list.
   The window with widget parameters opens.
5. Edit the widget settings.
6. If you want to see how the data will be displayed in the widget, click **Preview**.
7. Then click the **Add** button.

The widget appears in the dashboard layout.

Editing a widget

To edit widget:

1. In the main menu, go to **Monitoring** → **Dashboard**, and the select the **Analysis and response** tab.
2. Expand the list in the upper right corner of the window.
3. Hover the mouse cursor over the relevant layout.
4. Click the edit button ( ).
   The **Customizing layout** window opens.
5. In the widget you want to edit, click the settings icon ( ).
6. Select **Edit**.
   The window with widget parameters opens.
7. Edit the widget settings.
8. Click **Save** in the widget settings window.
9. Click **Save** in the **Customizing layout** window.

The widget is edited.

Deleting a widget

To delete a widget:

1. In the main menu, go to **Monitoring** → **Dashboard**, and the select the **Analysis and response** tab.
2. Expand the list in the upper right corner of the window.
3. Hover the mouse cursor over the relevant layout.
4. Click the edit button ( ).
   The **Customizing layout** window opens.
5. In the widget you want to delete, click the settings icon ( ).
6. Select **Delete**.
7. In the opened confirmation window, click **OK**.
8. Click **Save**.

The widget is deleted.

Widget settings

This section describes the settings of all widgets available in KUMA.

Events widget

You can use the **Events** widget to get analytics based on SQL queries.

When creating this widget, you must specify the settings described in the tables below.

General tab

The following table describes the settings on the **General** tab.

Description of parameters

Parameter	Description
Graph	Graph type. The following graph types are available: • **Pie chart** • **Bar chart** • **Counter** • **Line chart** • **Table** • **Date Histogram** • **Stacked Bar chart** • **Speedometer chart**
Format	Data display format: **Absolute values** or **Relative values, %**. The setting is available for a **Stacked Bar chart**. If you select the **Absolute values** format, the heights of the bars correspond to the sum of the values of the measured indicator. If you select the Relative values, % format, all bars have the same height of 100%, and the relative heights of colored zones on the bars correspond to the ratios of indicator values. By default, **Absolute values** is selected.

Parameter	Description
Timeline view	Time data display format: **Bar chart** or **Line chart**. This setting is available for charts of the **Date Histogram** type. When you select the **Bar chart** format, the data is displayed as vertical bars by default. If the SQL query contains an additional field with the category alias, the chart becomes a stacked bar chart, that is, each bar is divided into stripes in accordance with the values of this field. When you select the **Line chart** format, the data is displayed as one or more (depending on the query) polylines drawn through points on the time axis. The **Bar chart** format is selected by default.
Tenant	The tenant for which data is displayed in the widget. You can select multiple tenants. By default, data is displayed for tenants selected in layout settings.
Time interval	Period for which data is displayed in the widget. The default is **As layout**, meaning that data is displayed for the period selected for the layout. You can also specify a period for the widget in one of the following ways: • Select the exact start and end date and time of the period in the calendar and click **Apply**. • Select a period relative to the present time in the **Relative period** list. • Specify a value manually: select an exact date and time or a relative period, or a combination of both. For details, see the *Configuring a period* subsection below.
Show data for previous period	Enable the display of data for two periods at the same time: for the current period and for the previous period. When using a **Stacked Bar chart**, the **Show data for previous period** setting is taken into account if the query contains standard aliases: `value`, `category`, `metric`. However, if instead of the standard metric, the query uses a custom metric calculation with non-standard aliases, the **Show data for previous period** is not taken into account.
Defined variables	Local or global variables that you can use to filter widget data. Then click the **Add** button. If you are adding a local variable, enter an arbitrary name for the variable, then enter the value of the variable. If you are adding a global variable, in the list, select the name of the variable that you specified in the dashboard properties.
Storage	Storage that is searched for events. The list displays the available spaces. You can select only one storage, but you can select one or more spaces. The values in the **Storage** field are independent of the selected tenants in the **Tenant** field. The field displays storages and spaces, like in the **Events** section. When a new space is created in the storage, this new space is not selected by default in the widget settings. You must manually select the new space. If the user has access to all spaces listed in the widget, the widget can display the event information for tenants specified in the space set in the user's permissions. If the user does not have access rights to one or more spaces of the storage, the widget cannot display information; the user cannot edit the widget, but can duplicate the widget using the **Duplicate** button. Duplication does not depend on access rights to spaces. If a template is duplicated in widgets that have spaces specified that are not accessible to the user, the value in the **Storage** field is reset. Such widgets display an error: Access denied (Operation returns no results because of allowed and selected event spaces). To save the template, you need to specify spaces in widgets. In widgets that have spaces that are accessible to the user, the value of the **Storage** field is not reset and is saved when the template is duplicated. When the user downloads the template, the data of inaccessible files are hidden in the downloaded file. If the user's email address is included in the list of recipients of the scheduled report, the user gets the full version of the report, regardless of which spaces are accessible.

Parameter	Description

SQL query field	Query for filtering and searching for events manually. You can create a query in Builder by clicking **Use sql builder**.
	You can use extended event schema fields to create a chart of the **Table** type.
	Example
	Prerequisite:
	Events are coming from a FWSaaS system.
	10.08.2023 12:12:12 src=10.10.10.10 ReqUrls=[https://google.com, https:/ya.ru]
	10.08.2023 12:12:23 src=10.10.10.20 ReqUrls=[https://google.com, https:/yandex.ru]
	10.08.2023 12:12:33 src=10.10.10.30 ReqUrls=[https://google.com, https:/ya.ru, https://mail.ru]
	The KUMA Main administrator has added an extended event schema field in KUMA in the **Settings** → **Other** → **Advanced event schema fields** section. At the KUMA normalizer, field mapping is configured for the **ReqUrls** and **SA.urls** fields.
	In KUMA, normalized events look as follows:
	DeviceReceiptTime=10.08.2023 12:12:12 SourceAddress=10.10.10.10 SA.urls=[https://google.com, https:/ya.ru]
	DeviceReceiptTime=10.08.2023 12:12:23 SourceAddress=10.10.10.20 SA.urls=[https://google.com, https:/yandex.ru]
	DeviceReceiptTime=10.08.2023 12:12:30 SourceAddress=10.10.10.30 SA.urls=[https://google.com, https:/ya.ru, https://mail.ru]
	You want to build a "Top URLs for 30 minutes" dashboard. Here is an example of a request in the **Events** section and in widgets:
	`SELECT res.1 AS url, res.2 AS count FROM ( SELECT arrayJoin(groupArray((url, count))) AS res FROM ( SELECT url, count() AS count FROM ( SELECT SA.urls AS urls FROM `events` ) ARRAY JOIN urls AS url GROUP BY url ) GROUP BY url )`
	Result:
	url count
	google.com 3
	ya.ru 2
	mail.ru 1
	yandex.ru 1
	
	KUMA supports the following functions that allow using arrays in queries:
	• The `groupArray` function packs all values of the x argument into an array and is used in aggregate functions when grouping data.
	• The `arrayJoin` function expands the array into separate strings as a result of the query.
	You can use variables in the SQL query. You can specify variables only when creating the query manually. You cannot use variables in the SQL builder.
	Example with variables
	Example SQL query with a local variable:
	`SELECT count(ID) AS 'metric', Name AS 'value', TenantID AS 'category' FROM 'events' WHERE filter(Name = $Name) GROUP BY Name, TenantID ORDER BY metric DESC LIMIT 250`
	This query uses the local variable `$Name`. Value of the **Name event** field are substituted into this variable. You can apply the variable by clicking the funnel icon ( ) on the widget. This opens a window; in that window, you can specify a value for the variable. The widget filters the selection by the selected value of the **Name** field.
	Note that if in the SQL query you specify a variable for a field that takes a numeric value, such a value must be converted to a string. You can do this using the `toString` function. Otherwise, the SQL query returns an error. Example:
	`SELECT count(ID) AS `metric`, SourcePort AS `value` FROM `events` WHERE (filter(toString(SourcePort) like $SourcePort)) GROUP BY SourcePort ORDER BY value ASC LIMIT 250`
	In this query, the **SourcePort event** field has a numeric value, therefore it is converted to a string: `toString(SourcePort)`.
	
	For detailed information on creating an SQL query in the query constructor, see below.
	The following limitations apply:
	• The `metric` and `value` aliases in SQL queries cannot be edited for any type of event analytics widget, except tables.
	• Aliases in widgets with charts of the **Table** type can contain Latin and Cyrillic characters, as well as spaces. When using spaces or Cyrillic, the alias must be enclosed in quotation marks: `"An alias with a space"`, `` `Another alias` ``.
	• `ARRAY JOIN SQL` queries are not supported.
	• When displaying data for the previous period, sorting by the `count(ID)` parameter may not work correctly. It is recommended to sort by the metric parameter. For example, `SELECT count(ID) AS "metric", Name AS "value" FROM `events` GROUP BY Name ORDER BY metric ASC LIMIT 250`.
	• In widgets with charts of the **Counter** type, you must specify the method of data processing for the values of the `SELECT` function: `count`, `max`, `min`, `avg`, `sum`.
	• In widgets with charts of the **Table** type, the gradient is drawn based on the values of a number or time field (for example, `Timestamp`) specified in the SQL query. This field can be selected from the **Field for gradient indicator** drop-down list (if the query contains multiple number or time fields, any one of these can be selected). After this, the cells of the selected column are highlighted with gradient fill markers. If a field is not present in the query, the **Appearance** tab does not display the **Gradient** and **Field for gradient indicator** fields.
	• In Stacked Bar chart widgets, `Timestamp` values are not displayed on the x-axis when using a standard query. If you want to display time along the X axis, we recommend using a **Line chart**. If you need to use a **Stacked Bar chart**, the `Timestamp` value must be converted to string: `toString(Timestamp) AS `category``.

Configuring a period

To configure the data display period, do one of the following:

- If necessary, change the date and time in the **Time period** setting in one of the following ways:

  - If you want to specify an exact date, in the calendar on the left, select the start and end date of the period and click **Apply**.

    You can select a date up to and including the current date. The date and time format depends on your browser settings. If the **Range from** or **Range to** field has a value and you have not edited the time value manually, when you select a date in the calendar, the **Range from** field is automatically populated with 00:00:00.000, and the **Date to** field with 23:59:59.999. If you have manually deleted the value in the **Range from** or **Range to** field, when you select a date in the calendar, the field is automatically populated with the current time. After you select a value in one of the fields, the focus switches to the other field. If your **Range to** is earlier than your **Range from**, this earlier value is automatically inserted into the **Range from** field.

  - If you want to specify a relative period, select one of the available periods in the **Relative period** list on the right.

    The period is calculated relative to the current time.

  - If you want to specify a custom period, edit the value of the **Range from** and **Range to** fields.

    You can enter an exact date and time in the **DD.MM.YYYY HH:mm:ss.SSS** format for the Russian localization and **YYYY-MM-DD HH:mm:ss.SSS** for the English localization or a period relative to the current time as a formula. You can also combine these methods if necessary. If you do not specify milliseconds when entering the exact date, 000 is substituted automatically. If you have edited the time in the **Range from** or **Range to** fields, picking a date in the calendar does not change the time component.

    In the relative period formulas, you can use the **now** parameter for the current date and time and the interval parameterization language: + (only in the **Range to** field), -, / (rounding to the nearest), as well as time units: **y** (year), **M** (month), **w** (week), **d** (day), **h** (hour), **m** (minute), **s** (second). For example, you can specify the period **now-5d** to get data for the last five days, or **now/w** to get data from the beginning of the first day of the current week (00:00:00:000 UTC) to the current time (**now**).

    > The **Range from** field is required, and its value cannot exceed the value of the **Range to** field, and also cannot be earlier than 1970-01-01 (if specifying an exact date or a relative period). The **Range to** cannot be earlier than the **Range from**. If you do not specify a value in the **Range to** from field, **now** is specified automatically.

KUMA stores time values in UTC, but in the user interface time is converted to the time zone of your browser. This is relevant to the relative periods: **Today**, **Yesterday**, **This week**, and **This month**. For example, if the time zone in your browser is UTC+3, and you select **Today** as the data display period, data will be displayed for the period from 03:00:00.000 until now, not from 00:00:00.000 until now.

If you want to take your time zone into account when selecting a relative data display period, such as **Today**, **Yesterday**, **This week**, or **This month**, you need to manually add a time offset in the **Range from** and **Range to** (if a value other than now is specified) by adding or subtracting the correct number of hours. For example, if your browser's time zone is UTC+3 and you want to display data for **Yesterday**, you need to change **Range from** to **now-1d/d-3h** and **Date to** to **now/d-3h**. If you want to display data for the **Today** period, you only need to change the value in the **Range from** field to **now/d-3h**.

> If you need results up to 23:59:59:999 UTC of yesterday, you can use an SQL query with a filter by Timestamp or specify an exact date and time.

The bounds of the period are inclusive: for example, for the **Today** time range, events are displayed from the beginning (00:00:00:000 UTC) of the current day to the current time (**now**) inclusive, and for the **Yesterday** period, events are displayed from the beginning (00:00:00:000 UTC) of the previous day to 00:00:00:000 UTC of the current day. You can view the date and time of the last data update and the exact period for which the data is displayed by hovering over the period icon in the widget.

If the Show data for previous period setting is enabled for the widget, and the widget is displaying data for a relative period, the tooltip also displays the previous period. The previous period is calculated relative to the current period as start and end values of the current period minus the duration of the current period. For example, if data is updated daily and displayed for a month, but only the first 10 days of the month have passed, the previous period is taken to be the last 10 days of the previous month.

- If you want the widget to display data for the period selected for the layout, click the **Reset** button. Changing the displayed period on the layout also changes the period displayed in the widget.

How to create a query in Builder

To create a query in Builder:

1. Specify the values of the following parameters:

   a. **SELECT**—event fields that should be returned. The number of available fields depends on the selected graph type.

   - In the drop-down list on the left, select the event fields for which you want to display data in the widget.
   - The middle field displays what the selected field is used for in the widget: **metric** or **value**.

     If you selected the **Table** graph type, in the middle fields, you must specify column names using ANSII-ASCII characters.

   - In the drop-down list on the right, you can select an operation to be performed on the data:
     - **count**—event count. This operation is available only for the **ID** event field. Used by default for line charts, pie charts, bar charts, and counters. This is the only option for date histogram.
     - **max** is the maximum value of the **event** field from the event selection.
     - **min** is the minimum value of the **event** field from the event selection.
     - **avg** is the average value of the **event** field from the event selection.
     - **sum** is the sum of event field values from the event selection.

   b. **SOURCE** is the type of the data source. Only the **events** value is available for selection.

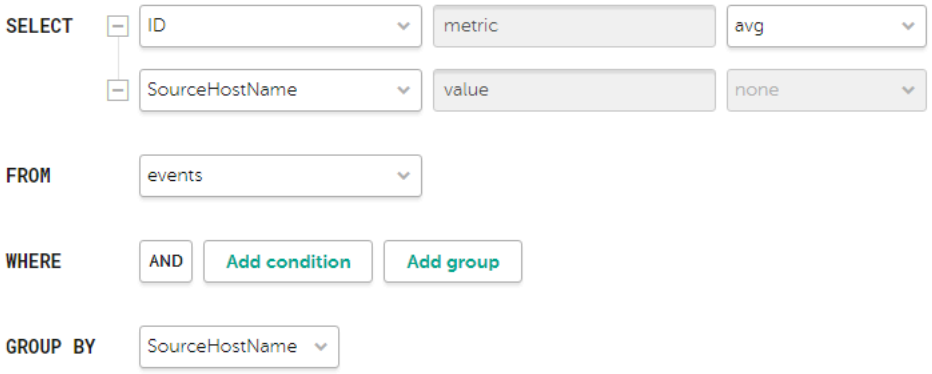
   c. **WHERE**—conditions for filtering events.

   - In the drop-down list on the left, select the event field that you want to use for filtering.
   - Select the necessary operator from the middle drop-down list. The available operators depend on the type of value of the selected event field.
   - In the drop-down list on the right, enter the value of the condition. Depending on the selected type of field, you may have to manually enter the value, select it from the drop-down list, or select it on the calendar.

You can add search conditions by clicking **Add condition** or remove search conditions by clicking ×.

You can also add groups of conditions by clicking **Add group**. By default, groups of conditions are added with the **AND** operator, but you can change the it if necessary. Available values: **AND**, **OR**, **NOT**. Group conditions are deleted using the **Delete group** button.

d. **GROUP BY**—event fields or aliases to be used for grouping the returned data. This parameter is not available for Counter graph type.



e. **ORDER BY**—columns used as the basis for sorting the returned data. This parameter is not available for the **Date Histogram** and **Counter** graph types.

- In the drop-down list to the left, select the value that will be used for sorting.
- Select the sort order from the drop-down list on the right: **ASC** for ascending, **DESC** for descending.
- For **Table** type graphs, you can add sorting conditions by clicking **Add column**.

f. **LIMIT** is the maximum number of data points for the widget. This parameter is not available for the **Date Histogram** and **Counter** graph types.

2. Click **Apply**.

Example of search conditions in the query builder

Parameters of search conditions for displaying the average number of bytes per host in the widget

Axes tab

The following table describes the settings on the **Axis** tab.

The tab is displayed if on the **General tab in the Graph** field you have selected one of the following values: **Bar chart**, **Line chart**, **Date Histogram**.

Description of parameters

Setting	Description
Point size	Point size on the graph. This field is displayed for the **Line chart** graph type.
Line-width	Width of the line on the graph. This field is displayed for the **Line chart** graph type.
Minimum and maximum values for the Y-axis	Scale of the Y axis. Negative values can be displayed on chart axes. This is due to the scaling of charts on the widget and can be fixed by setting zero as the minimum chart values instead of **Auto**.

Setting	Description
Minimum and maximum values for the X-axis	Scale of the X axis. Negative values can be displayed on chart axes. This is due to the scaling of charts on the widget and can be fixed by setting zero as the minimum chart values instead of **Auto**.
Decimals	Number of decimals to which the displayed value must be rounded off.

Appearance tab

The following table describes the settings on the **Appearance** tab.

Description of parameters

Setting	Description
Name	Name of the widget.
Description	Description of the widget.
Show legend	Displays a legend for the analytics. The toggle switch is turned on by default.
Show nulls in legend	Displays parameters with a null value in the legend for analytics. The toggle switch is enabled by default. Null values are displayed only when the **Show data for previous period** setting is enabled and there is no data for the current period, but there was some data for the previous period.
Color	The color used for displaying the information: • **default** for your browser's default font color • **green** • **red** • **blue** • **yellow** This setting is available for graphs such as **Bar chart**, **Counter**, **Line chart**, **Date Histogram**.
Gradient	Gradient fill of the chart: • Two colors (red and green) • Three colors (red, yellow, and green) This setting is available for charts such as **Bar chart**, **Date Histogram**(with the **Bar chart** type), **Table**. You can adjust the direction of the fill by clicking the toggle direction icon (⇆); you can also set thresholds. If not set manually, gradient thresholds are calculated automatically from the data. If there is no data between the specified thresholds, the gradient is not applied. Instead, two colors are used: one for values below the lower threshold, and the other for values above the upper threshold.
Field for gradient indicator	The column in which the gradient fill indicators are displayed. This setting is available for charts of the **Table** type.
Horizontal	Makes the histogram horizontal instead of vertical. When this option is enabled, when a widget displays a large amount of data, horizontal scrolling is not available and all available information is fit into the fixed size of the widget. If there is a lot of data to display, it is recommended to increase the widget size.
Show total	Shows sums total of the values.
Period segments length	Duration of the segments into which you want to divide the period. Available for a graph of the **Date Histogram** type.
Scale	Scale for displaying data. Available for a **Stacked Bar** chart. The following values are possible: • **Linear** • **Square** • **Logarithm** The default is **Linear**.
Regression	An option for indicating the average value on the chart. The following values are possible: • **Not set** • **Linear** • **LOESS** (curve with locally estimated scatterplot smoothing). Available for the **Date Histogram** and **Line chart** types.

Actions tab

This tab is not displayed if you have selected one of the following values on the **General** tab, in the Graph field: **Counter**, **Speedometer chart**, **Table**.

Settings on this tab let you configure left-click actions on various elements of widgets, for example, on a chart segment or the text of a legend item. You can select the following actions:

- Go to events.
- Filter by variable.

  The settings are described in the scenario for filtering data in multiple widgets.
- Drill down to another dashboard.

  The settings are described in the scenario for drilling down to another dashboard.

Active lists widget

You can use the **Active lists** widget to get analytics based on SQL queries.

When creating this widget, you must specify the settings described in the tables below.

General tab

The following table lists the settings that must be specified on the **Common** tab.

Description of parameters

Parameter	Description
Graph	Graph type. The following graph types are available: • **Bar chart** • **Pie chart** • **Counter** • **Table**
Tenant	The tenant for which data is displayed in the widget. You can select multiple tenants. By default, data is displayed for tenants selected in layout settings.
Correlator	The name of the correlator that contains the active list for which you want to receive data.
Active list	The name of the active list for which you want to receive data. The same active list can be used by different correlators. However, a separate entity of the active list is created for each correlator. Therefore, the contents of the active lists used by different correlators differ even if the active lists have the same names and IDs.

Parameter	Description
SQL query field	This field lets you manually enter a query for filtering and searching active list data. The query structure is similar to that used in event search. When creating a query based on active lists, you must consider the following: • For the FROM function, you must specify the `records` value. • If you want to receive data for fields whose names contain spaces and Cyrillic characters, you must also enclose such names in quotes in the query: • In the SELECT function, enclose aliases in double quotes or backticks: "alias", `another alias`. • In the ORDER BY function, enclose aliases in backticks: `another alias`. • Event field values are enclosed in straight single quotes: WHERE DeviceProduct = 'Microsoft'. • Names of event fields do not need to be enclosed in quotes. • If the name of an active list field begins or ends with spaces, these spaces are not displayed by the widget. The field name must not contain spaces only. • If the values of the active list fields contain trailing or leading spaces, it is recommended to use the LIKE '%field value%' function to search by them. • In your query, you can use service fields: _key (the field with the keys of active list records) and _count (the number of times this record has been added to the active list), as well as custom fields. • The "metric" and "value" aliases in SQL queries cannot be edited for any type of active lists analytics widget, except tables. • If a date and time conversion function is used in an SQL query (for example, fromUnixTimestamp64Milli) and the field being processed does not contain a date and time, an error will be displayed in the widget. To avoid this, use functions that can handle a null value. Example: SELECT _key, fromUnixTimestamp64Milli(toInt64OrNull(DateTime)) as Date FROM `records` LIMIT 250. • Large values for the LIMIT function may lead to browser errors. • If you select Counter as the graph type, you must specify the method of data processing for the values of the SELECT function: `count`, `max`, `min`, `avg`, `sum`. • In widgets with a chart of the **Table** type, the gradient is drawn based on the values of the field specified in the SQL query (for example, `_count`, `value`, `temp`, or `name`). This field can be selected from the **Field for gradient indicator** drop-down list (if the query contains multiple number or time fields, any one of these can be selected). After this, the cells of the selected column are highlighted with gradient fill markers. If a field is not present in the query, the **Appearance** tab does not display the **Gradient** and **Field for gradient indicator** fields. Special considerations apply when using aliases in SQL functions and SELECT, you can use double quotes and backticks: ", `. If you selected Counter as the graph type, aliases can contain Latin and Cyrillic characters, as well as spaces. When using spaces or Cyrillic, the alias must be enclosed in quotation marks: "An alias with a space", `Another alias`. When displaying data for the previous period, sorting by the count(ID) parameter may not work correctly. It is recommended to sort by the metric parameter. For example, SELECT count(ID) AS "metric", Name AS "value" FROM `events` GROUP BY Name ORDER BY metric ASC LIMIT 250.

You can get the names of the tenants in the widget instead of their IDs.

If you want the names of tenants to be displayed in active list widgets instead of tenant IDs, in correlation rules of the correlator, configure the function for populating the active list with information about the corresponding tenant. The configuration process involves the following steps:

1. Export the list of tenants.
2. Create a dictionary of the **Table** type and import the previously obtained list of tenants into the dictionary.
3. Add a local variable with the **dict** function for mapping the tenant name to tenant ID to the correlation rule.

Example:

- Variable: `TenantName`
- Value: `dict ('<Name of the previously created dictionary with tenants>', TenantID)`

4. Add an action with active lists to the correlation rule. his action will write the value of the previously created variable in the key-value format to the active list using the **Set** function. As the key, specify the field of the active list (for example, `Tenant`), and in the **Value** field, reference the previously created variable (for example, `$TenantName`).

When this rule triggers, the name of the tenant mapped by the **dict** function to the ID from the tenant dictionary is placed in the active list. When creating widgets for active lists, you can get the name of the tenant by referring to the name of the field of the active list (in the example above, `Tenant`).

The method described above can be applied to other event fields with IDs.

Examples of SQL queries for receiving analytics based on active lists:

- `SELECT * FROM `records` WHERE "Event source" = 'Johannesburg' LIMIT 250`
  This query returns the key of the active list where the field name is "Event source" and the value of this field is "Johannesburg".
- `SELECT count(_key) AS metric, Status AS value FROM `records` GROUP BY value ORDER BY metric DESC LIMIT 250`
  Query for a pie chart, which returns the number of keys in the active list ('count' aggregation over the '_key' field) and all variants of the Status custom field. The widget displays a pie chart with the total number of records in the active list, divided proportionally by the number of possible values for the **Status** field.
- `SELECT Name, Status, _count AS Number FROM `records` WHERE Description ILIKE '%ftp%' ORDER BY Name DESC LIMIT 250`
  Query for a table, which returns the values of the **Name** and **Status** custom fields, as well as the service field '_count' for those records of the active list in which the value of the Description custom field matches ILIKE '%ftp%'. The widget displays a table with the **Status**, **Name**, and **Number** columns.

Axes tab

The following table lists the settings that must be specified on the **Axis** tab.

This tab is displayed if on the **Common** tab, in the **Graph** field, you have selected **Bar chart**.

Description of parameters

Settings	Description
Y-min and Y-max	Scale of the Y axis. Negative values can be displayed on chart axes. This is due to the scaling of charts on the widget and can be fixed by setting zero as the minimum chart values instead of **Auto**.
X-min and X-max	Scale of the X axis. Negative values can be displayed on chart axes. This is due to the scaling of charts on the widget and can be fixed by setting zero as the minimum chart values instead of **Auto**.

Appearance tab

The following table lists the settings that must be specified on the **Appearance** tab.

Description of parameters

Parameter	Description
Name	Name of the widget.
Description	Description of the widget.

Parameter	Description
Color	The color used for displaying the information: • **default** for your browser's default font color • **green** • **red** • **blue** • **yellow**
Gradient	Gradient fill of the chart: • Two colors (red and green) • Three colors (red, yellow, and green) The setting is available for Bar charts and Tables. You can adjust the direction of the fill by clicking the toggle direction icon (⇆); you can also set thresholds. If not set manually, gradient thresholds are calculated automatically from the data. If there is no data between the specified thresholds, the gradient is not applied. Instead, two colors are used: one for values below the lower threshold, and the other for values above the upper threshold.
Field for gradient indicator	The column in which the gradient fill indicators are displayed. This setting is available for charts of the **Table** type.
Horizontal	Makes the histogram horizontal instead of vertical. When this setting is enabled, all available information is fitted into the configured widget size. If the amount of data is great, you can increase the size of the widget to display it optimally.
Show total	Shows sums total of the values.
Show legend	Displays a legend for the analytics. The toggle switch is turned on by default.
Show nulls in legend	Displays parameters with a null value in the legend for analytics. The toggle switch is enabled by default. Null values are displayed only when the **Show data for previous period** setting is enabled and there is no data for the current period, but there was some data for the previous period.

Context tables widget

You can use the **Context tables** widget to get analytics based on SQL queries.

When creating this type of widget, you must set values for the following settings:

The tab:

The following table lists the settings that must be specified on the **Common** tab.

Description of parameters

Setting	Description
Graph	The following graph types are available: • **Bar chart** • **Pie chart** • **Counter** • **Table**
Tenant	The tenant for which data is displayed in the widget. You can select multiple tenants. By default, data is displayed for tenants selected in layout settings.
Correlator	Name of the correlator that contains the context table for which you want to receive information.
Context table	Name of the context table for which you want to receive information. The same context table can be used in multiple correlators. However, a separate entity of the context table is created for each correlator. Therefore, the contents of the context tables used by different correlators are different even if the context tables have the same name and ID.

Setting	Description
SQL query field	This field lets you manually enter a query for filtering and searching context table data. By default, for each widget type, the field contains a query that obtains the context table schema and the key by key fields. The query structure is similar to that used in event search. When creating a query based on context tables, you must consider the following: • For the `FROM` function, you must specify the `` `records` `` value. • You can get data only for the fields specified in the context table schema. • You can use supported features of ClickHouse. • If you want to receive data for fields whose names contain spaces and Cyrillic characters, you must also enclose such names in quotes in the query: • In the `SELECT` function, enclose aliases in double quotes or backticks: "`<alias>`", `` `<another alias>` ``. • In the `ORDER BY` function, enclose aliases in backticks: `` `<another alias>` ``. • Event field values are enclosed in straight quotes: `WHERE DeviceProduct = 'Microsoft'`. • Names of event fields do not need to be enclosed in quotes. • If the name of an active list field begins or ends with spaces, these spaces are not displayed by the widget. The field name must not contain spaces only. • If the values of the active list fields contain trailing or leading spaces, it is recommended to use the `LIKE '%< field value >%'` function to search by them. • You can use the `_count` service field (how many times this record has been added to the context table), as well as custom fields. • The `metric` and `value` aliases in SQL queries cannot be edited for any type of active lists analytics widget, except tables. • If a date and time conversion function is used in an SQL query (for example, `fromUnixTimestamp64Milli`) and the field being processed does not contain a date and time, an error will be displayed in the widget. To avoid this, use functions that can handle a null value. Example: `SELECT _key, fromUnixTimestamp64Milli(toInt64OrNull(DateTime)) as Date FROM` `` `records` `` `LIMIT 250`. • Large values for the `LIMIT` function may lead to browser errors. • If you select **Counter** as the chart type, you must specify the method of data processing for the values of the `SELECT` function: `count`, `max`, `min`, `avg`, `sum`. • In widgets with a chart of the **Table** type, the gradient is available only for fields of the **INT** and **FLOAT** types and for the **_count** field. You can select the field in the **Field for gradient indicator** drop-down list. After this, the cells of the selected column are highlighted with gradient fill markers. Special considerations when using aliases in SQL functions and `SELECT` statements: you may use double quotes and backquotes: ",`. When using spaces or Cyrillic characters, the alias must be enclosed in double quotes: "`<Alias with a space>`", values must be enclosed in straight single quotes: '`<Value with a space>`' When displaying data for the previous period, sorting by the count(ID) parameter may not work correctly. We recommend sorting by the `metric` parameter. For example, `SELECT count(ID) AS "metric", Name AS "value" FROM` `` `events` `` `GROUP BY Name ORDER BY metric ASC LIMIT 250`.

You can get the names of the tenants in the widget instead of their IDs.

If you want the names of tenants to be displayed in active list widgets instead of tenant IDs, in correlation rules of the correlator, configure the function for populating the active list with information about the corresponding tenant. The configuration process involves the following steps:

1. Export the list of tenants.
2. Create a dictionary of the **Table** type and import the previously obtained list of tenants into the dictionary.
3. Add a local variable with the **dict** function for mapping the tenant name to tenant ID to the correlation rule.

Example:

- Variable: `TenantName`
- Value: `dict ('<Name of the previously created dictionary with tenants>', TenantID)`

4. Add an action with active lists to the correlation rule. his action will write the value of the previously created variable in the key-value format to the active list using the **Set** function. As the key, specify the field of the active list (for example, `Tenant`), and in the **Value** field, reference the previously created variable (for example, `$TenantName`).

When this rule triggers, the name of the tenant mapped by the **dict** function to the ID from the tenant dictionary is placed in the active list. When creating widgets for active lists, you can get the name of the tenant by referring to the name of the field of the active list (in the example above, `Tenant`).

The method described above can be applied to other event fields with IDs.

Examples of SQL queries for receiving analytics based on active lists:

- `SELECT * FROM `records` WHERE "Event source" = 'Johannesburg' LIMIT 250`
  This query returns the key of the active list where the field name is "`Event source`" and the value of this field is "`Johannesburg`".
- `SELECT count(_key) AS metric, Status AS value FROM `records` GROUP BY value ORDER BY metric DESC LIMIT 250`
  Query for a pie chart, which returns the number of keys in the active list ('`count`' aggregation over the '**_key**' field) and all variants of the Status custom field. The widget displays a pie chart with the total number of records in the active list, divided proportionally by the number of possible values for the **Status** field.
- `SELECT Name, Status, _count AS Number FROM `records` WHERE Description ILIKE '%ftp%' ORDER BY Name DESC LIMIT 250`
  Query for a table, which returns the values of the **Name** and **Status** custom fields, as well as the service field '**_count**' for those records of the active list in which the value of the Description custom field matches `ILIKE '%ftp%'`. The widget displays a table with the **Status**, **Name**, and **Number** columns.

The tab:

The following table lists the settings that must be specified on the **Axis** tab.

This tab is displayed if on the **Common** tab, in the **Graph** field, you have selected **Bar chart**.

Description of parameters

Setting	Description
Y axis and **Min - Max**	Scale of the Y axis. Negative values can be displayed on chart axes. This is due to the scaling of charts on the widget and can be fixed by setting zero as the minimum chart values instead of **Auto**.
X axis and **Min - Max**	Scale of the X axis. Negative values can be displayed on chart axes. This is due to the scaling of charts on the widget and can be fixed by setting zero as the minimum chart values instead of **Auto**.

The tab:

The following table lists the settings that must be specified on the **Appearance** tab.

Description of parameters

Settings	Description
Name	Name of the widget.
Description	Description of the widget.
Color	The color used for displaying the information: • **default** for your browser's default font color • **green** • **red** • **blue** • **yellow**
Gradient	Gradient fill of the chart: • Two colors (red and green) • Three colors (red, yellow, and green) The setting is available for **Bar charts** and **Tables**. You can adjust the direction of the fill by clicking the toggle direction icon (⇆); you can also set thresholds. If not set manually, gradient thresholds are calculated automatically from the data. If there is no data between the specified thresholds, the gradient is not applied. Instead, two colors are used: one for values below the lower threshold, and the other for values above the upper threshold.
Field for gradient indicator	The column in which the gradient fill indicators are displayed. This setting is available for charts of the **Table** type.
Horizontal	Makes the histogram horizontal instead of vertical. When this setting is enabled, all available information is fitted into the configured widget size. If the amount of data is great, you can increase the size of the widget to display it optimally.
Show total	Shows sums total of the values.
Show legend	Displays a legend for the analytics. The toggle switch is turned on by default.
Show nulls in legend	Displays parameters with a null value in the legend for analytics. The toggle switch is enabled by default. Null values are displayed only when the **Show data for previous period** setting is enabled and there is no data for the current period, but there was some data for the previous period.

Assets customized widget

You can use the **Assets → Customized widget** to get advanced asset analytics from processed events using the query builder. In the query, you need to specify the asset field and the corresponding condition or set of conditions by which you want the assets to be counted (Y-axis). You can also specify one or more additional conditions (categories) to be used for comparing the number of assets for each field.

When creating the custom widget for assets, you must specify the settings described in the tables below.

General tab

The following table describes the settings on the **General** tab.

Description of parameters

Parameter	Description
Name	Name of the widget. When saving a report in Excel format, the name of the widget displayed in the header of the sheet is limited to 31 characters. We recommended keeping this limitation in mind when naming widgets.
Graph	Graph type. The following graph types are available: • **Pie chart**. The distribution of assets by the specified categories is displayed for all selected tenants. • **Counter**. Assets are counted based on a single condition. The chart displays the sum of assets that match the condition across all selected tenants. • **Table**. Assets are counted by the specified categories across all selected tenants. Each category in the chart has a corresponding row. The category name is displayed in the **value** column. The number of assets matching the condition is displayed in the **metric** column. • **Stacked bar chart** Assets are counted by the specified categories across all selected tenants, and you can group assets by tenants (in this case, individual tenants are arranged along the X axis). Each category has its own zone on the bars of the chart, represented by its own color. Category names are displayed in the legend. You can use check boxes to the left of category names to hide or show the corresponding areas on the bars. • **Speedometer chart** Displays the ratio of the number of assets that match the specified criteria to the total number of assets. The values on the graph are indicated as percentages.
Format	The setting is available for a **Stacked bar chart**. Data display format: **Absolute values** or **Relative values, %**. If you select the **Absolute values** format, the heights of the bars correspond to the sum of the values of the measured indicator. If you select the **Relative values, %** format, all bars have the same height of 100%, and the relative heights of colored zones on the bars correspond to the ratios of indicator values. By default, **Absolute values** is selected.
Tenant	The tenant for which data is displayed in the widget. You can select multiple tenants. By default, data is displayed for tenants selected in layout settings.
Asset category	The asset category for which the widget is displaying data.
Search in uncategorized assets	This setting lets you display assets that do not have a category. This check box is cleared by default.
Selecting Graphic Axes group of settings	
Y-axis	Required setting. Asset field and the condition or set of conditions specified for this field, that define how assets are to be counted.
Y axis category	Category for the selected field. Not used for a graph of the **Counter** type. This setting is optional for Y-axis fields whose values are enumerations (can be selected from a finite list of values). For all other fields, this parameter is required.
Group by tenant	The setting is available for a **Stacked bar chart**. Enables additional grouping of assets by tenant. If the check box is selected, assets on the chart are broken up along the X-axis into bars corresponding to individual tenants. If the check box is cleared, all assets are displayed on the same bar. This check box is cleared by default.

Appearance tab.

The following table describes the settings on the **Appearance** tab.

Description of parameters

Setting	Description
Description	Description of the widget.
Show total	This setting is available for charts of the **Pie chart** type. Enables the display of totals in the chart, in addition to the selected categories. If this check box is enabled, the sum of the values of all specified categories is displayed in the center of the pie chart and in the legend in a separate **Total** column. The toggle switch is turned off by default.
Color	This setting is available for charts of the **Counter** type. The color used for displaying the information: • **default** for your browser's default font color • **green** • **red** • **blue** • **yellow**

Setting	Description
Gradient	Gradient fill of the chart: • Two colors (red and green) • three colors (red, yellow, and green) This setting is available for charts of the **Table** type. You can adjust the direction of the fill by clicking the toggle direction icon (⇆); you can also set thresholds. If not set manually, gradient thresholds are calculated automatically from the data. If there is no data between the specified thresholds, the gradient is not applied. Instead, two colors are used: one for values below the lower threshold, and the other for values above the upper threshold.
Field for gradient indicator	The column in which the gradient fill indicators are displayed. This column is determined by the **Metric** field selected in the drop-down list. This setting is available for charts of the **Table** type.
Horizontal	Makes the histogram horizontal instead of vertical. When this option is enabled, when a widget displays a large amount of data, horizontal scrolling is not available and all available information is fit into the fixed size of the widget. If there is a lot of data to display, it is recommended to increase the widget size.
Show legend	Displays a legend for the analytics. The toggle switch is turned on by default.
Show nulls in legend	Displays parameters with a null value in the legend for analytics. The toggle switch is enabled by default. Null values are displayed only when the **Show data for previous period** setting is enabled and there is no data for the current period, but there was some data for the previous period.
Show percentages in legend	Displays percentage values in the legend. The toggle switch is enabled by default.
Decimals	Number of decimals to which the displayed value must be rounded off.
Scale	Available for a **Stacked bar chart**. Scale for displaying data. The following values are possible: • **Linear** • **Square** • **Logarithm** The default is **Linear**.
Threshold	Available for a **Speedometer chart**. By default, the following ranges are specified: 0–30, 30–70, 70–100.

Other widgets

This section describes the settings of all widgets except the **Events**, Active lists, Context tables, and **Custom Asset** widget.

The set of parameters available for a widget depends on the type of graph that is displayed on the widget. The following graph types are available in KUMA:

- Pie chart ().
- Counter ().
- Table ().
- Bar chart ().
- Date Histogram ().
- Line chart

Settings for pie charts

The following table below lists the settings of a **Pie chart**.

Description of parameters

Setting	Description
Name	Name of the widget.
Description	Description of the widget.
Tenant	The tenant for which data is displayed in the widget. You can select multiple tenants. By default, data is displayed for tenants selected in layout settings.
Time interval	Period for which data is displayed in the widget. The default is **As layout**, meaning that data is displayed for the period selected for the layout. You can also specify a period for the widget in one of the following ways: • Select the exact start and end date and time of the period in the calendar and click **Apply**. • Select a period relative to the present time in the **Relative period** list. • Specify a value manually: select an exact date and time or a relative period, or a combination of both. For details, see the *Configuring a period* subsection below.
Show total	Shows sums total of the values.
Show legend	Displays a legend for the analytics. The toggle switch is turned on by default.
Show nulls in legend	Displays parameters with a null value in the legend for analytics. The toggle switch is enabled by default.
Decimals	Number of decimals to which the displayed value must be rounded off.

Settings for counters

The following table below lists the settings of a **Counter**.

Description of parameters

Parameter	Description
Name	Name of the widget.
Description	Description of the widget.
Tenant	The tenant for which data is displayed in the widget. You can select multiple tenants. By default, data is displayed for tenants selected in layout settings.
Time interval	Period for which data is displayed in the widget. The default is **As layout**, meaning that data is displayed for the period selected for the layout. You can also specify a period for the widget in one of the following ways: • Select the exact start and end date and time of the period in the calendar and click **Apply**. • Select a period relative to the present time in the **Relative period** list. • Specify a value manually: select an exact date and time or a relative period, or a combination of both. For details, see the *Configuring a period* subsection below.

Settings for tables

The following table below lists the settings of a **Table**.

Description of parameters

Setting	Description
Name	Name of the widget.
Description	Description of the widget.
Tenant	The tenant for which data is displayed in the widget. You can select multiple tenants. By default, data is displayed for tenants selected in layout settings.

Setting	Description
Time interval	Period for which data is displayed in the widget. The default is **As layout**, meaning that data is displayed for the period selected for the layout. You can also specify a period for the widget in one of the following ways: • Select the exact start and end date and time of the period in the calendar and click **Apply**. • Select a period relative to the present time in the **Relative period** list. • Specify a value manually: select an exact date and time or a relative period, or a combination of both. For details, see the *Configuring a period* subsection below.
Gradient	Gradient fill of the chart: • Two colors (red and green) • Three colors (red, yellow, and green) You can adjust the direction of the fill by clicking the toggle direction icon (⇆); you can also set thresholds. If not set manually, gradient thresholds are calculated automatically from the data. If there is no data between the specified thresholds, the gradient is not applied. Instead, two colors are used: one for values below the lower threshold, and the other for values above the upper threshold.
Field for gradient indicator	The column in which the gradient fill indicators are displayed. This column is determined by the field selected in the drop-down list. The type of the field depends on the type of the widget: • For **Affected assets**, it is the **Frequency** field. • For **Affected assets in incidents**, **Real-time protection extended status of KSC assets**, **Affected users in incidents**, it is the **Count** field.
Decimals	Number of decimals to which the displayed value must be rounded off.

Settings for Bar charts and Date Histograms

The table below lists the settings for the **Bar chart** and **Date Histogram** type graphs located on the **Axis** tab.

Description of parameters

Setting	Description
Y axis and **Min - Max**	Scale of the Y axis. Negative values can be displayed on chart axes. This is due to the scaling of charts on the widget and can be fixed by setting zero as the minimum chart values instead of **Auto**.
X axis and **Min - Max**	Scale of the X axis. Negative values can be displayed on chart axes. This is due to the scaling of charts on the widget and can be fixed by setting zero as the minimum chart values instead of **Auto**.
Decimals	Number of decimals to which the displayed value must be rounded off.

The table below lists the settings for the **Bar chart**, **Stacked Bar chart**, and **Date Histogram** type graphs located on the **Appearance** tab.

Description of parameters

Parameter	Description
Name	Name of the widget.
Description	Description of the widget.
Time interval	Period for which data is displayed in the widget. The default is **As layout**, meaning that data is displayed for the period selected for the layout. You can also specify a period for the widget in one of the following ways: • Select the exact start and end date and time of the period in the calendar and click **Apply**. • Select a period relative to the present time in the **Relative period** list. • Specify a value manually: select an exact date and time or a relative period, or a combination of both. For details, see the *Configuring a period* subsection below.

Parameter	Description
Format	Data display format: **Absolute values** or **Relative values, %**. The setting is available for a **Stacked Bar chart**. If you select the **Absolute values** format, the heights of the bars correspond to the sum of the values of the measured indicator. If you select the **Relative values, %** format, all bars have the same height of 100%, and the relative heights of colored zones on the bars correspond to the ratios of indicator values. By default, **Absolute values** is selected.
Timeline view	Time data display format: **Bar chart** or **Line chart**. This setting is available for charts of the **Date Histogram** type. When you select the **Bar chart** format, the data is displayed as vertical bars by default. If the SQL query contains an additional field with the category alias, the chart becomes a stacked bar chart, that is, each bar is divided into stripes in accordance with the values of this field. When you select the **Line chart** format, the data is displayed as one or more (depending on the query) polylines drawn through points on the time axis. The Bar chart format is selected by default.
Show data for previous period	Enable the display of data for two periods at the same time: the current period and the previous period.
Color	The color used for displaying the information: • **default** for your browser's default font color • **green** • **red** • **blue** • **yellow**
Gradient	Gradient fill of the chart: • Two colors (red and green) • Three colors (red, yellow, and green) You can adjust the direction of the fill by clicking the toggle direction icon (⇆); you can also set thresholds. If not set manually, gradient thresholds are calculated automatically from the data. If there is no data between the specified thresholds, the gradient is not applied. Instead, two colors are used: one for values below the lower threshold, and the other for values above the upper threshold. Gradient fill is not applied to stacked bar charts. In this case, colors are assigned automatically.
Horizontal	Makes the histogram horizontal instead of vertical. When this setting is enabled, all available information is fitted into the configured widget size. If the amount of data is great, you can increase the size of the widget to display it optimally.
Show total	Shows sums total of the values.
Show legend	Displays a legend for the analytics. The toggle switch is turned on by default.
Show nulls in legend	Displays parameters with a null value in the legend for analytics. The toggle switch is enabled by default. Null values are displayed only when the **Show data for previous period** setting is enabled and there is no data for the current period, but there was some data for the previous period.
Period segments length	Duration of the segments into which you want to divide the period. Available for graphs of the **Date Histogram** type.

Settings for Speedometer charts

The table below lists the settings for a **Speedometer chart**.

The values on the graph are indicated as percentages.

Description of parameters

Setting	Description
General tab	
Name	Name of the widget.
Tenant	The tenant whose data is displayed in the widget. You can only select tenants that you selected earlier in the dashboard settings.
Asset category	Assets of the selected category in which values will be searched.

Setting	Description
Search in uncategorized assets	When searching for assets for the chart, asset categories are disregarded.
Y-axis	The value of the parameter by which the search for assets and subsequent calculation of the speedometer reading will be performed. You can specify multiple parameter values to search for assets.
Appearance tab	
Description	Description of the chart that is displayed on the widget.
Threshold	To help you visually identify the severity of an event, the dial of the speedometer is divided into three areas: green, yellow, and red. By default, the following intervals are configured for these areas: • Green: 0–30 • Yellow: 30–70 • Red: 70–100 You can change the ranges as necessary.

Configuring a period

For graphs such as **Pie chart**, **Counter**, **Table**, **Bar chart**, **Stacked bar chart**, **Date Histogram**, you can configure the period for displaying data in the widget using the **Period** setting. By default, the data display period of the widget is the same as the data display period of the dashboard.

To configure the data display period, do one of the following:

- If necessary, change the date and time in the **Time period** setting in one of the following ways:

  - If you want to specify an exact date, in the calendar on the left, select the start and end date of the period and click **Apply**.

    You can select a date up to and including the current date. The date and time format depends on your browser settings. If the **Range from** or **Range to** field has a value and you have not edited the time value manually, when you select a date in the calendar, the **Range from** field is automatically populated with 00:00:00.000, and the **Date to** field with 23:59:59.999. If you have manually deleted the value in the **Range from** or **Range to** field, when you select a date in the calendar, the field is automatically populated with the current time. After you select a value in one of the fields, the focus switches to the other field. If your **Range to** is earlier than your **Range from**, this earlier value is automatically inserted into the **Range from** field.

  - If you want to specify a relative period, select one of the available periods in the **Relative period** list on the right.

    The period is calculated relative to the current time.

  - If you want to specify a custom period, edit the value of the **Range from** and **Range to** fields.

    You can enter an exact date and time in the **DD.MM.YYYY HH:mm:ss.SSS** format for the Russian localization and **YYYY-MM-DD HH:mm:ss.SSS** for the English localization or a period relative to the current time as a formula. You can also combine these methods if necessary. If you do not specify milliseconds when entering the exact date, 000 is substituted automatically. If you have edited the time in the **Range from** or **Range to** fields, picking a date in the calendar does not change the time component.

    In the relative period formulas, you can use the **now** parameter for the current date and time and the interval parameterization language: + (only in the **Range to** field), -, / (rounding to the nearest), as well as time units: **y** (year), **M** (month), **w** (week), **d** (day), **h** (hour), **m** (minute), **s** (second). For example, you can specify the period **now-5d** to get data for the last five days, or **now/w** to get data from the beginning of the first day of the current week (00:00:00:000 UTC) to the current time (**now**).

The **Range from** field is required, and its value cannot exceed the value of the **Range to** field, and also cannot be earlier than 1970-01-01 (if specifying an exact date or a relative period). The **Range to** cannot be earlier than the **Range from**. If you do not specify a value in the **Range to** from field, **now** is specified automatically.

KUMA stores time values in UTC, but in the user interface time is converted to the time zone of your browser. This is relevant to the relative periods: **Today**, **Yesterday**, **This week**, and **This month**. For example, if the time zone in your browser is UTC+3, and you select **Today** as the data display period, data will be displayed for the period from 03:00:00.000 until now, not from 00:00:00.000 until now.

If you want to take your time zone into account when selecting a relative data display period, such as **Today**, **Yesterday**, **This week**, or **This month**, you need to manually add a time offset in the **Range from** and **Range to** (if a value other than now is specified) by adding or subtracting the correct number of hours. For example, if your browser's time zone is UTC+3 and you want to display data for **Yesterday**, you need to change **Range from** to **now-1d/d-3h** and **Date to** to **now/d-3h**. If you want to display data for the **Today** period, you only need to change the value in the **Range from** field to **now/d-3h**.

If you need results up to 23:59:59:999 UTC of yesterday, you can use an SQL query with a filter by Timestamp or specify an exact date and time.

The bounds of the period are inclusive: for example, for the **Today** time range, events are displayed from the beginning (00:00:00:000 UTC) of the current day to the current time (**now**) inclusive, and for the **Yesterday** period, events are displayed from the beginning (00:00:00:000 UTC) of the previous day to 00:00:00:000 UTC of the current day. You can view the date and time of the last data update and the exact period for which the data is displayed by hovering over the period icon in the widget.

If the Show data for previous period setting is enabled for the widget, and the widget is displaying data for a relative period, the tooltip also displays the previous period. The previous period is calculated relative to the current period as start and end values of the current period minus the duration of the current period. For example, if data is updated daily and displayed for a month, but only the first 10 days of the month have passed, the previous period is taken to be the last 10 days of the previous month.

If you want the widget to display data for the period selected for the layout, click the **Reset** button. Changing the displayed period on the layout also changes the period displayed in the widget.

Filtering widget data

KUMA allows you to filter data in widgets of the **Events** type by selecting filtering parameters in the dashboard. You can filter data in the following cases:

- Filtering data on a single widget

  For this type of filtering, you need to specify one or more local variables in the SQL query in widget properties. Variables allow you to modify this SQL query by substituting the data from the widget on the dashboard into the query. The widget filters the data based on the new values of the variables and refreshes the chart. You do not need to manually change the SQL query in the properties of the widget.

  You can apply local variables by clicking the funnel icon (▽) in the widget. This opens a window in which you can select or enter values for local variables.

- Filtering data in multiple widgets within the same dashboard

  For this type of filtering, you need to specify one or more global variables in dashboard properties. Then add global variables to the SQL queries of the widgets to which you want to apply these global variables. When you assign a new value to a global variable, all widgets that use this variable automatically rebuild charts based on the new value.

Global variables are applied by clicking on a segment of the chart or on text from the legend of the chart. KUMA displays a menu with commands that apply the data category of the selected chart segment or plot legend item to a variable.

- Drilling down to another dashboard while passing filtering parameters

  Global variables can be used to pass values to another dashboard. When drilling down from one dashboard to another, KUMA substitutes the selected value of the variable and the selected time period, and the charts on the new dashboard are automatically rebuilt.

  Local variables cannot be used when drilling down to another dashboard.

We do not recommend setting more than five variables within a dashboard. This can lead to unstable operation of the dashboard.

Filtering data on a single widget

KUMA allows you to filter data in widgets of the **Events** type by selecting filtering parameters in the dashboard.

For filtering data on a single widget, you need to specify one or more local variables in the SQL query in widget properties. Variables allow you to modify this SQL query by substituting the data from the widget on the dashboard into the query. The widget filters the data based on the new values of the variables and refreshes the chart. You do not need to manually change the SQL query in the properties of the widget.

We do not recommend setting more than five variables within a dashboard. This can lead to unstable operation of the dashboard.

Configuring data filtering on a single widget

To configure local variables for data filtering within a widget:

1. In the **Dashboards** section, select a dashboard and click the **Edit** button to enter the dashboard editing mode.
2. Select an existing **Events** widget or click the **Add widget** button and then select the **Events** widget type.
3. In the widget properties window, select the **General** tab.
4. Under **Defined variables**, click **Add**.
5. Enter an arbitrary name for the variable, then specify the value of the variable. Local and global variable names must be unique within a dashboard.

   As the value of the variable, specify `value` or `category`, that is, the field aliases used in the query. If you want to enter the value of this variable manually when filtering data in the widget, leave this field empty.

   For charts of the table type, you can specify the name of the event field as the value of the variable. This lets you filter the data in the table by the selected value of this field. The name of the event field is displayed in the header of the table column.
6. In the **SQL query** field, in the WHERE clause, add a function to handle the variables.

   The syntax for variables with a specific value is as follows:

   ```
   filter(<event_field_name> = $variable_name)
   ```

   The syntax for variables with an arbitrary value to be entered manually is as follows:

   ```
   filter(<event_field_name> like $variable_name)
   ```

In this case, when typing manually, you can use the % metacharacter to search for partial text matches. For detailed information, see the ClickHouse documentation.

> You cannot use the SQL builder to add variables to an SQL query.

View example

Example SQL query with a local variable

```
SELECT count(ID) AS 'metric', Name AS 'value', TenantID AS 'category' FROM 'events' WHERE filter(Name = $Name)
GROUP BY Name, TenantID ORDER BY metric DESC LIMIT 250
```

This query uses the local variable `$Name`. The value of the `Name` event field is substituted into this variable. You can apply the variable by clicking the funnel icon ( ) on the widget. This opens a window; in that window, you can specify a value for the variable. The widget filters the selection by the selected value of the `Name` field.

Note that if in the SQL query you specify a variable for a field that takes a numeric value, such a value must be converted to a string. You can do this using the `toString` function. Otherwise, the SQL query returns an error.

Example

```
SELECT count(ID) AS `metric`, SourcePort AS `value` FROM `events` WHERE (filter(toString(SourcePort) like
$SourcePort)) GROUP BY SourcePort ORDER BY value ASC LIMIT 250
```

In this query, the `SourcePort event` field has a numeric value, therefore it is converted to a string: `toString(SourcePort)`.

7. Save your changes.

Applying data filtering to a single widget

To apply a local variable for data filtering within a widget:

1. In the **Dashboards** section, select the dashboard that contains the relevant widget. At least one local variable must be set in the properties of this widget.
2. On the widget, click the funnel icon ( ).
3. This opens a window; in that window, select local variables that you want to apply.
4. Save your changes.

   The widget rebuilds the chart taking into account the new value of the variable.

Filtering data in multiple widgets

KUMA allows you to filter data in widgets of the **Events** type by selecting filtering parameters in the dashboard.

To filter data in multiple widgets within one dashboard, you need to specify one or more global variables in the properties of the dashboard. Then add global variables to the SQL queries of the widgets to which you want to apply these global variables. When you assign a new value to a global variable, all widgets that use this variable automatically rebuild charts based on the new value.

Global variables are applied by clicking on a segment of the chart or on text from the legend of the chart. KUMA displays a menu with commands that apply the data category of the selected chart segment or plot legend item to a variable.

> We do not recommend setting more than five variables within a dashboard. This can lead to unstable operation of the dashboard.

Configuring data filtering for multiple widgets at the dashboard level

To configure global variables for filtering data at the dashboard level:

1. In the **Dashboards** section, select a dashboard and click the **Edit** button to enter the dashboard editing mode.
2. Click the **Settings** button.
3. This opens a window; in that window, in the **Variables** section, select the **Global variables** tab.
4. Click **Add**.
5. In the new row, enter the name of the variable. Local and global variable names must be unique within a dashboard.

   The names of all dashboard widgets to which you add global variables are listed in the **Used in widgets** column.

   The names of the global variables are displayed in the commands of the context menu when you click a segment of the chart or an item in the legend of the chart.
6. Save your changes.
7. Select an existing **Events** widget or click the **Add widget** button and then select the **Events** widget type. In this widget, you will be configuring actions on click.
8. In the widget properties window, select the **General** tab.
9. In the **Defined variables** section, add one or more global variables that you have added in the dashboard properties.
10. If necessary, in the SQL query field, add global variables to the WHERE clause using the filter() function. This also applies the configured actions to this widget.
11. Select the **Actions** tab.

    If you want to display a menu with a command to filter data by the selected segment category when a segment of the chart is clicked:

    a. In the **Chart segment** section, enable the **Filter by variable** option.

    b. In the **Category** list, select the variable into which you want to substitute the value of the `category` alias specified in the SQL query.

    The **Category** option is available only for the stacked bar chart type.

    c. In the **Value** list, select the variable into which you want to substitute the value of the `value` alias specified in the SQL query.

If you want to display a menu with a command to filter data by the selected value when a legend item is clicked:

a. In the **Legend** item section, enable the **Filter by variable** option.

   If necessary, click the **Copy from chart segment settings** button to automatically transfer the selected parameter values from the **Chart segment** group of settings to the **Legend item** group of settings.

b. In the **Value** list, select the variables in which you want to be able to substitute legend item variables.

12. In the properties of other widgets to which you want to apply global variables:

- On the **General** tab, in the **Defined variables** section, add one or more global variables.
- In the SQL query field of the widget, add global variables to the WHERE clause using the filter() function.

Applying data filtering to multiple widgets at the dashboard level

To apply a global variable to filter data between widgets:

1. In the **Dashboards** section, select the dashboard to whose widgets you want to apply the global variable.
2. Find a widget that has actions on click configured. Click a segment of the graph or on the arrow icon (⌄) next to the legend item to open a menu.
3. In the menu, click **Apply category to variable <variable name>** or **Apply value to variable <variable name>**.

   The value of the selected category or legend item is assigned to the variable. Within the current dashboard, all widgets that use this variable rebuild their charts based on the new value of the variable. Such widgets are marked with a funnel icon with a number indicating the number of filters applied (). A list of applied global variables is displayed in the upper part of the screen. To clear data filtering for a widget, click the funnel icon with the number (). To clear data filtering for all widgets on the dashboard, click **Reset all** in the upper part of the dashboard.

Drilling down to a related dashboard

KUMA allows filtering data in widgets of the **Events** type in the current dashboard and drill down to another dashboard while keeping the configured filtering parameters and period.

This is achieved using global variables. The global variables must be configured in both dashboards, as well as in the properties of widgets: on the target dashboard, the variable is specified in the SQL query, and in the source dashboard, the variable is specified when managing the **Drill down to another dashboard** setting. When drilling down from one dashboard to another, KUMA automatically substitutes the selected value of the variable and the period, after which the charts in the target dashboard are rebuilt. Both dashboards must be in the same tenant.

Local variables cannot be used when drilling down to another dashboard.

Configuring the target dashboard

To configure the target dashboard:

1. In the KUMA web interface, in the **Dashboards** section, select a dashboard and create a global variable.

   The variable name may contain only English letters and numerals and may not contain spaces.

2. Save your changes.

3. On the dashboard, select an existing **Events** widget or click the **Add widget** button and then select the **Events** widget type.

4. On the **General** tab, specify the previously created variable:

   - Under **Defined variables**

   - In the **SQL query** field For the SQL query to take into account the value of the variable, add the `filter()` function to the `WHERE` clause.

     The syntax for variables with a specific value is as follows:

     `filter(<event_field_name> = $variable_name)`

     The syntax for variables with an arbitrary value entered manually is as follows:

     `filter(<event_field_name> like $variable_name)`

     Query example

     Query with a `$ServiceName` variable:

     ```
     SELECT DestinationHostName AS Host, Name AS Status, Message AS Reason, ServiceName,
     Timestamp AS Time
     FROM events
     WHERE DeviceEventClassID = 'KLSRV_HOST_STATUS_CRITICAL' OR DeviceEventClassID =
     'KLSRV_HOST_STATUS_WARNING' AND filter(ServiceName = $ServiceName)
     ORDER BY Time DESC
     LIMIT 25
     ```

     If a value is passed in the `$ServiceName` variable when drilling down to the target dashboard, the value is automatically substituted into the query and the data is filtered. If the value of the variable is not specified, the query is executed as if the variable was not present.

5. Save your changes.

Configuring the source dashboard

To configure the source dashboard:

1. In the KUMA web interface, in the **Dashboards** section, select a dashboard and create a global variable.

   The variable name must be the same as the name of the variable created in the target dashboard. The name may contain only English letters and numerals and may not contain spaces.

2. Save your changes.

3. On the dashboard, select an existing **Events** widget or click the **Add widget** button and then select the **Events** widget type.

4. On the **General** tab, in the **Defined variables** section, specify the previously created variable.

5. On the **Actions** tab, specify the following settings:

   a. In the **Chart segment** or **Legend item** section, enable **Drill down to another dashboard**.

   b. In the **Dashboards** drop-down list, select the target dashboard.

c. In the **Value** drop-down list, select the variable whose value you want to pass when drilling down to another dashboard. This must be the same variable that you created earlier.

The selected variable must be specified in the SQL query of the widget on the target dashboard, so that the data on this widget is automatically filtered after the drill-down.

6. Save your changes.

Drilling down from source dashboard to target dashboard

To drill down to the target dashboard:

1. In the KUMA web interface, under **Dashboards**, select the source dashboard.

2. Find the widget for which you have enabled the **Drill down to another dashboard** option. Click the segment or item in the legend of the chart for which this action is configured.

   This opens the target dashboard in a new tab. The period of the original widget is automatically applied to the entire dashboard, and the selected value from the **Value** drop-down list is passed as a variable to widgets of the **Event** type, in which this variable is used in the SQL query through the `filter()` function. The charts in the widgets on the other dashboards are rebuilt with the passed values taken into account.

   > If you change or delete a variable that is specified in the action on the target dashboard to which you are drilling down to, the drill-down is still performed, but the value of the variable is not passed.

Displaying tenant names in Active list type widgets

If you want the names of tenants to be displayed in **Active list** widgets instead of tenant IDs, in correlation rules of the correlator, configure the function for populating the active list with information about the corresponding tenant.

The configuration process involves the following steps:

1. Export the list of tenants.

2. Create a dictionary of the **Table** type.

3. Import the list of tenants obtained at step 1 into the dictionary created at step 2 of these instructions.

4. Add a local variable with the **dict** function for mapping the tenant name to tenant ID to the correlation rule.

   Example:

   - Variable: `TenantName`
   - Value: `dict ('<Name of the previously created dictionary with tenants>', TenantID)`

5. Add a **Set** action to the correlation rule, which writes the value of the previously created variable to the active list in the <key>-<value> format. As the key, specify the field of the active list (for example, `Tenant`), and in the **Value** field, specify the variable (for example, `$TenantName`).

When this rule triggers, the name of the tenant mapped by the **dict** function to the ID in the tenant dictionary is placed in the active list. When creating widgets based on active lists, the widget displays the name of the tenant instead of the tenant ID.

Analysis and response dashboard

In the **Dashboard** section, you can monitor the security status of your organization's network.

The dashboard is a set of widgets that display network security data analytics. You can view data only for those tenants to which you have access.

A selection of widgets used in the dashboard is called a *layout*. You can create layouts manually or use predefined layouts. You can edit widget settings in predefined layouts as necessary. By default, the dashboard displays the Alerts Overview predefined layout.

Only users with the Main administrator, Tenant administrator, Tier 2 analyst, and Tier 1 analyst roles can create, edit, or delete layouts. Users accounts with all roles can view layouts and set default layouts. If a layout is set as default, that layout is displayed for the account every time the user navigates to the **Dashboard** section. The selected default layout is saved for the current user account.

The information on the dashboard is updated in accordance with the schedule configured in layout settings. If necessary, you can force the update of the data.

For convenient presentation of information on the dashboard, you can enable TV mode. This mode lets you view the dashboard in full-screen mode in FullHD resolution. In TV mode, you can also configure a slide show display for the selected layouts.

Creating a dashboard layout

To create a layout:

1. In the main menu, go to **Monitoring** → **Dashboard**, and the select the **Analysis and response** tab.
2. Open the drop-down list in the top right corner of the window and select **Create layout**.

   The **New layout** window opens.
3. In the **Tenants** drop-down list, select the tenants that will own the created layout and whose data will be used to fill the widgets of the layout.

   The selection of tenants in this drop-down list does not matter if you want to create a universal layout (step 8).
4. In the **Time period** drop-down list, select the time period from which you require analytics:

   - **1 hour**
   - **1 day** (this value is selected by default)
   - **7 days**
   - **30 days**
   - **For a period**: get analytics for the selected period. The period is set using the calendar that is displayed when this option is selected.

     The upper boundary of the period is not included in the time slice defined by it. In other words, to receive analytics for a 24-hour period, you should configure the period as Day 1, 00:00:00 – Day 2, 00:00:00 instead of Day 1, 00:00:00 – Day 1, 23:59:59.

5. In the **Refresh every** drop-down list, select how often data should be updated in layout widgets:

   - **1 minute**
   - **5 minutes**
   - **15 minutes**
   - **1 hour** (this value is selected by default)
   - **24 hours**

6. In the **Add widget** drop-down list, select the required widget and configure its settings.

   You can add multiple widgets to the layout.

   You can also drag widgets around the window and resize them using the diagonal button ( ) that appears when you hover the mouse over a widget.

   You can edit or delete widgets added to the layout. To do this, click the settings icon ( ) and select **Edit** to change their configuration or **Delete** to delete them from the layout.

7. In the **Layout name** field, enter a unique name for this layout. Must contain 1 to 128 Unicode characters.

   A custom dashboard cannot have the same name as a predefined dashboard.

   An error is returned when trying to create a dashboard with the same name as a predefined dashboard or change the name of a custom dashboard to the name of a predefined dashboard in the Main tenant. In tenants other than Main, you can create or duplicate a custom dashboard with the same name as a predefined dashboard.

8. If necessary, click the settings icon ( ) on the right of the layout name field, and then select the check box next to the **Universal** setting.

   The layout widgets display data from tenants that you select in the **Selected tenants** section in the menu on the left. This means that the data in the layout widgets will change based on your selected tenants without having to edit the layout settings. For universal layouts, tenants selected in the **Tenants** drop-down list are not taken into account.

   If the check box is cleared, layout widgets display data from the tenants that are selected in the **Tenants** drop-down list in the layout settings. If any of the tenants selected in the layout are not available to you, their data will not be displayed in the layout widgets.

   > You cannot use the **Active Lists** widget in universal layouts.
   > Universal layouts can only be created and edited by a user who has been assigned the Main administrator role. Such layouts can be viewed by all users.

9. Click **Save**.

The new layout is created and is displayed on the **Analysis and response** tab of the dashboard.

Selecting a dashboard layout

To select a dashboard layout:

1. In the main menu, go to **Monitoring** → **Dashboard**, and the select the **Analysis and response** tab.
2. Expand the list in the upper right corner of the window.
3. Select the relevant layout.

The selected layout is displayed on the **Analysis and response** tab of the dashboard.

Selecting a dashboard layout as the default

To set a dashboard layout as the default:

1. In the main menu, go to **Monitoring** → **Dashboard**, and the select the **Analysis and response** tab.
2. Expand the list in the upper right corner of the window.
3. Hover the mouse cursor over the relevant layout.
4. Click the star icon (☆).

The selected layout is displayed on the **Analysis and response** tab of the dashboard by default.

Editing a dashboard layout

To edit a dashboard layout:

1. In the main menu, go to **Monitoring** → **Dashboard**, and the select the **Analysis and response** tab.
2. Expand the list in the upper right corner of the window.
3. Hover the mouse cursor over the relevant layout.
4. Click the edit icon (✎).

   The **Customizing layout** window opens.
5. Edit the dashboard layout. The settings that are available for editing are the same as the settings available when creating a layout.
6. Click **Save**.

The dashboard layout is edited and displayed on the **Analysis and response** tab.

If the layout is deleted or assigned to a different tenant while you are editing it, an error is displayed when you click **Save**. The layout is not saved. Refresh the Kaspersky EDR Expert interface page to see the list of available layouts in the drop-down list.

Deleting a dashboard layout

To delete layout:

1. In the main menu, go to **Monitoring** → **Dashboard**, and the select the **Analysis and response** tab.
2. Expand the list in the upper right corner of the window.

3. Hover the mouse cursor over the relevant layout.

4. Click the delete icon ( ) and confirm this action.

The layout is deleted.

Enabling and disabling TV mode

It is recommended to create a separate user with the minimum required set of right to display analytics in TV mode.

To enable TV mode:

1. In the KUMA Console, select the **Dashboard** section.

2. Click the button in the upper-right corner.

   The **Settings** window opens.

3. Move the **TV mode** toggle switch to the **Enabled** position.

4. To configure the slideshow display of the layouts, do the following:

   a. Move the **Slideshow** toggle switch to the **Enabled** position.

   b. In the **Timeout** field, indicate how many seconds to wait before switching layouts.

   c. In the **Queue** drop-down list, select the layouts to view. If no layout is selected, the slideshow mode displays all layouts available to the user one after another.

   d. If necessary, change the order in which the layouts are displayed by clicking the button to drag and drop them.

5. Click **Save**.

TV mode will be enabled. To return to working with the KUMA Console, disable TV mode.

To disable TV mode:

1. Open the KUMA Console and select the **Dashboard** section.

2. Click the button in the upper-right corner.

   The **Settings** window opens.

3. Move the **TV mode** toggle switch to the **Disabled** position.

4. Click **Save**.

TV mode will be disabled. The left part of the screen shows a pane containing sections of the KUMA Console.

When you make changes to the layouts selected for the slideshow, those changes will automatically be applied to the active slideshow sessions.

Preconfigured dashboard layouts

Kaspersky EDR Expert includes a set of predefined layouts that contain the following widgets:

- **Alerts Overview** layout (Alert overview):
  - Active alerts—number of alerts that have not been closed.
  - Unassigned alerts—number of alerts that have no assignee.
  - Latest alerts—table with information about the last 10 unclosed alerts belonging to the tenants selected in the layout.
  - Alerts distribution—number of alerts created during the period configured for the widget.
  - Alerts by priority—number of unclosed alerts grouped by their priority.
  - Alerts by users—number of alerts with the **In progress** status. The grouping is by account name.
  - Alerts by status—number of alerts grouped by their status.
  - Alerts by groups—number of alerts grouped by user groups.
  - Affected users in alerts—users associated with unclosed alerts.
  - Affected assets is a table with information about assets, their importance level, and the number of unclosed alerts associated with them. The importance level of an asset is calculated based on the categories to which the asset belongs, including all parent categories up to the root of the hierarchy.
  - Affected assets categories—chart displaying the number of asset categories specified in unclosed alerts and incidents. For each asset referenced in alerts or incidents, the importance level of an asset is calculated based on the categories the asset belongs to, including all parent categories up to the root of the hierarchy.
  - Top event source by alerts number—number of unclosed alerts grouped by the event source that generated the alerts.

    The widget displays up to 10 event sources.

  - Alerts by rule—number of unclosed alerts grouped by correlation rules.

Unclosed alerts are alerts that have one of the following statuses: **New**, **In progress**, **In incident**.

- **Incidents Overview** layout (Incidents overview):
  - Active incidents—number of incidents that are not in the **Done** status category.
  - Unassigned incidents—number of incidents that have no assignee.
  - Latest incidents—table with information about the last 10 unclosed incidents belonging to the tenants selected in the layout.
  - Incidents distribution—number of incidents created during the period configured for the widget.

- Incidents by priority—number of incidents grouped by their priority.
- Incidents by users—number of incidents with the **In progress** status. The grouping is by user account name.
- Incidents by status—number of incidents grouped by their status.
- Incidents by groups—number of incidents grouped by their user groups.
- Affected assets in incidents—table displaying the number of assets associated with unclosed incidents. The table lists assets and their importance level, which is calculated based on the categories the asset belongs to together with all parent categories up to the root of the hierarchy.
- Affected users in incidents—users associated with unclosed incidents.
- Affected asset categories in incidents—chart displaying the number of asset categories associated with unclosed incidents. For each asset linked to an incident, the importance level of an asset is calculated based on the categories the asset belongs to, including all parent categories up to the root of the hierarchy.
- Active incidents by tenant—number of unclosed incidents, grouped by tenant.

> Unclosed incidents are incidents that are not in the **Done** status category.

- **Network Overview** layout (Network activity overview):
  - Netflow top internal IPs—total volume of netflow traffic received by the asset, in bytes. The data is grouped by internal IP addresses of assets.

    The widget displays up to 10 IP addresses.
  - Netflow top external IPs—total volume of netflow traffic received by the asset, in bytes. The data is grouped by external IP addresses of assets.
  - Netflow top hosts for remote control—number of events associated with access attempts to one of the following ports: 3389, 22, 135. The data is grouped by asset name.
  - Netflow total bytes by internal ports—number of bytes sent to internal ports of assets. The data is grouped by port number.
  - Top Log Sources by Events count—top 10 sources from which the greatest number of events was received.
- **NGFW Aggregated Dashboards** layout:
  - NGFW. Firewall Sessions & Actions—number of Firewall profiles actions which were triggered and for which the logging option was set.
  - NGFW. DNS Security Sessions & Actions—number of DNS Security profiles actions which were triggered and for which the logging option was set.
  - NGFW. Web Control Sessions & Actions—number of Web Control profiles actions which were triggered and for which the logging option was set.

    - NGFW. IDPS Sessions & Actions—number of IDPS profiles actions which were triggered and for which the logging option was set.
    - NGFW. Anti-Virus Sessions & Actions—number of Anti-Virus profiles actions which were triggered and for which the logging option was set.
- **NGFW IDPS & File Web Antivirus** layout:
    - NGFW. IDPS. Top-5 Threats Name—five most frequent threats detected by IDPS profiles.
    - NGFW. IDPS. Top-5 MITRE Tactics & Techniques—five most frequent MITRE ATT&CK tactics and techniques detected by IDPS profiles.
    - NGFW. IDPS. Top-5 Threats Type—five most frequent types of threat detected by IDPS profiles.
    - NGFW. IDPS. Top-5 Destination IP Addresses With the Most Blocked Web Traffic—five destination IP addresses with the largest volume of web traffic which is blocked by IDPS profiles.
    - NGFW. IDPS. Top-5 Source IP Addresses With the Most Blocked Web Traffic—five source IP addresses with the largest volume of web traffic which is blocked by IDPS profiles.
    - NGFW. File Web Antivirus. Top-5 Threats Name—five most frequent threats detected by Antivirus profiles.
    - NGFW. File Web Antivirus. Top-5 Source IP Addresses With the Most Blocked Web Traffic—five destination IP addresses with the largest volume of web traffic which is blocked by Antivirus profiles.
    - NGFW. File Web Antivirus. Top-5 Destination IP Addresses With the Most Blocked Web Traffic—five source IP addresses with the largest volume of web traffic which is blocked by Antivirus profiles.
- **NGFW DNS Security** layout:
    - NGFW. DNS Security. Top-5 Threats for Blocked Addresses—five most frequent threats from the IP addresses blocked by DNS Security profiles.
    - NGFW. DNS Security. Top-5 Threats for Redirected Addresses—five most frequent threats from the IP addresses redirected by DNS Security profiles.
    - NGFW. DNS Security. Top-5 Source IP Addresses With the Most Blocked Web Traffic—five source IP addresses with the largest volume of web traffic which is blocked by DNS Security profiles.
    - NGFW. DNS Security. Top-5 Redirected Hostnames—five domain names most frequently redirected by DNS Security profiles.
    - NGFW. DNS Security. Top-5 Destination IP Addresses With the Most Blocked Web Traffic—five destination IP addresses with the largest volume of web traffic which is blocked by DNS Security profiles.
    - NGFW. DNS Security. Top-5 Source IP Addresses With the Most Redirected Web Traffic—five source IP addresses most frequently redirected by DNS Security profiles.
- **NGFW Web Control & URL Web Antivirus** layout:
    - NGFW. URL Web Antivirus. Top-5 Web Categories for Blocked URLs—five most frequent categories of URLs blocked by Web Antivirus profiles.
    - NGFW. URL Web Antivirus. Top-5 Destination IP Addresses With the Most Blocked Web Traffic—five destination IP addresses with the largest volume of web traffic blocked by Web Antivirus profiles.

- NGFW. Web Control. Top-5 Categories of Sites With the Most Warning Web Traffic—five categories of websites for which the warning from Web Control profiles is most frequently displayed.
- NGFW. Web Control. Top-5 Categories of Sites With the Most Blocked Web Traffic—five categories of websites with the largest volume of web traffic blocked by Web Antivirus profiles.
- NGFW. Web Control. Top-5 Destination IP Addresses With the Most Warning Web Traffic—five destination IP addresses for which the warning from Web Control profiles is most frequently displayed.
- NGFW. Web Control. Top-5 Destination IP Addresses With the Most Blocked Web Traffic—five destination IP addresses with the largest volume of web traffic blocked by Web Control profiles.
- NGFW. Web Control. Top-5 Web Control Category Sources for Blocked Addresses—five sources from which the categories of blocked URLs are most frequently obtained.
- NGFW. Web Control. Top-5 Web Control Category Sources for Redirected Addresses—five sources from which the categories of redirected URLs are most frequently obtained.

- **NGFW Firewall** layout:
  - NGFW. Top-5 Application Services by Sessions—five most used application services by number of sessions.
  - NGFW. Top-5 Application Services by Traffic, MB—five most used application services by web traffic volume (MB).
  - NGFW. Top-5 Application Protocols by Sessions—five most used application protocols by number of sessions.
  - NGFW. Top-5 Application Protocols by Traffic, MB—five most used application protocols by web traffic volume (MB).
  - NGFW. Top-5 Client Applications by Sessions—five most used client applications by number of sessions.
  - NGFW. Top-5 Client Applications by Traffic, MB—five most used client applications by web traffic volume (MB).
  - NGFW. Top-5 Source IP by Traffic, MB—five source IP addresses with the largest volume of web traffic (MB).
  - NGFW. Top-5 Destination IP by Traffic, MB—five destination IP addresses with the largest volume of web traffic (MB).
  - NGFW. Top-5 Web Sites by Sessions—five websites with the largest number of sessions.
  - NGFW. Top-5 Web Sites by Traffic, MB—five websites with the largest volume of web traffic (MB).

The default refresh period for predefined layouts is **Never**. You can edit these layouts as needed.

About the Dashboard-only mode

You can configure the Dashboard-only mode for employees who do not manage the network but who want to view the network protection statistics in Open Single Management Platform (for example, a top manager). When a user has this mode enabled, only a dashboard with a predefined set of widgets is displayed to the user. Thus, he or she can monitor the statistics specified in the widgets, for example, the protection status of all managed devices, the number of recently detected threats, or the list of the most frequent threats in the network.

When a user works in the Dashboard-only mode, the following restrictions are applied:

- The main menu is not displayed to the user, so he or she cannot change the network protection settings.
- The user cannot perform any actions with widgets, for example, add or hide them. Therefore, you need to put all widgets required for the user on the dashboard and configure them, for instance, set the rule of counting objects or specify the time interval.

You cannot assign the Dashboard-only mode to yourself. If you want to work in this mode, contact a system administrator, Managed Service Provider (MSP), or a user with the **Modify object ACLs** right in the **General features: User permissions** functional area.

Configuring the Dashboard-only mode

Before you begin to configure the Dashboard-only mode, make sure that the following prerequisites are met:

- You have the **Modify object ACLs** right in the **General features: User permissions** functional area. If you do not have this right, the tab for configuring the mode will be missing.
- The user has the **Read** right in the **General features: Basic functionality** functional area.

If a hierarchy of Administration Servers is arranged in your network, for configuring the Dashboard-only mode go to the Server where the user account is available on the **Users** tab of the **Users & roles** → **Users & groups** section. It can be a primary Server or physical secondary Server. It is not possible to adjust the mode on a virtual server.

To configure the Dashboard-only mode:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.
2. Click the user account name for which you want to adjust the dashboard with widgets.
3. In the account settings window that opens, select the **Dashboard** tab.

   On the tab that opens, the same dashboard is displayed for you as for the user.
4. If the **Display the console in Dashboard-only mode** option is enabled, switch the toggle button to disable it.

   When this option is enabled, you are also unable to change the dashboard. After you disable the option, you can manage widgets.
5. Configure the dashboard appearance. The set of widgets prepared on the **Dashboard** tab is available for the user with the customizable account. He or she cannot change any settings or size of the widgets, add, or remove any widgets from the dashboard. Therefore, adjust them for the user, so he or she can view the network protection statistics. To do this, on the **Dashboard** tab, you can perform the same actions with widgets as in the **Monitoring** → **Dashboard** section:
   - Add new widgets to the dashboard.
   - Hide widgets that the user doesn't need.
   - Move widgets into a specific order.

- Change the size or appearance of widgets.
- Change the widget settings.

6. Switch the toggle button to enable the **Display the console in Dashboard-only mode** option.

   After that, only the dashboard is available for the user. He or she can monitor statistics but cannot change the network protection settings and dashboard appearance. As the same dashboard is displayed for you as for the user, you are also unable to change the dashboard.

   If you keep the option disabled, the main menu is displayed for the user, so he or she can perform various actions in Open Single Management Platform, including changing security settings and widgets.

7. Click the **Save** button when you finish configuring the Dashboard-only mode. Only after that will the prepared dashboard be displayed to the user.

8. If the user wants to view statistics of supported Kaspersky applications and needs access rights to do so, configure the rights for the user. After that, Kaspersky applications data is displayed for the user in the widgets of these applications.

Now the user can log in to Open Single Management Platform under the customized account and monitor the network protection statistics in the Dashboard-only mode.

Administration and protection reports

This section describes how to use reports, manage custom report templates, use report templates to generate new reports, and create report delivery tasks.

Using reports

The Reports feature allows you to get detailed numerical information about the security of your organization's network, save this information to a file, send it by email, and print it.

Reports are available in the OSMP Console, in the **Monitoring** section, by clicking **Reports**.

By default, reports include information for the last 30 days.

Kaspersky EDR Expert has a default set of reports for the following categories:

- **Protection status**
- **Deployment**
- **Updating**
- **Threat statistics**
- **Other**

You can create custom report templates, edit report templates, and delete them.

You can create reports that are based on existing templates, export reports to files, and create tasks for report delivery.

Report template

Report templates are used to specify the conditions and data that a report is to be based on, as well as the reporting period. Users with the Main administrator, Tenant administrator, Tier 2 analyst, and Tier 1 analyst roles can create, edit, or delete report templates. Reports that were generated using report templates are displayed in the **Generated reports** tab.

Report templates are available in the **Templates** tab of the **Reports** section, where the table of existing templates is displayed. The table contains the following information:

- **Name** is the name of the report template.

  You can sort report templates by clicking the sort icon and in the column header and selecting **Ascending** or **Descending**.

  You can also search report templates by using the **Search** field above the table.

  > Regular expressions are used when searching for report templates.

- **Tenant** is the name of the tenant that owns the report template.
- **Updated** is the date and time of the last update of a resource template.

  You can sort the table by this column by clicking the sort icon and in the column header and selecting **Ascending** or **Descending**.

- **Created by** is the name of the user who created the report template.
- **Description** is optional information about the report template.
- **Tags** to help find the report template. You can search for report templates by clicking the sort icon in the column header, by specifying a value to search for in the **Search** field, or by selecting tags using check boxes.
- **Schedule** is the rate at which reports must be generated using the template. If the report schedule was not configured, the `disabled` value is displayed.
- **Last report** is the date and time when the last report was generated based on the report template.
- **Package name** is the name of the package of tools for processing events.
- **Send by email** indicates that email notification is configured for generated reports.

If necessary, you can customize the columns by clicking the gear icon.

After selecting a report template in the list, you can click the menu icon to open a drop-down list of available actions:

- **Show dependencies** opens the dependency graph window for the selected report template. If necessary, in the graph window, you can download dependency data in SVG format and configure filters to be applied to dependencies displayed on the graph.
- **View versions history** displays the version history of a report template. If necessary, in the sidebar, you can compare the versions and restore a previous version.

- **Run report** generates a report. The generated reports are displayed on the **Generated reports** tab.
- **View all generated reports** displays a list of all reports generated for the selected report template. If necessary, you can save the selected report in one of the supported formats or delete the report.
- **Edit schedule** lets you configure the reporting schedule and select users that you want to receive email notifications about generated reports.

You can also view the list of report templates available to you in the **Resources** → **List** section. To do this, select **Report template** in the **Resource kind** column.

Creating a report template

To create report template:

1. In the main menu, go to **Monitoring** → **Reports**.
2. Click **Add**.

   The New report template wizard starts. Proceed through the wizard by using the **Next** button.
3. Enter the report name and select the report type.
4. On the **Scope** step of the wizard, select the set of client devices (administration group, device selection, selected devices, or all networked devices) whose data will be displayed in reports that are based on this report template.
5. On the **Reporting period** step of the wizard, specify the report period. Available values:
   - Between the two specified dates
   - From the specified date to the report creation date
   - From the report creation date, minus the specified number of days, to the report creation date

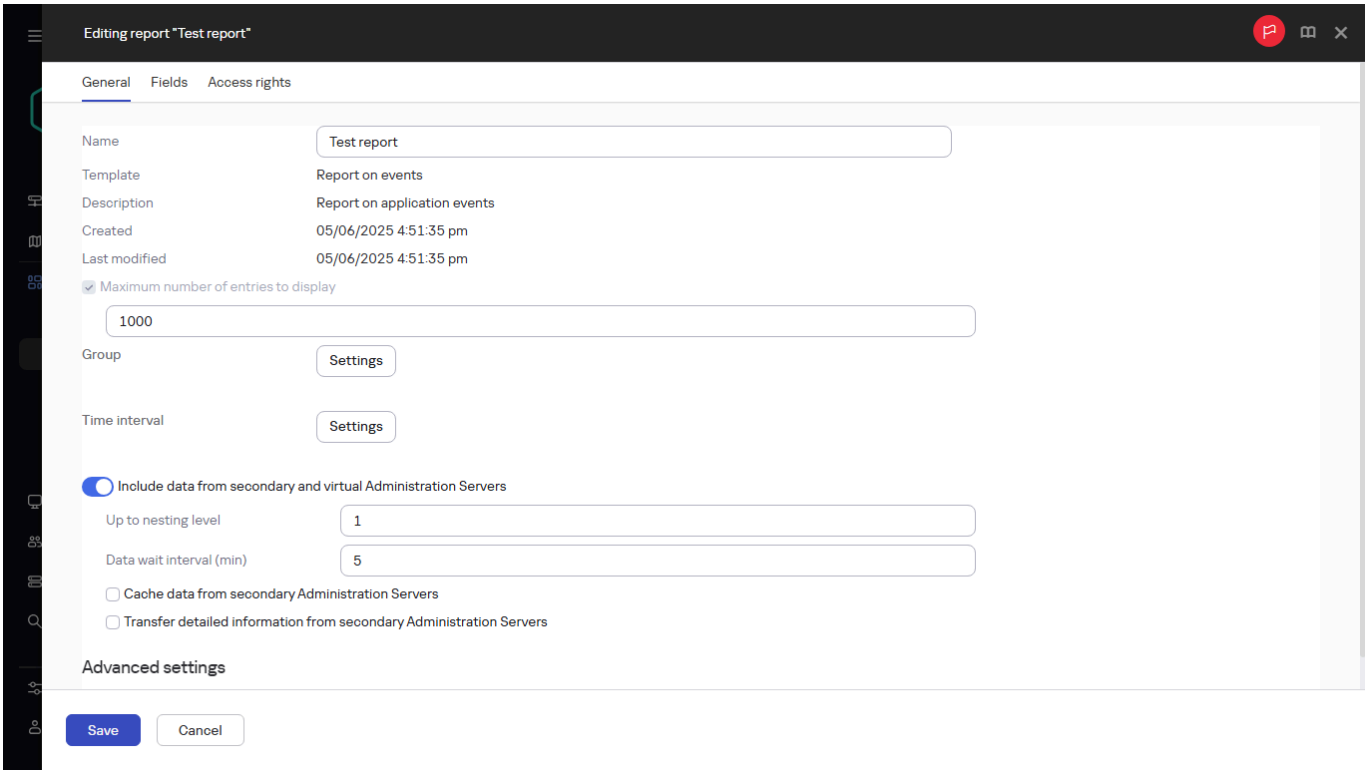
   This page may not appear for some reports.
6. Click **OK** to close the wizard.
7. Do one of the following:
   - Click the **Save and run** button to save the new report template and to run a report based on it.

     The report template is saved. The report is generated.
   - Click the **Save** button to save the new report template.

     The report template is saved.

You can use the new template for generating and viewing reports.

Viewing and editing report template properties



You can view and edit basic properties of a report template, for example, the report template name or the fields displayed in the report.

To view and edit properties of a report template:

1. In the main menu, go to **Monitoring** → **Reports**.
2. Select the check box next to the report template whose properties you want to view and edit.

   As an alternative, you can first generate the report, and then click the **Edit** button.
3. Click the **Open report template properties** button.

   The **Editing report <Report name>** window opens with the **General** tab selected.

The report template properties

4. Edit the report template properties:

   - **General** tab:

     - Report template name

     - **Maximum number of entries to display**

       If this option is enabled, the number of entries displayed in the table with detailed report data does not exceed the specified value. Note that this option does not affect the maximum number of events that you can include in the report when you export the report to a file.

       Report entries are first sorted according to the rules specified in the **Fields** → **Detailed fields** section of the report template properties, and then only the first of the resulting entries are kept. The heading of the table with detailed report data shows the displayed number of entries and the total available number of entries that match other report template settings.

If this option is disabled, the table with detailed report data displays all available entries. We do not recommend that you disable this option. Limiting the number of displayed report entries reduces the load on the database management system (DBMS) and reduces the time required for generating and exporting the report. Some of the reports contain too many entries. If this is the case, you may find it difficult to read and analyze them all. Also, the device may run out of memory while generating such a report. This may prevent you from viewing the report.

By default, this option is enabled. The default value is 1000.

- **Group**

  Click the **Settings** button to change the set of client devices for which the report is created. For some types of the reports, the button may be unavailable. The actual settings depend on the settings specified during creation of the report template.

- **Time interval**

  Click the **Settings** button to modify the report period. For some types of the reports, the button may be unavailable. Available values:

  - Between the two specified dates
  - From the specified date to the report creation date
  - From the report creation date, minus the specified number of days, to the report creation date

- **Include data from secondary and virtual Administration Servers**

  If this option is enabled, the report includes the information from the secondary and virtual Administration Servers that are subordinate to the Administration Server for which the report template is created.

  Disable this option if you want to view data only from the current Administration Server.

  By default, the option is enabled.

- **Up to nesting level**

  The report includes data from secondary and virtual Administration Servers that are located under the current Administration Server on a nesting level that is less than or equal to the specified value.

  The default value is 1. You may want to change this value if you have to retrieve information from secondary Administration Servers located at lower levels in the tree.

- **Data wait interval (min)**

  Before generating the report, the Administration Server for which the report template is created waits for data from secondary Administration Servers during the specified number of minutes. If no data is received from a secondary Administration Server at the end of this period, the report runs anyway. Instead of the actual data, the report shows data taken from the cache (if the **Cache data from secondary Administration Servers** option is enabled), or **N/A** (not available) otherwise.

  The default value is 5 minutes.

- **Cache data from secondary Administration Servers**

  Secondary Administration Servers regularly transfer data to the Administration Server for which the report template is created. There, the transferred data is stored in the cache.

  If the current Administration Server cannot receive data from a secondary Administration Server while generating the report, the report shows data taken from the cache. The date when the data was transferred to the cache is also displayed.

Enabling this option allows you to view the information from secondary Administration Servers even if the up-to-date data cannot be retrieved. However, the displayed data can be obsolete.

By default, this option is disabled.

- **Cache update frequency (h)**

  Secondary Administration Servers at regular intervals transfer data to the Administration Server for which the report template is created. You can specify this period in hours. If you specify 0 hours, data is transferred only when the report is generated.

  The default value is 0.

- **Transfer detailed information from secondary Administration Servers**

  In the generated report, the table with detailed report data includes data from secondary Administration Servers of the Administration Server for which the report template is created.

  Enabling this option slows the report generation and increases traffic between Administration Servers. However, you can view all data in one report.

  Instead of enabling this option, you may want to analyze detailed report data to detect a faulty secondary Administration Server, and then generate the same report only for that faulty Administration Server.

  By default, this option is disabled.

- **Fields** tab

  Select the fields that you want to be displayed in the report. Use the **Move up** and **Move down** buttons to change the display order of fields. Use the **Add** button or **Edit** button to specify whether the information in the report must be sorted and filtered by each of the fields.

  In the **Filters of Details fields** section, you can also click the **Convert filters** button to start using the extended filtering format. This format enables you to combine filtering conditions specified in various fields by using the logical OR operation. After you click the button, the **Convert filters** panel opens on the right. Click the **Convert filters** button to confirm conversion. You can now define a converted filter with conditions from the **Details fields** section that are applied by using the logical OR operation.

  > Conversion of a report to the format supporting complex filtering conditions will make the report incompatible with the previous versions of Kaspersky Security Center (11 and earlier). Also, the converted report will not contain any data from secondary Administration Servers running such incompatible versions.

5. Click **Save** to save the changes.

6. Close the **Editing report <Report name>** window.

The updated report template appears in the list of report templates.

Deleting report templates

To delete one or several report templates:

1. In the main menu, go to the **Monitoring** → **Reports**.

2. Select check boxes next to the report templates that you want to delete.

3. Next, click the **Delete** button.

4. In the window that opens, click **OK** to confirm your selection.

The selected report templates are deleted. If these report templates were included in the report delivery tasks, they are also removed from the tasks.

Universal report templates

A report template in KUMA is considered universal if it is created in the Shared tenant. Report templates created in other tenants are non-universal.

To manage a universal report template, the user needs the following roles:

- For creation, management, or deletion, the Manage shared resources role is needed. This role rights grant access to all shared resources.

  The CII attribute can be set by any user with the Manage shared resources role if the user's role involves managing CII resources.

- The Read shared resources role allows viewing the list of universal report templates. With such rights, the user gains read access to all shared resources.

Widgets in a universal report template are displayed based on the following:

- Widget data for tenants is displayed according to the user's access to tenants, the global tenant filter, and the configuration of the report template or widget.

- You can view the widget data when managing report template settings by clicking the **Update preview** button.

- Event widget data is received from the database in accordance with the space set settings of the user. If, when generating a report, it turns out that the user does not have access to the spaces of one or more tenants, KUMA generates an empty report and displays a message indicating that other results cannot be provided because of the lack of access to the relevant spaces.

- Widget data in the report can include or exclude CII. For access to reports in which data includes CII, the user must have the Interaction with CII role.

- Limitations for active list and context table widgets apply to universal reports.

Exporting a report to a file

You can save one or multiple reports as XML, HTML, or PDF. Open Single Management Platform allows you to export up to 10 reports to files of the specified format at the same time.

PDF format is available only if you are connected to the secondary Administration Server in OSMP Console.

To export a report to a file:

1. In the main menu, go to **Monitoring → Reports**.
2. Choose the reports that you want to export.

   If you choose more than 10 reports, the **Export report** button will be disabled.
3. Click the **Export report** button.
4. In the window that opens, specify the following export parameters:

   - **File name**.

     If you select one report to export, specify the report file name.

     If you select more than one report, the report file names will coincide with the name of the selected report templates.

   - **Maximum number of entries**.

     Specify the maximum number of entries included in the report file. The default value is 10,000.

     You can export a report with an unlimited number of entries. Note that if your report contains a large number of entries, the time required for generating and exporting the report increases.

   - **File format**.

     Select the report file format: XML, HTML, or PDF. If you export multiple reports, all selected reports are saved in the specified format as separate files.

     PDF format is available only if you are connected to the secondary Administration Server in OSMP Console.

     The wkhtmltopdf tool is required to convert a report to PDF. When you select the PDF option, secondary Administration Server checks whether the wkhtmltopdf tool is installed on the device. If the tool is not installed, the application displays a message about the necessity to install the tool on the Administration Server device. Install the tool manually, and then proceed to the next step.
5. Click the **Export report** button.

The report is saved to a file in the specified format.

Generating and viewing a report

To create and view a report:

1. In the main menu, go to **Monitoring** → **Reports**.
2. Click the name of the report template that you want to use to create a report.

   A report using the selected template is generated and displayed.

Report data is displayed according to the localization set for the Administration Server.

In the generated reports, some fonts may be displayed incorrectly on the diagrams. To resolve this issue, install the fontconfig library. Also, please check that the fonts corresponding to your operating system locale are installed in the operating system.

The report displays the following data:

- On the **Summary** tab:
  - The name and type of report, a brief description and the reporting period, as well as information about the group of devices for which the report is generated.
  - Graph chart showing the most representative report data.
  - Consolidated table with calculated report indicators.
- On the **Details** tab, a table with detailed report data is displayed.

Creating a report delivery task

You can create a task that will deliver selected reports.

To create a report delivery task:

1. In the main menu, go to **Monitoring** → **Reports**.
2. Select the check boxes next to the report templates for which you want to create a report delivery task.
3. Click the **Create delivery task** button.

   The New task wizard starts. Proceed through the wizard by using the Next button.
4. At the **New task settings** step of the wizard, enter the task name.

   The default name is **Deliver reports.** If a task with this name already exists, a sequence number (<N>) is added to the task name.

5. At the **Report configuration** step of the wizard, specify the following settings:

   a. Report templates to be delivered by the task.

   b. The report format: HTML, XLS, or PDF.

      The wkhtmltopdf tool is required to convert a report to PDF. When you select the PDF option, Administration Server checks whether the wkhtmltopdf tool is installed on the device. If the tool is not installed, the application displays a message about the necessity to install the tool on the Administration Server device. Install the tool manually, and then proceed to the next step.

   c. Whether the reports are to be sent by email, together with email notification settings.

      You can specify up to 20 email addresses. To separate email addresses, press **Enter**. You can also paste a comma-separated list of email addresses, and then press **Enter**.

   d. Whether the reports are to be saved to a folder, together with the corresponding settings.

      After you enable the **Save to a folder** option, you must specify a POSIX path to the folder. If you want to save the reports to a shared folder, you also have to select the **Specify account for access to shared folder** check box, and then specify the user account and password for accessing this folder.

      > If you select to save the reports to a shared folder, you have to ensure the access to this folder from the device with Administration Server installed. The ways to ensure the access and the tools used depend on your infrastructure.

      When saving the reports to a local folder, credentials are usually not needed since the account under which the Administration Server is running has the access to this folder. If necessary, you can specify the user credentials at the **Selecting an account to run the task** step of the wizard.

      Regardless of the folder choice, you can also select the **Overwrite older reports of the same type** check box if you want the new report file to overwrite the file that was saved in the reports folder at the previous task startup.

6. At the **Configure task schedule** step of the wizard, select the task start schedule.

   The following task schedule options are available:

   - **Manually**

     The task does not run automatically. You can only start it manually.

     By default, this option is selected.

   - **Every N minutes**

     The task runs regularly, with the specified interval in minutes, starting from the specified time on the day that the task is created.

     By default, the task runs every 30 minutes, starting from the current system time.

   - **Every N hours**

     The task runs regularly, with the specified interval in hours, starting from the specified date and time.

     By default, the task runs every 6 hours, starting from the current system date and time.

- **Every N days**

  The task runs regularly, with the specified interval in days. Additionally, you can specify a date and time of the first task run. These additional options become available, if they are supported by the application for which you create the task.

  By default, the task runs every day, starting from the current system date and time.

- **Every N weeks**

  The task runs regularly, with the specified interval in weeks, on the specified day of week and at the specified time.

  By default, the task runs every Friday at the current system time.

- **Monthly**

  The task runs regularly, on the specified day of the month, at the specified time.

  In months that lack the specified day, the task runs on the last day.

  By default, the task runs on the first day of each month, at the current system time.

- **On specified days**

  The task runs regularly, on the specified days of each month, at the specified time.

  By default, the start time is 18:00, and no days of the month are selected.

  > Note that you select neither a specific date in the month, nor the number of the week (first, second week of the month) but the sequence number of the weekday within a month. For example, if you set the cursor in the **Tu** cell of the **First** row, it means the task will run every first Tuesday of each new month.

  You can select several days of week.

- **On virus outbreak**

  The task runs after a *Virus outbreak* event occurs. Select application types that will monitor virus outbreaks. The following application types are available:

  - Anti-virus for workstations and file servers
  - Anti-virus for perimeter defense
  - Anti-virus for mail systems

  By default, all application types are selected.

  You may want to run different tasks depending on the security application type that reports a virus outbreak. In this case, remove the selection of the application types that you do not need.

- **On completing another task**

  The current task starts after another task completes. This option only works if both tasks are assigned to the same devices. For example, you may want to run the *Manage devices* task with the **Turn on the device** option and, after it completes, run the *Virus scan* task as a triggering task.

  You have to select the triggering task from the table and the status with which this task must complete (**Completed successfully** or **Failed**).

If necessary, you can search, sort, and filter the tasks in the table as follows:

- Enter the task name in the search field, to search the task by its name.
- Click the sort icon to sort the tasks by name.

  By default, the tasks are sorted in alphabetical ascending order.
- Click the filter icon, and in the window that opens, filter the tasks by group, and then click the **Apply** button.

7. At this step of the wizard, configure other task schedule settings:

- In the **Task schedule** section, check or reconfigure the previously selected schedule and set the time interval, days of the month or week, set the virus outbreak condition or completing another task as a trigger to start the task. A start time can also be specified in this section if an applicable schedule is selected.
- In the **Additional settings** section, specify the following settings:
  - **Run missed tasks**

    This option determines the behavior of a task if a client device is not visible on the network when the task is about to start.

    If this option is enabled, the system attempts to start the task the next time the Kaspersky application is run on the client device. If the task schedule is **Manually**, **Once** or **Immediately**, the task is started immediately after the device becomes visible on the network or immediately after the device is included in the task scope.

    If this option is disabled, only scheduled tasks run on client devices. For **Manually**, **Once** and **Immediately** schedule, tasks run only on those client devices that are visible on the network. For example, you may want to disable this option for a resource-consuming task that you want to run only outside of business hours.

    By default, this option is enabled.
  - **Use automatically randomized delay for task starts**

    If this option is enabled, the task is started on client devices randomly within a specified time interval, that is, *distributed task start*. A distributed task start helps to avoid a large number of simultaneous requests by client devices to the Administration Server when a scheduled task is running.

    The distributed start time is calculated automatically when a task is created, depending on the number of client devices to which the task is assigned. Later, the task is always started on the calculated start time. However, when task settings are edited or the task is started manually, the calculated value of the task start time changes.

    If this option is disabled, the task starts on client devices according to the schedule.

    By default, this option is enabled.
  - **Use automatically randomized delay for task starts within an interval of**

    If this option is enabled, the task is started on client devices randomly within the specified time interval. A distributed task start helps to avoid a large number of simultaneous requests by client devices to the Administration Server when a scheduled task is running.

    If this option is disabled, the task starts on client devices according to the schedule.

    By default, this option is disabled. The default time interval is one minute.

- **Stop the task if it runs longer than**

  After the specified time period expires, the task is stopped automatically, whether it is completed or not.

  Enable this option if you want to interrupt (or stop) tasks that take too long to execute.

  By default, this option is disabled. The default task execution time is 120 minutes.

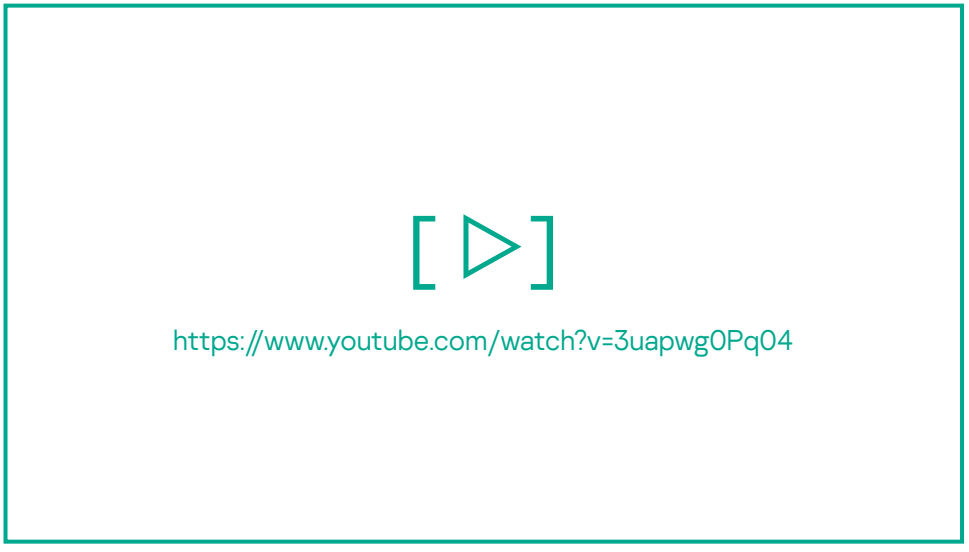
8. At the **Selecting an account to run the task** step of the wizard, specify the credentials of the user account that is used to run the task.

9. If you want to modify other task settings after the task is created, at the **Finish task creation** step of the wizard, enable the **Open task details when creation is complete** option. By default, the option is enabled.

10. Click the **Finish** button to create the task and close the wizard.

    The report delivery task is created. If the **Open task details when creation is complete** option is enabled, the task settings window opens.

Analysis and response reports



You can schedule the generation of process and object status reports in KUMA.

Reports are generated using *report templates*. You can find report templates in the **Reports** section on the **Templates** tab.

You can find the generated reports in the **Reports** section on the **Generated reports** tab.

To save the generated reports in HTML and PDF formats, install the required packages on the device with the KUMA Core.

When deploying KUMA in a high availability version, the time zone of the KUMA Core server and the time in the user's browser may differ. This difference is manifested by the discrepancy between the time in reports generated by schedule and the data that the user can export from widgets. To avoid this discrepancy, it is recommended to configure the report generation schedule to take into account the difference between the users' time zone and UTC.

Report template

Report templates are used to specify the conditions and data that a report is to be based on, as well as the reporting period. Users with the Main administrator, Tenant administrator, Tier 2 analyst, and Tier 1 analyst roles can create, edit, or delete report templates. Reports that were generated using report templates are displayed in the **Generated reports** tab.

Report templates are available in the **Templates** tab of the **Reports** section, where the table of existing templates is displayed. The table contains the following information:

- **Name** is the name of the report template.

  You can sort report templates by clicking the sort icon and in the column header and selecting **Ascending** or **Descending**.

  You can also search report templates by using the **Search** field above the table.

  > Regular expressions are used when searching for report templates.

- **Tenant** is the name of the tenant that owns the report template.
- **Updated** is the date and time of the last update of a resource template.

  You can sort the table by this column by clicking the sort icon and in the column header and selecting **Ascending** or **Descending**.

- **Created by** is the name of the user who created the report template.
- **Description** is optional information about the report template.
- **Tags** to help find the report template. You can search for report templates by clicking the sort icon in the column header, by specifying a value to search for in the **Search** field, or by selecting tags using check boxes.
- **Schedule** is the rate at which reports must be generated using the template. If the report schedule was not configured, the `disabled` value is displayed.
- **Last report** is the date and time when the last report was generated based on the report template.
- **Package name** is the name of the package of tools for processing events.
- **Send by email** indicates that email notification is configured for generated reports.

If necessary, you can customize the columns by clicking the gear icon.

After selecting a report template in the list, you can click the menu icon to open a drop-down list of available actions:

- **Show dependencies** opens the dependency graph window for the selected report template. If necessary, in the graph window, you can download dependency data in SVG format and configure filters to be applied to dependencies displayed on the graph.
- **View versions history** displays the version history of a report template. If necessary, in the sidebar, you can compare the versions and restore a previous version.

- **Run report** generates a report. The generated reports are displayed on the **Generated reports** tab.
- **View all generated reports** displays a list of all reports generated for the selected report template. If necessary, you can save the selected report in one of the supported formats or delete the report.
- **Edit schedule** lets you configure the reporting schedule and select users that you want to receive email notifications about generated reports.

You can also view the list of report templates available to you in the **Resources** → **List** section. To do this, select **Report template** in the **Resource kind** column.

Creating report template

To create report template:

1. Open OSMP Console and go to one of the following sections:
   - **Reports** → **Templates**
   - **Resources** → **List**

     If you have selected this section, for the convenience of viewing objects, you can select **Report template** in the **Resource kind** column of the table.
2. Depending on the selected section, do one of the following:
   - In the **Reports** → **Templates** section, click the **Create new** button above the table of report templates.
   - In the **Resources** → **List** section, click the **Create new** button and select **Report template** in the list of resources.
3. This opens a window; in that window, enter a unique name for the report template. The name must contain 1 to 128 Unicode characters.

   Custom report templates cannot have the same names as predefined report templates in the Main tenant.

   In the Main tenant, if you try to create a report template with the same name as a predefined report template or assign the name of a predefined report template to a custom report template, an error is returned. In tenants other than Main, you can create or duplicate a custom report template with the same name as a predefined report template. We recommend using custom names for custom report templates.
4. In the **Template tenant** drop-down list, select the tenant that will own the report template being created.
5. In the **Collect data from tenants** drop-down list, select one or more tenants. Reports are generated based on data of the selected tenants.

6. If necessary, in the **Time period** drop-down list, select the time period from which you want to get analytics in one of the following ways:

   - If you want to specify an exact date, in the calendar on the left, select the start and end date of the period and click **Apply**.

     You can select a date up to and including the current date. The date and time format depends on your browser settings. If the **Range from** or **Range to** field has a value and you have not edited the time value manually, when you select a date in the calendar, the **Range from** field is automatically populated with 00:00:00.000, and the **Date to** field with 23:59:59.999. If you have manually deleted the value in the **Date from** or **Date to** field, when you select a date in the calendar, the field is automatically populated with the current time. After you select a value in one of the fields, the focus switches to the other field. If your **Date to** is earlier than your **Date from**, this earlier value is automatically inserted into the **Date from** field.

   - If you want to specify a relative period, select one of the available periods in the **Relative period** list on the right.

     The period is calculated relative to the current time.

   - If you want to specify a custom period, edit the value of the **Date from** and **Date to** fields.

     You can enter an exact date and time in the **DD.MM.YYYY HH:mm:ss.SSS** format for the Russian localization and **YYYY-MM-DD HH:mm:ss.SSS** for the English localization or a period relative to the current time as a formula. You can also combine these methods if necessary. If you do not specify milliseconds when entering the exact date, 000 is substituted automatically. If you have edited the time in the **Date from** or **Date to** fields, picking a date in the calendar does not change the time component.

     In the relative period formulas, you can use the now parameter for the current date and time and the interval parameterization language: + (only in the **Range to** field), -, / (rounding to the nearest), as well as time units: **y** (year), **M** (month), **w** (week), **d** (day), **h** (hour), **m** (minute), **s** (second). For example, you can specify the period **now-5d** to get data for the last five days, or **now/w** to get data from the beginning of the first day of the current week (00:00:00:000 UTC) to the current time (**now**).

     > The **Range from** field is required, and its value cannot exceed the value of the **Range to** field, and also cannot be earlier than 1970-01-01 (if specifying an exact date or a relative period). The **Date to** cannot be earlier than the **Date from**. If you do not specify a value in the **Range to** from field, **now** is specified automatically.

   By default, the **1 day (now-1d)** relative period is selected. The bounds of the period are included. For example, for the **Today** time range, events are displayed from the beginning (00:00:00:000) of the current day to the current time (**now**) inclusive, and for the **Yesterday** period, events are displayed from the beginning (00:00:00:000) of the previous day to 00:00:00:000 of the current day.

   KUMA stores time values in UTC, but in the user interface time is converted to the time zone of your browser. This is relevant to the relative periods: **Today**, **Yesterday**, **This week**, and **This month**. For example, if the time zone in your browser is UTC+3, and you select **Today** as the data display period, data will be displayed for the period from 03:00:00.000 until now, not from 00:00:00.000 until now.

   If you want to take your time zone into account when selecting a relative data display period, such as **Today**, **Yesterday**, **This week**, or **This month**, you need to manually add a time offset in the **Range from** and **Range to** (if a value other than now is specified) by adding or subtracting the correct number of hours. For example, if your browser's time zone is UTC+3 and you want to display data for **Yesterday**, you need to change **Range from** to **now-1d/d-3h** and **Date to** to **now/d-3h**. If you want to display data for the **Today** period, you only need to change the value in the **Date from** field to **now/d-3h**.

   > If you need results up to 23:59:59:999 UTC of yesterday, you can use an SQL query with a filter by Timestamp or specify an exact date and time.

7. If necessary, in the **Retention period** field, specify how long you want to store reports that are generated according to this template.

   The default value is 3 months.

8. If necessary, select tags for the report template from the **Tags** drop-down list.

9. If necessary, add a description of the report template.

10. Use the **CII status** toggle switch to enable the display of information for assets, alerts, and incidents related to critical information infrastructure (CII). In this case, reports in which the calculated data includes CII information, can be viewed only by users in whose settings the **Access to CII facilities** check box is selected.

    If this toggle switch is disabled, widgets of the reports do not display information for assets, alerts, and incidents related to critical information infrastructure (CII) even if the user has access to CII facilities.

11. Click **Save**.

12. This opens a window; in that window, you can change the logo of the report template by clicking the **Upload a file** link. In the file selection window, select the image file for the logo. The format of the image must be JPEG, PNG, or GIF, and its size may not exceed 3 MB.

    The added logo is displayed in the report instead of KUMA logo.

13. Click the **Add widget** button and select a widget. This opens a window; in that window, configure the selected widget.

14. You can add multiple widgets. You can drag widgets around the window by the handle icon (⠿) in the upper-left corner of the widget. If you need to resize the widget, you can do so using the resize icon (⤡) that is displayed when you hover over the lower-right corner of the widget.

15. The following limitations apply to widgets with the **Pie chart**, **Bar chart**, **Line chart**, **Counter**, and **Date Histogram** chart types:

    - In `SELECT` queries, you can use extended event schema fields of `String`, `Number`, and `Float` types.
    - In `WHERE` queries, you can use all types of extended event schema fields (`String`, `Number`, `Float`, `Array of strings`, `Array of numbers`, and `Array of floats`).

    For widgets with the `Table` chart type, in `SELECT` queries, you can use all types of extended event schema fields (`String`, `Number`, `Float`, `Array of strings`, `Array of numbers`, and `Array of floats`).

16. By clicking the menu ⋮ icon in the upper-right corner of the widget, you can do the following:

    - Manage the settings of widgets
    - Create copies of widgets
    - Remove widgets
    - Download widget data in CSV format

17. Click **Create**.

    The new report template is displayed on the **Reports** → **Templates** and **Resources** → **List** tabs of OSMP Console. You can run this report manually. If you want to have the reports generated automatically, you need to configure a schedule.

Configuring report schedule

To configure the report schedule:

1. Open the KUMA web interface and select **Reports** → **Templates**.
2. In the table with the list of report templates, select a report template and click the menu icon ⋮.
3. In the drop-down list, select **Edit schedule**.

   This opens the **Edit schedule** window.
4. If you want the report to be generated regularly:

   a. Enable the **Send report by schedule** toggle switch.

   b. Under **Recur every**, specify how often the reports must be generated.

   You can specify the frequency of generating reports by days, weeks, months, or years. Depending on the selected period, you should specify the time, day of the week, day of the month or the date of the report generation.

   c. In the **Time** field, enter the time when the report must be generated.

   d. In the **Timezone** drop-down list, select the time zone for the report generation time.
5. Under **Notification settings**, specify the following:

   a. In the **Notification template** drop-down list, select a notification form that you want to be sent to the user on a schedule.

   b. In the **Send to** group of settings, click **Add**.

   c. This opens a window; in that window, add a group of users that you want to get the report and select a format. To do so:

   - In the **Emails** drop-down list, select email addresses of report recipients.
   - In the **Format** drop-down list, select the format of the report. The following formats are available: PDF, HTML, CSV, split CSV, Excel.

   You can add multiple groups of report recipients by clicking the **Add group** button.

   Reports are sent to the specified addresses every time you generate a report manually or KUMA generates a report automatically on schedule.

   > If you want the generated reports to be sent by email, you need to configure an SMTP connection.

   If recipients of an emailed report are KUMA users, they can download or view the report by clicking links in the email message. If the recipients are not KUMA users, they can follow the links but cannot log in to KUMA, so only attachments are available to them.

   We recommend viewing HTML reports by clicking links in the web interface, because at some screen resolutions, the HTML report from the attachment may not be displayed correctly.

If you send an email message without attachments, the recipients can only get reports by following links, and only if they can authorize in KUMA, without restrictions on roles or tenants.

d. Then click the **Add** button.

6. Click **Save**.

Report schedule is configured.

Editing report template

To edit report template:

1. Open the KUMA web interface and go to one of the following sections:

   - **Reports** → **Templates**
   - **Resources** → **List**

     If you have selected this section, for the convenience of viewing objects, you can select **Report template** in the **Resource kind** column of the table.

2. Depending on the selected section, do one of the following:

   - In the **Reports** → **Templates** section, click the name of the report template in the table of report templates.
   - In the **Resources** → **List** section, click the edit settings icon (↗) next to the name of the report template in the list of resources.

   This opens the **Edit template** window.

   You can also open this window on the Reports → Generated reports tab by selecting an existing report and clicking the Edit template button.

   > You can also open this window on the **Reports** → **Generated reports** tab by selecting an existing report and clicking the **Edit report** button.

3. Make the necessary changes:

   - Change the name of the report template.
   - Modify the list of tenants that send data for the report.
   - Click the **Settings** button to change the time period for getting analytical data, the retention period, tags, and description of the report template.
   - Click the **Add widget** button to add a widget to the report template.
   - Click the menu icon (⋮) to view the list of reports generated by this template, or to delete the report template.
   - Change the report logo by clicking the **Upload a file** link and uploading a new logo. If the template already contains a logo, you must first delete it.

- Change widgets positions by dragging them.
- Resize widgets using the resize (↘) icon that appears when you hover over a widget.
- Click the menu icon (⋮) on the widget to manage widget settings, copy widgets, delete widgets, or download widget data in CSV format.

4. Click **Save**.

The report template is modified and displayed on the **Reports** → **Templates** and **Resources** → **List** tabs of the KUMA web interface.

Copying report template

To create a copy of a report template:

1. Open the KUMA web interface and go to one of the following sections:
   - **Reports** → **Templates**
   - **Resources** → **List**

     If you have selected this section, for the convenience of viewing objects, you can select **Report template** in the **Resource kind** column of the table.
2. In the table, select a report template and click the **Duplicate** button above the table.
3. This opens a window; in that window, enter the name of the report template. When you copy a report template, the name of the report mentions that it is a copy.
4. In the **Template tenant** drop-down list, select the tenants that will own the report template being created.
5. In the **Collect data from tenants** drop-down list, select one or more tenants whose data you want to be represented in the report template.
6. Change the following settings as needed:
   - Report generation period.
   - Report retention period.
   - Tags of the report template.
   - Description of the report template.
   - Generation of report data with CII information.
7. Click **Save**.

The copy of the report template is created and is displayed on the **Reports** → **Templates** and **Resources** → **List** tabs of the KUMA web interface.

Deleting report template

To delete a report template:

1. Open the KUMA web interface and go to one of the following sections:

   - **Reports** → **Templates**
   - **Resources** → **List**

     If you have selected this section, for the convenience of viewing objects, you can select **Report template** in the **Resource kind** column of the table.

2. In the table of report templates, select the check box of a report template and click the **Delete** button above the table.

   The confirmation window opens.

3. Do one of the following:

   - If you want to delete only the report template, click the **Delete** button.
   - If you want to delete a report template and all the reports that were generated using that template, click the **Delete with reports** button.

The report template is deleted.

Exporting or importing a report template

To export a report template:

1. Open the KUMA web interface and go to one of the following sections:

   - **Reports** → **Templates**
   - **Resources** → **List**

     If you have selected this section, for the convenience of viewing objects, you can select **Report template** in the **Resource kind** column of the table.

   This opens a window with a list of all report templates available to you in KUMA.

2. Use the check box to select the report template to be exported.

3. Click the **Export** button above the table of report templates.

4. In the sidebar that is displayed:

   a. Enter the password for the file with exported resources. The password must satisfy the following requirements:

      - At least 16 characters.
      - At least one lowercase character.
      - At least one uppercase character.
      - At lease one numeral.
      - At least one special character.

   b. In the **Tenant** drop-down list, select the tenant from which you want to export the selected resources.

   c. Select check boxes to specify the resources that you want to export.

      If you select the **All resources** check box, all resources in folders of the selected tenant are exported.

5. Click the **Export** button.

Consider the following when exporting report templates:

- Report templates are exported without tenants, storage, and space information because these parameters are configured individually for each KUMA deployment.
- Report template widgets are also exported without tenant, storage, and space information.

To import a report template:

1. Open the KUMA web interface and go to one of the following sections:

   - **Reports → Templates**
   - **Resources → List**

     If you have selected this section, for the convenience of viewing objects, you can select **Report template** in the **Resource kind** column of the table.

   This opens a window with a list of all report templates available to you in KUMA.

2. Use the check box to select the report template to be imported.
3. Click the **Import** button above the table of resources.
4. In the sidebar, in the **Tenant** drop-down list, select the tenant to which you want to import the report template.
5. Select the import source: **File** or **Repository**.

6. Depending on the selected import source, follow these steps:

   a. If you selected **File** as the import source, follow these steps:

      - Specify the password for the imported file.
      - Click the **Select file** button to select the file that you want to import.
      - Select the check boxes of the resources that you want to import.

   b. If you selected **Repository** as the import source, select one or more repository packages in the displayed table.

7. Click the **Import** button.

8. If necessary, resolve conflicts between the resources imported from the file and the existing resources.

Consider the following when importing report templates:

- If a report template is imported into any tenant, the tenant of the imported report template is specified as the resource tenant and the data source tenant.
- After importing resources, you need to specify spaces for widgets with events and if necessary, expand the list of tenants.

Universal report templates

A report template in KUMA is considered universal if it is created in the Shared tenant. Report templates created in other tenants are non-universal.

To manage a universal report template, the user needs the following roles:

- For creation, management, or deletion, the Manage shared resources role is needed. This role rights grant access to all shared resources.

  The CII attribute can be set by any user with the Manage shared resources role if the user's role involves managing CII resources.

- The Read shared resources role allows viewing the list of universal report templates. With such rights, the user gains read access to all shared resources.

Widgets in a universal report template are displayed based on the following:

- Widget data for tenants is displayed according to the user's access to tenants, the global tenant filter, and the configuration of the report template or widget.
- You can view the widget data when managing report template settings by clicking the **Update preview** button.
- Event widget data is received from the database in accordance with the space set settings of the user. If, when generating a report, it turns out that the user does not have access to the spaces of one or more tenants, KUMA generates an empty report and displays a message indicating that other results cannot be provided because of the lack of access to the relevant spaces.

- Widget data in the report can include or exclude CII. For access to reports in which data includes CII, the user must have the Interaction with CII role.
- Limitations for active list and context table widgets apply to universal reports.

Generated reports

All reports are generated using report templates. Generated reports are available in the **Generated reports** tab of the **Reports** section and are displayed in the table with the following information:

- **Name**—the name of the report template.

  You can sort report templates by clicking the sort icon ⌄ in the column header and selecting **Ascending** or **Descending**.

  You can also search for report templates by name using the **Search** field above the table.
- **Time period**—the time period for which the report analytics were extracted.
- **Last report**—date and time when the last report was generated.
- You can sort the table by this column by clicking the sort icon ⌄ in the column header and selecting **Ascending** or **Descending**.
- **Tenant**—name of the tenant that owns the report.
- **User**—name of the user who generated the report manually. If the report was generated by schedule, the value is blank. If the report was generated in KUMA lower than 2.1, the value is blank.

If necessary, you can customize the columns by clicking the gear icon ⚙.

After selecting a report in the list of generated reports, you can:

- Create a report.
- Open and view a report.
- Save a generated report in a certain format. Available formats: HTML, PDF, CSV, split CSV, Excel. By default, 250 rows are displayed in all formats. The maximum number of table rows in PDF and HTML formats is 500. If you want to output more than 500 rows in a report, set your value for the LIMIT parameter in the SQL query and save the report in CSV format.
- Manage the settings of a report template.
- Delete a report.

Viewing reports

To open report:

1. Open the KUMA web interface and select **Reports** → **Generated reports**.
2. In the table of reports, click the name of the generated report.

   The new browser window opens with the widgets displaying report analytics. If a widget displays data on events, alerts, incidents, or active lists, you can click its header to open the corresponding section of the KUMA web interface with an active filter and/or search query that is used to display data from the widget. Default values are applied to widgets.

   To view the full data, download the report in the CSV format with the specified settings from the request.

   If you have enabled the **Show total** toggle switch in the widget settings, the widget displays the **Total** value, but when you attach or upload a report in CSV or extended CSV format, the **Total** value is not displayed. To display the **Total** value in the report, you can use Excel formulas or copy and paste the total value from the widget, or use PDF or HTML attachments.
3. If necessary, save the report in the selected format by clicking the **Save as** button.

Generating reports

You can generate report manually or configure a schedule to have it generated automatically.

To generate report manually:

1. Open the KUMA web interface and go to the **Reports** section.
2. Do one of the following:

   a. On the **Generated reports** tab:

   - Select the check box of a report in the table of reports.
   - Click the **Generate report** button above the table.

   b. In the **Templates** tab:

   - Select a report in the table of report templates by selecting its check box.
   - Click the menu icon ⋮ and select **Generate report** from the drop-down list.

   Within 15 seconds, the report is generated and displayed on the Reports → Generated reports tab.

You can also configure a reporting schedule for automatic generation of reports.

Saving reports

To save the report in the desired format:

1. Open the KUMA web interface and select **Reports** → **Generated reports**.
2. Select the check box of a generated report in the table of generated reports.
3. In the **Save as** drop-down list above the table, select a format: HTML, PDF, CSV, Split CSV, Excel.
   The report is saved to the download folder configured in your browser.

You can also save the report in the desired format when you view it.

Updating reports

To update a generated report:

1. Open the KUMA web interface and go to the **Reports** → **Generated reports** section.
2. In the table of generated reports, select a report.
3. Click the **Generate report** button above the table.
   The report is updated within 15 seconds and becomes available in the **Reports** → **Generated reports** section.

Deleting reports

To delete report:

1. Open the KUMA web interface and select **Reports** → **Generated reports**.
2. In the table of generated reports, select a report.
3. Click the **Delete** button above the table.
   The confirmation window opens.
4. Click the **Delete** button.
   The selected report is deleted.

Events and event selections

This section provides information about events and event selections, about the types of events that occur in Kaspersky EDR Expert components, and about managing frequent events blocking.

About events in Kaspersky EDR Expert

Kaspersky EDR Expert allows you to receive information about events that occur during the operation of Administration Server and Kaspersky applications installed on managed devices. Information about events is saved in the Administration Server database.

Events by type

In Kaspersky EDR Expert, there are the following types of events:

- General events. These events occur in all managed Kaspersky applications. An example of a general event is Virus outbreak. General events have strictly defined syntax and semantics. General events are used, for instance, in reports and dashboards.
- Managed Kaspersky applications-specific events. Each managed Kaspersky application has its own set of events.

Events by source

You can view the full list of the events that can be generated by an application on the **Event configuration** tab in the application policy. For Administration Server, you can additionally view the event list in the Administration Server properties.

Events can be generated by the following applications:

- Kaspersky EDR Expert components:
  - Administration Server
  - Network Agent
- Managed Kaspersky applications

  For details about the events generated by Kaspersky managed applications, please refer to the documentation of the corresponding application.

Events by importance level

Each event has its own importance level. Depending on the conditions of its occurrence, an event can be assigned various importance levels. There are four importance levels of events:

- A *critical event* is an event that indicates the occurrence of a critical problem that may lead to data loss, an operational malfunction, or a critical error.
- A *functional failure* is an event that indicates the occurrence of a serious problem, error, or malfunction that occurred during operation of the application or while performing a procedure.
- A *warning* is an event that is not necessarily serious, but nevertheless indicates a potential problem in the future. Most events are designated as warnings if the application can be restored without loss of data or functional capabilities after such events occur.
- An *info* event is an event that occurs for the purpose of informing about successful completion of an operation, proper functioning of the application, or completion of a procedure.

Each event has a defined storage term, during which you can view or modify it in Kaspersky EDR Expert. Some events are not saved in the Administration Server database by default because their defined storage term is zero. Only events that will be stored in the Administration Server database for at least one day can be exported to external systems.

Events of Kaspersky EDR Expert components

Each Kaspersky EDR Expert component has its own set of event types. This section lists types of events that occur in Administration Server and Network Agent. Types of events that occur in Kaspersky applications are not listed in this section.

For each event that can be generated by an application, you can specify notification settings and storage settings on the **Event configuration** tab in the application policy. For Administration Server, you can additionally view and configure the event list in the Administration Server properties. If you want to configure notification settings for all the events at once, configure general notification settings in the Administration Server properties.

Data structure of event type description

For each event type, its display name, identifier (ID), alphabetic code, description, and the default storage term are provided.

- **Event type display name**. This text is displayed in Kaspersky EDR Expert when you configure events and when they occur.
- **Event type ID**. This numerical code is used when you process events by using third-party tools for event analysis.
- **Event type** (alphabetic code). This code is used when you browse and process events by using public views that are provided in the Kaspersky EDR Expert database and when events are exported to a SIEM system.
- **Description**. This text contains the situations when an event occurs and what you can do in such a case.

- **Default storage term**. This is the number of days during which the event is stored in the Administration Server database and is displayed in the list of events on Administration Server. After this period elapses, the event is deleted. If the event storage term value is 0, such events are detected but are not displayed in the list of events on Administration Server. If you configured to save such events to the operating system event log, you can find them there.

  You can change the storage term for events: Setting the storage term for an event.

Administration Server events

This section contains information about the events related to the Administration Server.

Administration Server critical events

The table below shows events of Administration Server that have the **Critical** severity.

For each event that can be generated by an application, you can specify notification settings and storage settings on the **Event configuration** tab in the application policy. For Administration Server, you can additionally view and configure the event list in the Administration Server properties. If you want to configure notification settings for all the events at once, configure general notification settings in the Administration Server properties.

Administration Server critical events

Event type display name	Event type ID	Event type	Description	Default storage term
Administration Server certificate for mobile devices has expired	6129	KLSRV_EV_SRV_CERT_EXPIRED_DN	Events of this type occur when the Administration Server certificates for mobile devices and UEFI devices expires. You need to update the expired certificate.	180 days
Audit: Export to SIEM failed	5130	KLAUD_EV_SIEM_EXPORT_ERROR	Events of this type occur when exporting events to the SIEM system failed due to a connection error with the SIEM system.	180 days
Device has become unmanaged	4111	KLSRV_HOST_OUT_CONTROL	Events of this type occur if a managed device is visible on the network but has not connected to Administration Server for a specific period. Find out what prevents the proper functioning of Network Agent on the device. Possible causes include network issues and removal of Network Agent from the device.	180 days
Device status is Critical.	4113	KLSRV_HOST_STATUS_CRITICAL	Events of this type occur when a managed device is assigned the *Critical* status. You can configure the conditions under which the device status is changed to *Critical*.	180 days

Event type display name	Event type ID	Event type	Description	Default storage term
License expires soon.	4129	KLSRV_EV_LICENSE_SRV_EXPIRE_SOON	Events of this type occur when the commercial license expiration date is approaching. Once a day Open Single Management Platform checks whether a license expiration date is approaching. Events of this type are published 30 days, 15 days, 5 days, and 1 day before the license expiration date. This number of days cannot be changed. If the Administration Server is turned off on the specified day before the license expiration date, the event will not be published until the next day. When the commercial license expires, Kaspersky EDR Expert provides only basic functionality. You can respond to the event in the following ways: • Make sure that a reserve license key is added to Administration Server. • If you use a subscription, make sure to renew it. An unlimited subscription is renewed automatically if it has been prepaid to the service provider by the due date.	180 days
License limit has been exceeded.	4099	KLSRV_EV_LICENSE_CHECK_MORE_110	Once a day Kaspersky EDR Expert checks whether a licensing limit is exceeded. Events of this type occur when Administration Server detects that some licensing limits are close to being exceeded by Kaspersky applications installed on client devices and if the number of currently used licensing units covered by a single license constitute over 110% of the total number of units covered by the license. Even when this event occurs, client devices are protected. You can respond to the event in the following ways: • Look through the managed devices list. Delete devices that are not in use. • Provide a license for more devices (add a valid activation code or a key file to Administration Server). Kaspersky EDR Expert determines the rules to generate events when a licensing limit is exceeded.	180 days
Limited functionality mode.	4130	KLSRV_EV_LICENSE_SRV_LIMITED_MODE	Events of this type occur when Kaspersky EDR Expert starts to operate with basic functionality, without Vulnerability and patch management and without Mobile Device Management features. Following are causes of, and appropriate responses to, the event: • License term has expired. Provide a license to use the full functionality mode of Kaspersky EDR Expert (add a valid activation code or a key file to Administration Server). • Administration Server manages more devices than specified by the license limit. Move devices from the administration groups of an Administration Server to those of another Administration Server (if the license limit of the other Administration Server allows).	180 days

Event type display name	Event type ID	Event type	Description	Default storage term
Certificate has expired.	4132	KLSRV_CERTIFICATE_EXPIRED	Events of this type occur when the client certificate on mobile devices expires.	180 days
Key file has been blacklisted.	4124	KLSRV_LICENSE_BLACKLISTED	Events of this type occur when Kaspersky has added the activation code or key file that you use to the denylist. Contact Technical Support for more details.	180 days
Updates for Kaspersky software modules have been revoked.	4142	KLSRV_SEAMLESS_UPDATE_REVOKED	Events of this type occur if updates have been revoked by Kaspersky experts, for example, to replace them with newer versions. For such updates, the status is *Revoked*. The event concerns Kaspersky EDR Expert patches and does not concern modules of managed Kaspersky applications. The event provides the reason that the seamless updates are not installed.	180 days
Virus outbreak.	• 26 (for File Threat Protection) • 27 (for Mail Threat Protection) • 28 (for firewall)	GNRL_EV_VIRUS_OUTBREAK	Events of this type occur when the number of malicious objects detected on several managed devices exceeds the threshold within a short period. You can respond to the event in the following ways: • Configure the threshold in the Administration Server properties. • Create a stricter policy that will be activated, or create a task that will be run, at the occurrence of this event.	

Administration Server functional failure events

The table below shows the events of Administration Server that have the **Info** importance level.

For each event that can be generated by an application, you can specify notification settings and storage settings on the **Event configuration** tab in the application policy. For Administration Server, you can additionally view and configure the event list in the Administration Server properties. If you want to configure notification settings for all the events at once, configure general notification settings in the Administration Server properties.

Administration Server functional failure events

Event type display name	Event type ID	Event type	Description	Default storage term
Error copying updates to the specified folder.	4123	KLSRV_UPD_REPL_FAIL	Events of this type occur when software updates are copied to an additional shared folder(s). You can respond to the event in the following ways: • Check whether the user account that is employed to gain access to the folder(s) has write permission. • Check whether a user name and/or a password to the folder(s) is/are changed. • Check the internet connection, as it might be the cause of the event. Follow the instructions to update databases and software modules.	180 days
Failed to poll the cloud segment.	4143	KLSRV_KLCLOUD_SCAN_ERROR	Events of this type occur when Administration Server fails to poll a network segment in a cloud environment. Read the details in the event description and respond accordingly.	Not stored

Event type display name	Event type ID	Event type	Description	Default storage term
Limit of installations has been exceeded for one of the licensed applications groups.	4126	KLSRV_INVLICPROD_EXCEDED	Administration Server generates events of this type periodically (every hour). Events of this type occur if in Kaspersky EDR Expert you manage license keys of third-party applications and if the number of installations has exceeded the limit set by the license key of the third-party application. You can respond to the event in the following ways: • Look through the managed devices list. Delete the third-party application from devices on which the application is not in use. • Use a third-party license for more devices. You can manage license keys of third-party applications using the functionality of licensed applications groups. A licensed applications group includes third-party applications that meet criteria set by you.	180 days
No free disk space.	4107	KLSRV_DISK_FULL	Events of this type occur when the hard drive of the device on which Administration Server is installed runs out of free space. Free up disk space on the device.	180 days
No free space in the Administration Server database.	4110	KLSRV_DATABASE_FULL	Events of this type occur when there is no free space in the Administration Server database. Administration Server does not function when its database has reached its capacity and when further recording to the database is not possible. Following are the causes of this event, depending on the DBMS that you use, and appropriate responses to the event: • Limit the number of events to store in the Administration Server database. • In the Administration Server database, there are too many events sent by the Application Control component. You can change the settings of the Kaspersky Endpoint Security policy relating to Application Control event storage in the Administration Server database. Review the information on DBMS selection.	180 days
Runtime error.	4125	KLSRV_RUNTIME_ERROR	Events of this type occur because of unknown issues. Most often these are DBMS issues, network issues, and other software and hardware issues. Details of the event can be found in the event description.	180 days
Shared folder is not available.	4108	KLSRV_SHARED_FOLDER_UNAVAILABLE	Events of this type occur if the shared folder of Administration Server is not available. You can respond to the event in the following ways: • Check whether the Administration Server (where the shared folder is located) is turned on and available. • Check whether a user name and/or a password to the folder is/are changed. • Check the network connection.	180 days

Event type display name	Event type ID	Event type	Description	Default storage term
Administration Server database is not available.	4109	KLSRV_DATABASE_UNAVAILABLE	Events of this type occur if the Administration Server database becomes unavailable. You can respond to the event in the following ways: • Check whether the remote server that has the DBMS installed is available. • View the DBMS logs to discover the reason for Administration Server database unavailability.	180 days

Administration Server warning events

The table below shows the events of Network Agent that have the **Warning** severity level.

For each event that can be generated by an application, you can specify notification settings and storage settings on the **Event configuration** tab in the application policy. For Administration Server, you can additionally view and configure the event list in the Administration Server properties. If you want to configure notification settings for all the events at once, configure general notification settings in the Administration Server properties.

Administration Server warning events

Event type display name	Event type ID	Event type	Description	Default storage term
Administration Server certificate for mobile devices is expiring	6128	KLSRV_EV_SRV_CERT_EXPIRES_SOON	Events of this type occur when the Administration Server certificates for mobile devices and UEFI devices expires. You need to update the expired certificate.	90 days
APNs certificate expires soon	4136	KLSRV_APN_CERTIFICATE_EXPIRES_SOON	Events of this type occur when there are fewer than 14 days left before the APNs certificate expires. When the APNs certificate expires, you need to manually renew the APNs certificate and install it on an iOS MDM Server. We recommend that you schedule the APNs certificate renewal in advance of the expiration date.	Not stored
APNs certificate has expired	4135	KLSRV_APN_CERTIFICATE_EXPIRED	Events of this type occur when an APNs certificate expires. You need to manually renew the APNs certificate and install it on an iOS MDM Server.	Not stored
Audit: Test connection to SIEM server failed	5120	KLAUD_EV_SIEM_TEST_FAILED	Events of this type occur when an automatic connection test to the SIEM server failed.	90 days
Certificate has been removed	4134	KLSRV_CERTIFICATE_REMOVED	Events of this type occur when an administrator removes any type of certificate (General, Mail, VPN) for Mobile Device Management. After removing a certificate, mobile devices connected via this certificate will fail to connect to Administration Server. This event might be helpful when investigating malfunctions associated with the management of mobile devices.	90 days

Event type display name	Event type ID	Event type	Description	Default storage term
Certificate has been requested	4133	KLSRV_CERTIFICATE_REQUESTED	Events of this type occur when a certificate for Mobile Device Management fails to be automatically reissued. Following might be the causes and appropriate responses to the event: • Automatic reissue was initiated for a certificate for which the **Reissue certificate automatically if possible** option is disabled. This might be due to an error that occurred during creation of the certificate. Manual reissue of the certificate might be required. • If you use an integration with a public key infrastructure, the cause might be a missing SAM-Account-Name attribute of the account used for integration with PKI and for issuance of the certificate. Review the account properties.	90 days
Conflict of device names	4102	KLSRV_EVENT_HOSTS_CONFLICT	Events of this type occur when Administration Server considers two or more managed devices as a single device. Most often this happens when a cloned hard drive was used for software deployment on managed devices and without switching the Network Agent to the dedicated disk cloning mode on a reference device. To avoid this issue, switch Network Agent to the disk cloning mode on a reference device before cloning the hard drive of this device.	90 days
Connection to the primary Administration Server has been interrupted	4118	KLSRV_EV_MASTER_SRV_DISCONNECTED	Events of this type occur when a connection to the primary Administration Server is interrupted. Read the operating system log on the device where the primary Administration Server is installed and respond accordingly.	90 days
Connection to the secondary Administration Server has been interrupted	4116	KLSRV_EV_SLAVE_SRV_DISCONNECTED	Events of this type occur when a connection to the secondary Administration Server is interrupted. Read the operating system log on the device where the secondary Administration Server is installed and respond accordingly.	90 days
Device has remained inactive on the network for a long time	4103	KLSRV_EVENT_HOSTS_NOT_VISIBLE	Events of this type occur when a managed device shows inactivity for some time. Most often, this happens when a managed device is decommissioned. You can respond to the event in the following ways: • Manually remove the device from the list of managed devices. Specify the time interval after which the **Device has remained inactive on the network in a long time.** event is created by using OSMP Console. • Specify the time interval after which the device is automatically removed from the group by using OSMP Console.	90 days

Event type display name	Event type ID	Event type	Description	Default storage term
Device status is Warning	4114	KLSRV_HOST_STATUS_WARNING	Events of this type occur when a managed device is assigned the *Warning* status. You can configure the conditions under which the device status is changed to *Warning*.	90 days
Failed to download file to device	4165	KLSRV_FILE_DOWNLOAD_FAILED	Events of this type occur in the following cases: • You try to download a file to the corporate container, but a corporate container has not been created. • There is not enough space on the device. • Information about the file failed to download from the server. • The file contents failed to download from the server. • The folder could not be created on the device. • The file access permission is missing on the personal device. • The file access permission is missing in the corporate container.	90 days
Failed to send the FCM message to the FCM server	4140	KLSRV_GCM_GENERAL_ERROR	Events of this type occur due to unexpected errors on the Administration Server side when working with the Google Firebase Cloud Messaging HTTP protocol. Read the details in the event description and respond accordingly. If you cannot find the solution to an issue on your own, we recommend that you contact Kaspersky Technical Support.	90 days
Failed to send the FCM message to the mobile device	4138	KLSRV_GCM_DEVICE_ERROR	Events of this type occur when Mobile Device Management is configured to use Google Firebase Cloud Messaging (FCM) for connecting to managed mobile devices with an Android operating system and FCM Server fails to handle some of the requests received from Administration Server. It means that some of the managed mobile devices will not receive a push notification. Read the HTTP code in the details of the event description and respond accordingly. For more information on the HTTP codes received from FCM Server and related errors, please refer to the Google Firebase service documentation (see chapter "Downstream message error response codes").	90 days
Frequent events have been detected		KLSRV_EVENT_SPAM_EVENTS_DETECTED	Events of this type occur when Administration Server detects a frequent event on a managed device. Refer to the following section for details: Blocking frequent events.	90 days
Hard drive almost full	4105	KLSRV_NO_SPACE_ON_VOLUMES	Events of this type occur when the hard drive of the device on which Administration Server is installed almost runs out of free space. Free up disk space on the device.	90 days

Event type display name	Event type ID	Event type	Description	Default storage term
HTTP error sending the FCM message to the FCM server	4139	KLSRV_GCM_HTTP_ERROR	Events of this type occur when Mobile Device Management is configured to use Google Firebase Cloud Messaging (FCM) for connecting managed mobile devices with the Android operating system and FCM Server reverts to the Administration Server a request with a HTTP code other than 200 (OK). Following might be the causes and appropriate responses to the event: • Problems on the FCM server side. Read the HTTP code in the details of the event and respond accordingly. For more information on the HTTP codes received from FCM Server and related errors, please refer to the Google Firebase service documentation (see chapter "Downstream message error response codes"). • Problems on the proxy server side (if you use proxy server). Read the HTTP code in the details of the event and respond accordingly.	90 days
License limit has been exceeded	4098	KLSRV_EV_LICENSE_CHECK_100_110	Once a day Kaspersky EDR Expert checks whether a licensing limit is exceeded. Events of this type occur when Administration Server detects that some licensing limits are exceeded by Kaspersky applications installed on client devices and if the number of currently used licensing units covered by a single license constitute 100% to 110% of the total number of units covered by the license. Even when this event occurs, client devices are protected. You can respond to the event in the following ways: • Look through the managed devices list. Delete devices that are not in use. • Provide a license for more devices (add a valid activation code or a key file to Administration Server). Kaspersky EDR Expert determines the rules to generate events when a licensing limit is exceeded.	90 days
Limit of installations will soon be reached for one of the licensed applications groups	4128	KLSRV_INVLICPROD_EXPIRED_SOON	Events of this type occur when one of the license keys for third-party applications included in a licensed applications group is about to expire. As a result, the installation limit for one of the groups will be reduced. You can respond to the event in the following ways: • If the third-party application is not in use on some of the managed devices, delete the application from these devices. • If you expect that the number of installations for the third-party application will exceed the allowed maximum in the near future, consider obtaining a third-party license for a greater number of devices in advance. You can manage license keys of third-party applications using the functionality of licensed applications groups.	90 days
New updates for Kaspersky application modules have been registered	4141	KLSRV_SEAMLESS_UPDATE_REGISTERED	Events of this type occur when Administration Server registers new updates for the Kaspersky software installed on managed devices that require approval to be installed. Approve or decline the updates by using Kaspersky Security Center Web Console.	90 days

Event type display name	Event type ID	Event type	Description	Default storage term
No free space in the Administration Server database	4106	KLSRV_NO_SPACE_IN_DATABASE	Events of this type occur if space in the Administration Server database is too limited. If you do not remedy the situation, soon the Administration Server database will reach its capacity and Administration Server will not function. Following are the causes of this event, depending on the DBMS that you use, and the appropriate responses to the event. • Do not limit the number of events to store in the Administration Server database • Reduce the list of events to store in the Administration Server database Review the information on DBMS selection.	90 days
The limit on the number of events in the database is exceeded, deletion of events has started	4145	KLSRV_EVP_DB_TRUNCATING	Events of this type occur when deletion of old events from the Administration Server database has started after the Administration Server database capacity is reached. You can respond to the event in the following ways: • Change the maximum number of events stored in the Administration Server database • Reduce the list of events to store in the Administration Server database	Not stored
The limit on the number of events in the database is exceeded, the events have been deleted	4146	KLSRV_EVP_DB_TRUNCATED	Events of this type occur when old events have been deleted from the Administration Server database after the Administration Server database capacity is reached. You can respond to the event in the following ways: • Change the allowed maximum number of events to be stored in the Administration Server database • Reduce the list of events to store in the Administration Server database	Not stored

Administration Server informational events

The table below shows the events of Administration Server that have the **Info** importance level.

For each event that can be generated by an application, you can specify notification settings and storage settings on the **Event configuration** tab in the application policy. For Administration Server, you can additionally view and configure the event list in the Administration Server properties. If you want to configure notification settings for all the events at once, configure general notification settings in the Administration Server properties.

Administration Server informational events

Event type display name	Event type ID	Event type	Description	Default storage term
Administration Server certificate for mobile devices is being renewed	6127	KLSRV_EV_SRV_CERT_RENEWED	This event occurs when the Administration Server certificate has been renewed.	30 days
Audit: Command has been sent to device	4170	KLAUD_EV_COMMAND_SENT	Events of this type occur when the user sends a command to the mobile device.	30 days
Audit: Connection to Administration Server has been terminated	4151	KLAUD_EV_SERVERDISCONNECT		30 days

Event type display name	Event type ID	Event type	Description	Default storage term
Audit: Connection to the Administration Server has been established	4147	KLAUD_EV_SERVERCONNECT	Events of this type occur when a user connects to Administration Server by using OSMP Console. These events include the IP address of the device where the OSMP Console Server is installed.	30 days
Audit: Encryption keys imported/exported	5100	KLAUD_EV_DPEKEYSEXPORT	For example, this event occurs during migration.	30 days
Audit: Group settings have been modified	4149	KLAUD_EV_ADMGROUP_CHANGED	Events of this type occur when a security group has been edited.	30 days
Audit: Object has been modified	4148	KLAUD_EV_OBJECTMODIFY	This event tracks changes in the following objects: • Administration group • Security group • User • Managed device • Package • Task • Policy • Server • Virtual Server	30 days
Audit: Object properties have been modified	4152	KLAUD_EV_OBJECTPROPMODIFIED	This event tracks changes in the following properties: • User • License • Server • Virtual server	30 days
Audit: Object status has changed	4150	KLAUD_EV_TASK_STATE_CHANGED	For example, this event occurs when a task has failed with an error.	30 days
Audit: Test connection to SIEM server succeeded	5110	KLAUD_EV_SIEM_TEST_SUCCESS	Events of this type occur when a test connection to the SIEM server succeeded.	30 days
Audit: User permissions have been modified	4153	KLAUD_EV_OBJECTACLMODIFIED	This event occurs when user permissions have been modified	30 days
Connection to the primary Administration Server has been established	4117	KLSRV_EV_MASTER_SRV_CONNECTED		30 days
Connection to the secondary Administration Server has been established	4115	KLSRV_EV_SLAVE_SRV_CONNECTED	Refer to the following article for details: Creating a hierarchy of Administration Servers: adding a secondary Administration Server.	30 days
Databases have been updated	4144	KLSRV_UPD_BASES_UPDATED	Events of this type occur when the Download updates to the Administration Server repository task finishes updating databases.	30 days
Device has been automatically moved according to a rule	1074	KLSRV_HOST_MOVED_WITH_RULE_EX	Events of this type occur when devices have been moved to administration groups by using device moving rules. A separate event is published for each moved device.	30 days

Event type display name	Event type ID	Event type	Description	Default storage term
Device has been removed from the group: inactive on the network for a long time	4104	KLSRV_INVISIBLE_HOSTS_REMOVED	Events of this type occur when devices have been automatically removed from a group for inactivity.	30 days
FCM Instance ID has changed on this mobile device	4137	KLSRV_GCM_DEVICE_REGID_CHANGED	Events of this type occur when the Firebase Cloud Messaging token has changed on the device. For information on the FCM token rotation, please refer to the Firebase service documentation.	30 days
File uploaded to Administration Server	4162	KLSRV_FILE_UPLOADED	Events of this type occur if the administrator has uploaded a file to the list in Web Console: **Asset management** → **Mobile devices** → **Applications and files** → **Files**.	30 days
File deleted from Administration Server	4163	KLSRV_FILE_REMOVED	Events of this type occur if the administrator has deleted a file from the list in Web Console: **Asset management** → **Mobile devices** → **Applications and files** → **Files**.	30 days
File downloaded to device	4164	KLSRV_FILE_DOWNLOADED	This event occurs in the following cases: • The administrator has downloaded a file to the administrator's workstation from the list in the Web Console: **Asset management** → **Mobile devices** → **Applications and files** → **Files**. • A file from the **Asset management** → **Mobile devices** → **Applications and files** → **Files** list has been downloaded to a device on which Kaspersky Endpoint Security for Android is installed.	30 days
Failed to download file to device	4165	KLSRV_FILE_DOWNLOAD_FAILED	Events of this type occur in the following cases: • An error occurred when the administrator tried to download a file from the **Asset management** → **Mobile devices** → **Applications and files** → **Files** list in the Web Console to the administrator's workstation. • An error occurred while downloading a file from the **Asset management** → **Mobile devices** → **Applications and files** → **Files** list to a device on which Kaspersky Endpoint Security for Android is installed.	30 days
Files have been found to send to Kaspersky for analysis	4131	KLSRV_APS_FILE_APPEARED		30 days

Event type display name	Event type ID	Event type	Description	Default storage term
Limit of installations will soon be exceeded (more than 95% is used up) for one of the licensed applications groups.	4127	KLSRV_INVLICPROD_FILLED	Events of this type occur when the number of installations for third-party applications included in a licensed applications group reaches 90% of the maximum allowed value specified in the license key properties. You can respond to the event in the following ways: • If the third-party application is not in use on some of the managed devices, delete the application from these devices. • If you expect that the number of installations for the third-party application will exceed the allowed maximum in the near future, consider obtaining a third-party license for a greater number of devices in advance. You can manage license keys of third-party applications using the functionality of licensed applications groups.	30 days
New device has been detected	4100	KLSRV_EVENT_HOSTS_NEW_DETECTED	Events of this type occur when new networked devices have been discovered.	30 days
Over 90% of the license key is used up	4097	KLSRV_EV_LICENSE_CHECK_90	Events of this type occur when Administration Server detects that some licensing limits are close to being exceeded by Kaspersky applications installed on client devices and if the number of currently used licensing units covered by a single license constitute over 90% of the total number of units covered by the license. Even when a licensing limit is exceeded, client devices are protected. You can respond to the event in the following ways: • Look through the managed devices list. Delete devices that are not in use. • Provide a license for more devices (add a valid activation code or a key file to Administration Server). Kaspersky EDR Expert determines the rules to generate events when a licensing limit is exceeded.	30 days
Reserve Administration Server certificate for mobile devices has been created	6126	KLSRV_EV_SRV_CERT_RESERVE_CREATED	This event occurs when an Administration Server certificate has been created.	30 days
Updates have been successfully copied to the specified folder	4122	KLSRV_UPD_REPL_OK	Events of this type occur when the **Download updates to the Administration Server repository** task finishes copying files to a specified folder.	30 days

The events **Reserve Administration Server certificate for mobile devices has been created** and **Administration Server certificate for mobile devices is being renewed** are automatically published by Administration Server and displayed in Administration Console only when the operations corresponding to these events are performed for Administration Server certificates for mobile devices and UEFI devices.

Network Agent events

This section contains information about the events related to Network Agent.

Network Agent warning events

The table below shows the events of Network Agent that have the **Warning** severity level.

For each event that can be generated by an application, you can specify notification settings and storage settings on the **Event configuration** tab in the application policy. If you want to configure notification settings for all the events at once, configure general notification settings in the Administration Server properties.

Network Agent warning events

Event type display name	Event type ID	Event type	Description	Default storage term
KSN proxy server has started. Failed to check KSN for availability.	7718	KSNPROXY_STARTED_CON_CHK_FAILED	Events of this type occur when test connection fails for the configured KSN proxy connection.	30 days
Incident has occurred.	549	GNRL_EV_APP_INCIDENT_OCCURED	Events of this type occur when an incident has been found on a device. For example, this event occurs when the device has low disk space.	30 days
Sudoers file found does not match reference value	7724	KLNAG_EV_SUDOER_DIFFERENT	Events of this type occur when there is a mismatch between the sudoers file and the reference file.	30 days
Third-party software update installation has been postponed.	7698	KLNAG_EV_3P_PATCH_INSTALL_SLIPPED	For example, events of this type occur when EULA for a third-party update installation is declined.	30 days
Third-party software update installation has completed with a warning.	7696	KLNAG_EV_3P_PATCH_INSTALL_WARNING	Download the trace files and check the KLRI_PATCH_RES_DESC field value for details.	30 days
User management: warnings	7722	KLNAG_EV_USR_MNG_WRN	General warning event.	30 days
Warning has been returned during installation of the software module update.	7701	KLNAG_EV_PATCH_INSTALL_WARNING	Download the trace files and check the KLRI_PATCH_RES_DESC field value for details.	30 days

Network Agent informational events

The table below shows the events of Network Agent that have the **Info** severity level.

For each event that can be generated by an application, you can specify notification settings and storage settings on the **Event configuration** tab in the application policy. If you want to configure notification settings for all the events at once, configure general notification settings in the Administration Server properties.

Network Agent informational events

Event type display name	Event type ID	Event type	Default storage term
Application has been installed.	7703	KLNAG_EV_INV_APP_INSTALLED	30 days
Application has been uninstalled.	7704	KLNAG_EV_INV_APP_UNINSTALLED	30 days
Certificate received for Web Server HTTPS port	—	WEB_SERVER_CERTIFICATE_RENEWED	30 days
Device has been authorized.	7711	KLNAG_EV_NAC_HOST_AUTHORIZED	30 days
Device has been detected.	7710	KLNAG_EV_NAC_DEVICE_DISCOVERED	30 days
Device has been removed.	7709	KLNAG_EV_DEVICE_REMOVE	30 days

Event type display name	Event type ID	Event type	Default storage term
Installation of update for software modules has started.	7700	KLNAG_EV_PATCH_INSTALL_STARTING	30 days
KSN proxy has started. KSN availability check has completed successfully.	7719	KSNPROXY_STARTED_CON_CHK_OK	30 days
KSN proxy server has stopped.	7720	KSNPROXY_STOPPED	30 days
Monitored application has been installed.	7705	KLNAG_EV_INV_OBS_APP_INSTALLED	30 days
Monitored application has been uninstalled.	7706	KLNAG_EV_INV_OBS_APP_UNINSTALLED	30 days
New device has been added.	7708	KLNAG_EV_DEVICE_ARRIVAL	30 days
Root certificates installed	7727	KLNAG_EV_ROOT_CERT_INSTALLED	30 days
Root certificates removed	7729	KLNAG_EV_ROOT_CERT_REMOVED	30 days
Sudoers file successfully restored to reference value	7725	KLNAG_EV_SUDOER_RESTORED	30 days
Third-party application has been installed.	7707	KLNAG_EV_INV_CMPTR_APP_INSTALLED	30 days
Third-party software update has been installed successfully.	7694	KLNAG_EV_3P_PATCH_INSTALLED_SUCCESSFULLY	30 days
Third-party software update installation has started.	7695	KLNAG_EV_3P_PATCH_INSTALL_STARTING	30 days
Update for software modules has been installed successfully	7699	KLNAG_EV_PATCH_INSTALLED_SUCCESSFULLY	30 days
User management: info	7721	KLNAG_EV_USR_MNG_INF	30 days
Web Server started on host	—	WEB_SERVER_STARTED	30 days
Web Server stopped on host	—	WEB_SERVER_STOPPED	30 days
Windows Desktop Sharing: Application has been started.	7714	KLUSRLOG_EV_PROCESS_LAUNCHED	30 days
Windows Desktop Sharing: File has been modified.	7713	KLUSRLOG_EV_FILE_MODIFIED	30 days
Windows Desktop Sharing: File has been read.	7712	KLUSRLOG_EV_FILE_READ	30 days
Windows Desktop Sharing: Started.	7715	KLUSRLOG_EV_WDS_BEGIN	30 days
Windows Desktop Sharing: Stopped.	7716	KLUSRLOG_EV_WDS_END	30 days

Using event selections

Event selections provide an onscreen view of named sets of events that are selected from the Administration Server database. These sets of events are grouped according to the following categories:

- By importance level—**Critical events**, **Functional failures**, **Warnings**, and **Informational messages**
- By time—**Recent events**
- By type—**User requests** and **Audit events**

You can create and view user-defined event selections based on the settings available, in the OSMP Console interface, for configuration.

Event selections are available in the OSMP Console, in the **Monitoring** section, by clicking **Event selections**.

By default, event selections include information for the last seven days.

Kaspersky EDR Expert has a default set of event (predefined) selections:

- Events with different importance levels:
  - **Critical events**
  - **Functional failure**
  - **Warnings**
  - **Informational messages**
- **User requests** (events of managed applications)
- **Recent events** (over the last week)
- Audit events.

In Kaspersky EDR Expert, audit events related to service operations in your OSMP Console are displayed. These events are conditioned by actions of Kaspersky specialists. These events, for example include the following: logging in to Administration Server; Administration Server ports changing; Administration Server database backup; creation, modification, and deletion of user accounts.

You can also create and configure additional user-defined selections. In user-defined selections, you can filter events by the properties of the devices they originated from (device names, IP ranges, and administration groups), by event types and severity levels, by application and component name, and by time interval. It is also possible to include task results in the search scope. You can also use a simple search field where a word or several words can be typed. All events that contain any of the typed words anywhere in their attributes (such as event name, description, component name) are displayed.

Both for predefined and user-defined selections, you can limit the number of displayed events or the number of records to search. Both options affect the time it takes Kaspersky EDR Expert to display the events. The larger the database is, the more time-consuming the process can be.

You can do the following:

- Edit properties of event selections
- Generate event selections
- View details of event selections
- Delete event selections
- Delete events from the Administration Server database

Creating an event selection

To create an event selection:

1. In the main menu, go to the **Monitoring** → **Event selections**.
2. Click **Add**.
3. In the **New event selection** window that opens, specify the settings of the new event selection. Do this in one or more of the sections in the window.
4. Click **Save** to save changes.

   A confirmation window opens.
5. To view the event selection result, keep the **Go to selection result** check box selected.
6. Click **Save** to confirm the event selection creation.

If you kept the **Go to selection result** check box selected, the event selection result is displayed. Otherwise, the new event selection appears in the list of event selections.

Editing an event selection

To edit an event selection:

1. In the main menu, go to **Monitoring** → **Event selections**.
2. Select the check box next to the event selection that you want to edit.
3. Click the **Properties** button.

   An event selection settings window opens.
4. Edit the properties of the event selection.

   > For predefined event selections, you can edit only the properties on the following tabs: **General** (except for the selection name), **Time**, and **Access rights**.

   For user-defined selections, you can edit all properties.
5. Click **Save** to save changes.

The edited event selection is shown in the list.

Viewing a list of an event selection

To view an event selection:

1. In the main menu, go to the **Monitoring** → **Event selections**.
2. Select the check box next to the event selection that you want to start.
3. Do one of the following:
   - If you want to configure sorting in the event selection result, do the following:
     a. Click the **Reconfigure sorting and start** button.
     b. In the displayed **Reconfigure sorting for event selection** window, specify the sorting settings.
     c. Click the name of the selection.
   - Otherwise, if you want to view the list of events as they are sorted on the Administration Server, click the name of the selection.

The event selection result is displayed.

Exporting an event selection

Open Single Management Platform allows you to save an event selection and its settings to a KLO file. You can use this KLO file to import the saved event selection both to Kaspersky Security Center Windows and Kaspersky Security Center Linux.

Note that you can export only user-defined event selections. Event selections from the default set of Open Single Management Platform (predefined selections) cannot be saved to a file.

To export an event selection:

1. In the main menu, go to **Monitoring** → **Event selections**.
2. Select the check box next to the event selection that you want to export.
   You cannot export multiple event selections at the same time. If you select more than one selection, the **Export** button will be disabled.
3. Click the **Export** button.
4. In the opened **Save as** window, specify the event selection file name and path, and then click the **Save** button.
   The **Save as** window is displayed only if you use Google Chrome, Microsoft Edge, or Opera. If you use another browser, the event selection file is automatically saved in the **Downloads** folder.

Importing an event selection

Open Single Management Platform allows you to import an event selection from a KLO file. The KLO file contains the exported event selection and its settings.

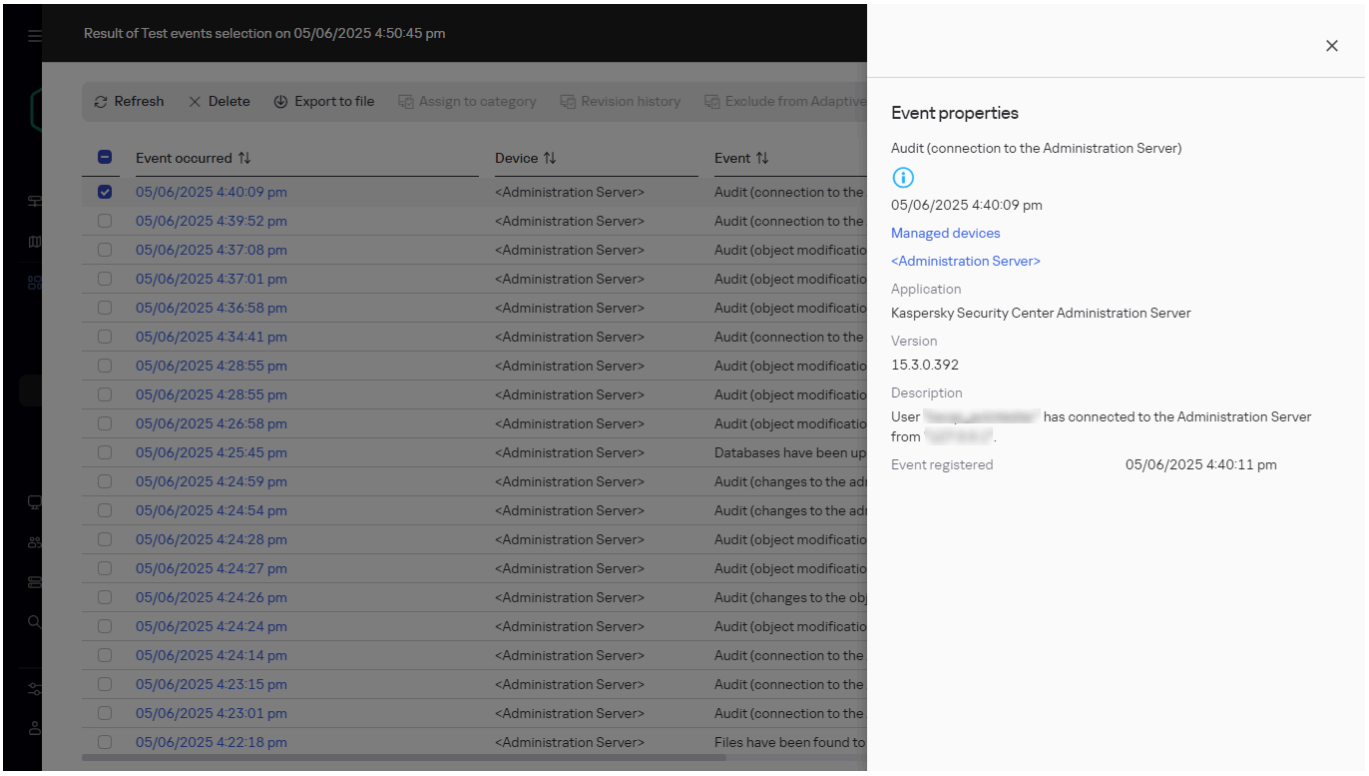
To import an event selection:

1. In the main menu, go to **Monitoring** → **Event selections**.
2. Click the **Import** button, and then choose an event selection file that you want to import.
3. In the opened window, specify the path to the KLO file, and then click the **Open** button. Note that you can select only one event selection file.

   The event selection processing starts.

The notification with the import results appears. If the event selection is imported successfully, you can click the **View import details** link to view the event selection properties.

After a successful import, the event selection is displayed in the selection list. The settings of the event selection are also imported.



> If the newly imported event selection has a name identical to that of an existing event selection, the name of the imported selection is expanded with the **(<next sequence number>)** index, for example: **(1)**, **(2)**.

Viewing details of an event

To view details of an event:

1. Start an event selection.
2. Click the time of the required event.

The **Event properties** window opens.

The event properties window

3. In the displayed window, you can do the following:

   - View the information about the selected event
   - Go to the device on which the event occurred
   - Go to the administration group that includes the device on which the event occurred
   - For an event related to a task, go to the task properties

Exporting events to a file

Open Single Management Platform allows you to save events from an event selection to a TXT file.

To export events to a file:

1. Start an event selection.
2. Select the check box next to the required event.
   You can also select several events or the entire event selection.
3. Click the **Export to file** button.

The selected event is exported to a TXT file.

Viewing an object history from an event

From an event of creation or modification of an object that supports revision management, you can switch to the revision history of the object.

To view an object history from an event:

1. Start an event selection.
2. Select the check box next to the required event.
3. Click the **Revision history** button.

   The revision history of the object is opened.

Deleting events

To delete events from an event selection:

1. Start an event selection.
2. Select the events:
   - If you want to delete one or several events, select the check boxes next to it.
   - If you want to delete all events on current page, select the check box above the list of events and click the **Select all on current page** option.
   - If you want to delete all events from a selection, select the check box above the list of events and click the **Select all** option.
3. Then click the **Delete** button.
4. In the window that opens, click **Delete**.

To delete events from a device events list:

1. Open the device list.
   - For managed devices: **Asset management** → **Assets (Devices)**.
   - For unassigned devices: **Asset management** → **Unassigned devices**.
2. In the list of devices, click the link with the name of the required device, and then go to the **Events** tab.

3. Select the events:

   - If you want to delete one or several events, select the check boxes next to it.
   - If you want to delete all events on current page, select the check box above the list of events and click the **Select all on current page** option.
   - If you want to delete all events from a selection, select the check box above the list of events and click the **Select all** option.

4. Click **Delete**, and then confirm the action.

5. In the window that opens, click **Delete**.

   The selected events are deleted and cannot be restored.

Deleting event selections

You can delete only user-defined event selections. Predefined event selections cannot be deleted.

To delete one or several event selections:

1. In the main menu, go to **Monitoring** → **Event selections**.

2. Select the check boxes next to the event selections that you want to delete.

3. Then click the **Delete** button.

4. In the window that opens, click **OK**.

   The event selection is deleted.

Setting the storage term for an event

Kaspersky EDR Expert allows you to receive information about events that occur during the operation of Administration Server and Kaspersky applications installed on managed devices. Information about events is saved in the Administration Server database. You might need to store some events for a longer or shorter period than specified by default values. You can change the default settings of the storage term for an event.

If you are not interested in storing some events in the database of Administration Server, you can disable the appropriate setting in the Administration Server policy and Kaspersky application policy, or in the Administration Server properties (only for Administration Server events). This will reduce the number of event types in the database.

The longer the storage term for an event, the faster the database reaches its maximum capacity. However, a longer storage term for an event lets you perform monitoring and reporting tasks for a longer period.

To set the storage term for an event in the database of Administration Server:

1. In the main menu, go to **Asset management** → **Policies**.
2. Click the name of the required policy.

   You can select a policy of a managed Kaspersky application, Network Agent, or Administration Server. For Administration Server, you can also configure the storage term of the events by clicking the Administration Server name.
3. Select the **Event configuration** tab.

   A list of event types related to the **Critical** section is displayed. If necessary, you can move to the **Functional failure**, **Warning**, or **Info** section.
4. In the list of event types in the right pane, click the link for the event whose storage term you want to change.

   In the **Event registration** section of the window that opens, the **Store in the Administration Server database for (days)** toggle button is enabled.
5. In the edit box below this toggle button, enter the number of days to store the event.
6. If you do not want to store an event in the Administration Server database, disable the **Store in the Administration Server database for (days)** option.

   > If you configure Administration Server events in Administration Server properties window and if event settings are locked in the Administration Server policy, you cannot redefine the storage term value for an event.
7. Click **OK**, and then after the right pane is closed, click the **Save** button.

   The properties window of the policy is closed.

From now on, when Administration Server receives and stores the events of the selected type, they will have the changed storage term. Administration Server does not change the storage term of previously received events.

Blocking frequent events

This section provides information about managing frequent events blocking and about removing blocking of frequent events.

About blocking frequent events

A managed application, for example, Kaspersky Endpoint Security for Linux, installed on a single or several managed devices can send a lot of events of the same type to the Administration Server. Receiving frequent events may overload the Administration Server database and overwrite other events. Administration Server starts blocking the most frequent events when the number of all the received events exceeds the specified limit for the database.

> Administration Server blocks the frequent events from receiving automatically. You cannot block the frequent events yourself, or choose which events to block.

If you want to find out if an event is blocked, you can view the notification list or you can check if this event is present in the **Blocking frequent events** section of the Administration Server properties. If the event is blocked, you can do the following:

- If you want to prevent overwriting the database, you can continue blocking such type of events from receiving.
- If you want, for example, to find the reason of sending the frequent events to the Administration Server, you can unblock frequent events and continue receiving the events of this type anyway.
- If you want to continue receiving the frequent events until they become blocked again, you can remove from blocking the frequent events.

Managing frequent events blocking

Administration Server blocks the automatic receiving of frequent events, but you can unblock and continue to receive frequent events. You can also block receiving frequent events that you unblocked before.

To manage frequent events blocking:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Blocking frequent events** section.
3. In the **Blocking frequent events** section:
   - If you want to unblock the receiving of frequent events:
     a. Select the frequent events you want to unblock, and then click the **Exclude** button.
     b. Click **Save**.
   - If you want to block receiving frequent events:
     a. Select the frequent events you want to block, and then click the **Block** button.
     b. Click **Save**.

Administration Server receives the unblocked frequent events and does not receive the blocked frequent events.

Removing blocking of frequent events

You can remove blocking for frequent events and start receiving them until Administration Server blocks these frequent events again.

To remove blocking for frequent events:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Blocking frequent events** section.

3. In the **Blocking frequent events** section, select the frequent event types for which you want to remove blocking.

4. Click the **Remove from blocking** button.

The frequent event is removed from the list of frequent events. Administration Server will receive events of this type.

Event processing and storage on the Administration Server

Information about events that occur during the operation of the application and managed devices is saved in the Administration Server database. Each event is attributed to a certain type and level of severity (*Critical event*, *Functional failure*, *Warning*, or *Info*). Depending on the conditions under which an event occurred, the application can assign different levels of severity to events of the same type.

You can view types and levels of severity assigned to events in the **Event configuration** section of the Administration Server properties window. In the **Event configuration** section, you can also configure processing of every event by the Administration Server:

- Registration of events on the Administration Server and in event logs of the operating system on a device and on the Administration Server.

- Method used for notifying the administrator of an event (for example, an SMS or email message).

In the **Events repository** section of the Administration Server properties window, you can edit the settings of events storage in the Administration Server database by limiting the number of event records and record storage term. When you specify the maximum number of events, the application calculates an approximate amount of storage space required for the specified number. You can use this approximate calculation to evaluate whether you have enough free space on the disk to avoid database overflow. The default capacity of the Administration Server database is 400,000 events. The maximum recommended capacity of the database is 45 million events.

The application checks the database every 10 minutes. If the number of events reaches the specified maximum value plus 10,000, the application deletes the oldest events so that only the specified maximum number of events remains.

When the Administration Server deletes old events, it cannot save new events to the database. During this period, information about events that were rejected is written to the operating system log. The new events are queued and then saved to the database after the deletion operation is complete. By default, the event queue is limited to 20,000 events. You can customize the queue limit by editing the KLEVP_MAX_POSTPONED_CNT flag value.

Retroscan

In normal mode, the correlator handles only events coming from collectors in real time. A **retrospective scan** allows applying correlation rules to past events if you want to debug correlation rules or analyze data.

To test a correlation rule, you do not need to replay the incident in real time. Instead, you can run the correlation rule in **Retrospective scan** mode to process the existing events which include the required incident.

You can use a search query to define a list of events for retrospective scan, as well as specify a search period and the storage that you want to search for events. You can configure a task to have alerts generated and response rules applied during the retrospective scan of events.

To run a retrospective scan:

1. In the **Monitoring** → **Threat hunting** section of the solution web interface, create the required event selection:
   - Select the storage.

     Before running a retrospective scan, make sure that the correct clusters and spaces are selected.

   - Configure search expression using the constructor or search query.

     Before running a retrospective scan, make sure that the correct expression is specified in the SQL query field.

   - Set a period as needed.

     Before running a retrospective scan, make sure that the correct period is selected in the period field.

2. In the ••• drop-down list, select **Retrospective scan**.
   The retrospective scan window opens.

3. In the **Correlator** drop-down list, select the Correlator to feed selected events to.

   Before running a retrospective scan, check the number of events found by the SQL query. This information is displayed under **Show timeline** → **Total**. If a **LIMIT** is not specified in the SQL query, all events for the period are sent to the correlator, and the task takes longer to complete. If a relative period is set (for example, *now-1h*), new events may be produced by the start of the retrospective scan; such events are also sent to the correlator. If the correlator is installed in a tenant other than the main tenants (Main, RootTenant), it can only receive events of its own tenant.

4. In the **Correlation rules** drop-down list, select the Correlation rules that must be used when processing events. If no rules are selected at this step, the scan is performed with all correlation rules applied.

5. In the **EPS limit** field, specify the maximum EPS to be used for a retrospective scan. The specified value sets the maximum load when performing a retrospective scan. The default setting is 0, which means that no EPS limit is applied to a retrospective scan.

   Negative EPS values are not allowed.

6. If you want responses to be executed when processing events, turn on the **Execute responses** toggle switch.

7. If you want alerts to be generated during event processing, turn on the **Create alerts** toggle switch.

8. Click the **Create task** button.

The retrospective scan task is created and displayed in the **Task manager** section.

To view scan results, in the **Task manager** section of the KUMA web interface, click the task you created and in the drop-down list, select **Go to Events**.

Retrospective scan results only show the generated correlation events.
The start of the period in retrospective scan results is displayed as <date and time of the task creation>, and the end of the period is shown as <date and time of task creation + one hour> (or the current time if one hour has not yet elapsed since the task creation).
If there are no events in the retrospective scan results, it means that the correlator was not triggered by events from the SQL selection that were sent to it.

A new browser tab is opened, containing events that were processed during the retrospective scan, as well as aggregated and correlation events created during event processing. Correlation events generated by the retrospective scan have an additional ReplayID field that stores a unique ID of the retrospective scan. An analyst can restart the retroscan from the context menu of the task. New correlation events will have a different ReplayID.

Depending on your browser settings, you may be prompted to confirm the opening of the retrospective scan results tab. For more details, please refer to the documentation for your specific browser.

Events processed as part of a retrospective scan are not enriched with data from CyberTrace or the Kaspersky Threat Intelligence Portal.

Active lists are updated during retrospective scan.

Retrospective scan cannot be performed based on SQL queries that contain arithmetic expressions or only aggregation fields. You can retrospectively scan groups of events obtained using a grouping SQL query only after the processing of the query has finished. To do this, first run SQL query with data grouping and get a list of event groups, and then run a retrospective scan on one of the groups.

Notifications and device statuses

This section contains information on how to view notifications, configure notification delivery, use device statuses, and enable changing device statuses.

Using notifications

Notifications alert you about events and help you to speed up your responses to these events by performing recommended actions or actions you consider as appropriate.

Depending on the notification method chosen, the following types of notifications are available:

- Onscreen notifications
- Notifications by SMS

- Notifications by email
- Notifications by executable file or script

Onscreen notifications

Onscreen notifications alert you to events grouped by importance levels (*Critical*, *Warning*, and *Informational*).

Onscreen notification can have one of two statuses:

- *Reviewed*. It means you have performed recommended action for the notification, or you have assigned this status for the notification manually.
- *Not Reviewed*. It means you have not performed recommended action for the notification, or you have not assigned this status for the notification manually.

By default, the list of notifications include notifications in the *Not Reviewed* status.

You can monitor your organization's network viewing onscreen notifications and responding to them in a real time.

Notifications by email, by SMS, and by executable file or a script

Kaspersky EDR Expert provides the capability to monitor your organization's network by sending notifications about any event that you consider important. For any event, you can configure notifications by email, by SMS, or by running an executable file or a script.

Upon receiving notifications by email or by SMS, you can decide on your response to an event. This response should be the most appropriate for your organization's network. By running an executable file or a script, you predefine a response to an event. You can also consider running an executable file or a script as a primary response to an event. After the executable file runs, you can take other steps to respond to the event.

Viewing onscreen notifications

You can view notifications onscreen in three ways:

- In the **Monitoring** → **Notifications** section. Here you can view notifications relating to predefined categories.
- In a separate window that can be opened no matter which section you are using at the moment. In this case, you can mark notifications as reviewed.
- In the **Notifications by selected severity level** widget on the **Monitoring** → **Dashboard** section. In the widget, you can view only notifications of events that are at the *Critical* and *Warning* importance levels.

You can perform actions, for example, you can response to an event.

To view notifications from predefined categories:

1. In the main menu, go to **Monitoring → Notifications**.

   The **All notifications** category is selected in the left pane, and in the right pane, all the notifications are displayed.

2. In the left pane, select one of the categories:

   - **Deployment**
   - **Devices**
   - **Protection**
   - **Updates**

     This notification includes notifications about Kaspersky applications available for download, notifications about anti-virus database updates that have been downloaded, as well as notifications about the devices (if any) that require to be restarted after a Network Agent update.

   - **Exploit Prevention**
   - **Administration Server**.

     This includes events concerning only Administration Server.

   - **Useful links**.

     This includes links to Kaspersky resources, for example, Kaspersky Technical Support, Kaspersky forum, license renewal page, or the Kaspersky IT Encyclopedia.

   A list of notifications of the selected category is displayed. The list contains the following:

- Icon related to the topic of the notification: deployment (), protection (), updates (), device management (), Exploit Prevention (), Administration Server ().
- Notification importance level. Notifications of the following importance levels are displayed: **Critical notifications** (), **Warning notifications** (), **Info notifications**. Notifications in the list are grouped by importance levels.
- **Notification**. This contains a description of the notification.
- **Action**. This contains a link to a quick action that we recommend you perform. For example, by clicking this link, you can proceed to the repository and install security applications on devices, or view a list of devices or a list of events. After you perform the recommended action for the notification, this notification is assigned the *Reviewed* status.
- **Status registered**. This contains the number of days or hours that have passed from the moment when the notification was registered on the Administration Server.

To view onscreen notifications in a separate window by importance level:

1. In the upper-right corner of OSMP Console, click the flag icon ().

   If the flag icon has a red dot, there are notifications that have not been reviewed.

A window opens listing the notifications. By default, the **All notifications** tab is selected and the notifications are grouped by importance level: *Critical*, *Warning*, and *Info*.

2. Select the **System** tab.

   The list of *Critical* ( ) and *Warning* ( ) importance levels notifications is displayed. The notification list includes the following:

   - Color marker. Critical notifications are marked in red. Warning notifications are marked in yellow.
   - Icon indicating the topic of the notification: deployment ( ), protection ( ), updates ( ), device management ( ), Exploit Prevention ( ), Administration Server ( ).
   - Description of the notification.
   - The check mark icon. The flag icon is gray if notifications have been assigned the *Not Reviewed* status. When you select the gray flag icon and assign the *Reviewed* status to a notification, the icon changes color to white.
   - Link to the recommended action. When you perform the recommended action after clicking the link, the notification gets the *Reviewed* status.
   - Number of days that have passed since the date when the notification was registered on the Administration Server.

3. Select the **More** tab.

   The list of *Info* importance level notifications is displayed.

   The organization of the list is the same as for the list on the **System** tab (see the description above). The only difference is the absence of a color marker.

You can filter notifications by the date interval when they were registered on Administration Server. Use the **Show filter** check box to manage the filter.

To view onscreen notifications in the widget:

1. In the **Dashboard** section, select **Add or restore widget**.

2. In the window that opens, click the **Other** category, select the **Notifications by selected severity level** widget, and click Add.

   The widget now appears on the **Dashboard** tab. By default, the notifications of *Critical* importance level are displayed on the widget.

   You can click the **Settings** button on the widget and change the widget settings to view notifications of the *Warning* importance level. Or, you can add another widget: **Notifications by selected severity level**, with a *Warning* importance level.

   The list of notifications on the widget is limited by its size and includes two notifications. These two notifications relate to the latest events.

The notification list in the widget includes the following:

- Icon related to the topic of the notification: deployment ( ), protection ( ), updates ( ), device management ( ), Exploit Prevention ( ), Administration Server ( ).
- Description of the notification with a link to the recommended action. When you perform the recommended action after clicking the link, the notification gets the *Reviewed* status.

- Number of days or number of hours that have passed since the date when the notification was registered on the Administration Server.
- Link to other notifications. Upon clicking this link, you are transferred to the view of notifications in the **Notifications** section of the **Monitoring** section.

About device statuses

Kaspersky EDR Expert assigns a status to each managed device. The particular status depends on whether the conditions defined by the user are met. In some cases, when assigning a status to a device, Kaspersky EDR Expert takes into consideration the device's visibility flag on the network (see the table below). If Kaspersky EDR Expert does not find a device on the network within two hours, the visibility flag of the device is set to *Not Visible*.

The statuses are the following:

- *Critical* or *Critical/Visible*
- *Warning* or *Warning/Visible*
- *OK* or *OK/Visible*

The table below lists the default conditions that must be met to assign the *Critical* or *Warning* status to a device, with all possible values.

Conditions for assigning a status to a device

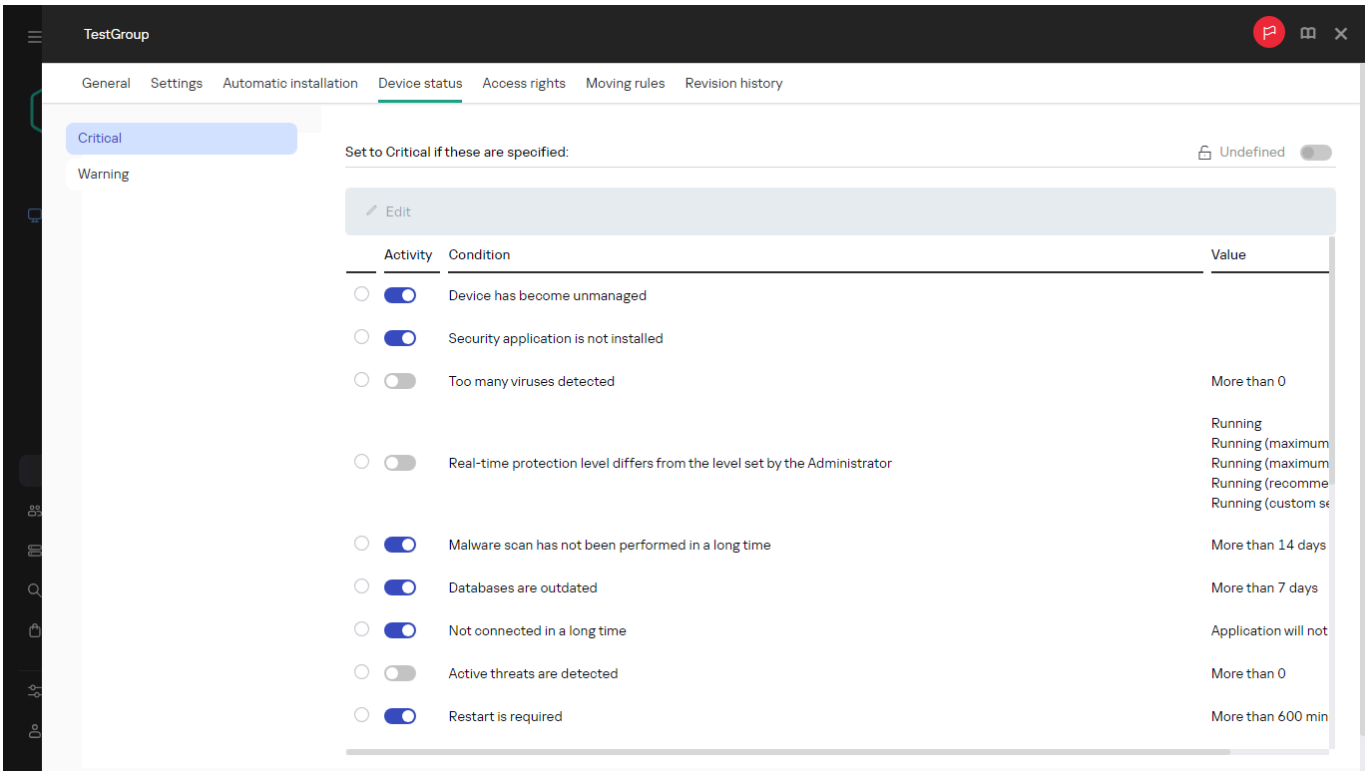
Condition	Condition description	Available values
Security application is not installed	Network Agent is installed on the device, but a security application is not installed.	• Toggle button is on. • Toggle button is off.
Too many viruses detected	Some viruses have been found on the device by a task for virus detection, for example, the Malware scan task, and the number of viruses found exceeds the specified value.	More than 0.
Real-time protection level differs from the level set by the Administrator	The device is visible on the network, but the real-time protection level differs from the level set (in the condition) by the administrator for the device status.	• Stopped. • Suspended. • Running.
Malware scan has not been performed in a long time	The device is visible on the network and a security application is installed on the device, but neither the *Malware scan* task nor a local scan task has been run within the specified time interval. The condition is applicable only to devices that were added to the Administration Server database 7 days ago or earlier.	More than 1 day.
Databases are outdated	The device is visible on the network and a security application is installed on the device, but the anti-virus databases have not been updated on this device within the specified time interval. The condition is applicable only to devices that were added to the Administration Server database 1 day ago or earlier.	More than 1 day.
Not connected in a long time	Network Agent is installed on the device, but the device has not connected to an Administration Server within the specified time interval, because the device was turned off.	More than 1 day.
Active threats are detected	The number of unprocessed objects in the **Active threats** folder exceeds the specified value.	More than 0 items.

Condition	Condition description	Available values
Time since restart required	The device is visible on the network, but a restart has been required by an application for longer than the specified time interval.	More than 0 minutes.
Restart reason	The device is visible on the network, but an application requires a device restart for one of the selected reasons.	• Unknown reason • Application will not run until restart • Restart is required to complete update; application is running • Restart is required to launch update • Restart is required to complete scan or disinfection • Restart is required to complete remote installation/uninstallation • Completing data encryption on disk
Incompatible applications are installed	The device is visible on the network, but software inventory performed through Network Agent has detected incompatible applications installed on the device.	• Toggle button is off. • Toggle button is on.
Software vulnerabilities have been detected	The device is visible on the network and Network Agent is installed on the device, but the *Find vulnerabilities and required updates* task has detected vulnerabilities with the specified severity level in applications installed on the device.	• Critical • High. • Medium. • Ignore if the vulnerability cannot be fixed. • Ignore if an update is assigned for installation.
License expired	The device is visible on the network, but the license has expired.	• Toggle button is off. • Toggle button is on.
License expires soon	The device is visible on the network, but the license will expire on the device in less than the specified number of days.	Less than 0 days.
Check for Windows Update updates has not been performed in a long time	The device is visible on the network, but the *Find vulnerabilities and required updates* task has not been run within the specified time interval.	More than 1 day.
Invalid encryption status	Network Agent is installed on the device, but the device encryption result is equal to the specified value.	• Does not comply with the policy due to the user's refusal (for external devices only). • Does not comply with the policy due to an error. • Restart is required when applying the policy. • No encryption policy is specified. • Not supported. • When applying the policy.
Mobile device settings do not comply with the policy	The mobile device settings are other than the settings that were specified in the Kaspersky Endpoint Security for Android policy during the check of compliance rules.	• Toggle button is off. • Toggle button is on.
Unprocessed security issues detected	Some unprocessed security issues have been found on the device. Security issues can be created either automatically, through managed Kaspersky applications installed on the client device, or manually by the administrator.	• Toggle button is off. • Toggle button is on.
Device status defined by application	The status of the device is defined by the managed application.	• Toggle button is off. • Toggle button is on.
Device is out of disk space	Free disk space on the device is less than the specified value, or the device could not be synchronized with the Administration Server. The *Critical* or *Warning* status is changed to the *OK* status when the device is successfully synchronized with the Administration Server and free space on the device is greater than or equal to the specified value.	More than 0 MB.
Device has become unmanaged	During device discovery, the device was recognized as visible on the network, but more than three attempts to synchronize with the Administration Server failed.	• Toggle button is off. • Toggle button is on.
Protection is disabled	The device is visible on the network, but the security application on the device has been disabled for longer than the specified time interval. In this case, the state of the security application is *stopped* or *failure*, and differs from the following: *starting*, *running*, or *suspended*.	More than 0 minutes.
Security application is not running	The device is visible on the network and a security application is installed on the device but is not running.	• Toggle button is off. • Toggle button is on.

Kaspersky EDR Expert allows you to set up automatic switching of the status of a device in an administration group when specified conditions are met. When the specified conditions are met, the client device is assigned one of the following statuses: *Critical* or *Warning*. When the specified conditions are not met, the client device is assigned the *OK* status.

Different statuses may correspond to different values of one condition. For example, by default, if the **Databases are outdated** condition has the **More than 3 days** value, the client device is assigned the *Warning* status; if the value is **More than 7 days**, the *Critical* status is assigned.

When Kaspersky EDR Expert assigns a status to a device, for some conditions (see the Condition description column in the table above) the visibility flag is taken into consideration. For example, if a managed device was assigned the *Critical* status because the Databases are outdated condition was met, and later the visibility flag was set for the device, then the device is assigned the *OK* status.



Configuring the switching of device statuses

You can change conditions to assign the *Critical* or *Warning* status to a device.

To enable changing the device status to Critical:

1. In the main menu, go to **Asset management** → **Hierarchy of groups**.
2. Go to the properties of the administration group for which you want to change the device statuses in one of the following ways:
   - Click the name of the administration group.
   - Click the **Show hierarchy** button at the top of the page. In the navigation pane that opens, hover the mouse cursor over the name of the required group, and then click the settings icon (⚙).

   The administration group properties window opens.
3. In the properties window, select the **Device status** tab.
4. In the left pane, select **Critical**.
5. In the right pane, in the **Set to Critical if the following settings are specified** section, enable the condition to switch a device to the *Critical* status.

You can change only settings that are not locked in the parent policy.

6. Select the radio button next to the condition in the list.
7. In the upper-left corner of the list, click the **Edit** button.
8. Set the required value for the selected condition.

   Values cannot be set for every condition.
9. Click **OK**.
10. Click **Save** to save changes.

When specified conditions are met, the managed device is assigned the *Critical* status.

To enable changing the device status to Warning:

1. In the main menu, go to **Asset management** → **Hierarchy of groups**.
2. In the list of groups that opens, click the link with the name of a group for which you want to change switching the device statuses.
3. In the properties window that opens, select the **Device status** tab.
4. In the left pane, select **Warning**.
5. In the right pane, in the **Set to Warning if the following settings are specified** section, enable the condition to switch a device to the *Warning* status.

You can change only settings that are not locked in the parent policy.

6. Select the radio button next to the condition in the list.
7. In the upper-left corner of the list, click the **Edit** button.
8. Set the required value for the selected condition.

   Values cannot be set for every condition.
9. Click **OK**.
10. Click **Save** to save changes.

When specified conditions are met, the managed device is assigned the *Warning* status.

Configuring notification delivery

You can configure notification about events occurring in Kaspersky EDR Expert. Depending on the notification method chosen, the following types of notifications are available:

- Email—When an event occurs, Kaspersky EDR Expert sends a notification to the email addresses specified.
- SMS—When an event occurs, Kaspersky EDR Expert sends a notification to the phone numbers specified.
- Executable file—When an event occurs, the executable file is run on the Administration Server.

To configure notification delivery of events occurring in Kaspersky EDR Expert:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens with the **General** tab selected.
2. Click the **Notification** section, and in the right pane select the tab for the notification method you want:

   - **Email**

     The **Email** tab allows you to configure event notification by email.

     In the **SMTP servers** field, specify mail server addresses, separating them with semicolons. You can use the following values:

     - IPv4 or IPv6 address
     - DNS name of the SMTP server

     In the **SMTP server port** field, specify the number of an SMTP server communication port. The default port number is 25.

     If you enable the **Use DNS MX lookup** option, you can use several MX records of the IP addresses for the same DNS name of the SMTP server. The same DNS name may have several MX records with different values of priority of receiving email messages. Administration Server attempts to send email notifications to the SMTP server in ascending order of MX records priority.

     > If you enable the **Use DNS MX lookup** option and do not enable usage of TLS settings, we recommend that you use the DNSSEC settings on your server device as an additional measure of protection for sending email notifications.

If the **Use ESMTP authentication** option is enabled, you can specify the ESMTP authentication settings in the **User name** and **Password** fields. By default, the option is disabled, and the ESMTP authentication settings are not available.

You can specify TLS settings of connection with an SMTP server:

- **Do not use TLS**

You can select this option if you want to disable encryption of email messages.

- **Use TLS if supported by the SMTP server**

You can select this option if you want to use a TLS connection to an SMTP server. If the SMTP server does not support TLS, Administration Server connects the SMTP server without using TLS.

- **Always use TLS, check server certificate validity**

You can select this option if you want to use TLS authentication settings. If the SMTP server does not support TLS, Administration Server cannot connect the SMTP server.

> We recommend that you use this option for better protection of the connection with an SMTP server. If you select this option, you can set authentication settings for a TLS connection.

If you select **Always use TLS, check server certificate validity** value, you can specify a certificate for authentication of the SMTP server and choose whether you want to enable communication through any version of TLS or only through TLS 1.2 or later versions. Also, you can specify a certificate for client authentication on the SMTP server.

You can specify certificates for a TLS connection by clicking the **Specify certificates** link:

- Browse for an SMTP server certificate file:

You can receive a file with the list of certificates from a trusted certification authority and upload the file to Administration Server. Kaspersky EDR Expert checks whether the certificate of an SMTP server is also signed by a trusted certification authority. Kaspersky EDR Expert cannot connect to an SMTP server if the certificate of the SMTP server is not received from a trusted certification authority.

- Browse for a client certificate file:

You can use a certificate that you received from any source, for example, from any trusted CA. You must specify the certificate and its private key by using one of the following certificate types:

- X-509 certificate:

You must specify a file with the certificate and a file with the private key. The two files are independent of each other. The order in which the files are loaded does not matter. When both files are loaded, you must specify the password for decoding the private key. The password can have an empty value if the private key is not encoded.

- pkcs12 container:

You must upload a single file that contains the certificate and its private key. When the file is loaded, you must then specify the password for decoding the private key. The password can have an empty value if the private key is not encoded.

Clicking the **Send test message** button allows you to check whether you configured notifications properly: the application sends a test notification to the email addresses that you specified.

In the **Recipients (email addresses)** field, specify the email addresses to which the application will send notifications. You can specify multiple addresses in this field, by separating them with semicolons.

In the **Subject** field, enter the email subject using substitution parameters, for example: `[KSC-SAMARA-1] [%SEVERITY%] %EVENT%`. Example of what the subject line looks like in case of a detected threat: `[KSC-SAMARA-1] [Critical] Threat detected`. You can leave this field empty.

In the **Subject template** drop-down list, select the template for your subject. A variable determined by the selected template is placed automatically in the **Subject** field. You can construct an email subject selecting several subject templates.

In the **Sender email address: If this setting is not specified, the recipient address will be used instead. Warning: We do not recommend using a fictitious email address** field, specify the sender email address. If you leave this field empty, by default, the recipient address is used. It is not recommended to use fictitious email addresses.

The **Notification message** field contains standard text with information about the event that the application sends when an event occurs. This text includes substitute parameters, such as event name, device name, and domain name. You can edit the message text by adding other substitute parameters with more relevant details about the event.

Example of field value

```
Sender - KSC-SAMARA-1

Host: %COMPUTER%

Product: %KL_PRODUCT%

Version: %KL_VERSION%

Occurred at: %RISE_TIME%

Event: %EVENT%

Details:

%DESCR%
```

The `Sender` string is optional. For example, if you have multiple Administration Servers, you can specify the name of the Administration Server from which the notification was received: `Sender - KSC-SAMARA-1`.

Example of what the notification text looks like:

```
Sender - KSC-SAMARA-1

Host: nb-123456.example.net

Product: Kaspersky Endpoint Security 12.5 for Linux

Version: 12.5.0.1569

Occurred at: 2026-08-17T13:15:36

Event: Threat detected

Details:
```

```
Initiator: Product; Task type: ODS; ID of running task: 107; User receiving access:
root; Object type: File; File owner: user; Detection certainty: Sure; File:
/home/user/eicar_com.zip//eicar.com; Detected object name: EICAR-Test-File; Detected
object type: Virware; MD5 hash: <hash>; Unique ID: <ID>
```

If the notification text contains a percent sign (%), you have to type it twice in a row to allow message sending. For example, "CPU load is 100%%".

Clicking the **Configure numeric limit of notifications** link allows you to specify the maximum number of notifications that the application can send during the specified time interval.

- SMS

The **SMS** tab allows you to configure the transmission of SMS notifications about various events to a cell phone. SMS messages are sent through a mail gateway.

In the **SMTP servers** field, specify mail server addresses, separating them with semicolons. You can use the following values:

- IPv4 or IPv6 address
- DNS name of the SMTP server

In the **SMTP server port** field, specify the number of an SMTP server communication port. The default port number is 25.

If the **Use ESMTP authentication** option is enabled, you can specify the ESMTP authentication settings in the **User name** and **Password** fields. By default, the option is disabled, and the ESMTP authentication settings are not available.

You can specify TLS settings of connection with an SMTP server:

- **Do not use TLS**

You can select this option if you want to disable encryption of email messages.

- **Use TLS if supported by the SMTP server**

You can select this option if you want to use a TLS connection to an SMTP server. If the SMTP server does not support TLS, Administration Server connects the SMTP server without using TLS.

- **Always use TLS, check server certificate validity**

You can select this option if you want to use TLS authentication settings. If the SMTP server does not support TLS, Administration Server cannot connect the SMTP server.

We recommend that you use this option for better protection of the connection with an SMTP server. If you select this option, you can set authentication settings for a TLS connection.

If you select **Always use TLS, check server certificate validity** value, you can specify a certificate for authentication of the SMTP server and choose whether you want to enable communication through any version of TLS or only through TLS 1.2 or later versions. Also, you can specify a certificate for client authentication on the SMTP server.

You can specify SMTP server certificate file by clicking the **Specify certificates** link. You can receive a file with the list of certificates from a trusted certification authority and upload the file to Administration Server. Kaspersky EDR Expert checks whether the certificate of an SMTP server is also signed by a trusted certification authority. Kaspersky EDR Expert cannot connect to an SMTP server if the certificate of the SMTP server is not received from a trusted certification authority.

In the **Recipients (email addresses)** field, specify the email addresses to which the application will send notifications. You can specify multiple addresses in this field, by separating them with semicolons. The notifications will be delivered to the phone numbers associated with the specified email addresses.

In the **Subject** field, specify the email subject.

In the **Subject template** drop-down list, select the template for your subject. A variable according to the selected template is put in the **Subject** field. You can construct an email subject selecting several subject templates.

In the **Sender email address: If this setting is not specified, the recipient address will be used instead. Warning: We do not recommend using a fictitious email address** field, specify the sender email address. If you leave this field empty, by default, the recipient address is used. It is not recommended to use fictitious email addresses.

In the **Phone numbers of SMS message recipients** field, specify the cell phone numbers of the SMS notification recipients.

In the **Notification message** field, specify a text with information about the event that the application sends when an event occurs. This text can include substitute parameters, such as event name, device name, and domain name.

> If the notification text contains a percent sign (%), you have to type it twice in a row to allow message sending. For example, "CPU load is 100%%".

Click the **Send test message** to check whether you configured notifications properly: the application sends a test notification to the recipient that you specified.

Click the **Configure numeric limit of notifications** link to specify the maximum number of notifications that the application can send during the specified time interval.

- **Executable file to be run**

  The executable file must contain the environment variables of the event that you want the administrator to receive.

  In the **Executable file to be run on the Administration Server when an event occurs** field, specify the folder and the name of the file to be run.

  Example of field value:

  ```
  /opt/scripts/notifications.sh
  ```

  The file must be prepared in advance by specifying substitution parameters that stand for the event information that will be sent in the message. The folder and the file must be located on the Administration Server.

  Example of script for testing or debugging:

  ```
  #!/usr/bin/env bash

  touch /tmp/ksc_notification.txt

  echo "$RISE_TIME $COMPUTER $EVENT" >> /tmp/ksc_notification.txt
  ```

  Clicking the **Configure numeric limit of notifications** link allows you to specify the maximum number of notifications that the application can send during the specified time interval.

Selecting the notification method

3. On the tab, define the notification settings.

4. Click **Save** to save the changes and close the Administration Server properties window.

The saved notification delivery settings are applied to all events that occur in Kaspersky EDR Expert.

You can override notification delivery settings for certain events in the **Event configuration** section of the Administration Server settings, of a policy's settings, or of an application's settings.

Testing notifications

To check whether event notifications are sent, the application uses the notification of the EICAR test virus detection on client devices.

To verify sending of event notifications:

1. Stop the real-time file system protection task on a client device and copy the EICAR test virus to that client device. Then, re-enable real-time protection of the file system.

2. Run a scan task for client devices in an administration group or for specific devices, including one with the EICAR test virus.

   If the scan task is configured correctly, the test virus will be detected. If notifications are configured correctly, you are notified that a virus has been detected.

To open a record of the test virus detection:

1. In the main menu, go to **Monitoring → Event selections**.
2. Click the **Recent events** selection name.

   In the window that opens, the notification about the test virus is displayed.

The EICAR test virus contains no code that can do harm to your device. However, most manufacturers' security applications identify this file as a virus. You can download the test virus from the official EICAR website.

Parameters and environment variables for describing an event

When configuring notifications about Kaspersky EDR Expert events, you can use parameters and environment variables to describe the events (see the table below).

If you have chosen to run an executable file as a notification method, use variables when writing the file.

If you want to send notifications about events by email or SMS, when configuring notifications on the corresponding tab, you can also specify variables in the **Subject** and **Notification message** fields.

Parameters and environment variables for describing an event

Substitution parameter (for use in notifications)	Environment variable (for use in scripts)	Environment variable description
%SEVERITY%	$SEVERITY	Event severity. Possible values: • **Info** • **Warning** • **Error** • **Critical**
%COMPUTER%	$COMPUTER	Name of the device where the event occurred. Maximum length of the device name is 256 characters.
%DOMAIN%	$DOMAIN	Domain name of the device where the event occurred.
%EVENT%	$EVENT	Name of the event type. Maximum length of the event type name is 50 characters.
%DESCR%	$DESCR	Event description. Maximum length of the description is 1000 characters.
%RISE_TIME%	$RISE_TIME	Event creation time.
%KLCSAK_EVENT_TASK_DISPLAY_NAME%	$KLCSAK_EVENT_TASK_DISPLAY_NAME	Task name. Maximum length of the task name is 100 characters.
%KL_PRODUCT%	$KL_PRODUCT	Application name.
%KL_VERSION%	$KL_VERSION	Application version number.
%$KLCSAK_EVENT_SEVERITY_NUM%	$KLCSAK_EVENT_SEVERITY_NUM	Event severity number. Possible values: • 1—**Info** • 2—**Warning** • 3—**Error** • 4—**Critical**

Substitution parameter (for use in notifications)	Environment variable (for use in scripts)	Environment variable description
%HOST_IP%	$HOST_IP	IP address of the device where the event occurred.
%HOST_CONN_IP%	$HOST_CONN_IP	Connection IP address of the device where the event occurred.

Monitoring event sources

This section provides information about monitoring event sources.

Source status

In KUMA, you can monitor the state of the sources of data received by collectors. There can be multiple sources of events on one server, and data from multiple sources can be received by one collector.

You can configure automatic identification of event sources using one of the following sets of fields:

- Custom set of fields. You can specify from 1 to 9 fields in the order you want. TenantID does not need to be specified separately, it is determined automatically.
- **Apply default mapping**—DeviceProduct, DeviceHostName, DeviceAddress, DeviceProcessName. The field order cannot be changed.

  Sources are identified if the following fields in events are not empty: the DeviceProduct field, the DeviceAddress and/or DeviceHostname field, and the TenantID field (you do not need to specify the TenantID field, it is determined automatically). The DeviceProcessName field can be empty. If the DeviceProcessName field is not empty, and the other required fields are filled, a new source is identified.

  Identification of event sources depending on non-empty event fields

DeviceProduct	DeviceHostName	DeviceAddress	DeviceProcessName	TenantID (determined automatically)	
+	+			+	Source 1 identified
+		+		+	Source 2 identified
+	+	+		+	Source 3 identified
+	+		+	+	Source 4 identified
+		+	+	+	Source 5 identified
+	+	+	+	+	Source 6 identified
	+	+		+	Source not identified
	+		+	+	Source not identified
		+	+	+	Source not identified
+			+	+	Source not identified

Only one set of fields is applied for the entire installation. When upgrading to a new KUMA version, the default set of fields is applied. Only a user with the Main administrator role can configure the set of fields for identifying an event source. After you save changes to the set of fields, previously identified event sources are deleted from the KUMA Console and from the database. If necessary, you can revert to using a set of fields to determine default event sources. For the edited settings to take effect and KUMA to begin identifying sources based on the new settings, you must restart the collectors.

To identify event sources:

1. In the main menu, go to **Monitoring → Source status**.
2. This opens the **Source status** window; in that window, click the **Settings** button.
3. This opens the **Settings of event source detection** window; in that window, in the **Grouping fields for source detection** drop-down list, select the event fields by which you want to identify event sources.

   You can specify from 1 to 9 fields in the order you want. In a custom configuration, KUMA identifies sources in which the TenantID field is filled (you do not need to specify this field separately, it is determined automatically) and at least one field from the **Identical fields for source identification** is filled. For numeric fields, 0 is considered an empty value. If a single numeric field is selected for source identification, and the value of the numeric field is 0, the source is not detected.

   After you save the modified set of fields, an audit event is created and all previously identified sources are deleted from the KUMA Console and from the database; assigned policies are disabled.
4. If you want to go back to the list of fields for identifying the default event source, click **Apply default mapping**. The default field order cannot be changed. If you manually specify the fields in the wrong order, an error is displayed and the save settings button becomes unavailable. The correct default sequence of fields is DeviceProduct, DeviceHostName, DeviceAddress, DeviceProcessName. Minimum configuration for identifying event sources using the default set of events: non-empty values in the DeviceProduct field, the DeviceAddress and/or DeviceHostName field, and the TenantID field (TenantID is determined automatically).
5. Click **Save**.
6. Restart the collectors to apply the changes and begin identifying event sources by the specified list of fields.

Source identification is configured.

To view events that are associated with an event source:

1. In the main menu, go to **Monitoring → Source status**.

   This opens the **Source status** window.
2. On the **Event sources** tab, select an event source from the list. In the **Name** column, in the drop-down list for the selected event source, select **Events for <number> days**.

   KUMA takes you to the **Events** section, where you can view a list of events for the selected source over the last 5 minutes. Values of fields configured in the event source identification settings are automatically specified in the query. If necessary, in the **Events** section, you can change the time period in the query and click **Run query** again to view the queried data for the specified time period.

Limitations

1. In a configuration with the default field set, KUMA registers the event source only if the raw event contains the DeviceProduct field and the DeviceAddress and/or DeviceHostName fields.

If the raw event does not contain the DeviceProduct field and the DeviceAddress and/or DeviceHostName fields, you can:

- Configure enrichment in the normalizer: on the **Enrichment** tab of the normalizer, select the **Event** data type, specify the **Source field** setting, and for the **Target field**, select the DeviceProduct + DeviceAddress and/or DeviceHostName and click OK.
- Use an enrichment rule: select the **Event** data source type, specify the **Source field** setting, and as the **Target field**, select DeviceProduct + DeviceAddress and/or DeviceHostName, then click **Create**. The created enrichment rule must be linked to the collector at the Event enrichment step.

KUMA will perform enrichment and register the event source.

2. If KUMA receives events with identical values of the fields that identify the source, KUMA registers different sources if the following conditions are satisfied:
   - The values of the required fields are identical, but different tenants are determined for the events.
   - The values of the required fields are identical, but one of the events has an optional DeviceProcessName field specified.
   - The values of the required fields are identical, but the data in these fields have different character case.

If you want KUMA to log such events under the same source, you can further configure the fields in the normalizer.

Lists of sources are generated in collectors, merged in the KUMA Core, and displayed in the program web interface under **Source status** on the **List of event sources** tab. Data is updated every minute.

The rate and number of incoming events serve as an important indicator of the state of the observed system. You can configure monitoring policies such that changes are tracked automatically and notifications are automatically created when indicators reach specific boundary values. Monitoring policies are displayed in the KUMA Console in the **Monitoring** → **Source status** section, on the **Monitoring policies** tab.

When monitoring policies are triggered, monitoring events are created and include data about the source of events.

List of event sources

Sources of events are displayed in the table under **Monitoring** → **Source status** → **Event sources**. One page can display up to 250 sources. You can sort the table by clicking the column heading of the relevant parameter and selecting **Ascending** or **Descending**.

You can use the **Search** field to search for event sources. The search is performed using regular expressions (RE2). You can also filter the table by the **Status** or **Monitoring policy** columns by clicking the heading of the relevant column and selecting the values that you want to display.

If necessary, you can configure the interval for updating data in the table. Available update periods: **1 minute**, **5 minutes**, **15 minutes**, **30 minutes**, **1 hour**. The default value is **No refresh**. You may need to configure the update period to track changes made to the list of sources.

Viewing information about event sources

On the **Event sources** tab, information about event sources is displayed in the following columns:

- **Status**—status of the event source:
  - Green—events are being received within the limits of the assigned monitoring policies.
  - Red—the frequency or number of incoming events go beyond the boundaries defined in at least one assigned monitoring policy.
  - Gray—monitoring policies have not been assigned to the source of events.

  If the status is red, an event of the Monitoring type generated. The monitoring event is generated in the tenant that owns the event source and is sent to the storage of the Main tenant (the storage must already be deployed in the Main tenant). If you have access to the tenant of the event source and do not have access to the Main tenant, you can still search for monitoring events in the storage of the Main tenant; the monitoring events of the tenants available to you will be displayed for you. You can also configure notifications to be sent to an arbitrary email address.

  The table can be filtered by status.

- **Name**—name of the event source. The name is generated automatically from the values of fields configured in the event source identification settings.

  You can rename an event source in the table of event sources by hovering over its name and clicking the pencil icon. The name can contain no more than 128 Unicode characters.

- **Host name or IP address**—name or IP address of the host from which the events originate if the DeviceHostName or DeviceAddress fields are specified in the event source identification settings.

- **Monitoring policy**—list of the monitoring policies assigned to the event source.

  If you want to filter the list of event sources by applied monitoring policies, click the name of this column and select one or more monitoring policies. If necessary, you can find policies in the list using the **Search** field.

  You can view information about all monitoring policies assigned to an event source by clicking the row of the source. This opens a window that displays the settings of monitoring policies, as well as the status of the source according to each policy. If several monitoring policies are assigned to the source, the red status in the table of sources in this window lets you identify the policy that was triggered. You can also see which policies are enabled and which are disabled, and when the disabled policies will be enabled again.

- **Stream**—frequency at which events are received from the event source. If only monitoring policies of the **byCount** type or monitoring policies of different types are assigned to the source, this value is displayed as the number of events. If only monitoring policies of the **byEPS** type are assigned to the source, or no policies are assigned, the value is displayed as the number of events per second.

- **Tenant**—the tenant that owns the events received from the event source.

Managing event sources

You can select one or more event sources by selecting the check boxes in the first column of the table. You can select multiple event sources at once for performing group operations by selecting the check box in the heading of the first column and selecting **Select all** or **Select all in page**. The **Select all in page** option applies only to event sources displayed in the list: if only 500 out of 1500 sources are displayed in the list, then group actions to download, enable or disable policies, or delete event sources are applied only to the selected 500 sources. If you want to perform an action on all sources in the table, select **Select all**.

If you select sources of events, the following buttons become available:

- The **Enable policy** button enables the monitoring policy for event sources. You must select policies in the displayed window to apply them.
- You can use the **Disable policy** to disable the monitoring policy for event sources. When disabling a policy, you must select how long you want to disable the policy: temporarily or forever.
- The **Update policy** button applies the monitoring policies that are enabled for the event sources, or change the monitoring policies that are already assigned. When a policy is updated, a task is started in the task manager.

  This button becomes available after you change the monitoring policies assigned to event sources.
- You can click the **Remove** button to remove event sources from the table. The statistics on this source will also be removed. If a collector continues to receive data from the source, the event source will re-appear in the table but its old statistics will not be taken into account.

  If you want to delete all event sources, but some time has passed since the table was last refreshed, sources added during this time may not be displayed in the table, but they will be deleted regardless.

  If you delete more than 100,000 event sources to which a filter or search was applied, only the first 100,000 event sources will be deleted. You can select all filtered event sources again and delete them, and then repeat this until you have deleted all event sources that you intended to delete. You can delete over 100,000 event sources if no filters or searches are applied to them by selecting sources using the **Select all** button.
- You can click **CSV** to download the data of the selected event sources to a CSV file.

  The `Stream` field is downloaded only if a monitoring policy has been assigned to the event source; in that case, the unit of measurement taken from the policy is specified in the downloaded file. If no policy is assigned an empty `Stream` field is expected behavior.
- You can click the **Chart** button to plot a chart of incoming events for the last seven days for the selected event sources. You can select up to five event sources.

  .

Downloading event source information to a CSV file

You can download information about one or more event sources and the monitoring policies applied to them to a CSV file in UTF-8 encoding. If multiple monitoring policies are applied to a source, in the file for that source, each monitoring policy and its parameters starts on a new line. For each monitoring policy applied to a source, the following parameters are exported to the file: **Status**, **Name**, **Monitoring policy**, **Lower limit**, **Upper limit**, **Stream**, **Tenant**.

To download event source information to a CSV file:

1. In the main menu, go to **Monitoring** → **Source status** → **Event sources**, select one or more event sources in the table by selecting the check boxes in the first column next to the relevant sources.

   In the lower left part of the table, you can find the number of selected sources and the total number of sources in the table. You can select up to 150,000 event sources.

   You can select several event sources by clicking the check box in the heading of the first column and selecting one of the following options:

   - **Select all** to select all event sources on all pages of the table. If you have used search to filter sources, this will select all sources that match the search query.
   - **Select all in page** to select all event sources on the currently displayed page. If you have used search to filter sources, this will select all sources on the currently displayed page that match the search query.

2. Click the **CSV** button in the upper part of the table.

   > Depending on the size of your browser window, the **CSV** button may be found in the additional menu that you can open by clicking on the icon with the three dots ⋮.

   A new event source export task is created in the task manager.

3. Go to the **Task manager** section and find the created task.

   When the file is ready, the **Status** column of the task displays the **Completed** status.

4. Click the task type name and select **Download** from the drop-down list.

The CSV file with event source information is downloaded in accordance with your browser settings. The default file name is event-source-list.csv.

Viewing the dynamics of incoming events

You can examine the dynamics of events received from a source over the last seven days, taking into account the applied monitoring policies, in one of the following ways:

- View the graph for an individual event source.
- Plot a chart based on graphs for several (up to five) sources.

To view the graph for a single event source, go to **Monitoring** → **Source status** → **Event sources**, and then click the arrow icon › in the row of the relevant event source. The graph of incoming events is displayed under the row of the source.

The data in the graph is displayed as follows:

- The data is displayed for the days on which the events were received. The maximum period is seven days.

  In the upper left corner above the graph, the number of days is displayed, and in the upper right corner, the data display period is displayed. You can click the **Events for <number> days** button to go to the **Events** section and view the list of events for the selected source.

- The X-axis represents days, and the Y-axis represents the frequency of events (EPS).
- The lines represent the average, maximum, and minimum number of events for every 15-minute period during the last seven days.

  If you want to view the number of events at a specific time, hover over a point on the graph. A tooltip is displayed with the average, maximum, and minimum event count at a specific date and time.

You can also plot a chart of incoming events based on graphs for several event sources, for example, if you need to compare the activity of event sources of the same type that should behave in a similar way, but in fact behave in different ways.

To plot a chart based on graphs for multiple event sources:

1. In the main menu, go to **Monitoring** → **Source status** → **Event sources**, then select one or more event sources in the table by selecting the check boxes in the first column next to the relevant sources.

   You can plot a chart for up to 5 event sources at the same time.

2. Click the **Chart** button in the upper part of the table.

   > Depending on the size of your browser window, the **Chart** button may be found in the additional menu that you can open by clicking on the icon with the three dots ⋮.

   The displayed **Chart** pane contains a chart of incoming events for all selected sources as well as a table that displays the current number of events, the maximum number of events, and the average number of events for each source, calculated based on the data from the chart. You can compare how the data for the selected sources relates to each other over time.

   The data in the chart is displayed as follows:

   - The data is displayed for the days on which the events were received. The maximum period is seven days.

     In the upper right corner above the chart, the data display period is displayed.
   - The X-axis represents days, and the Y-axis represents the frequency of events (EPS).
   - The lines in the chart represent the average number of incoming events from the selected event sources for every 15-minute interval during the last seven days.

   You can hover over the chart to view the average number of events for each source at a specific time.

3. If necessary, clear the check boxes in the table below the chart next to the event sources that you want to hide in the chart.

4. If you want to display the diagram in more detail, click the two arrows ↙↗ icon to open the panel in full screen mode and zoom in on the diagram.

Monitoring policies

The rate and number of incoming events serve as an important indicator of the state of the system. For example, you can detect when there are too many events, too few, or none at all. Monitoring policies are designed to detect such situations. In a policy, you can specify a lower threshold, an optional upper threshold, and the way the events are counted: by frequency or by total number.

The policy must be applied to the event source. You can apply one or more monitoring policies to a source. After applying the policy, you can monitor the status of the source on the **List of event sources** tab.

Policies for monitoring the sources of events are displayed in the table under **Monitoring → Source status → Monitoring policies**. You can sort the table by clicking the column header of the relevant setting. The maximum size of the policy list is not limited.

In the **Sources** column, you can click the **Show** button to view all event sources to which the policy is applied. When you click this button, you are taken to the **Event sources** tab, and the table of sources is filtered by the selected policy.

Algorithm of monitoring policies

Monitoring policies are applied to an event source in accordance with the following algorithm:

1. The event stream is counted at the collector.
2. The KUMA Core server gets information about the stream from the collectors every 15 seconds.
3. The obtained data is stored on the KUMA Core server in the Victoria Metrics time series database, and the data storage depth on the KUMA Core server is 15 days.
4. An inventory of event sources is taken once per minute.
5. The stream is counted separately for each event source in accordance with the following rules:
   - If a monitoring policy is applied to the event source, the displayed maximum number of events is calculated in accordance with the currently applied monitoring policies for the time interval specified in the policy.

     Depending on the policy type, the number of the event stream is counted as the number of events (for the **byCount** policy type) or as the number events per second (EPS, for the **byEPS** policy type). You can look up how the stream is counted for the applied policy in the **Stream** column on the **Event sources** tab.
   - If no monitoring policy is applied to the event source, the number for the event stream corresponds to the last value.
6. Once a minute, the application checks if any monitoring policies exist that must be applied to event sources or stopped according to the monitoring policy schedule.
7. The event stream is checked against the constraints of the policy once a minute.

If the event stream from the source crosses the thresholds specified in the monitoring policy, information about this is recorded in the following way:

- A notification about a monitoring policy getting triggered is sent to the email addresses specified in the policy. For each policy, you can also configure a notification template.
- A stream monitoring informational event of type `5(Type=5)` is generated. The fields of the event are described in the table below.

Fields of the monitoring event

Event field name	Field value
ID	Unique ID of the event.
Timestamp	Event time.
Type	Type of the audit event. For the audit event, the value is `5` (monitoring).
Name	Name of the monitoring policy.
DeviceProduct	`KUMA`
DeviceCustomString1	The value from the `value` field in the notification. Displays the value of the metric for which the notification was sent.

The generated monitoring event is sent to the following resources:

- All storages of the Main tenant
- All correlators of the Main tenant
- All correlators of the tenant in which the event source is located

Adding a monitoring policy

To add a new monitoring policy:

1. In the main menu, go to **Monitoring** → **Source status** → **Monitoring policies**, then click **Add policy** and configure the monitoring policy in the displayed window:
2. In the **Policy name** field, enter a unique name for the policy you are creating. The name must contain 1 to 128 Unicode characters.

   We recommend choosing a name that reflects the configured schedule of the monitoring policy.
3. In the **Tenant** drop-down list, select the tenant that you want to own the policy. Your tenant selection determines the specific sources of events that can covered by the monitoring policy.
4. In the **Type** field, select one of the following monitoring policy types:
   - **by count**—by the number of events over a certain period of time.
   - **by EPS**—by the number of events per second (EPS) over a certain period of time. The average value over the entire period is calculated. You can additionally track spikes during specific periods.
5. In the **Count interval** field, specify the period during which the monitoring policy must take into account the data from the monitoring source. You can use the drop-down list on the right to select a value in minutes, hours, or days. The maximum value is 14 days.
6. If you selected the **by EPS** policy type, in the **Control interval, minutes** field, specify the control time interval (in minutes) within which the number of events must cross the threshold for the monitoring policy to trigger:
   - If, during this time period, all checks (performed once per minute) find that the stream is crossing the threshold, the monitoring policy is triggered.
   - If, during this time period, one of the checks (performed once per minute) finds that the stream is within the thresholds, the monitoring policy is not triggered, and the count of check results is reset.

If you do not specify the frequency of measurement, the monitoring policy is triggered immediately after the stream is found to cross the threshold.

7. In the **Lower limit** and **Upper limit** fields, define the boundaries representing normal behavior. Deviations outside of these boundaries will trigger the monitoring policy, create an alert, and forward notifications.

   The **Lower limit** setting is required.

8. In the **Evaluation interval** field, specify the frequency with which the VMalert service will query VictoriaMetrics for policy data while the policy is being applied to the event source. You can use the drop-down list on the right to select a value in minutes, hours, or days. The default interval is 5 minutes.

   When specifying the evaluation interval, keep in mind the policy schedule. For example, if you configured the policy to be applied once every few hours, we do not recommend configuring a short interval and causing excessive load on VictoriaMetrics.

9. If necessary, in the **Send notifications** field, specify the email addresses to which notifications about the activation of the KUMA monitoring policy must be sent. To add an address, enter it in the field and press **Enter** or click **Add**. You can specify multiple email addresses.

   To forward notifications, you must configure a connection to the SMTP server.

10. In the **Notification template** drop-down list, select the template that you want to use for notifications. If necessary, click the **Create new** button to start creating a new notification template.

    By default, the basic notification template is selected. You can reset the template selection and switch to the base template by clicking the X icon.

11. In the **Schedule** section, configure how often you want to apply the monitoring policy to event sources. By default, the policy is applied every week, every day, from 00:00 to 23:59. To configure the monitoring policy schedule, do some of the following:

    - If you want to apply the monitoring policy weekly on specific days of the week:

      a. Enable the **Configure schedule by days of the week** toggle switch.

      b. In the **Days of the week** drop-down list, select the days of the week on which you want the policy to be applied to the source.

         If you want to clear the selection, click the X icon.

      c. In the **Time** field, specify the start and end time of the policy, with minute precision.

         The policy applicability interval is inclusive of its bounds; for example, if the end time is set to 23:59, the policy will be applied until 23:59:59.999. The default interval is 00:00 to 23:59. The start time must be earlier than the end time.

      d. If you want to add another period, click the **Add period** button and repeat steps 'b' and 'c'.

         You can add any number of periods.

    - If you want to apply the monitoring policy weekly on specific calendar dates:

      a. Enable the **Configure schedule by days of the month** toggle switch.

      b. Click the **Days of the month** field and use the calendar to select the dates on which you want to apply the policy to the source. You can select a period of several days or an individual day. The start date of the period must be earlier than the end date of the period.

         The dates are configured without a year value, so the policy will be applied annually on the specified days until you delete this period. If you want to clear the selection, click the X icon.

c. In the **Time** field, specify the start and end time of the policy, with minute precision.

The policy applicability interval is inclusive of its bounds; for example, if the end time is set to 23:59, the policy will be applied until 23:59:59.999. The default interval is 00:00 to 23:59. The start time must be earlier than the end time.

d. If you want to add another period, click the **Add period** button and repeat steps 'b' and 'c'.

You can add any number of periods.

If you applied a schedule by day of the week and by day of the month at the same time, the day-of-the-month policy is applied first.

12. Click **Add**.

The monitoring policy will be added.

Editing monitoring policies

The **Monitoring → Source status → Monitoring policies** section displays the added monitoring policies and their settings that you specified when creating the policy. You can click a policy to display a sidebar with all of its settings. If necessary, you can edit the policy settings in this sidebar.

If a monitoring policy is applied to an event source, if you edit certain policy settings, you may need to update the policy to apply the changes. Every 30 minutes, KUMA checks if any monitoring policies require updating, and if that is the case, it automatically runs a task to update those monitoring policies. You can also run the update task manually by clicking the **Update policy** button at the top of the table. One task updates all policies that need updating.

The **Update policy** button becomes active only if some monitoring policies need updating. Information about whether the policy needs updating is displayed in the table of monitoring policies in the **Policy update status** as one of the following statuses:

- **Update required** if one of the following monitoring policy settings was edited, but the changes have not been applied to event sources:
  - **Policy name**
  - **Type**
  - **Lower limit**
  - **Upper limit**
  - **Count interval**
  - **Control interval**
  - **Evaluation interval**

- **Updated** in any of the following cases:
  - After editing the policy, the task to apply the policy was started, and the changes were applied to event sources.
  - You have edited one of the following policy settings, which does not require starting the update task:
    - **Send notifications**
    - **Notification template**
    - **Schedule**

    In this case, the edited policy settings are applied to event sources after a minute. Changes of the **Notification template** setting are applied instantly.
  - The modified monitoring policy is not applied to event sources.

The date and time when the policy was last applied to event sources is displayed in the **Policy last applied** column.

> While the policy update task is running, the **Update policy** button is unavailable for all users. If another user has edited the settings of the policy that necessitate an update, the **Update policy** button becomes active for you only after you refresh the page or edit the policy or an event source.

Applying monitoring policies

To apply monitoring policies to event sources:

1. In the main menu, go to **Monitoring** → **Source status** → **Event sources**, then select one or more event sources in the table by selecting the check boxes in the first column next to the relevant sources. You can select several event sources by clicking the check box in the heading of the first column and selecting one of the following options:
   - **Select all** to select all event sources on all pages of the table. If you have used search to filter sources, this will select all sources that match the search query.
   - **Select all in page** to select all event sources on the currently displayed page. If you have used search to filter sources, this will select all sources on the currently displayed page that match the search query.

   In the lower left part of the table, you can find the number of selected sources and the total number of sources in the table.

   After you select the event sources to which you want to apply the monitoring policy, the **Enable policy** button becomes available on the toolbar.
2. Click **Apply policy**.
3. This opens the **Apply policy** window; in that window, select one or more monitoring policies that you want to apply to the selected event sources. The table lists only monitoring policies that you can assign to the selected sources: policies that belong to the same tenant or to the Shared tenant, if you have access to it. If no shared policies exist for the selected event sources and you do not have access to the Shared tenant, the policy table is empty.

To select all available policies, you can select the check box in the heading of the first column. You can also use context search by policy name or sort the policies by clicking the heading of the column by which you want to sort the table and selecting **Ascending** or **Descending**.

> Search and sorting is not available for the **Sources**, **Schedule**, **Policy update status**, **Policy last applied** columns.

4. Click **Apply**.

5. In the table of sources, click **Update policy** to apply the changes to event sources.

   The monitoring policies are applied to the selected event sources; the status of these sources changes to green. The names of the policies applied to the sources are displayed in the **Monitoring policy** column. A message is also displayed indicating the number of sources to which the policies have been applied. If the monitoring policy is triggered for an event source, the new status of that source is displayed after you manually refresh the page or it is refreshed automatically. We recommend configuring an automatic data refresh period to keep track of changes in the list of sources.

If you have selected more than 100,000 event sources and applied one or more policies to them, these policies are applied only to the first 100,000 sources to which these policies have not yet been applied. If you need to apply policies to the remaining sources, you can do one of the following:

- Select all sources again and apply the policies to them.
- Filter the table of sources by any parameter so that the table displays less than 100,000 sources, then apply the policies to them.

Repeat the action until the policies have been applied to all the sources that you need.

Disabling monitoring policies

To disable monitoring policies for event sources:

1. In the main menu, go to **Monitoring** → **Source status** → **Event sources**, then select one or more event sources in the table by selecting the check boxes in the first column next to the relevant sources.

   In the lower left part of the table, you can find the number of selected sources and the total number of sources in the table. After you select the event sources to which monitoring policies are applied in the list, the **Disable policy** button becomes available on the toolbar.

   You can select several event sources by clicking the check box in the heading of the first column and selecting one of the following options:

   - **Select all** to select all event sources on all pages of the table. If you have used search to filter sources, this will select all sources that match the search query.
   - **Select all in page** to select all event sources on the currently displayed page. If you have used search to filter sources, this will select all sources on the currently displayed page that match the search query.

2. Click **Disable policy**.

3. This opens the **Disable policy** window; in that window, select one or more monitoring policies that you want to disable for the selected event sources. The table lists all monitoring policies applied to at least one of the selected event sources.

   To select all available policies, you can select the check box in the heading of the first column. You can also use context search or sort the policies by clicking the heading of the column by which you want to sort the table and selecting **Ascending** or **Descending**.

   Search and sorting is not available for the **Sources**, **Schedule**, **Policy update status**, **Policy last applied** columns.

4. In the settings section above the policy table, do one of the following:

   - If you want to temporarily suspend the policies, select **For the specified time** and specify the time in minutes, hours, or days after which the selected policies will be reapplied to event sources. Maximum values:
     - For days: 30
     - For hours: 743
     - For minutes: 44579
   - If you want to permanently disable the selected policies for event sources, select **Until manually enabled**.

   The default selection is **For the specified time**, and the value is set to **5 minutes**.

5. Click **Disable**.

6. In the table of sources, click **Update policy** to apply the changes to event sources.

   The monitoring policies are disabled for selected event sources or suspended for the specified time. The status of these sources in the table changes to gray. A message is displayed indicating the number of sources for which the policies have been disabled.

If you have selected more than 100,000 event sources and disabled one or more policies for them, these policies are disabled only for the first 100,000 sources to which these policies are applied. If you need to disable policies for the remaining sources, you can do one of the following:

- Select all sources again and disable the policies for them.
- Filter the table of sources by any parameter so that the table displays less than 100,000 sources, then disable the policies for them.

Repeat the action until the policies have been disabled for all the sources that you need.

Adding a new monitoring policy based on an existing policy

To create a new monitoring policy based on an existing one:

1. In the main menu, go to **Monitoring** → **Source status** → **Monitoring policies**, then select the monitoring policy that you want to base the new policy on.

   If necessary, you can find monitoring policies in the list using the **Search** field. The search will be carried out in the following columns: **Name**, **Tenant**, **Type**, **Schedule** (name of the day and time).

2. Click **Duplicate policy**.

3. This opens the **Add policy** window, in which you can edit policy settings.

   By default, `- copy` is appended to the name of the new policy. The rest of the settings are the same as in the policy that you are duplicating.

4. Click the **Add** button to create the new policy.

The monitoring policy is created based on an existing policy.

Deleting monitoring policies

To delete a monitoring policy:

1. In the main menu, go to **Monitoring** → **Source status** → **Monitoring policies**, then select one or more monitoring policies that you want to delete.

   If necessary, you can find monitoring policies in the list using the **Search** field. The search will be carried out in the following columns: **Name**, **Tenant**, **Type**, **Schedule** (name of the day and time).

2. Click **Delete policy** and confirm the action.

The selected monitoring policies are deleted.

> You cannot remove predefined monitoring policies or policies that are assigned to data sources.

Kaspersky announcements

This section describes how to use, configure, and disable Kaspersky announcements.

About Kaspersky announcements

The Kaspersky announcements section (**Monitoring** → **Kaspersky announcements**) keeps you informed by providing information related to your version of Open Single Management Platform and managed applications installed on the managed devices. Open Single Management Platform periodically updates the information in the section by removing outdated announcements and adding new information.

Open Single Management Platform shows only those Kaspersky announcements that relate to the currently connected Administration Server and the Kaspersky applications installed on the managed devices of this Administration Server. The announcements are shown individually for any type of Administration Server—primary, secondary, or virtual.

> Administration Server must have an internet connection to receive Kaspersky announcements.

The announcements include information of the following types:

- Security-related announcements

  Security-related announcements are intended to keep the Kaspersky applications installed in your network up-to-date and fully functional. The announcements may include information about critical updates for Kaspersky applications, fixes for found vulnerabilities, and ways to fix other issues in Kaspersky applications. By default, security-related announcements are enabled. If you do not want to receive the announcements, you can disable this feature.

  To show you the information that corresponds to your network protection configuration, Open Single Management Platform sends data to Kaspersky cloud servers and receives only those announcements that relate to the Kaspersky applications installed in your network. The data set that can be sent to the servers is described in the End User License Agreement that you accept when you install Administration Server.

- Marketing announcements

  Marketing announcements include information about special offers for your Kaspersky applications, advertisements, and news from Kaspersky. Marketing announcements are disabled by default. You receive this type of announcements only if you enabled Kaspersky Security Network (KSN). You can disable marketing announcements by disabling KSN.

  To show you only relevant information that might be helpful in protecting your network devices and in your everyday tasks, Open Single Management Platform sends data to Kaspersky cloud servers and receives the appropriate announcements. The data set that can be sent to the servers is described in the Processed Data section of the KSN Statement.

New information is divided into the following categories, according to importance:

1. Critical info
2. Warning
3. Info

When new information appears in the Kaspersky announcements section, OSMP Console displays a notification label that corresponds to the importance level of the announcements. You can click the label to view this announcement in the Kaspersky announcements section.

If you do not want to receive announcements, you can disable this feature.

Disabling Kaspersky announcements

The Kaspersky announcements section (**Monitoring → Kaspersky announcements**) keeps you informed by providing information related to your version of Open Single Management Platform and managed applications installed on the managed devices. If you do not want to receive Kaspersky announcements, you can disable this feature.

The Kaspersky announcements include two types of information: security-related announcements and marketing announcements.

To disable security-related announcements:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Kaspersky announcements** section.

3. Switch the toggle button to the **Security-related announcements are disabled** position.

4. Click the **Save** button.

   Kaspersky announcements are disabled.

Marketing announcements are disabled by default. You receive marketing announcements only if you enabled Kaspersky Security Network (KSN). You can disable this type of announcement by disabling KSN.

Disabling KSN may affect managed Kaspersky applications that use KSN services. Such applications may no longer be able to communicate with Kaspersky to send or receive reputation data, telemetry, or statistics.

Cloud Discovery

Open Single Management Platform allows you to monitor the use of cloud services on managed devices running Windows and to block access to cloud services that you consider unwanted. Cloud Discovery tracks user attempts to gain access to these services through both browsers and desktop applications. It also tracks user attempts to gain access to cloud services over unencrypted connections (for example, using the HTTP protocol). This feature helps you to detect and halt the use of cloud services by shadow IT.

The blocking capability is available only if you activated Open Single Management Platform under a Kaspersky EDR Expert license.

The blocking capability is available only if you use Kaspersky Endpoint Security 11.2 for Windows or later. Earlier versions of the security application only allow you to monitor the use of cloud services.

You can enable the Cloud Discovery feature and select the security policies or profiles for which you want to enable the feature. You can also enable or disable the feature separately in each security policy or profile. You can block access to cloud services that you do not want users to access.

To be able to block access to unwanted cloud services, make sure that the following prerequisites are met:

- You use Kaspersky Endpoint Security 11.2 for Windows or later. Earlier versions of the security application only allow you to monitor the use of cloud services.
- You have purchased a Kaspersky Next license tier that includes the ability to block access to unwanted cloud services. For details, refer to Kaspersky Next Help.

The Cloud Discovery widget and the Cloud Discovery reports display information about successful and blocked attempts to gain access to cloud services. The widget also displays the risk level of each cloud service. Open Single Management Platform gets information about the use of cloud services from all of the managed devices that are protected only by the security policies or profiles that have the feature enabled.

Enabling Cloud Discovery by using the widget

The Cloud Discovery feature allows you to get information about the use of cloud services from all of the managed devices that are protected only by the security policies that have the feature enabled. You can enable or disable Cloud Discovery for the Kaspersky Endpoint Security for Windows policy only.

There are two ways to enable the Cloud Discovery feature:

- By using the Cloud Discovery widget.
- In the properties of the Kaspersky Endpoint Security for Windows policy.

  For details on how to enable the Cloud Discovery feature in the Kaspersky Endpoint Security for Windows policy properties, refer to the Cloud Discovery section of Kaspersky Endpoint Security for Windows Help.

Note that you can disable the Cloud Discovery feature in the Kaspersky Endpoint Security for Windows policy parameters only.

To enable Cloud Discovery, you must have the **Write** right in the **General features: Basic functionality** functional area.

To enable the Cloud Discovery feature by using the Cloud Discovery widget:

1. Open Kaspersky EDR Expert.
2. In the main menu, go to **Monitoring** → **Dashboard**.
3. On the **Cloud Discovery** widget, click the **Enable** button.

   If you have Kaspersky Endpoint Security for Windows version 12.4 installed, enable the Cloud Discovery feature in the Kaspersky Endpoint Security for Windows policy properties. For details, refer to the Cloud Discovery section of Kaspersky Endpoint Security for Windows Help.

   If you have Kaspersky Endpoint Security for Windows earlier than version 12.4, update the Kaspersky Endpoint Security for Windows plug-in to version 12.5.

4. In the **Enable Cloud Discovery** window that opens, select the security policies for which you want to enable the feature, and then click the **Enable** button.

   The following policy settings will be enabled automatically: **Inject script into web traffic to interact with web pages**, **Web Session monitor**, and **Encrypted connections scan**.

The Cloud Discovery feature is enabled and the widget is added to the dashboard.

Adding the Cloud Discovery widget to the dashboard

You can add the **Cloud Discovery** widget to the dashboard to monitor the use of cloud services on managed devices.

To add the Cloud Discovery widget to the dashboard, you must have the **Write** right in the **General features: Basic functionality** functional area.

To add the Cloud Discovery widget to the dashboard:

1. Open Kaspersky EDR Expert.
2. In the main menu, go to **Monitoring** → **Dashboard**.
3. Click the **Add or restore widget** button.
4. In the list of available widgets, click the chevron icon (>) next to the **Other** category.
5. Select the **Cloud Discovery** widget, and then click the **Add** button.

   If the Cloud Discovery feature is disabled, follow the instructions in the Enabling Cloud Discovery by using the widget section.

The selected widget is added at the end of the dashboard.

Viewing information about the use of cloud services

You can view the **Cloud Discovery** widget that shows information about attempts to gain access to cloud services. The widget also displays the risk level of each cloud service. Open Single Management Platform gets information about the use of cloud services from all of the managed devices that are protected only by the security profiles that have the feature enabled.

Before viewing, make sure that:

- The Cloud Discovery widget is added to the dashboard.
- The Cloud Discovery feature is enabled.
- You have the **Read** right in the **General features: Basic functionality** functional area.

To view the Cloud Discovery widget:

1. Go to Open Single Management Platform.
2. In the main menu, go to **Monitoring** → **Dashboard**.

   The **Cloud Discovery** widget is displayed on the dashboard.
3. On the left side of the **Cloud Discovery** widget, select a category of cloud services.

   The table on the right side of the widget displays up to five services from the selected category, to which users most often try to gain access. Both successful and blocked attempts are counted.
4. On the right side of the widget, select a specific service.

   The table below displays up to ten devices that most often attempt to gain access to the service. In this table, you can generate two types of reports: report on successful access attempts and report on blocked access attempts.

   In addition, in this table you can block access to the cloud service for a specific device.

The widget displays the requested information.

From the displayed widget, you can do the following:

- Proceed to the **Monitoring** → **Reports** section, to view the Cloud Discovery reports.
- Block or allow access to the selected cloud service.

The blocking capability is available only if you activated Open Single Management Platform under a Kaspersky EDR Expert license.

The blocking capability is available only if you use Kaspersky Endpoint Security 11.2 for Windows or later. Earlier versions of the security application only allow you to monitor the use of cloud services.

Risk level of a cloud service

For each cloud service, Cloud Discovery provides you with a risk level. The risk level helps you determine which services do not fit the security requirements of your organization. For example, you may want to take the risk level into account when deciding whether to block access to a certain service.

The risk level is an estimated index and does not say anything about the quality of a cloud service or about the service manufacturer. The risk level is simply a recommendation from Kaspersky experts.

Risk levels of cloud services are displayed in the Cloud Discovery widget and in the list of all monitored cloud services.

Blocking access to unwanted cloud services

You can block access to cloud services that you do not want users to access. You can also allow access to cloud services that were previously blocked.

Among other considerations, you may want to take the risk level into account when deciding whether to block access to a certain service.

You can block or allow access to cloud services for a security policy or profile.

There are two ways to block access to unwanted cloud services:

- By using the Cloud Discovery widget.

  In this case, you can block access to the services one by one.

- In the properties of the Kaspersky Endpoint Security for Windows policy.

  In this case, you can block access to the services one by one or block an entire category at once.

  For details on how to enable the Cloud Discovery feature in the Kaspersky Endpoint Security for Windows policy properties, refer to the Cloud Discovery section of Kaspersky Endpoint Security for Windows Help.

To block or allow access to a cloud service by using the widget:

1. Open the Cloud Discovery widget, and then select the required cloud service.
2. In the **Top 10 devices that use the service** pane, find the security policy or profile for which you want to block or allow the service.
3. On the required line, in the **Access status in policy or profile** column, do any of the following:
   - To block the service, select **Blocked** in the drop-down list.
   - To allow the service, select **Allowed** in the drop-down list.
4. Click the **Save** button.

Access to the selected service is blocked or allowed for the security policy or profile.

Export of events to SIEM systems

This section describes how to configure export of events to the SIEM systems.

Configuring event export to SIEM systems

Kaspersky EDR Expert allows configuring event export to SIEM systems by one of the following methods: export to any SIEM system that uses Syslog format, export to Kaspersky SIEM, QRadar, Splunk, ArcSight SIEM systems that use LEEF and CEF formats, or export of events to SIEM systems directly from the Kaspersky Security Center database. When you complete this scenario, Administration Server sends events to a SIEM system automatically.

Prerequisites

Before you start configuration export of events in the Kaspersky EDR Expert:

- Learn more about the methods of event export.
- Make sure that you have the values of system settings.

You can perform the steps of this scenario in any order.

The process of export of events to a SIEM system consists of the following steps:

- **Configuring the SIEM system to receive events from Kaspersky EDR Expert**

  How-to instructions: Configuring event export in a SIEM system

- **Selecting the events that you want to export to the SIEM system**

  Mark which events you want to export to the SIEM system. First, mark the general events that occur in all managed Kaspersky applications. Then, you can mark the events for specific managed Kaspersky applications.

- **Configuring export of events to the SIEM system**

  You can export events by using one of the following methods:

  - Using TCP, UDP, or TLS over TCP protocols.
  - Exporting events directly from the Kaspersky Security Center database. The Kaspersky Security Center database contains a collection of public views; you can find a description of these public views in the klakdb.chm document.

Results

After configuring export of events to a SIEM system you can view export results if you selected events which you want to export.

Prerequisites

When setting up automatic export of events in the Kaspersky EDR Expert, you must specify some of the SIEM system settings. It is recommended that you check these settings in advance in order to prepare for setting up Kaspersky EDR Expert.

To successfully configure automatic sending of events to a SIEM system, you must know the following settings:

- **SIEM system server address**

  The IP address of the server on which the currently used SIEM system is installed. Check this value in your SIEM system settings.

- **SIEM system server port**

  Port number used to establish a connection between Kaspersky EDR Expert and your SIEM system server. You specify this value in the Kaspersky EDR Expert settings and in the receiver settings of your SIEM system.

- **Protocol**

  Protocol used for transferring messages from Kaspersky EDR Expert to your SIEM system. You specify this value in the Kaspersky EDR Expert settings and in the receiver settings of your SIEM system.

About event export

Kaspersky EDR Expert allows you to receive information about events that occur during the operation of Administration Server and Kaspersky applications installed on managed devices. Information about events is saved in the Administration Server database.

You can use event export within centralized systems that deal with security issues on an organizational and technical level, provide security monitoring services, and consolidate information from different solutions. These are SIEM systems, which provide real-time analysis of security alerts and events generated by network hardware and applications, or Security Operation Centers (SOCs).

These systems receive data from many sources, including networks, security, servers, databases, and applications. SIEM systems also provide functionality to consolidate monitored data in order to help you avoid missing critical events. In addition, the systems perform automated analysis of correlated events and alerts in order to notify the administrators of immediate security issues. Alerting can be implemented through a dashboard or can be sent through third-party channels such as email.

The process of exporting events from Kaspersky EDR Expert to external SIEM systems involves two parties: an event sender, Kaspersky EDR Expert, and an event receiver, a SIEM system. To successfully export events, you must configure this in your SIEM system and in Kaspersky EDR Expert. It does not matter which side you configure first. You can either configure the transmission of events in the Kaspersky EDR Expert, and then configure the receipt of events by the SIEM system, or vice versa.

Methods for sending events from Kaspersky EDR Expert

There are three methods for sending events from Kaspersky EDR Expert to external systems:

- Sending events over the Syslog protocol to any SIEM system

  Using the Syslog protocol, you can relay any events that occur on the Administration Server and in Kaspersky applications that are installed on managed devices. The Syslog protocol is a standard message-logging protocol. You can use it to export events to any SIEM system.

  For this purpose, you need to mark the events that you want to relay to the SIEM system. You can mark the events in OSMP Console. Only marked events will be relayed to the SIEM system. If you marked nothing, no events will be relayed.

- Sending events over the CEF and LEEF protocols to Kaspersky SIEM, QRadar, Splunk, and ArcSight systems

  You can use the CEF and LEEF protocols to export general events. When exporting events over the CEF and LEEF protocols, you do not have the capability to select specific events to export. Instead, all general events are exported. To convert Open Single Management Platform events to events in the CEF and LEEF format, you need to use the siem_conversion_rules.xml file. This file contains the list of Kaspersky EDR Expert event attributes and corresponding attributes of events in the CEF and LEEF format. Also, the siem_conversion_rules.xml file contains the rules for generating messages corresponding to events. This file is included in the Kaspersky EDR Expert distribution kit.

  Unlike the Syslog protocol, the CEF and LEEF protocols are not universal. CEF and LEEF are intended for the appropriate SIEM systems (Kaspersky SIEM, QRadar, Splunk, and ArcSight). Therefore, when you choose to export events over one of these protocols, you use the required parser in the SIEM system.

- Directly from the Kaspersky EDR Expert database to any SIEM system

  This method of exporting events can be used to receive events directly from public views of the database by means of SQL queries. The results of a query are saved to an XML file that can be used as input data for an external system. Only events available in public views can be exported directly from the database.

Receipt of events by the SIEM system

The SIEM system must receive and correctly parse the events received from Kaspersky EDR Expert. To achieve this, you need to correctly configure the SIEM system. The configuration depends on the specific SIEM system utilized. However, there are a number of general steps in the configuration of all SIEM systems, such as configuring the receiver and the parser.

About configuring event export in a SIEM system

The process of exporting events from Kaspersky EDR Expert to external SIEM systems involves two parties: an event sender, Kaspersky EDR Expert, and an event receiver, a SIEM system. You must configure the export of events in your SIEM system and in the Kaspersky EDR Expert.

The settings that you specify in the SIEM system depend on the particular system that you are using. Generally, for all SIEM systems you must set up a receiver and, optionally, a message parser to parse received events.

Setting up the receiver

To receive events sent by Kaspersky EDR Expert, you must set up the receiver in your SIEM system. In general, the following settings must be specified in the SIEM system:

- **Export protocol**

  A message transfer protocol, either UDP, TCP, or TLS over TCP. This protocol must be the same as the protocol you specified in Kaspersky EDR Expert.

- **Port**

  Specify the port number to connect to Kaspersky EDR Expert. This port must be the same as the port you specify in Kaspersky EDR Expert during configuration with a SIEM system.

- **Data format**

  Specify the Syslog, CEF, or LEEF format.

Depending on the SIEM system that you use, you may have to specify some additional receiver settings.

The figure below shows the receiver setup screen in ArcSight.

Receiver setup in ArcSight

Message parser

Exported events are passed to SIEM systems as messages. A parser is then applied to these messages to make sure that the event information can be used by the SIEM system. A message parser is part of the SIEM system; it is used to split the contents of the message into fields such as event code, severity, description, parameters. This enables the SIEM system to process events received from Kaspersky EDR Expert so that they can be stored in the SIEM system database.

Marking of events for export to SIEM systems in Syslog format

After enabling automatic export of events, you must select which events will be exported to the external SIEM system.

You can configure export of events in the Syslog format to an external system based on one of the following conditions:

- Marking general events. If you mark events to export in a policy, in the settings of an event, or in the Administration Server settings, the SIEM system will receive the marked events that occurred in all applications managed by the specific policy. If exported events were selected in the policy, you will not be able to redefine them for an individual application managed by this policy.

- Marking events for a managed application. If you mark events to export for a managed application installed on a managed device, the SIEM system will receive only the events that occurred in this application.

For policy change events, you can only enable or disable the export of all such events to a SIEM system.

About marking events for export to SIEM system in the Syslog format

After enabling automatic export of events, you must select which events will be exported to the external SIEM system.

You can configure export of events in the Syslog format to an external system based on one of the following conditions:

- Marking general events. If you mark events to export in a policy, in the settings of an event, or in the Administration Server settings, the SIEM system will receive the marked events that occurred in all applications managed by the specific policy. If exported events were selected in the policy, you will not be able to redefine them for an individual application managed by this policy.

- Marking events for a managed application. If you mark events to export for a managed application installed on a managed device, the SIEM system will receive only the events that occurred in this application.

Marking events of a Kaspersky application for export in the Syslog format

If you want to export events that occurred in a specific managed application installed on the managed devices, mark the events for export in the application policy. In this case, the marked events are exported from all of the devices included in the policy scope.

To mark events for export for a specific managed application:

1. In the main menu, go to **Asset management** → **Policies**.

2. Click the policy of the application for which you want to mark events.

   The policy settings window opens.

3. Go to the **Event configuration** section.

4. Select the check boxes next to the events that you want to export to a SIEM system.

5. Click the **Mark for export to SIEM system by using Syslog** button.

   > You can also mark an event for export to a SIEM system in the **Event registration** section, which opens by clicking the link of the event.

6. A check mark (✓) appears in the **Syslog** column of the event or events that you marked for export to the SIEM system.

7. Click the **Save** button.

The marked events from the managed application are ready to be exported to a SIEM system.

You can mark which events to export to a SIEM system for a specific managed device. If previously exported events were marked in an application policy, you will not be able to redefine the marked events for a managed device.

To mark events for export for a managed device:

1. In the main menu, go to **Asset management** → **Assets (Devices)**.

   The list of managed devices is displayed.

2. Click the link with the name of the required device in the list of managed devices.

   The properties window of the selected device is displayed.

3. Go to the **Applications** section.

4. Click the link with the name of the required application in the list of applications.

5. Go to the **Event configuration** section.

6. Select the check boxes next to the events that you want to export to a SIEM system.

7. Click the **Mark for export to SIEM system by using Syslog** button.

   > You can also mark an event for export to a SIEM system in the **Event registration** section, which opens by clicking the link of the event.

8. A check mark (✓) appears in the **Syslog** column of the event or events that you marked for export to the SIEM system.

From now on, Administration Server sends the marked events to the SIEM system if export to the SIEM system is configured.

Marking general events for export in Syslog format

You can mark general events that Administration Server will export to SIEM systems by using the Syslog format.

To mark general events for export to a SIEM system:

1. In the main menu, do one of the following:

   - Click the Administration Server name.
   - Go to **Asset management** → **Policies**, and then click a link of a policy.

2. In the window that opens, go to the **Event configuration** tab.

3. Click **Mark for export to SIEM system by using Syslog**.

   > You can also mark an event for export to a SIEM system in the **Event registration** section, which opens by clicking the link of the event.

4. A check mark (✓) appears in the **Syslog** column of the event or events that you marked for export to the SIEM system.

From now on, Administration Server sends the marked events to the SIEM system if export to the SIEM system is configured.

About exporting events using Syslog format

You can use the Syslog format to export to SIEM systems the events that occur in Administration Server and other Kaspersky applications installed on managed devices.

Syslog is a standard for message logging protocol. It permits separation of the software that generates messages, the system that stores them, and the software that reports and analyzes them. Each message is labeled with a facility code, indicating the software type that generates the message, and is assigned a severity level.

The Syslog format is defined by Request for Comments (RFC) documents published by the Internet Engineering Task Force (internet standards). The RFC 5424 standard is used to export the events from Kaspersky EDR Expert to external systems.

In Kaspersky EDR Expert, you can configure export of the events to the external systems using the Syslog format.

The export process consists of two steps:

1. Enabling automatic event export. At this step, Kaspersky EDR Expert is configured so that it sends events to the SIEM system. Kaspersky EDR Expert starts sending events immediately after you enable automatic export.

2. Selecting the events to be exported to the external system. At this step, you select which event to export to the SIEM system.

About exporting events using CEF and LEEF formats

You can use the CEF and LEEF formats to export to SIEM systems general events, policy change events, and the events transferred by Kaspersky applications to the Administration Server. The set of export events is predefined, and you cannot select the events to be exported. Before sending events to the SIEM system (Kaspersky SIEM, QRadar, ArcSight, or Splunk), it is necessary to interpret Open Single Management Platform events to events in the CEF and LEEF format by using the rules specified in the siem_conversion_rules.xml file.

Select the format of export on the basis of the SIEM system used. The table below shows SIEM systems and the corresponding formats of export.

Formats of event export to a SIEM system

SIEM system	Format of export
Kaspersky SIEM	CEF
ArcSight	CEF

SIEM system	Format of export
Splunk	CEF
QRadar	LEEF

- LEEF (Log Event Extended Format) is a specialized event format for the IBM Security QRadar SIEM. QRadar can receive, identify and process events transmitted over the LEEF protocol. LEEF events must use UTF-8 character encoding. You can find detailed information on LEEF protocol in IBM Knowledge Center.

- CEF (Common Event Format)—An open log management standard that improves the interoperability of security-related information from different security and network devices and applications. CEF enables you to use a common event log format so that data can easily be integrated and aggregated for analysis by an enterprise management system. CEF events must use UTF-8 character encoding.

Automatic export means that Kaspersky EDR Expert sends general events to the SIEM system. Automatic export of events starts immediately after you enable it. This section explains in detail how to enable automatic event export.

Converting events to the CEF or LEEF format

Before sending events to the SIEM system (Kaspersky SIEM, QRadar, ArcSight, or Splunk), it is necessary to interpret Open Single Management Platform events to events in the CEF and LEEF format by using the rules specified in the siem_conversion_rules.xml file. This file is included in the Open Single Management Platform distribution kit.

The siem_conversion_rules.xml file contains the predefined interpretation rules to convert events to the CEF and LEEF format. If you want to use additional event interpretation rules, you can add them to the file manually.

The siem_conversion_rules.xml file includes the following sections:

- `<product name="SP_QRADAR" vendor="IBM">`

  This section contains rules for generating events in the LEEF format, which can be exported to the QRadar SIEM system.

- `<product name="SP_ARCSIGHT" vendor="HP">`.

  This section contains rules for generating events in the CEF format, which can be exported to the ArcSight or Splunk SIEM system.

- `<product name="Kaspersky SIEM" vendor="Kaspersky">`.

  This section contains rules for generating events in the CEF format, which can be exported to KUMA.

Each section has the `<common>` subsection, in which Open Single Management Platform event attributes and corresponding attributes of events in the LEEF format are located. These common attributes are used for all types of events that can be exported.

Also, each section has the `<event>` subsections. Each `<event>` subsection contains additional attributes that are added to those listed in the `<common>` section.

You can add a new event generation rule to the siem_conversion_rules.xml file manually.

To add a new event generation rule:

1. Add a new `<event>` subsection to the `<product name="SP_QRADAR" vendor="IBM">`, `<product name="SP_QRADAR" vendor="IBM">`, or `<product name="Kaspersky SIEM" vendor="Kaspersky">` section, and then specify the additional event attributes, if needed.

2. If an event consist only of common attributes, the `<event>` subsection will be empty.

siem_conversion_rules.xml

```
<conversion_rules>
 <product name="SP_QRADAR" vendor="IBM">
 <common> <!-- Common Open Single Management Platform event attributes and corresponding LEEF event attributes -->
 <param name="KLSPLG_HOST_DISP_NAME" type="STRING_T">
 <attr name="EVC_EV_DISP_HOST_NAME" type="AT_STRING" limit="255"/>
 </param>
 ...
 </common>
 <event id="GNRL_EV_VIRUS_FOUND"> <!-- Generation rule for the GNRL_EV_VIRUS_FOUND event with additional
attributes -->
 <param name="GNRL_EA_PARAM_1" type="STRING_T">
 <attr name="EVC_EV_SHA256" type="AT_STRING" limit="255"/>
 </param>
 ...
 </event>
...
</product>
 <product name="SP_ARCSIGHT" vendor="HP">
 <common> <!-- Common Open Single Management Platform event attributes and corresponding LEEF event attributes -->
 <param name="KLSPLG_HOST_DISP_NAME" type="STRING_T">
 <attr name="dhost" type="AT_STRING" limit="1023"/>
 </param>
 ...
 </common>
 <event id="GNRL_EV_VIRUS_FOUND">
 <param name="GNRL_EA_PARAM_1" type="STRING_T">
 <attr name="cs4" type="AT_STRING" limit="255"/>
 <attr name="cs4Label" type="AT_STRING" val="SHA256"/>
 </param>
 ...
</product>
 <product name="Kaspersky SIEM" vendor="Kaspersky">
 <common> <!-- Common Open Single Management Platform event attributes and corresponding LEEF event attributes -->
 <param name="KLSPLG_HOST_DISP_NAME" type="STRING_T">
 <attr name="dhost" type="AT_STRING" limit="1023"/>
 </param>
 ...
 </common>
 <event id="GNRL_EV_VIRUS_FOUND">
 <param name="GNRL_EA_PARAM_1" type="STRING_T">
 <attr name="cs4" type="AT_STRING" limit="255"/>
 <attr name="cs4Label" type="AT_STRING" val="SHA256"/>
 </param>
 ...
</product>
</conversion_rules>
```

Configuring Kaspersky EDR Expert for export of events to a SIEM system

To export events to a SIEM system, you have to configure the process of export in Kaspersky EDR Expert.

Before sending events to the SIEM system (Kaspersky SIEM (KUMA), QRadar, ArcSight, or Splunk), it is necessary to interpret Kaspersky EDR Expert events to events in the CEF and LEEF format by using the rules specified in the siem_conversion_rules.xml file.

To configure export to SIEM systems in the OSMP Console:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Export to SIEM** section.

3. Click the **Settings** link.

   The **Export settings** section opens.

4. Specify the settings in the **Export settings** section:

   - **SIEM system server address**

     The IP address of the server on which the currently used SIEM system is installed. Check this value in your SIEM system settings.

   - **SIEM system port**

     Port number used to establish a connection between Kaspersky EDR Expert and your SIEM system server. You specify this value in the Kaspersky EDR Expert settings and in the receiver settings of your SIEM system.

   - **Protocol**

     Select the protocol to be used for transferring messages to the SIEM system. You can select TCP, UDP, or TLS over TCP protocol.

     Specify the following TLS settings if you select the TLS over TCP protocol:

     - **Server authentication**

       In the **Server authentication** field, you can select the **Trusted certificates** or **SHA fingerprints** values:

       - **Trusted certificates**. You can receive a complete certificate chain (including the root certificate) from a trusted certification authority (CA) and upload the file to Open Single Management Platform. Open Single Management Platform checks whether the certificate chain of the SIEM system server is also signed by a trusted CA or not.

         To add a trusted certificate, click the **Browse for CA certificates file** button, and then upload the certificate.

       - **SHA fingerprints**. You can specify SHA1 thumbprints of the complete certificate chain of the SIEM system (including the root certificate) in Open Single Management Platform. To add a SHA1 thumbprint, enter it in the **Thumbprints** field, and then click the **Add** button.

     By using the **Add client authentication** setting, you can generate a certificate to authenticate Open Single Management Platform. Thus, you will use a self-signed certificate issued by Open Single Management Platform. In this case, you can use both a trusted certificate and a SHA fingerprint to authenticate the SIEM system server.

- **Add Subject name/Subject alternative name**

  Subject name is a domain name for which the certificate is received. Open Single Management Platform cannot connect to the SIEM system server if the domain name of the SIEM system server does not match the subject name of the SIEM system server certificate. However, the SIEM system server can change its domain name if the name has changed in the certificate. In this case, you can specify subject names in the **Add Subject name/Subject alternative name** field. If any of the specified subject names matches the subject name of the SIEM system certificate, Open Single Management Platform validates the SIEM system server certificate.

- **Add client authentication**

  For client authentication, you can insert your certificate or generate it in Open Single Management Platform.

  - **Insert certificate**. You can use a certificate that you received from any source, for example, from any trusted CA. You must specify the certificate and its private key by using one of the following certificate types:

    - **X.509 certificate PEM**. Upload a file with a certificate in the **File with certificate** field, and a file with a private key in the **File with key** field. Both files do not depend on each other and the order of loading of the files is not significant. When both files are uploaded, specify the password for decoding the private key in the **Password or certificate verification** field. The password can have an empty value if the private key is not encoded.

    - **X.509 certificate PKCS12**. Upload a single file that contains a certificate and its private key in the **File with certificate** field. When the file is uploaded, specify the password for decoding the private key in the **Password or certificate verification** field. The password can have an empty value if the private key is not encoded.

  - **Generate key**. You can generate a self-signed certificate in Open Single Management Platform. As a result, Open Single Management Platform stores the generated self-signed certificate, and you can pass the public part of the certificate or SHA1-fingerprint to the SIEM system.

- **Data format**

  You can select Kaspersky SIEM, IBM QRadar SIEM, ArcSight, Splunk, or System log formats, depending on the requirements of the SIEM system.

  If you select the System log data format, you must specify **Maximum message size, in bytes**.

  Specify the maximum size (in bytes) of one message relayed to the SIEM system. Each event is relayed in one message. If the actual length of a message exceeds the specified value, the message is truncated and data may be lost. The default size is 2048 bytes. This field is available only if you selected the System log format in the **Protocol** field.

5. If you want, you can export archived events from the Administration Server database and set the start date from which you want to start the export of archived events:

   a. Click the **Set the export start date** link.

   b. In the section that opens, specify the start date in the **Date to start export from** field.

   c. Click **OK**.

6. Enable the **Export events to SIEM** option.

7. To send policy change events to SIEM, enable the **Export extended events for policy changes to SIEM** option. A separate event will be sent to SIEM for each changed policy setting.

8. To check that the SIEM system connection is configured, click the **Check connection** button.

   The connection with the SIEM system server is established, and a test event is sent. The connection status will be displayed.

9. Click the **Save** button.

Export to a SIEM system is configured. From now on, if you configured the receiving of events in a SIEM system, Administration Server exports the marked events or policy change events to a SIEM system. If you set the start date of export, Administration Server also exports the marked events stored in the Administration Server database from the specified date.

Monitoring of policy and policy profile changes

When a policy setting is changed, a policy change event is generated, which you can then export to a SIEM system to monitor policy changes and generate alerts. Policy change events can only be accessed through a SIEM system.

Policy change events are not stored in the Administration Server database after generation and cannot be viewed in the **Monitoring** → **Event selections** section of OSMP Console. You also cannot specify notification settings and storage settings for these events on the **Event configuration** tab.

When you create a policy, the policy change event is generated for each policy setting. When you change a policy, the policy change event is generated for every changed setting of a policy. Deletion of a policy generates one event. For example, Kaspersky Security Center policy creation generates around 1000 events, and Kaspersky Endpoint Security policy creation generates more than 7000 events.

Conditions for generating policy change events

A policy change event is generated whenever a user performs any of the following actions with a policy or policy profile:

- Create, edit, or delete a policy
- Create, edit, or delete a policy profile
- Roll back the policy to a selected revision
- Import or copy a policy
- Import or copy a policy profile
- Move a policy to another administration group

A policy modification event is generated when the following conditions are satisfied:

- The policies of the following applications are changed:
  - Kaspersky Security Center Network Agent
  - Kaspersky Security Center Administration Server

- Kaspersky Endpoint Security 14.1 for Windows or a later version
- Kaspersky Endpoint Security 12.5 for Linux or a later version
- Kaspersky Endpoint Security 12.4 for Linux or a later version
- Kaspersky Endpoint Security 12.2.1 for Mac or a later version

- The **Export extended events for policy changes to SIEM** option in the Administration Server properties is enabled.
- The policy is modified manually using the OSMP Console.

Policy change events are not created in the following cases:

- General policy settings are modified.
- Policy settings inherited from a parent policy are modified.
- Policy settings are changed via the Kaspersky Security Center OpenAPI.
- Kaspersky application settings are modified directly in the application.

Policy change event fields

The table below shows a set of policy change event field. The representation of these fields depends on the output event format (for example, Syslog, CEF, or LEEF). For the exact field names and event templates, refer to the siem_conversion_rules.xml file. Event parameters are available only in English.

Event field	Data type	Description
`EventType`	string	Type of the event. Allows creating correlation rules for the specific type of event. Possible values: "Policy created", "Policy modified", "Policy deleted".
`srvName`	string	Administration Server name.
`eventTime`	datetime	Date and time of the event (in UTC).
`eventGroupID`	int	ID of the event group of a modification.
`objectID`	int	Internal ID of an object.
`objectName`	string	Policy display name.
`objectGroup`	string	Full path and name of the administration group that contains the policy.
`user`	string	Name of the user that authored the modification.
`operation`	string	Parameter modification's type. Possible values: "Added", "Removed", "Changed".
`path`	string	Parameter's path. Contains the path to the parent node of the end parameter. The path is created based on the names of the policy's sections and subsections. The path structure is identical to the ones described in Network Agent policy settings, General policy settings, and Comparing policy revisions.
`parameter`	string	Name of the policy setting that was changed.
`oldValue`	string	Old value of the end parameter.
`newValue`	string	New value of the end parameter.

Exporting events directly from the database

You can retrieve events directly from the Kaspersky EDR Expert database without having to use the Kaspersky EDR Expert interface. You can either query the public views directly and retrieve the event data, or create your own views on the basis of existing public views and address them to get the data you need.

Public views

For your convenience, a set of public views is provided in the Kaspersky EDR Expert database. You can find the description of these public views in the klakdb.chm document.

The v_akpub_ev_event public view contains a set of fields that represent the event parameters in the database. In the klakdb.chm document you can also find information on public views corresponding to other Kaspersky EDR Expert entities, for example, devices, applications, or users. You can use this information in your queries.

This section contains instructions for executing an SQL query by means of the klsql2 utility and a query example.

To create SQL queries or database views, you can also use any other program for working with databases. Information on how to view the parameters for connecting to the Kaspersky EDR Expert database, such as instance name and database name, is given in the corresponding section.

Executing an SQL query by using the klsql2 utility

This article describes how to use the klsql2 utility, and execute an SQL query by using this utility. Use klsql2 utility version that is included in your Kaspersky EDR Expert version installed.

To use the klsql2 utility:

1. Go to the directory where Administration Server is installed. The default installation path is /opt/kaspersky/ksc64/sbin.
2. In this directory, create a blank file with the .sql extension.
3. Open the created .sql file in any text editor.
4. In the .sql file, type the SQL query that you want, and then save the file.
5. On the device with Administration Server installed, in the command line, type the following command to execute the SQL query from the .sql file and save the results to the result.xml file:
   ```
   sudo ./klsql2 -i src.sql -u <username> -p <password> -o result.xml
   ```
   where `<username>` and `<password>` are credentials of the user account that has access to the database.
6. If required, enter the login and password of the user account that has access to the database.
7. Open the newly created result.xml files to view the SQL query results.

You can edit the .sql file and create any SQL query to the public views. Then, from the command line, execute your query and save the results to a file.

Example of an SQL query in the klsql2 utility

This section shows an example of an SQL query, executed by means of the klsql2 utility.

The following examples illustrate retrieval of the events that occurred on devices during the last seven days, and display of the events ordered by the time they occur. The most recent events are displayed first.

Example for PostgreSQL:

```
SELECT
 /* event identifier */
 "e"."nId",

 /* time, when the event occurred */
 "e"."tmRiseTime",

 /* internal name of the event type */
 "e"."strEventType",

 /* displayed name of the event */
 "e"."wstrEventTypeDisplayName",

 /* displayed description of the event */
 "e"."wstrDescription",

 /* displayed description of the event */
 "e"."wstrGroupName",

 /* displayed name of the device, on which the event occurred */
 "h"."wstrDisplayName",
 (
 CAST((("h"."nIp" / 16777216 )& 255 ) AS VARCHAR(4)) || '.' ||
 CAST((("h"."nIp" / 65536 )& 255 ) AS VARCHAR(4)) || '.' ||
 CAST((("h"."nIp" / 256 )& 255 ) AS VARCHAR(4)) || '.' ||

 /* IP address of the device, on which the event occurred */
 CAST((("h"."nIp" )& 255 ) AS VARCHAR(4))
 ) AS "strIp"
FROM "v_akpub_ev_event" AS "e"
 INNER JOIN "v_akpub_host" AS "h" ON "h"."nId" = "e"."nHostId"
WHERE "e"."tmRiseTime" >= NOW() AT TIME ZONE 'utc' + make_interval(days => CAST(-7 AS INT))
ORDER BY "e"."tmRiseTime" DESC ;
```

Example for MySQL or MariaDB:

```
SELECT

 /* event identifier */
 `e`.`nId`,

 /* time, when the event occurred */
 `e`.`tmRiseTime`,

 /* internal name of the event type */
 `e`.`strEventType`,

 /* displayed name of the event */
 `e`.`wstrEventTypeDisplayName`,

 /* displayed description of the event */
 `e`.`wstrDescription`,

 /* device group name */
 `e`.`wstrGroupName`,

 /* displayed name of the device, on which the event occurred */
 `h`.`wstrDisplayName`,
 CONCAT(
 LEFT(CAST(((`h`.`nIp` DIV 1677721) & 255) AS CHAR), 4), '.',
 LEFT(CAST(((`h`.`nIp` DIV 65536) & 255) AS CHAR), 4), '.',
 LEFT(CAST(((`h`.`nIp` DIV 256) & 255) AS CHAR), 4), '.',

 /* IP address of the device, on which the event occurred */
 LEFT(CAST(((`h`.`nIp`) & 255) AS CHAR), 4)
 ) AS `strIp`
FROM `v_akpub_ev_event` AS `e`
 INNER JOIN `v_akpub_host` AS `h` ON `h`.`nId` = `e`.`nHostId`
WHERE `e`.`tmRiseTime` >= ADDDATE( UTC_TIMESTAMP( ) , INTERVAL -7 DAY)
ORDER BY `e`.`tmRiseTime` DESC ;
```

Viewing the Kaspersky EDR Expert database name

If you want to access Kaspersky EDR Expert database by means of the MySQL, or MariaDB database management tools, you must know the name of the database in order to connect to it from your SQL script editor.

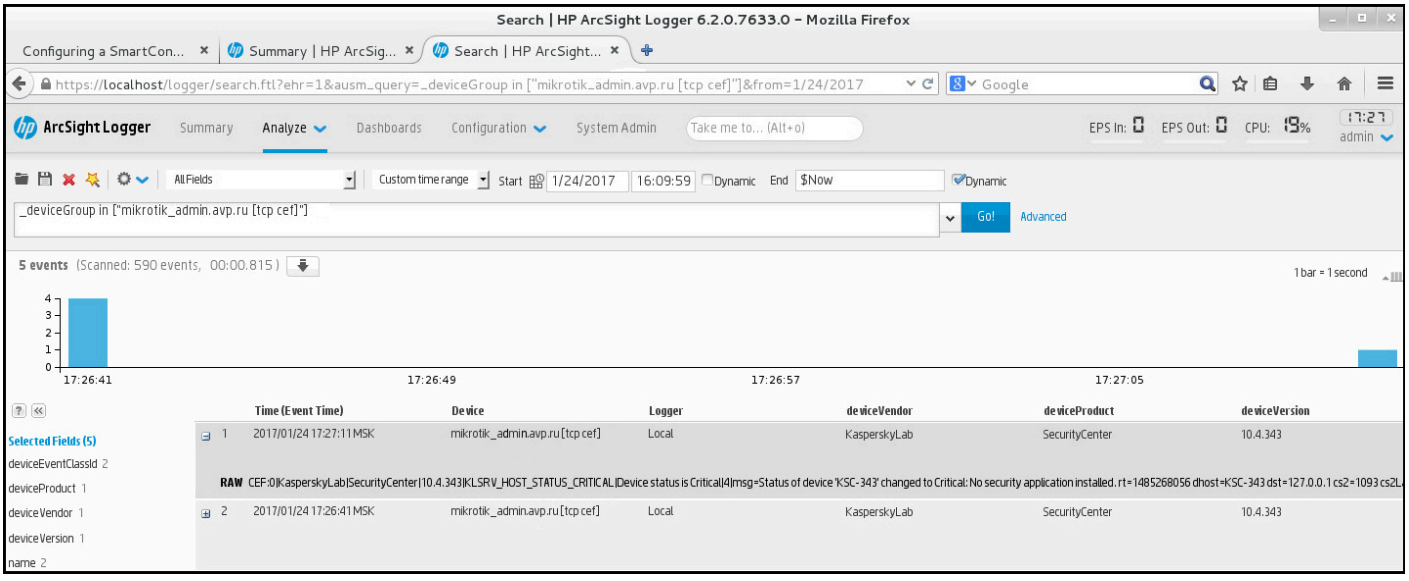
To view the name of the Kaspersky EDR Expert database:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **General** tab, select the **Details of current database** section.

   The database name is specified in the **Database name** field. Use the database name to address the database in your SQL queries.



Viewing export results

You can control for successful completion of the event export procedure. To do this, check whether messages with export events are received by your SIEM system.

If the events sent from Kaspersky EDR Expert are received and properly parsed by your SIEM system, configuration on both sides is done properly. Otherwise, check the settings you specified in Kaspersky EDR Expert against the configuration in your SIEM system.

The figure below shows the events exported to ArcSight. For example, the first event is a critical Administration Server event: "*Device status is Critical*".

The representation of export events in the SIEM system varies according to the SIEM system you use.

Example of events

Sending events from the OSMP collector to an external SIEM system collector

To configure events to be sent to a collector of an external SIEM system, the following conditions must be met:

1. You must be logged in to the OSMP Console under a user account with Main administrator rights.
2. In OSMP, the **[OOTB] Kaspersky EDR** collector must be installed in the Kubernetes cluster.
3. A collector with the following components must be installed in KUMA:
   - Connector of the **tcp** type with TLS enabled and the \n delimiter.
   - Normalizer of the **json** type without mapping and with the raw event included.
   - Destination of the **storage** type.
4. A Unix terminal must be available with the curl and openssl utilities installed.

Configuring the export of events from the OSMP collector to the collector of an external SIEM system involves the following steps:

1. **Getting a certificate and a key for sending events to the [OOTB] Kaspersky EDR collector**

   1. In the main application window, go to the **Settings** → **Tenants** section.
   2. Click the **Root tenant** and go to the **Settings** → **Certificates** subsection.
   3. Select the check box next to the TLS certificate and click **Export**.
   4. This opens a window; in that window, enter the password and click the **Export** button.

      The certificate in PFX format is downloaded to your default downloads directory.
   5. Extract the downloaded certificate to get a cert.pem file and a key.pem file by running the following commands:

      ```
      openssl pkcs12 -in certificate.pfx -clcerts -nokeys -out cert.pem && \
      openssl pkcs12 -in certificate.pfx -nocerts -nodes -out key.pem
      ```

      Enter and reenter the password that was specified when exporting the PFX certificate.

   The cert.pem certificate and key.pem key for sending events to the collector are obtained.

2. **Creating and configuring a TCP destination for event export to an external SIEM system**

   1. In the main application window, go to the **Monitoring** → **Resources and services** → **Active services** section.
   2. Select the **[OOTB] Kaspersky EDR** collector.
   3. In the collector editing window that is displayed, select the **Routing** tab and click the **Add** button.

4. Create a destination:

   a. On the **Basic settings** tab, in the **Type** drop-down list, select **tcp**.

   b. In the **URL** field, specify the URL that you need to connect to. Example: <KUMA_collector_host_name>:<KUMA_collector_port>.

   c. Go to the **Advanced settings** tab.

   d. In the **TLS mode** drop-down list, select **Enabled**.

   e. In the **Delimiter** drop-down list, select **\n**.

   f. Click **Save**.

5. Select the **Setup validation** tab and click the **Save and restart services** button.

6. Close the collector editing window.

A TCP destination with TLS mode for event export to an external SIEM system is configured.

3 Getting the Connector gateway URL of the Kaspersky EDR [OOTB] collector

1. In the **Monitoring** → **Resources and services** → **Active services** section, right-click the **[OOTB] Kaspersky EDR** collector and in the context menu, select **Deploy**.

2. This opens a window; in that window, copy the values of the **Connector gateway URL** setting.

4 Sending a test event to the [OOTB] Kaspersky EDR collector

1. Run the following command in your terminal:

```
curl -w "%{http_code}\n" -X POST \
--cert cert.pem \
--key key.pem \
-H "Content-Type: application/json" \
--data-binary $'{"Product":"EDR","HostOsFamily":"Test_send_to_external_SIEM_collector"}\n' \
https://<Connector gateway URL> -k
```

2. Replace `<Connector gateway URL>` with the value of the **Connector gateway URL** setting that you copied earlier.

Example

```
curl -w "%{http_code}\n" -X POST \
--cert cert.pem \
--key key.pem \
-H "Content-Type: application/json" \
--data-binary $'{"Product":"EDR","HostOsFamily":"Test_send_to_external_SIEM_collector"}\n' \
https://example.connector-gateway-url.ru:443 -k
```

You can see response code 200 in the terminal. The event has been sent to the collector of the external SIEM system.

5 Checking the arrival of the event in the external SIEM system

1. Log in to the KUMA web interface under a user account with Main administrator rights.

2. Go to the **Events** section.

3. Find the event with the **Test_send_to_external_SIEM_collector** value in the **KL_HostOsFamily** field.

Example contents of the Raw field

```
{
 "ID":"fca85cda-f760-48a8-8060-382bbaf7af14",
 "Timestamp":1776534533425,
 "TenantID":"d22648f7-bd98-4f55-a7ca-90b51f4d3fae",
 "ServiceID":"efd93e7c-1f8c-4035-bc76-a6efdd72197f",
 "ServiceName":"[OOTB] Kaspersky EDR",
 "Priority":0,
 "SpaceID":"",
 "DeviceTimeZone":"+03:00",
 "EndTime":1776534533425,
 "DeviceReceiptTime":1776534533425,
 "Type":1,
 "Extra":{
 "Product":"EDR"
 },
 "S":{
 "KL_HostOsFamily":"Test_send_to_external_SIEM_collector",
 "KL_Product":"EDR"
```

The event has arrived at the collector of the external SIEM system.

Managing object revisions

This section contains information about object revision management. Kaspersky EDR Expert allows you to track object modification. Every time you save changes made to an object, a *revision is created.* Each revision has a number.

Application objects that support revision management include:

- Administration Server properties
- Policies
- Tasks
- Administration groups
- User accounts
- Installation packages

You can perform the following actions on object revisions:

- View a selected revision (available only for policies)
- Roll back changes made to an object to a selected revision
- Save revisions as a JSON file (available only for policies)

In the properties window of any object that supports revision management, the **Revision history** section displays a list of object revisions with the following details:

- **Revision**—Object revision number.
- **Time**—Date and time the object was modified.

- **User**—Name of the user who modified the object.
- **User device IP address**—IP address of the device from which the object was modified.
- **Web Console IP address**—IP address of OSMP Console with which the object was modified.
- **Action**—Action performed on the object.
- **Description**—Description of the revision related to the change made to the object settings.

  By default, the object revision description is blank. To add a description to a revision, select the relevant revision and click the **Edit description** button. In the opened window, enter some text for the revision description.

Viewing and saving a policy revision

A policy revision is a saved state of a policy that is automatically created every time it is changed or saved. A revision contains policy settings, profiles, and rules for their activation, metadata about the date and the user and IP address that the revision was created by. Open Single Management Platform lets you view policy revisions to track changes of settings; you can also save a revision to a JSON file.

Viewing and saving a policy revision are available if the corresponding management web plug-in supports this functionality.
The options are available for the policies of Administration Server, Network Agent, Kaspersky Endpoint Security for Windows (starting from version 14.0 of the web plug-in), Kaspersky Endpoint Security for Linux (starting from version 12.4 of the web plug-in) and Kaspersky Endpoint Security for Mac (starting from 12.2.1 Patch A version of the web plug-in).

To view a policy revision:

1. In the main menu, go to **Asset management** → **Policies**.
2. Click the policy for the revision that you want to view, and then go to the **Revision history** section.
3. In the list of policy revisions, click the number of the revision that you want to view.

   The displayed report provides information about the settings of the policy, its profiles, and the activation rules for them.

   If the revision size is more than 10 MB, you will not be able to view it by using OSMP Console. You will be prompted to save the selected revision to a JSON file.

   If the revision size does not exceed 10 MB, a report in the HTML format with the settings of the selected policy revision is displayed. Since the report is displayed in a pop-up window, ensure that pop-ups are allowed in your browser.

For the policies of Kaspersky Endpoint Security for Windows and Kaspersky Endpoint Security for Mac, the report will not contain information about the policy profiles.

To save a policy revision to a JSON file,

In the list of policy revisions, select the revision that you want to save, and then click **Save to file**.

The revision is saved to a JSON file.

If necessary, you can compare policy revisions.

Comparing policy revisions

You can compare past revisions of a policy to its current revision, compare different revisions selected in the list, or compare a revision of one policy to a revision of another policy. The options are available for the policies of Administration Server, Network Agent, Kaspersky Endpoint Security for Windows (starting from 14.0 web plug-in version), and Kaspersky Endpoint Security for Mac (starting from 12.2.1 Patch A web plug-in version).

Policy revision comparison is available if the corresponding management web plug-ins support this functionality.

To compare revisions of a policy:

1. In the main menu, go to **Asset management** → **Policies**.
2. Click the policy whose revisions you want to compare.

   The policy settings window opens.
3. Go to the **Revision history** tab, and then select the check boxes next to the revisions to be compared.
4. In the toolbar, click the **Compare** button, and then from the drop-down list, select one of the following options:

   - **With current revision**, if you want to compare the revision that you selected at step 3 with the last saved revision of the same policy.
   - **Selected revisions**, if you want to compare the two revisions whose check boxes you selected at step 3.

     The order of selecting check boxes does not affect the comparison results. By default, the earlier revision of the selected revision is compared to the latest revision. For example, if you select check boxes next to the revisions 5 and 1, revision 1 is compared to revision 5. The report will contain information about the settings in revision 1 that were added, removed, or changed compared to the revision 5.
   - **With another policy revision**, if you want to compare the revisions of two different policies.

In the right pane that opens, do the following:

a. In the **Application name** field, select the policy you want to compare: Network Agent or Administration Server.

b. In the **Policy name** field, specify the name of the policy whose revision you want to compare with the one you selected at step 3.

The list of the policy revisions is displayed.

c. Select the required revision, and then click the **Compare** button.

A report on the revisions comparison is displayed in HTML format on a new tab of your browser.

If the comparison result exceeds 10 MB, the corresponding dialog box is displayed. You can either click the **Save to file** button to save the report as a file, or cancel the operation.

The report is displayed in the interface language of your OSMP Console. You can expand some sections of the report by clicking the arrow down icon (▼) next to the section or collapse the section by clicking the arrow up (▲) icon.

The report contains the following information:

- Kaspersky logo.
- The report name.
- Time and date of the report creation.
- The policy name, Administration Server, and administration group that includes the policy (policies) whose revisions were compared.
- The **Save as HTML** button. If you click the button, the report will be saved to your computer.
- The **Summary** section that displays general information on the compared revisions: policy (policies) name, revision number, time and date when the revision was saved, the user who saved the revision, and the revision description.

  For inherited polices, the user is not displayed.

- Differences between the compared revisions. The differences are displayed in the following sections:
  - **Added settings**
  - **Removed settings**
  - **Changed settings**
  - **Settings only available for object 1** (if you compared the revisions of two different policies)
  - **Settings only available for object 2** (if you compared the revisions of two different policies)

A section is not displayed if it has no data.

Rolling back an object to a previous revision

You can roll back changes made to an object, if necessary. For example, you may have to revert the settings of a policy to their state on a specific date.

To roll back changes made to an object:

1. In the object's properties window, open the **Revision history** tab.
2. In the list of object revisions, select the revision that you want to roll back changes for.
3. Click the **Roll back** button.
4. Click **OK** to confirm the operation.

   The object is now rolled back to the selected revision. The list of object revisions displays a record of the action that was taken. The revision description displays information about the number of the revision to which you reverted the object.

Rolling back operation is available only for policy and task objects.

Operation diagnostics of the Kaspersky EDR Expert components

This section describes how to obtain diagnostic information about Kaspersky EDR Expert components.

Obtaining log files of Kaspersky EDR Expert components

KDT allows you to obtain log files that contain diagnostic information about Kaspersky EDR Expert components and the Kubernetes cluster, to troubleshoot problems on your own or with the help of Kaspersky Technical Support.

Kaspersky EDR Expert generates the log file names according to the following template: pod_name.container_name.log. Here, pod_name is a Kubernetes pod name, and container_name is a Kubernetes container name.

To obtain log files of Kaspersky EDR Expert components and management web plug-ins,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt logs get <flags>
```

Where `<flags>` are the parameters of the command that allow you to configure the logging result.

You can specify the following logging parameters:

- `--app <list_of_components>`—Obtain logs for the listed Kaspersky EDR Expert components.
  For example, if you want to obtain logs for the last hour for Administration Server, run the following command:
  `./kdt logs get --app ksc`
  List of available Kaspersky EDR Expert components

- `--auto-dest-dir`—Obtain logs and save them to the kdt-default-logs-<current_date_and_time> directory that is automatically created in the current directory. If the logging period is not specified, you obtain diagnostic information for the last hour.

  For example, if you want to obtain logs for the last hour for Administration Server and KUMA, and then save these logs to the automatically created directory, run the following command:

  ```
  ./kdt logs get --app ksc,core --auto-dest-dir
  ```

- `-d, --destination <file_path>`—Obtain logs and save them to the specified file.

- `-D, --destination-dir <directory_path>`—Obtain logs and save them to the specified directory that must be created beforehand. If the `<directory_path>` is empty, logs are saved in the standard output stream (stdout). If the logging period is not specified, you obtain diagnostic information for the last hour.

- `--to-archive`—Obtain logs and save them to the kdt-default-logs-<current_date_and_time>.tar.gz archive. The created archive is saved to the current directory. If the logging period is not specified, you obtain diagnostic information for the last hour.

- `--last=<hours>h`—Obtain logs for the specified number of hours up to date.

  For example, if you want to get an archive with logs for the last three hours, run the following command:

  ```
  ./kdt logs get --to-archive --last=3h
  ```

- `--start=<date_and_time>`—Obtain logs starting from the specified date and time (in the Unix timestamp format) to the present time, or to the date and time specified in the `--end` parameter.

  For example, if you want to obtain logs starting from 03/26/2024 10:00:00 to the present time, and then save them to the kdt-default-logs-<current_date_and_time> directory created in the current directory, run the following command:

  ```
  ./kdt logs get --auto-dest-dir --start=1711447200
  ```

- `--end=<date_and_time>`—Obtain logs starting from the date and time specified in the `--start` parameter to the date and time specified in the `--end` parameter (in the Unix timestamp format). If the `--start` parameter in not specified, logs are obtained for the last hour before the date and time specified by the `--end` parameter.

  For example, if you want to save logs for the 10 minutes (from 03/26/2024 10:00:00 to 03/26/2024 10:10:00) to the logs directory, run the following command:

  ```
  ./kdt logs get -D ./logs/ start=1711447200 --end=1711447800
  ```

To view the available logging parameters, you can run one of the following commands:

- `./kdt logs get -h`

- `./kdt logs get --help`

Viewing OSMP metrics

The observability component of Kaspersky EDR Expert allows you to view OSMP metrics, monitor the state of each component by dashboards, view metrics of the data storage system (Longhorn) for the Kubernetes cluster, and notify users by email when the Kubernetes cluster node performance indicators exceed normal values.

You can monitor metrics for further analysis of the operability and performance of its components by using the observability component.

You can view OSMP metrics in one of the following ways:

- By using Grafana dashboards
- By using your own monitoring tools

To view OSMP metrics by using Grafana dashboards:

1. Go to the `<monitoring_host>.<smp_domain>` URL.

   The `<monitoring_host>` is a host name, and `<smp_domain>` is a domain name. These parameters constitute the FQDN of the Kaspersky EDR Expert monitoring service and are set in the configuration file when deploying Kaspersky EDR Expert.

2. Enter the Grafana credentials specified in the configuration file (the `grafana_admin_user` and `grafana_admin_password` parameters).

Alternatively, you can view OSMP metrics in the **Dashboard** section:

1. In the main menu, go to the **Monitoring** section. → **Dashboard**, and then select the **Analysis and response** tab.
2. Click the ellipsis (⋮) icon.
3. Click the Go to OSMP metrics button.

The Grafana interface is displayed. You can view diagnostic information for each Kaspersky EDR Expert component, view metrics of the data storage system (Longhorn) for the Kubernetes cluster, and configure email notifications about Kubernetes cluster health events.

To view OSMP metrics by using your own monitoring tools:

1. Configure your monitoring tools to obtain the metrics from the Kaspersky EDR Expert API.
2. Go to the API address `<api_host>.<smp_domain>/api/read-api` to obtain metrics.

   The `<api_host>` is a host name, and `<smp_domain>` is a domain name. These parameters constitute the FQDN of the service that provide access to the Kaspersky EDR Expert API. These parameters are set in the configuration file when deploying Kaspersky EDR Expert.

OSMP metrics in the OpenMetrics format are obtained.

If you want to view information about the performance of the KUMA Core, storage, collectors, and correlators, you have to view KUMA metrics.

Monitoring the state of Kaspersky EDR Expert components

The dashboard provides a graphical display of the state of each Kaspersky EDR Expert component.

For example, you can view the following component parameters:

- Usage of requests and limits of CPU
- Usage of requests of CPU and RAM
- Usage of CPU and RAM by containers
- Allocation of the component resources by containers
- Network performance indicators:
  - Bandwidth
  - Packets rate (number of received packets)
  - Packets dropped (number of lost packets)
  - Errors (number of network errors)

To view diagnostic information on the dashboard:

1. Go to the `<monitoring_host>.<smp_domain>` URL.

   The `<monitoring_host>` is a host name, and `<smp_domain>` is a domain name. These parameters constitute the FQDN of the Kaspersky EDR Expert monitoring service and are set in the configuration file when deploying Kaspersky EDR Expert. For example: `monitoring.smp.local`.

2. Enter the Grafana credentials that you specified in the configuration file (the `grafana_admin_user` and `grafana_admin_password` parameters).

3. In the menu, go to **Home** → **Dashboards** → **Kubernetes / Views / Pods**.

4. In the **namespace** drop-down list, select the component for which you want to view the diagnostic information.

5. You can also specify other parameters to customize the dashboard view.

The dashboard with diagnostic information about the selected Kaspersky EDR Expert component is displayed.

Viewing Longhorn metrics

Kaspersky EDR Expert includes a dashboard that displays key metrics for the cluster's data storage system (Longhorn). The Longhorn dashboard enables monitoring of data storage health and performance.

By default, the dashboard displays data for the last three hours. You can change this period. The dashboard refreshes every 15 seconds.

To view the Longhorn dashboard:

1. Go to `<monitoring_host>.<smp_domain>`.

   `<monitoring_host>` represents the host name, and `<smp_domain>` represents the domain name. Together, they form the FQDN of the Kaspersky EDR Expert monitoring service and are specified in the configuration file during Kaspersky EDR Expert deployment.

2. Enter the Grafana credentials that you specified in the configuration file (`grafana_admin_user` and `grafana_admin_password`).

3. In the menu, go to **Home** → **Dashboards** → **Longhorn Dashboard**.

   The Longhorn dashboard is displayed.

The Longhorn dashboard metrics are described below.

Nodes

- **Nodes**—total number of nodes in the system.
- **Schedulable Nodes**—number of nodes available for distributing volume replicas.
- **Disabled Nodes**—nodes disabled by a user.
- **Failed Nodes**—unresponsive, offline or otherwise unavailable node.

Volumes

- **Attached Volumes**—volumes currently attached to nodes.
- **Detached Volumes**—volumes not attached to nodes.
- **Degraded Volumes**—volumes with an insufficient number of replicas.
- **Faulty Volumes**—volumes without functioning replicas.

Capacity

- **Node Capacity**—total storage capacity on each node.
- **Disk Capacity**—storage capacity on each disk.
- **Volume Capacity**—capacity of each volume.

Resource usage

- **Node Storage Usage/Capacity**—percentage of storage capacity on each node.
- **Disk Space Usage**—percentage of capacity on each disk.
- **Volumes Per Node**—number of mounted volumes on each node.
- **Volume Size/Capacity**—current/maximum volume ratio.
- **Volume Write Throughput**—amount of data the system writes per second (bps).
- **Volume Read Throughput**—amount of data the system reads per second (bps).
- **Volume Write IOPS**—number of write input/output operations (IOPS).
- **Volume Read IOPS**—number of read input/output operations (IOPS).

- **Volume Write Latency**—time required to complete a single write operation (ns).
- **Volume Read Latency**—time required to complete a single read operation (ns).
- **Node CPU Usage/Capacity**—percentage of CPU utilization per node.
- **Node Memory Usage/Capacity**—percentage of memory utilization per node.
- **Longhorn Manager CPU Usage**—CPU load of the Longhorn Manager Longhorn (milliCPU).
- **Longhorn Manager Memory Usage**—memory load of the Longhorn Manager Longhorn.
- **Instance Manager CPU Usage**—CPU load of Longhorn instances (milliCPU).
- **Instance Manager Memory Usage**—memory used by Longhorn instances.

Disk usage

The indicators on the disk usage panel display the percentage of time the disk spends reading and writing. These indicators are based on the following metrics:

- `longhorn_volume_read_iops`
- `longhorn_volume_read_latency_seconds`
- `longhorn_volume_write_iops`
- `longhorn_volume_write_latency_seconds`

Viewing EDR dashboards and metrics

Kaspersky EDR Expert features EDR dashboards that display key metrics for components responsible for processing objects from Endpoint Agents. Monitoring these metrics helps ensure the components operate smoothly and securely, enabling proactive measures to prevent potential issues.

The following dashboards are available:

- EDR Agent Server
- EDR KSB
- EDR KSN proxy
- EDR Sandbox
- EDR Scanner

To view the EDR dashboards:

1. Go to `<monitoring_host>.<smp_domain>`.

   `<monitoring_host>` represents the host name, and `<smp_domain>` represents the domain name. Together, they form the FQDN of the Kaspersky EDR Expert monitoring service and are set in the configuration file when deploying Kaspersky EDR Expert.

2. Enter the Grafana credentials you specified in the configuration file (`grafana_admin_user` and `grafana_admin_password`).

3. In the menu, go to **Home** → **Dashboards**.

4. In the tag filtering drop-down menu (**Filter by tag**), select the **edr** tag.

   The list of available EDR dashboards is displayed.

5. Click the name of a dashboard you want to view.

   The selected dashboard opens.

Widgets and metrics available in each EDR dashboard are described below.

EDR Agent Server

By default, the dashboard displays data for the last two days. You can change this period by clicking **Last 2 days** at the top of the page and selecting a different time range.

EDR Agent Server widgets and metrics

Widget name	Metric name	Description
Tasks	xdr_agentserver_tasks_total	Total number of tasks received from Incident Response Platform.
Settings	xdr_agentserver_settings_total	Total number of configurations received from Incident Response Platform.
Active tasks	xdr_agentserver_tasks_active	Total number of tasks in progress.
Active settings	xdr_agentserver_settings_active	Total number of configuration applications in progress.
Tasks errors	xdr_agentserver_tasks_errors_total	Total number of tasks completed with an error.
Settings errors	xdr_agentserver_settings_errors_total	Total number of configuration application errors.
Object storage	xdr_agentserver_objectstorage_upload_errors_total	Total number of file upload errors to Object Storage.
Object storage	xdr_agentserver_objectstorage_download_errors_total	Total number of file download errors from Object Storage.
Agent info update	xdr_agentserver_agentinfo_updates_total	Total number of times Endpoint Agent information is updated and sent to the Asset Manager.
Assets resolve errors	xdr_agentserver_assets_resolve_errors_total	Total number of errors when mapping identifiers between OSMP and Endpoint Agents.
Assets	xdr_agentserver_assets_resolve_total	Total number of resolutions.
Agent server rate limit exceeded	xdr_agentserver_rate_limit_exceeded_total	Total number of cases when rate limit was exceeded.
Agent auth	xdr_agentserver_agent_auth_total	Total number of Endpoint Agent authentication attempts.
Agent auth	xdr_agentserver_agent_auth_errors_total	Total number of Endpoint Agent authentication errors.
Vtproxy sessions	xdr_agentserver_vtproxy_sessions_total	Total number of sessions created.

Widget name	Metric name	Description
Vtproxy auth errors	xdr_agentserver_vtproxy_auth_errors_total	Total number of session authentication errors.
Vtproxy successful auth	xdr_agentserver_vtproxy_successful_auths_total	Total number of successful session authentications.
Vtproxy active sensor sessions	xdr_agentserver_vtproxy_sensor_session_active	Active sessions for sensor.
Vtproxy active sessions	xdr_agentserver_vtproxy_sessions_active	Number of active sessions.
Vtproxy sessions duration	xdr_agentserver_vtproxy_session_duration_seconds	Session duration in seconds.
Vtproxy bytes transferred	xdr_agentserver_vtproxy_bytes_transferred_total	Total number of bytes transferred.

EDR KSB

By default, the dashboard displays data for the last two days. You can change this period by clicking **Last 2 days** at the top of the page and selecting a different time range.

EDR KSB widgets and metrics

Widget name	Metric name	Description
Multitasks	xdr_ksb_multitasks_total	Total number of scan tasks.
Active multitasks	xdr_ksb_multitasks_active	Number of active scan tasks.
Multitasks duplicates	xdr_ksb_multitask_duplicates_total	Number of duplicate scan tasks.
Multitasks files duplicates	xdr_ksb_multitask_file_duplicates_total	Number of duplicate files in scan tasks.
Multitasks files size	xdr_ksb_multitask_files_size_bytes_total	Size of multitask files in bytes.
Agents auth failures	xdr_ksb_agent_auth_failures_total	Number of Endpoint Agent authentication failures.
Rate limit exceeded	xdr_ksb_rate_limit_exceeded_total	Total number of cases when rate limit was exceeded.

EDR KSN proxy

By default, the dashboard displays data for the last six hours. You can change this period by clicking **Last 6 hours** at the top of the page and selecting a different time range.

EDR KSN proxy widgets and metrics

Widget name	Metric name	Description
Stats messages	xdr_scanner_ksnproxyfacade_stats_messages_total	Total number of statistics messages.
Integration mode changes	xdr_scanner_ksnproxyfacade_integration_mode_changes_total	Total number of integration type changes.
KSN Proxy starts	xdr_scanner_ksnproxysupervisor_ksnproxy_starts_total	Total number of KSN proxy starts.
KSN Proxy start errors	xdr_scanner_ksnproxysupervisor_ksnproxy_start_errors_total	Total number of KSN proxy start errors.
KSN availability	xdr_scanner_ksnproxy_ksn_proxy_ksn_available	KSN availability.

Widget name	Metric name	Description
KSN heartbeat failed requests	xdr_scanner_ksnproxy_ksn_proxy_ksn_heartbeat_failed_requests_total	Total number of failed heartbeat requests.
KSN heartbeat requests	xdr_scanner_ksnproxy_ksn_proxy_ksn_heartbeat_requests_total	Total number of heartbeat requests.

EDR Sandbox

By default, the dashboard displays data for the last six hours. You can change this period by clicking **Last 6 hours** at the top of the page and selecting a different time range.

To view the metrics of a certain Sandbox, select its IP address in the **Sandbox** menu at the top.

EDR Sandbox widgets and metrics

Widget name	Metric name	Description
Start time Uptime	xdr_scanner_sb_process_start_time_seconds	Time when the Sandbox process started and its uptime, in seconds.
SB last health check SB health check errors	xdr_scanner_sb_health_check_errors_current	Time of last health check and current number of detected errors.
SB bases age	xdr_scanner_sb_health_bases_age_seconds	Age of anti-virus databases in Sandbox, in seconds.
CPU	xdr_scanner_sb_process_cpu_seconds_total	Number of CPU cores used.
Memory usage	xdr_scanner_sb_go_memstats_sys_bytes	Memory requested from the system, in bytes.
Memory usage	xdr_scanner_sb_go_memstats_heap_inuse_bytes	Heap memory in use, in bytes.
Memory usage	xdr_scanner_sb_go_memstats_stack_inuse_bytes	Stack memory in use, in bytes.
Memory usage	xdr_scanner_sb_process_resident_memory_bytes	Resident memory (RSS), in bytes.
Disk writes/reads	xdr_scanner_sb_node_disk_read_bytes_total	Total bytes read from disk.
Disk writes/reads	xdr_scanner_sb_node_disk_written_bytes_total	Total bytes written to disk.
Network usage	xdr_scanner_sb_process_network_receive_bytes_total	Incoming traffic.
Network usage	xdr_scanner_sb_process_network_transmit_bytes_total	Outgoing traffic.
Malware channel availability	xdr_scanner_sbscanapi_sb_malware_channel_availability	Availability of malware channel for specific Sandbox.
SB images status	xdr_scanner_sb_vm_images_status	Current status of virtual machines in the Sandbox, indicating whether operating systems are installed.
SB image version status	xdr_scanner_sb_vm_image_version_status	The status of image versions used on virtual machines, indicating whether each version is correct.

EDR Scanner

By default, the dashboard displays data for the last two days. You can change this period by clicking **Last 2 days** at the top of the page and selecting a different time range.

In the **Scan engine** menu at the top, select the scanning engine to view its metrics:

- **AM**: Anti-Malware Engine metrics
- **YARA**: YARA metrics
- **SB**: Sandbox metrics

EDR Scanner widgets and metrics

Widget name	Metric name	Description
Last bases update	xdr_scanner_updater_updater_bases_age	Updater bases age.
Last bases update	xdr_scanner_updater_updater_retranslation_age	Updater retranslation age.
Last bases update	xdr_scanner_internalscanner_am_bases_age	Age of anti-virus databases for Anti-Malware Engine.
Last bases update	xdr_scanner_sb_health_bases_age_seconds	Time elapsed since the last update of the anti-virus databases in Sandbox, in seconds.
AM scan engine complete SB scan engine complete YARA scan engine complete	xdr_scanner_internalscanner_scan_engine_complete_total	Number of completed scan tasks for each scanning engine and object scanning results.
Scan health	xdr_scanner_internalscanner_total_scans	Number of scans.
Scan health	xdr_scanner_internalscanner_failed_scans	Number of failed scans.
AM scan tasks	xdr_scanner_internalscanner_am_queue_len	Number of jobs in the Anti-Malware Engine queue.
AM scan tasks	xdr_scanner_internalscanner_am_queue_total_items	Total number of tasks in all Anti-Malware Engine queues.
AM scan tasks	xdr_scanner_internalscanner_am_queue_failed_items_total	Total number of failed tasks in Anti-Malware Engine queues.
AM queue size	xdr_scanner_internalscanner_am_queue_size	File system size used by the Anti-Malware Engine queue.
AM queue size	xdr_scanner_internalscanner_am_storage_size_limit	Maximum allowed size of Anti-Malware Engine queue.
SB scan tasks	xdr_scanner_internalscanner_sb_wait_queue_len	Number of jobs in the Sandbox queue in OSMP scanner.
SB scan tasks	xdr_scanner_internalscanner_sb_queue_total_items	Total number of tasks in all Sandbox queues.
SB scan tasks	xdr_scanner_internalscanner_sb_queue_failed_items_total	Total number of failed tasks in Sandbox queues.
SB scan tasks	xdr_scanner_internalscanner_sb_queue_len	Number of tasks in Sandbox queue.
SB queue size	xdr_scanner_internalscanner_sb_queue_size	Approximate size of data (samples) in Sandbox queue.
SB queue size	xdr_scanner_internalscanner_sb_storage_size_limit	Maximum allowed size of Sandbox queue.
Average sandbox scan time	xdr_scanner_sbscanapi_sb_scan_time_total	Total Sandbox scanning time.
Average sandbox scan time	xdr_scanner_sbscanapi_sb_scan_count_total	Total number of scans on Sandbox.
YARA scan tasks	xdr_scanner_internalscanner_yr_queue_len	Number of jobs in the YARA queue.
YARA queue size	xdr_scanner_internalscanner_yr_queue_size	File system size used by YARA queue.
YARA queue size	xdr_scanner_internalscanner_yr_storage_size_limit	Maximum YARA queue size.
YARA scan tasks	xdr_scanner_internalscanner_yr_queue_total_items	Total number of tasks in all YARA queues.
YARA scan tasks	xdr_scanner_internalscanner_yr_queue_failed_items_total	Total number of failed tasks in YARA queues.
Last bases update	xdr_scanner_internalscanner_am_bases_age	Age of anti-virus databases for Anti-Malware Engine.

Viewing the Node Exporter Full dashboard

The Node Exporter Full dashboard displays key metrics for cluster node performance.

To view the Node Exporter Full dashboard:

1. Go to `<monitoring_host>.<smp_domain>`.

   `<monitoring_host>` represents the host name, and `<smp_domain>` represents the domain name. Together, they form the FQDN of the Kaspersky EDR Expert monitoring service and are specified in the configuration file when deploying Kaspersky EDR Expert.

2. Enter the Grafana credentials you specified in the configuration file (`grafana_admin_user` and `grafana_admin_password`).

3. In the menu, go to **Home** → **Dashboards**.

4. Click **Node Exporter Full**.

   The dashboard opens.

By default, the dashboard displays data for the last 24 hours. You can change this period by clicking **Last 24 hours** at the top of the page and selecting a different period.

Panes available in the dashboard are described in the table below.

Node Exporter Full panes

Pane	Description
Quick CPU / Mem / Disk	Quick overview of key resources: CPU load, memory usage, and disk usage.
Pressure	Pressure Stall Information (PSI): CPU, memory, and I/O. Shows where the system is under load.
CPU Busy	Percentage of time processors are busy with computations (user + system time).
Sys Load	Average system load (load average) over 1, 5, and 15 minutes.
RAM Used	Used RAM, including buffers and cache.
SWAP Used	Used swap space.
Root FS Used	Space used on the root file system (/).
CPU Cores	Number of cores (vCPU) on the node.
Uptime	Time elapsed since the last system boot.
RootFS Total	Total size of the root file system.
RAM Total	Total amount of RAM.
SWAP Total	Total amount of available swap memory.
Basic CPU / Mem / Net / Disk	Overview of key CPU, memory, network, and disk metrics.
CPU Basic	Basic CPU load panel, including user/system/idle/iowait metrics.
Memory Basic	Main RAM and swap usage metrics.
Network Traffic Basic	Total network traffic (inbound/outbound) by interface.
Disk Space Used Basic	Disk space usage and partitioning.
CPU	Detailed CPU usage metrics (in percent, by core).
Memory Stack	Diagram of memory layer usage (used, cache, buffers, free).

Pane	Description
Network Traffic	Total network traffic (in bytes/second) by interface.
Disk Space Used	Detailed disk space usage by partition.
Disk IOps	Number of input/output operations per second (I/O per second).
I/O Usage Read / Write	Data read and write speed on disks (bytes/second).
I/O Utilization	Storage device utilization: percentage of time the disk is busy with I/O.
CPU spent seconds in guests (VMs)	CPU time spent on running guest virtual machines (guest time).
Memory Active / Inactive	Active and inactive memory pages (used and potentially reclaimable).
Memory Committed	Amount of memory allocated to processes (including overcommit).
Memory Active / Inactive Detail	Details of active and inactive pages, including anon/file.
Memory Writeback and Dirty	Amount of pages waiting to be written to disk (dirty, writeback).
Memory Shared and Mapped	Shared and mapped memory.
Memory Slab	Memory allocated to kernel objects (slab, reclaimable/unreclaimable).
Memory Vmalloc	Kernel virtual memory allocation.
Memory Bounce	Number of bounce pages (rare, for old hardware).
Memory Anonymous	Anonymous memory (not file-backed).
Memory Kernel / CPU	Memory used by kernel and CPU structures.
Memory HugePages Counter	Number of huge pages used (HugePages).
Memory HugePages Size	Size and state of HugePages.
Memory DirectMap	Direct mapping of physical memory (DirectMap).
Memory Unevictable and MLocked	Memory locked in RAM (mlocked, unevictable).
Memory NFS	Memory usage by the NFS subsystem.
Memory Meminfo	Summary information from /proc/meminfo.
Memory Pages In / Out	Number of pages loaded/unloaded into memory.
Memory Pages Swap In / Out	Pages moved between RAM and swap.
Memory Page Faults	Number of page faults (minor/major faults).
OOM Killer	Events where system killed processes due to memory shortage.
Memory Vmstat	Extended virtual memory statistics (/proc/vmstat).
Time Synchronized Drift	Difference between system time and synchronization source.
Time PLL Adjust	Time adjustment parameters (PLL, offset).
Time Synchronized Status	Time synchronization status (for example, chrony/ntpd).
Time Misc	Other time-related metrics (offset, jitter).
System Timesync	Overall time synchronization status on the node.
Processes Status	Process statistics by state (running, sleeping, zombie).
Processes State	Histogram of process states.
Processes Forks	Number of processes created (forks).
Processes Memory	Memory usage by processes.
PIDs Number and Limit	Current and maximum number of PIDs in the system.
Process schedule stats Running / Waiting	Process distribution by "running" and "waiting" states.
Threads Number and Limit	Number of threads and system limit.
Context Switches / Interrupts	Context switches and hardware interrupts.
System Load	Average load (load average) over 1, 5, and 15 minutes.

Pane	Description
CPU Frequency Scaling	Current CPU frequency and scaling (governor, min/max).
Pressure Stall Information	CPU, memory, and I/O pressure - shows task delays.
Interrupts Detail	Detailed breakdown of interrupt types.
Schedule timeslices executed by each cpu	Number of time quanta executed by each core.
Entropy	Available entropy (random number generation quality).
CPU time spent in user and system contexts	Total CPU time spent in user and system modes.
File Descriptors	Number of open file descriptors.
Hardware temperature monitor	Temperature of system components (CPU, disks, sensors).
Throttle cooling device	State of cooling systems and throttling.
Power supply	Power data (voltage, current, battery).
Systemd Sockets	Active systemd sockets.
Systemd Units State	State of systemd units (active, failed, inactive).
Disk IOps Completed	Completed I/O operations.
Disk R/W Data	Amount of data read/written.
Disk Average Wait Time	Average I/O wait time.
Average Queue Size	Average I/O queue length.
Disk R/W Merged	Number of merged read/write operations.
Time Spent Doing I/Os	Time spent on I/O operations.
Instantaneous Queue Size	Current I/O queue length.
Disk IOps Discards completed / merged	Discard (TRIM) operations completed/merged.
Filesystem space available	Available space on file systems.
File Nodes Free	Number of free inodes.
File Descriptor	Number of file descriptors.
File Nodes Size	Inode table size.
Filesystem in ReadOnly / Error	File system state (errors, readonly mount).
Network Traffic by Packets	Number of Rx/Tx packets by interface.
Network Traffic Errors	Transmission and reception errors.
Network Traffic Drop	Dropped packets.
Network Traffic Compressed	Compressed traffic.
Network Traffic Multicast	Multicast traffic.
Network Traffic Fifo	FIFO errors on interfaces.
Network Traffic Frame	Frame errors.
Network Traffic Carrier	Link-level errors (carrier).
Network Traffic Colls	Network collisions.
NF Conntrack	Number of tracked network connections (conntrack).
ARP Entries	ARP table (number of entries).
MTU	Maximum packet size (MTU).
Speed	Network interface speed (bits/second).
Queue Length	interface packet queue length.
Softnet Packets	Softnet packet processing (kernel).
Softnet Out of Quota	Dropped packets due to softnet overflow.

Pane	Description
Network Operational Status	Current interface state (up/down).
Sockstat TCP / UDP / FRAG / RAW	Statistics for TCP, UDP, and other protocol sockets.
Sockstat Memory Size / Used	Memory usage by sockets and number of active sockets.
Netstat IP In / Out Octets	Number of incoming/outgoing IP packets (in bytes).
Netstat IP Forwarding	IP forwarding status.
ICMP In / Out / Errors	ICMP packet and error statistics.
UDP In / Out / Errors	UDP packet and error statistics.
TCP In / Out / Errors	TCP traffic and errors.
TCP Connections	Number of active TCP connections by state.
TCP SynCookie / Direct Transition / Stat	SYN cookie protection, direct TCP state transitions, and total TCP statistics.
Node Exporter Scrape Time / Scrape	Node Exporter performance, with focus on scrape durations and target status.

Configuring email notifications about Kubernetes cluster health events

The observability component of the Kaspersky EDR Expert allows you to notify users by email when the Kubernetes cluster node performance indicators exceed normal values. Email notifications are generated based on email notification rules in Grafana. These rules define the notification message, recipients, and conditions under which email alerts are sent.

You can view the list of available email notification rules in Grafana. Rules can be either predefined or custom. Predefined rules are provided by Kaspersky EDR Expert and cannot be changed. Custom rules can be created, modified, or deleted.

Predefined rules for generating email notifications

Kaspersky EDR Expert includes the following predefined rules for generating email notifications about Kubernetes cluster health events. You cannot delete or edit these rules.

Predefined email notifications

Metric	Severity	Notification message
High CPU Usage	Warning	CPU usage on node <node_name> has exceeded the warning threshold. This may indicate elevated load or insufficient CPU resources.
	Critical	Node <node_name> is experiencing critically high CPU usage. This can lead to CPU throttling, pod-scheduling issues, and degraded performance of cluster components.
High Disk I/O Utilization	Warning	Disk device <disk_name> on node <node_name> is under elevated I/O load. Applications may start seeing latency.
	Critical	Disk device <disk_name> on node <node_name> is overloaded. This can severely degrade performance of stateful applications.
High Disk Latency	Warning	Read/write latency on storage device <disk_name> on node <node_name> has crossed the warning threshold.
	Critical	Storage device <disk_name> on node <node_name> is experiencing critically high I/O latency.

Metric	Severity	Notification message
High Disk Usage (Filesystem)	Warning	Filesystem <mountpoint_name> on node <node_name> has reached a high utilization level. Approaching the limit may affect logging, pod scheduling, or kubelet stability.
	Critical	Filesystem <mountpoint_name> on node <node_name> is almost full. This can cause write errors, service failures, and node instability.
High Memory Usage	Warning	Memory usage on node <node_name> has exceeded the warning threshold. Workloads may encounter memory pressure.
	Critical	Node <node_name> is near memory exhaustion. This may trigger OOMKill or pod eviction. Immediate action is required to prevent workload failures.

To view predefined rules for generating email notifications:

1. Go to the `<monitoring_host>.<smp_domain>` URL.

   The `<monitoring_host>` is a host name, and `<smp_domain>` is a domain name. These parameters constitute the FQDN of the Kaspersky EDR Expert monitoring service and are set in the configuration file when deploying Kaspersky EDR Expert. For example: `monitoring.smp.local`.

2. Enter the Grafana credentials that you specified in the configuration file (the `grafana_admin_user` and `grafana_admin_password` parameters).

3. In the menu, go to **Home** → **Alerting** → **Alert rules**.

   In the **Alert rules** section, the list of predefined rules for generating email notifications is displayed.

Custom rules for generating email notifications

You can create your own rules for generating email notifications about Kubernetes cluster health events.

Email notifications will not be sent if SMTP server connection parameters are not specified in the configuration file: `grafana_smtp_host`, `grafana_smtp_user`, `grafana_smtp_password`, `grafana_smtp_bundle`, `grafana_smtp_skip_verify`, `grafana_smtp_from_address`, `grafana_smtp_from_name`, `grafana_smtp_ehlo_identity`, `grafana_starttls_policy`, `grafana_smtp_enable_tracing`. If you did not specify these parameters in the configuration file before deploying Kaspersky EDR Expert, you can add them later.

To create custom rules for generating email notifications:

1. Go to the `<monitoring_host>.<smp_domain>` URL.

   The `<monitoring_host>` is a host name, and `<smp_domain>` is a domain name. These parameters constitute the FQDN of the Kaspersky EDR Expert monitoring service and are set in the configuration file when deploying Kaspersky EDR Expert. For example: `monitoring.smp.local`.

2. Enter the Grafana credentials that you specified in the configuration file (the `grafana_admin_user` and `grafana_admin_password` parameters).

3. In the menu, go to **Home** → **Alerting** → **Alert rules**.

4. In the **Alert rules** section, click **New alert rule**, and then specify the parameters of a new email notification rule.
5. After you specify the rule parameters, click **Save rule and exit**.

The custom rule is created. You can also create folders and place the created rules in them.

To create custom rules for generating email notifications from a dashboard:

1. Go to the `<monitoring_host>.<smp_domain>` URL.
2. Enter the Grafana credentials that you specified in the configuration file (the `grafana_admin_user` and `grafana_admin_password` parameters).
3. In the menu, go to **Home** → **Dashboards**.
4. In the dashboard list, click the name of the dashboard that contains performance indicators you want to use for alerting.

   The dashboard opens.
5. Click the **Menu** icon (⋮) on the required panel of the dashboard, and then in the context menu, select **More...** → **New alert rule**.
6. In the **New alert rule** panel, specify the parameters of a new email notification rule.
7. Click **Save rule and exit**.

The custom rule from the dashboard is created.

To edit or delete custom rules for generating email notifications:

1. Go to the `<monitoring_host>.<smp_domain>` URL.
2. Enter the Grafana credentials that you specified in the configuration file (the `grafana_admin_user` and `grafana_admin_password` parameters).
3. In the menu, go to **Home** → **Alerting** → **Alert rules**.
4. In the **Alert rules** section, locate the required rule, and then do one of the following:
   - To edit the rule, click the pencil button, and then change the rule parameters.
   - To delete the rule, click **More**, and then click **Delete**.

The custom rule is changed or deleted.

Managing email notification recipients for Kubernetes cluster health events

Kaspersky EDR Expert allows you to specify, edit, and delete notification recipient email addresses.

Email notifications will not be sent if SMTP server connection parameters are not specified in the configuration file: `grafana_smtp_host`, `grafana_smtp_user`, `grafana_smtp_password`, `grafana_smtp_bundle`, `grafana_smtp_skip_verify`, `grafana_smtp_from_address`, `grafana_smtp_from_name`, `grafana_smtp_ehlo_identity`, `grafana_starttls_policy`, `grafana_smtp_enable_tracing`. If you did not specify these parameters in the configuration file before deploying Kaspersky EDR Expert, you can add them later.

To add a notification recipient email address:

1. Go to the `<monitoring_host>.<smp_domain>` URL.

   The `<monitoring_host>` is a host name, and `<smp_domain>` is a domain name. These parameters constitute the FQDN of the Kaspersky EDR Expert monitoring service and are set in the configuration file when deploying Kaspersky EDR Expert. For example: `monitoring.smp.local`.

2. Enter the Grafana credentials that you specified in the configuration file (the `grafana_admin_user` and `grafana_admin_password` parameters).

3. In the menu, go to **Home** → **Alerting** → **Contact points**.

4. In the **Contact points** workspace, click **Add contact point**, and then specify the following recipient parameters:

   - **Name**—Name of the recipient or group of recipients. Required field.
   - **Integration**—Type of integration. Use Email for email notifications.
   - **Addresses**—One or multiple recipient email addresses. Addresses can be separated by a comma, new line (`\n`), or semicolon.
   - **Single email**—Option to send a single email to all recipients. Possible parameter values:
     - **Enabled**—All recipients receive one single email notification.
     - **Disabled**—Each recipient receives a separate email notification.
   - **Message**—Email body. You can use templates or set custom text by clicking **Edit Message**.
   - **Subject**—Email subject. You can use templates or set custom text by clicking **Edit Subject**.
   - **Notification settings**—General notification settings.
   - **Disable resolved message**—Disables sending a message when an issue or alert is resolved.
   - **Test**—Sending a test notification. Allows checking that settings are correct.

- **Duplicate**—Creating a copy of the contact point configuration. Allows quickly creating similar contact points.
- **Delete**—Deleting the current contact point configuration.

5. Click **Save contact point**.

To edit or delete a notification recipient email address:

1. Go to the `<monitoring_host>.<smp_domain>` URL.
2. Enter the Grafana credentials that you specified in the configuration file (the `grafana_admin_user` and `grafana_admin_password` parameters).
3. In the menu, go to **Home** → **Alerting** → **Contact points**.
4. In the **Contact points** workspace, locate the required contact, and then do one of the following:
   - To edit the rule, click the pencil button, and then change the rule parameters.
   - To delete the rule, click **More**, and then click **Delete**.

The contact is changed or deleted.

Adding SMTP server connection parameters to the configuration file without reinstalling Kaspersky EDR Expert

To add SMTP server connection parameters to the configuration file without reinstalling Kaspersky EDR Expert:

1. On the administrator host, export the current configuration file.
2. In the exported configuration file, add and specify the following parameters in the `parameters` section: `grafana_smtp_host`, `grafana_smtp_user`, `grafana_smtp_password`, `grafana_smtp_bundle`, `grafana_smtp_skip_verify`, `grafana_smtp_from_address`, `grafana_smtp_from_name`, `grafana_smtp_ehlo_identity`, `grafana_starttls_policy`, `grafana_smtp_enable_tracing`.
3. Apply the parameter changes by using the command:

   ```
   ./kdt apply -i '< full_path_to_updated_configuration_file >'
   ```

   SMTP server connection parameters are added to the configuration file.

Service monitoring

You can use the following functionality to monitor the status of all services except cold storage and agent:

- Viewing Victoria Metrics alerts

Users with the Main administrator role can configure thresholds for KUMA services, and if a specified threshold is exceeded, the following changes take place:

- KUMA logs an audit event: VictoriaMetrics alert registered for service.
- KUMA sends a notification email message to the Main administrator.
- Services are displayed in the **Active services** section with a yellow status. If you hover over the status icon, the error message will be displayed.

  Possible service statuses

  - Green means that the service is running and accessible from the KUMA Core server.
  - Red means that the service is not running or is not accessible from the KUMA Core server.
  - Yellow means that the service is running, but there are errors in the service log, or there are alerts for the service from Victoria Metrics. You can view the error message by hovering the mouse pointer over the service status. Yellow is the status that applies to all services except for the agent.
  - Purple means that the service configuration file has changed, but no other errors are present. If a service has an incorrect configuration file and has errors, for example, from Victoria Metrics, status of the service is yellow.
  - Gray means that an active service exists in the remote tenant and continues to run. Services with the gray status are kept when you delete the tenant to let you copy the ID and remove services on your servers. Only the Main administrator can delete services with the gray status. When a tenant is deleted, the services of that tenant are assigned to the Main tenant.

- View VictoriaMetrics metrics if the user has a role with metrics access rights.

The following examples show how to monitor service status.

1. If the collector service has a yellow status in the **Active services** section and you see the **Enrichment errors increasing** message, you can:

   - Go to **Monitoring** → **Metrics** → <service type> → <service name> → **Enrichment** → **Errors** section for the service with the yellow status, find out which enrichment is causing errors, and view the chart to find out when the problem started and how it evolved.
   - The likely cause of the enrichment errors may be DNS server unavailability or CyberTrace enrichment errors, therefore you can check your DNS or CyberTrace connection settings.

2. If the collector service has a yellow status in the **Active services** section and you see the **Output Event Loss increasing** message, you can:

   - Go to the **Monitoring** → **Metrics** → <service type> → <service name> → **IO** → **Output Event Loss** section for the service with the yellow status and view the chart to find out when the problem started and how it evolved.
   - The likely cause of the enrichment errors may be a buffer overflow or unavailability of destination, therefore you can check the availability and the connection of the destination or find out why the buffer capacity is exceeded.

Configuring service monitoring

To configure the services:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under Other, click **Services monitoring**.

   This opens the **Services monitoring** window.

3. Specify the values of monitoring parameters for the services.

   Service monitoring does not apply to cold storage.

   If you specify an invalid value that does not fit the range or format, the value is reset to the previously configured value.

4. Click **Save**.

   After saving the parameters, KUMA registers an audit event: Monitoring thresholds changed for the service.

KUMA monitors the status of services in accordance with the specified parameters.

In the **Active services** section, you can filter services by statuses or enter a word from the error text, for example, "QPS" or "buffer", in the search field and press ENTER. This results in a list of services with errors. Do not use the special characters ", }, { in the search field. This makes the search results wrong.

Disabling service monitoring

To disable service monitoring:

1. In the main application window, go to the **Settings** → **KUMA** → **Open KUMA settings** section.

   This opens the KUMA settings window.

2. Under Other, click **Services monitoring**.

   This opens the **Services monitoring** window.

3. If you want to disable service monitoring only for collectors, in the **Service monitoring. Thresholds setting** window, under **Collectors**, select the **Disable connector errors** check box.

   This disables only the analysis of the **Connector errors** metric for collectors.

4. If you want to disable monitoring for all services, in the **Service monitoring. Thresholds setting** select the **Disable** check box.

KUMA service monitoring is disabled, and services do not get the yellow status.

Viewing KUMA metrics

To monitor the performance of its components, the event stream, and the correlation context, KUMA collects and stores a large number of parameters. The VictoriaMetrics time series database is used to collect, store and analyze the parameters. The collected metrics are visualized using Grafana. Dashboards that visualize key performance parameters of various KUMA components can be found in the **Monitoring** → **Metrics** section.
The KUMA Core service configures VictoriaMetrics and Grafana automatically, no user action is required.

Alternatively, you can view KUMA metrics in the **Dashboard** section:

1. In the main menu, go to the **Monitoring** section. → **Dashboard**, and then select the **Analysis and response** tab.
2. Click the ellipsis (⋮) icon.
3. Click the **Go to KUMA metrics** button.

The collected metrics are visualized using the Grafana solution. The RPM package of the 'kuma-core' service generates the Grafana configuration and creates a separate dashboard for visualizing the metrics of each service. Graphs in the **Metrics** section appear with a delay of approximately 1.5 minutes.

For full information about the metrics, you can refer to the **Metrics** section of OSMP Console. Selecting this section opens the Grafana portal deployed as part of KUMA Core installation and is updated automatically. If the **Metrics** section shows core: <port number>, this means that KUMA is deployed in a high availability configuration and the metrics were received from the host on which the **Core was installed**. In other configurations, the name of the host from which KUMA receives metrics is displayed.

To determine on which host the Core is running, run the following command in the terminal of one of the controllers:

```
k0s kubectl get pod -n kuma -o wide
```

Collector metrics

Metric name	Description
IO—metrics related to the service input and output.	
Processing EPS	The number of events processed per second.
Output EPS	The number of events per second sent to the destination.
Output Latency	The time in milliseconds that passed while sending an event packet and receiving a response from the destination. The median value is displayed.
Output Errors	The number of errors occurring per second while event packets were sent to the destination. Network errors and errors writing to the disk buffer of the destination are displayed separately.
Output Event Loss	The number of events lost per second. Events can be lost due to network errors or errors writing the disk buffer of the destination. Events are also lost if the destination responds with an error code, for example, in case of an invalid request.
Output Disk Buffer Size	The size of the disk buffer of the collector associated with the destination, in bytes. If a zero value is displayed, no event packets have been placed in the collector's disk buffer and the service is operating correctly.

Metric name	Description
Write Network BPS	The number of bytes received into the network per second.
Connector errors	The number of errors in the connector log.

Normalization—metrics related to the normalizers.	
Raw & Normalized event size	The size of the raw event and size of the normalized event. The median value is displayed.
Errors	The number of normalization errors per second.

Filtration—metrics related to filters.	
EPS	The number of events per second matching the filter conditions and sent for processing. The collector only processes events that match the filtering criteria if the user has added the filter to the configuration of the collector service.

Aggregation—metrics related to the aggregation rules.	
EPS	The number of events received and generated by the aggregation rule per second. This metric helps determine the effectiveness of aggregation rules.
Buckets	The number of buckets in the aggregation rule.

Enrichment—metrics related to enrichment rules.	
Cache RPS	The number of requests per second to the local cache.
Source RPS	The number of requests per second to an enrichment source, such as a dictionary.
Source Latency	Time in milliseconds passed while sending a request to the enrichment source and receiving a response from it. The median value is displayed.
Queue	The size of the enrichment request queue. This metric helps to find bottleneck enrichment rules.
Errors	The number of errors per second while sending requests to the enrichment source.

Correlator metrics

Metric name	Description
IO—metrics related to the service input and output.	
Processing EPS	The number of events processed per second.
Output EPS	The number of events per second sent to the destination.
Output Latency	The time in milliseconds that passed while sending an event packet and receiving a response from the destination. The median value is displayed.
Output Errors	The number of errors occurring per second while event packets were sent to the destination. Network errors and errors writing to the disk buffer of the destination are displayed separately.
Output Event Loss	The number of events lost per second. Events can be lost due to network errors or errors writing the disk buffer of the destination. Events are also lost if the destination responds with an error code, for example, in case of an invalid request.
Output Disk Buffer Size	The size of the disk buffer of the collector associated with the destination, in bytes. If a zero value is displayed, no event packets have been placed in the collector's disk buffer and the service is operating correctly.

Correlation—metrics related to correlation rules.	
EPS	The number of correlation events per second generated by the correlation rule.
Buckets	The number of buckers in a correlation rule of the standard type.
Rate Limiter Hits	The number of times the correlation rule exceeded the rate limit per second.
Active Lists OPS	The number of operations requests per second sent to the active list, and the operations themselves.
Active Lists Records	The number of records in the active list.
Active Lists On-Disk Size	The size of the active list on the disk, in bytes.

Enrichment—metrics related to enrichment rules.	
Cache RPS	The number of requests per second to the local cache.
Source RPS	The number of requests per second to an enrichment source, such as a dictionary.
Source Latency	Time in milliseconds passed while sending a request to the enrichment source and receiving a response from it. The median value is displayed.
Queue	The size of the enrichment request queue. This metric helps to find bottleneck enrichment rules.
Errors	The number of errors per second while sending requests to the enrichment source.

Response—metrics associated with response rules.	
RPS	The number of times a response rule was activated per second.

Storage metrics

Metric name	Description
ClickHouse / General—metrics related to the general settings of the ClickHouse cluster.	
Active Queries	The number of active queries sent to the ClickHouse cluster. This metric is displayed for each ClickHouse instance.
QPS	The number of queries per second sent to the ClickHouse cluster.
Failed QPS	The number of failed queries per second sent to the ClickHouse cluster.
Allocated memory	The amount of RAM, in gigabytes, allocated to the ClickHouse process.

ClickHouse / Insert—metrics related to inserting events into a ClickHouse instance.	
Insert EPS	The number of events per second inserted into the ClickHouse instance.
Insert QPS	The number of ClickHouse instance insert queries per second sent to the ClickHouse cluster. If the **Insert QPS** metric demonstrates a growing queue of queries and the metric is greater than 1, we recommend also looking at the **Batch size** metric value to adjust the storage buffering settings in the settings of the storage service configuration. Example: The **Insert QPS** metric is greater than 1 and equals 8. The **Batch size** metric is 1.2 GB (in bytes). In this case, you can find the buffer size by multiplying **Insert QPS** by **Batch size**: 8 * 1.2 = 9.6 GB. Round the resulting value of 9.6 and specify it in bytes (for example, 10000000000 bytes) as the **Buffer size** setting on the **Advanced settings** tab of the storage service configuration. Also specify a **Buffer flush interval** of 2 seconds. Increasing the buffer size and buffer flush interval will help relieve the query queue. Normally, the **Insert QPS** metric should be less than 1.
Failed Insert QPS	The number of failed ClickHouse instance insert queries per second sent to the ClickHouse cluster.
Delayed Insert QPS	The number of delayed ClickHouse instance insert queries per second sent to the ClickHouse cluster. Queries were delayed by the ClickHouse node due to exceeding the soft limit on active merges.
Rejected Insert QPS	The number of rejected ClickHouse instance insert queries per second sent to the ClickHouse cluster. Queries were rejected by the ClickHouse node due to exceeding the hard limit on active merges.
Active Merges	The number of active merges.
Distribution Queue	The number of temporary files with events that could not be inserted into the ClickHouse instance because it was unavailable. These events cannot be found using search.

ClickHouse / Select—metrics related to event selections in the ClickHouse instance.	
Select QPS	The number of ClickHouse instance event select queries per second sent to the ClickHouse cluster.
Failed Select QPS	The number of failed ClickHouse instance event select queries per second sent to the ClickHouse cluster.

ClickHouse / Replication—metrics related to replicas of ClickHouse nodes.	
Active Zookeeper Connections	The number of active connections to the Zookeeper cluster nodes. In normal operation, this number should be equal to the number of nodes in the Zookeeper cluster.
Read-only Replicas	The number of read-only replicas of ClickHouse nodes. In normal operation, no such replicas of ClickHouse nodes must exist.
Active Replication Fetches	The number of active processes of downloading data from the ClickHouse node during data replication.
Active Replication Sends	The number of active processes of sending data to the ClickHouse node during data replication.
Active Replication Consistency Checks	The number of active data consistency checks on replicas of ClickHouse nodes during data replication.

ClickHouse / Networking—metrics related to the network of the ClickHouse cluster.	
Active HTTP Connections	The number of active connections to the HTTP server of the ClickHouse cluster.
Active TCP Connections	The number of active connections to the TCP server of the ClickHouse cluster.
Active Interserver Connections	The number of active service connections between ClickHouse nodes.

Core metrics

Metric name	Description
Raft—metrics related to reading and updating the state of the Core.	
Lookup RPS	The number of lookup procedure requests per second sent to the Core, and the procedures themselves.
Lookup Latency	Time in milliseconds spent running the lookup procedures, and the procedures themselves. The time is displayed for the 99th percentile of lookup procedures. One percent of lookup procedures may take longer to run.
Propose RPS	The number of Raft (SQLite) propose procedure requests per second sent to the Core, and the procedures themselves.
Propose Latency	Time in milliseconds spent running the Raft (SQLite) propose procedures, and the procedures themselves. The time is displayed for the 99th percentile of propose procedures. One percent of propose procedures may take longer to run.
Data mining—metrics related to data collection and analysis	
Executing Rules	Number of running schedulers for executing data collection and analysis requests.
Queued Rules	Number of schedulers for executing queued data collection and analysis requests.
Execution Errors	Number of errors that occurred when running the data collection and analysis scheduler.
Execution Latency	How long takes a scheduler to execute requests.
Tasks—metrics related to monitoring the running of tasks on the KUMA Core	
Active tasks	Number of tasks run per unit time.
Task Execution latency	Duration of running tasks in seconds.
Errors	Number of errors when running tasks.

API—metrics related to API requests.	
RPS	The number of API requests made to the Core per second.
Latency	The time in milliseconds spent processing a single API request to the Core. The median value is displayed.
Errors	The number of errors per second while sending API requests to the Core.

Notification Feed—metrics related to user activity.	
Subscriptions	The number of clients connected to the Core via SSE to receive server messages in real time. This number is normally equal to the number of clients that are using the KUMA web interface.
Errors	The number of errors per second while sending notifications to users.

Schedulers—metrics related to Core tasks.	
Active	The number of repeating active system tasks. The tasks created by the user are ignored.
Latency	The time in milliseconds spent running the task. The median value is displayed.
Errors	The number of errors that occurred per second while performing tasks.

General metrics common for all services

Metric name	Description
Process—General process metrics.	
Memory	RAM usage (RSS) in megabytes.
DISK BPS	The number of bytes read from or written to the disk per second.
Network BPS	The number of bytes received/transmitted over the network per second.
Network Packet Loss	The number of network packets lost per second.
GC Latency	The time, in milliseconds, spent executing a GO garbage collection cycle. The median value is displayed.
Goroutines	The number of active goroutines. This number is different from the operating system's thread count.

OS—metrics related to the operating system.	
Load	Average load.
CPU	CPU load as a percentage.

Memory	RAM usage (RSS) as a percentage.
Disk	Disk space usage as a percentage.

Metrics storage period

KUMA operation data is saved for 3 months by default. This storage period can be changed.

To change the storage period for KUMA metrics:

1. Log in to the OS of the server where the KUMA Core is installed.
2. In the file /etc/systemd/system/multi-user.target.wants/kuma-victoria-metrics.service, in the ExecStart parameter, edit the `--retentionPeriod=<metrics storage period, in months>` flag by inserting the necessary period. For example, `--retentionPeriod=4` means that the metrics will be stored for 4 months.
3. Restart KUMA by running the following commands in sequence:
   a. `systemctl daemon-reload`
   b. `systemctl restart kuma-victoria-metrics`

   The storage period for metrics has been changed.

KUMA metric alert triggering conditions

If the value of a KUMA metric for a service exceeds the threshold of the corresponding parameter configured in the **Services monitoring** section of KUMA, VictoriaMetrics sends an alert, and an error message is displayed in the status of that service.

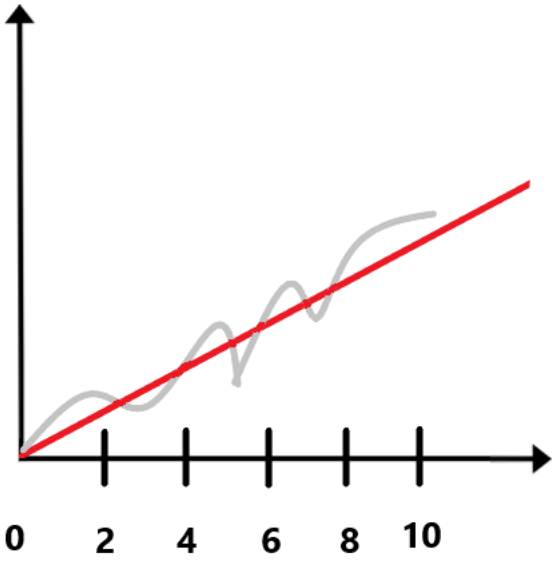
Alerts are received from VictoriaMetrics at the following intervals:

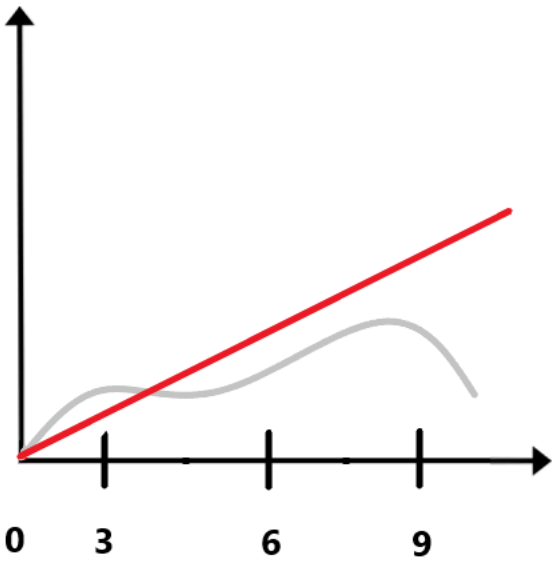
- VictoriaMetrics obtains information from KUMA services every 15 seconds.
- VictoriaMetrics updates alerts for KUMA services every minute.
- The KUMA Core service obtains information from VictoriaMetrics every 15 seconds.

Thus, the total delay before a service status is updated is less than 2–3 minutes.

If you disabled the receipt of alerts from VictoriaMetrics, some KUMA services may still be displayed with a yellow status. This can happen in the following cases:

- For a storage service:
  - If an alert was received in response to an API request in the /status parameter from ClickHouse
  - If cold storage of the Storage service is not being monitored





- For a collector service: If an alert was received in response to an API request in the /status parameter.
- For a correlator service: If a response rule exists that requires the Advanced Responses module, but this module is not covered by the current license, or the license that covers this module has expired.

The table below provides information on which error messages may appear in the service status when an alert is received from VictoriaMetrics, and which metrics and parameters they are based on and in what way. For details on KUMA metrics that can be used to create VictoriaMetrics alerts, see Viewing KUMA metrics.

For example, if the **Active services** table for a service displays a yellow status and the `High distribution queue` error message (the "Error message" column in the table below), you can view the information in the **Enrichment** widget, the **Distribution Queue** metric (the "KUMA metrics" column in the table below).

Description of error messages for KUMA services

Error message	Configurable alert parameters	KUMA metric	Description
`QPS threshold reached`	**QPS interval/window, minutes** **QPS Threshold**	Clickhouse / General → Failed QPS	An error message is displayed if the Failed QPS metric exceeds the specified **QPS Threshold** value for the duration specified by the **QPS interval/window, minutes** parameter. For example, if 25 out of 100 requests from VictoriaMetrics to the service were unsuccessful, and the **QPS Threshold** is 0.2, the alert is calculated as follows: (25 / 100) * 100 > 0.2 * 100 25% > 20% Because the percentage of unsuccessful requests is greater than the specified threshold, an error message is displayed for the service.
`Failed Insert QPS threshold reached`	**Failed insert QPS calculation interval/window, minutes** **Insert QPS threshold**	Clickhouse / Insert → Failed Insert QPS	An error message is displayed if the Failed Insert QPS metric exceeds the specified **QPS Insert Threshold** value for the duration specified by the **Failed Insert QPS calculation interval/window, minutes** parameter. For example, if 25 out of 100 requests from VictoriaMetrics to the service were unsuccessful, and the **QPS Insert Threshold** is 0.2, the alert is calculated as follows: (25 / 100) * 100 > 0.2 * 100 25% > 20% Because the percentage of unsuccessful requests is greater than the specified threshold, an error message is displayed for the service.
`High distribution queue`	**Distribution queue threshold** **Distribution queue calculation interval/window, minutes**	Clickhouse / Insert → Distribution Queue	An error message is displayed if the Distribution Queue metric exceeds the specified **Distribution queue threshold** value for the duration specified by the **Distribution queue calculation interval/window, minutes** parameter.
`Low disk space`	**Free space on disk threshold**	OS → Disk	An error message is displayed if the amount of free disk space (as a percentage) indicated by the Disk metric value is less than the value specified in the **Free disk space threshold** parameter. For example, an error message is displayed if the partition on which KUMA is installed takes up all the disk space.
`Low disk partition space`	**Free space on partition threshold**	OS → Disk	An error message is displayed if the amount of free space (as a percentage) on the disk partition that KUMA is using is less than the value specified in the **Free space on partition threshold** parameter. For example, an error message is displayed in the following cases: • If KUMA is installed in a high availability configuration, when the disk is mounted as a volume. • If the disk is mounted under /opt.
`Output Event Loss increasing`	**Output Event Loss**	IO → Output Event Loss	An error message is displayed if the Output Event Loss metric has been increasing for one minute. You can enable or disable the display of this error message using the **Output Event Loss** parameter.

Error message	Configurable alert parameters	KUMA metric	Description
`Disk buffer size increasing`	**Disk buffer increase interval/window, minutes**	IO → Output Disk Buffer Size	An error message is displayed if the Output Disk Buffer Size metric monotonically increases for 10 minutes with the sampling interval specified by the **Disk buffer increase interval/window, minutes** parameter. For example, if the **Disk buffer increase interval/window, minutes** is set to 2 minutes, an error message is displayed if the disk buffer size has monotonically increased for 10 minutes with a sampling interval of 2 minutes (see the figure below). 
`High enrichment queue`	**Growing enrichment queue interval/window, minutes**	Enrichment → Queue	An error message is displayed if the Queue metric monotonically increases for 10 minutes with the sampling interval specified by the **Growing enrichment queue interval/window, minutes** parameter. For example, if the value of the **Growing enrichment queue interval/window, minutes** is 3, an error message is displayed if the enrichment queue has monotonically increased every 10 minutes with a sampling interval of 3 minutes. In the case shown in the figure below, the error message is not displayed because at the ninth minute the value of the metric decreased instead of increasing monotonically. 

Error message	Configurable alert parameters	KUMA metric	Description
`Enrichment errors increasing`	**Enrichment errors**	Enrichment → Errors	An error message is displayed if the Errors metric has been increasing for one minute. You can enable or disable the display of this error message using the **Enrichment errors** parameter.
`Connector log errors increasing`	**Disable connector errors**	IO → Connector Errors	An error message is displayed if the Connector Errors metric has been increasing between consecutive polls of the metric by VictoriaMetrics for one minute. You can enable or disable the display of this error message using the **Disable connector errors** parameter.

Storing diagnostic information about Kaspersky EDR Expert components

Diagnostic information about Kaspersky EDR Expert components is stored on a worker node of the Kubernetes cluster. The amount of disk space required for storing this information is specified in the configuration file before the deployment of Kaspersky EDR Expert (the `loki_size` parameter).

To check the disk space used to store diagnostic information about Kaspersky EDR Expert components,

On the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke observability --action getPvSize
```

The amount of the allocated free disk space in gigabytes is displayed.

You can also increase the disk space used to store diagnostic information about Kaspersky EDR Expert components after the deployment of Kaspersky EDR Expert. You cannot set the amount of disk space to less than the previously specified amount.

To increase the disk space used to store diagnostic information about Kaspersky EDR Expert components,

On the administrator host where the KDT utility is located, run the following command and specify the required free disk space in gigabytes (for example, "50Gi"):

```
./kdt invoke observability --action setPvSize --param
loki_size='<new_disk_space_amount>Gi'
```

The amount of free disk space allocated to store diagnostic information about Kaspersky EDR Expert components is changed.

Obtaining trace files

KDT allows you to obtain trace files for Kaspersky EDR Expert and OSMP components, to troubleshoot infrastructure on your own or with the help of Kaspersky Technical Support.

Trace files are downloaded in OpenTelemetry format.

To obtain the trace file for the Kaspersky EDR Expert or OSMP component:

1. On the administrator host where the KDT utility is located, run the following command and specify the path to the file where you want to save the list of trace files:

   ```
   ./kdt traces find -o <output_file_path>
   ```

   The list of trace files with their IDs is output to the specified file.

2. To output a particular trace file run the following command and specify the output file path and the trace file ID:

   ```
   ./kdt traces get -o <output_file_path> --trace-id=<trace_ID>
   ```

   The specified trace file is saved.

Logging the launches of custom actions

KDT allows you to obtain the history of the custom action launches for a specific Kaspersky EDR Expert component, as well as the logs of a particular custom action launch. The obtained logs may help you to investigate problems with the operation of the Kaspersky EDR Expert components on your own or with the help of Kaspersky Technical Support.

To obtain the history of the custom action launches for a specific Kaspersky EDR Expert component,

On the administrator host where the KDT utility is located, run the following command, and then specify the component name:

```
./kdt state -H <component_name>
```

The list of executed custom actions with their IDs is displayed.

To obtain logs of the custom action launch,

On the administrator host where the KDT utility is located, run the following command, and then specify the component name and the ID of the custom action launch:

```
./kdt state -l <component_name> -m <custom_action_launch_ID>
```

The logs of the specified custom action launch are displayed.

Managing users and user roles

This section describes users and user roles, and provides instructions for creating and modifying them, for assigning roles and groups to users, and for associating policy profiles with roles.

About user accounts

Kaspersky EDR Expert allows you to manage user accounts and security groups. The application supports four types of accounts:

- Accounts of organization employees. Administration Server retrieves data of the accounts of those domain users when polling the organization's domain controller.
- Accounts of local users. Local accounts on managed devices, as well as the local accounts on the device on which Administration Server is installed.
- Accounts of internal users of Kaspersky EDR Expert. You can create accounts of internal users. These accounts are used only within Kaspersky EDR Expert.
- Service accounts. These accounts are only used to connect Kaspersky EDR Expert services to Administration Server. Service accounts are added automatically when the solution is deployed, and cannot be deleted or changed. The rights and roles of these accounts cannot be changed, either. You cannot use a service account to sign in to OSMP Console.

Local user accounts and the kladmins local group in the Linux operating system cannot be used for access to the OSMP Console in the Open Single Management Platform. The kladmins group can only contain accounts that are used to start Open Single Management Platform services. Employees of the organization will be able to use their user accounts to log in after configuring domain authentication.

The default authentication method in OSMP Console is to enter user name, password, and an additional single-use security code for two-factor authentication. Starting with Kaspersky EDR Expert 8.0, two-factor authentication is enabled automatically and the option to configure two-factor authentication at sign-in is disabled by default.

You can configure domain authentication over the Kerberos protocol. Domain authentication allows you to enable secure authentication in OSMP Console without having to re-enter the password on the corporate network (single sign-on).

To view tables of user accounts and security groups:

1. In the main menu, go to **Users & roles** → **Users & groups**.
2. Select the **Users** or the **Groups** tab.

The table of users or security groups opens.

If you want to view the table with only internal, or local, or domain users or groups, set the **Account type** filter criteria to the corresponding value.

If the table of users contains more than 50,000 users, only the first 50,000 users are displayed, and the remaining users are not shown.

About user roles

A *user role* (also referred to as a *role*) is an object containing a set of rights and privileges. A role can be associated with settings of Kaspersky applications installed on a user device. You can assign a role to a set of users or to a set of security groups at any level in the hierarchy of administration groups, Administration Servers, or at the level of specific objects.

If you manage devices through a hierarchy of Administration Servers that includes virtual Administration Servers, note that you can create, modify, or delete user roles only from a physical Administration Server. Then, you can propagate the user roles to secondary Administration Servers, including virtual ones.

You can associate user roles with policy profiles. If a user is assigned a role, this user gets security settings necessary to perform job functions.

A user role can be associated with users of devices in a specific administration group.

User role scope

A *user role scope* is a combination of users and administration groups. Settings associated with a user role apply only to devices that belong to users who have this role, and only if these devices belong to groups associated with this role, including child groups.

Advantage of using roles

An advantage of using roles is that you do not have to specify security settings for each of the managed devices or for each of the users separately. The number of users and devices in a company may be quite large, but the number of different job descriptions that require different security settings is considerably smaller.

Differences from using policy profiles

Policy profiles are properties of a policy that is created for each Kaspersky application separately. A role is associated with many policy profiles created for different applications. Therefore, a role is a method of uniting settings for a certain user type in one place.

Configuring access rights to application features. Role-based access control

Kaspersky EDR Expert provides facilities for role-based access to the features of Kaspersky EDR Expert and managed Kaspersky applications.

You can configure access rights to application features for Kaspersky EDR Expert users in one of the following ways:

- By configuring the rights for each user or group of users individually.
- By creating standard user roles with a predefined set of rights and assigning those roles to users depending on their scope of duties.

Application of user roles is intended to simplify and shorten routine procedures of configuring users' access rights to application features. Access rights within a role are configured in accordance with the standard tasks and the users' scope of duties.

User roles can be assigned names that correspond to their respective purposes. You can create an unlimited number of roles in the application.

You can use the predefined user roles with already configured set of rights, or create new roles and configure the required rights yourself.

Access rights to application features

The table below shows the Kaspersky EDR Expert features with the access rights to manage the associated tasks, reports, settings, and perform the associated user actions.

To perform the user actions listed in the table, a user has to have the right specified next to the action.

Read, **Write**, and **Execute** rights are applicable to any task, report, or setting. In addition to these rights, a user has to have the **Perform operations on device selections** right to manage tasks, reports, or settings on device selections.

All tasks, reports, settings, and installation packages that are missing in the table belong to the **General features: Basic functionality** functional area.

Functional area	Right	User action: right required to perform the action	Task	Report	Other
General features: **Management of administration groups**	**Write**	• Add device to an administration group: **Write** • Delete device from an administration group: **Write** • Add an administration group to another administration group: **Write** • Delete an administration group from another administration group: **Write**	None	None	None

Functional area	Right	User action: right required to perform the action	Task	Report	Other
General features: **Access objects regardless of their ACLs**	**Read**	Get read access to all objects: **Read**	None	None	The **General features: Access objects regardless of their ACLs** functional area is intended for audit purposes. A **Read** permission in this functional area grants full **Read** access to all objects. We recommend granting these rights carefully and to a limited set of users who need them to perform their official duties. Access is granted regardless of other rights, even if they prohibit read access to specific objects.
General features: **Basic functionality**	• **Read** • **Write** • **Execute** • **Perform operations on device selections**	• Device moving rules (create, modify, or delete) for the virtual Server: **Write**, **Perform operations on device selections** • Get Mobile (LWNGT) protocol user certificate: **Read** • Set Mobile (LWNGT) protocol user certificate: **Write** • Get NLA-defined network list: **Read** • Add, modify, or delete NLA-defined network list: **Write** • View Access Control List of groups: **Read** • View the operating system log: **Read**	• "Download updates to the Administration Server repository" • "Deliver reports" • "Distribute installation package" • "Install application on secondary Administration Servers remotely"	• "Report on protection status" • "Report on threats" • "Report on most heavily infected devices" • "Report on status of anti-virus databases" • "Report on errors" • "Report on network attacks" • "Summary report on perimeter defense applications installed" • "Summary report on types of applications installed" • "Report on users of infected devices" • "Report on incidents" • "Report on events" • "Report on activity of distribution points" • "Report on secondary Administration Servers" • "Report on Device Control events" • "Report on vulnerabilities" • "Report on prohibited applications" • "Report on Web Control"	None

Functional area	Right	User action: right required to perform the action	Task	Report	Other
				• "Report on encryption status of managed devices" • "Report on encryption status of mass storage devices" • "Report on rights to access encrypted drives" • "Report on file encryption errors" • "Report on blockage of access to encrypted files" • "Report on effective user permissions" • "Report on rights"	
General features: **Deleted objects**	• **Read** • **Write**	• View deleted objects in the Recycle Bin: **Read** • Delete objects from the Recycle Bin: **Write**	None	None	None
General features: **Event processing**	• **Delete events** • **Edit event notification settings** • **Edit event logging settings** • **Write**	• Change events registration settings: **Edit event logging settings** • Change events notification settings: **Edit event notification settings** • Delete events: **Delete events**	None	None	Settings: • The maximum number of events stored in the database • Period for storing events from the deleted devices
General features: **Operations on Administration Server**	• **Read** • **Write** • **Execute** • **Modify object ACLs** • **Perform operations on device selections**	• Specify ports of Administration Server for the network agent connection: **Write** • Specify ports of Activation Proxy launched on the Administration Server: **Write** • Specify ports of Activation Proxy for Mobile launched on the Administration Server: **Write** • Specify ports of the Web Server for distribution of standalone packages: **Write** • Specify ports of the Web Server for distribution of MDM profiles: **Write**	• "Backup of Administration Server data" • "Databases maintenance"	None	None

Functional area	Right	User action: right required to perform the action	Task	Report	Other
		• Specify SSL-ports of the Administration Server for connection via OSMP Console: **Write** • Specify ports of the Administration Server for mobile connection: **Write** • Specify the maximum number of events stored in the Administration Server database: **Write** • Specify the maximum number of events that can be sent by the Administration Server: **Write** • Specify time period during which events can be sent by the Administration Server: **Write**			
General features: **Kaspersky software deployment**	• **Manage Kaspersky patches** • **Read** • **Write** • **Execute** • **Perform operations on device selections**	Approve or decline installation of the patch: **Manage Kaspersky patches**	None	• "Report on license key usage by virtual Administration Server" • "Report on Kaspersky software versions" • "Report on incompatible applications" • "Report on versions of Kaspersky software module updates" • "Report on protection deployment"	Installation package: "Kaspersky"
General features: **Key management**	• **Export key file** • **Write**	• Export key file: **Export key file** • Modify Administration Server license key settings: **Write**	None	None	None
General features: **Enforced report management**	• **Read** • **Write**	• Create reports regardless of their ACLs: **Write** • Execute reports regardless of their ACLs: **Read**	None	None	None
General features: **Hierarchy of Administration Servers**	**Configure hierarchy of Administration Servers**	• Register, update, or delete secondary Administration Servers: **Configure hierarchy of Administration Servers**	None	None	None
General	**Modify object**	• Change Security	None	None	None

Functional area	Right	User action: right required to perform the action	Task	Report	Other
features: **User permissions**	**ACLs**	properties of any object: **Modify object ACLs** • Manage user roles: **Modify object ACLs** • Manage internal users: **Modify object ACLs** • Manage security groups: **Modiobject ACLs** • Manage aliases: **Modify object ACLs**			
General features: **Virtual Administration Servers**	• **Manage virtual Administration Servers** • **Read** • **Write** • **Execute** • **Perform operations on device selections**	• Get list of virtual Administration Servers: **Read** • Get information on the virtual Administration Server: **Read** • Create, update, or delete a virtual Administration Server: **Manage virtual Administration Servers** • Move a virtual Administration Server to another group: **Manage virtual Administration Servers** • Set administration virtual Server permissions: **Manage virtual Administration Servers**	None	None	None
General features: **Encryption Key Management**	**Write**	Approval of the launch of the playbook in training mode the encryption keys: **Write**	None	None	None
System management: **Vulnerability and patch management**	• **Read** • **Write** • **Execute** • **Perform operations on device selections**	• View third-party patch properties: **Read** • Change third-party patch properties: **Write**	• "Fix vulnerabilities" • "Install required updates and fix vulnerabilities"	"Report on software updates"	None

Predefined user roles

User roles assigned to Kaspersky EDR Expert users provide them with sets of access rights to application features.

You can use the predefined user roles with already configured set of rights, or create new roles and configure the required rights yourself. Some of the predefined user roles available in Kaspersky EDR Expert can be associated with specific job positions, for example, **Auditor**, **Security Officer**, **Supervisor**. Access rights of these roles are pre-configured in accordance with the standard tasks and scope of duties of the associated positions. The table below shows how roles can be associated with specific job positions.

Examples of roles for specific job positions

Role	Description
Auditor	Permits all operations with all types of reports, all viewing operations, including viewing deleted objects (grants the **Read** and **Write** permissions in the **Deleted objects** area). Does not allow other operations. You can assign this role to a person who performs the audit of your organization.
Supervisor	Permits all viewing operations; does not permit other operations. You can assign this role to a security officer and other managers in charge of the IT security in your organization.
Security Officer	Permits all viewing operations, permits reports management; grants limited permissions in the **System management**: **Connectivity** area. You can assign this role to an officer in charge of the IT security in your organization.

The table below shows the access rights assigned to each predefined user role.

Access rights of predefined user roles

Role	Description
Basic roles	
Administration Server Administrator	Permits all operations in the following functional areas: • **General features**: • **Basic functionality** • **Encryption Key Management** • **Event processing** • **Hierarchy of Administration Servers** • **Virtual Administration Servers** • **System management**: • **Connectivity** • **Equipment inventory** • **Software inventory**
Administration Server Operator	Grants the **Read** and **Execute** rights in all of the following functional areas: • **General features**: • **Basic functionality** • **Encryption Key Management** • **Virtual Administration Servers** • **System management**: • **Connectivity** • **Equipment inventory** • **Software inventory**
Auditor	Permits all operations in the following functional areas, in **General features**: • **Access objects regardless of their ACLs** • **Deleted objects** • **Managing reports** You can assign this role to a person who performs the audit of your organization.
Installation Administrator	Permits all operations in the following functional areas, in **General features**: • **Basic functionality** • **Deploying Kaspersky applications** • **License key management** Grants **Read** and **Execute** rights in the **General features: Virtual Administration Servers** functional area.
Installation Operator	Grants the **Read** and **Execute** rights in all of the following functional areas, in **General features**: • **Basic functionality** • **Kaspersky software deployment** (also grants the **Manage Kaspersky Lab patches** right in this area) • **Virtual Administration Servers**
Kaspersky Endpoint Security Administrator	Permits all operations in the following functional areas: • **General features: Basic functionality** • Kaspersky Endpoint Security area, including all features Grants the **Read** and **Write** rights in the **General features: Encryption key management** functional area.

Role	Description
Kaspersky Endpoint Security Operator	Grants the **Read** and **Execute** rights in all of the following functional areas: • **General features: Basic functionality** • Kaspersky Endpoint Security area, including all features
Main administrator	Permits all operations in functional areas, *except* for the following areas, in **General features**: • **Access objects regardless of their ACLs** • **Managing reports** Grants the **Read** and **Write** rights in the **General features: Encryption key management** functional area.
Main Operator	Grants the **Read** and **Execute** (where applicable) rights in all of the following functional areas: • **General features**: • **Basic functionality** • **Deleted objects** • **Operations with Administration Server** • **Deploying Kaspersky applications** • **Virtual Administration Servers** • Kaspersky Endpoint Security area, including all features
Mobile Device Management Administrator	Permits all operations in the **General features: Basic functionality** functional area.
Security Officer	Permits all operations in the following functional areas, in **General features**: • **Access objects regardless of their ACLs** • **Managing reports** Grants the **Read**, **Write**, **Execute**, **Save files from devices to the administrator's workstation**, and **Perform operations on device selections** rights in the **System management: Connectivity** functional area. You can assign this role to an officer in charge of the IT security in your organization.
Self Service Portal User	Permits all operations in the **Mobile Device Management: Self Service Portal** functional area. This feature is not supported in Kaspersky Security Center 11 and later version.
Supervisor	Grants the **Read** right in the **General features**: **Access objects regardless of their ACLs** and **General features**: **Enforced report management** functional areas. You can assign this role to a security officer and other managers in charge of the IT security in your organization.
EDR roles	
Main administrator	Permits all operations in the EDR functional areas: • **Alerts and Incidents** • **Analysis and response** • **Playbooks and response** • **Managing assets** • **IAM** • **Tenants** • **Kaspersky integrations** • **Third-party integrations** • **Licenses**
Tenant administrator	Permits all operations in the EDR functional areas: • **Alerts and Incidents** • **Analysis and response** • **Playbooks and response** • **Managing assets** • **IAM** • **Tenants** • **Kaspersky integrations** • **Third-party integrations** • **Licenses** This role corresponds to the Main administrator role, but it has a restriction. In KUMA, a tenant administrator has limited access to the preset objects.

Role	Description
SOC administrator	Grants the following rights in the EDR functional areas: • **Analysis and response**: **Read, Write** • **Playbooks and response**: **Read**, **Write, Delete** • **IAM**: **Read users and roles**, **Assign roles**, and **Lists users** • **Tenants**: **Read, Write** • **Kaspersky integrations**: **Read**, **Write** • **Third-party integrations**: **Read**, **Write** • **Licenses**: **Read** • **Asset management: Read, Write, Delete**

Role	Description
Junior analyst	Grants the following rights in the EDR functional areas: • **Alerts and incidents**: **Read** and **Write** • **Analysis and response**: **Read** • **Asset Management**: **Read** **Viewing the details** Read: • View the list of categories. • Add the list of devices in terms of categories. • Export devices in CSV format. • View devices that meet the criteria of active categorization. • View an asset card. • View the list of custom fields. • View TTL for the archived devices. • View assets audit settings. • View the integration with Kaspersky EDR Expert settings. • View the threshold settings to define the activity status of a device. Write: • Add categories. • Modify categories. • Add a device. • Modify a device, including the category. • Run forced synchronization of Kaspersky EDR Expert devices. • Run active categorization manually. • Add asset custom fields. • Modify asset custom fields. • Modify TTL for the archived devices. • Add assets audit settings. • Modify assets audit settings. • Duplicate assets audit settings. • Add the integration with Kaspersky EDR Expert settings. • Modify the integration with Kaspersky EDR Expert settings. • Modify the threshold settings to define the activity status of a device. Delete: • Delete categories. • Archive a device. • Delete asset custom fields. • Delete assets audit settings. • **IAM**: **Read users and roles** and **Lists users** • **Tenants**: **Read** • **Kaspersky integrations**: **Read** • **Third-party integrations**: **Read** • **Licenses**: **Read**

Role	Description
Tier 2 analyst	Grants the following rights in the EDR functional areas: • **Alerts and incidents**: **Read** and **Write** • **Analysis and response**: **Read** • **Playbooks and response**: **Read**, **Write**, **Execute** • **Managing assets** • **IAM**: **Read users and roles** and **Lists users** • **Tenants**: **Read** • **Kaspersky integrations**: **Read** • **Third-party integrations**: **Read** • **Licenses**: **Read**
Tier 1 analyst	Grants the following rights in the EDR functional areas: • **Alerts and incidents**: **Read** and **Write** • **Analysis and response**: **Read** • **Playbooks and response**: **Read**, **Write**, **Execute** • **Asset Management** • **IAM**: **Read users and roles** and **Lists users** • **Tenants**: **Read** • **Kaspersky integrations**: **Read** • **Third-party integrations**: **Read** • **Licenses**: **Read** This role corresponds to the Tier 2 analyst role, but it has a restriction. In KUMA, a Tier 1 analyst can only modify their own objects.

Role	Description
SOC manager	Grants the following rights in the EDR functional areas: • **Alerts and incidents**: **Read** and **Write** • **Analysis and response**: **Read** • **Playbooks and response**: **Read** • **Asset Management**: **Read** **Viewing the details** Read: • View the list of categories. • Add the list of devices in terms of categories. • Export devices in CSV format. • View devices that meet the criteria of active categorization. • View an asset card. • View the list of custom fields. • View TTL for the archived devices. • View assets audit settings. • View the integration with Kaspersky EDR Expert settings. • View the threshold settings to define the activity status of a device. Write: • Add categories. • Modify categories. • Add a device. • Modify a device, including the category. • Run forced synchronization of Kaspersky EDR Expert devices. • Run active categorization manually. • Add asset custom fields. • Modify asset custom fields. • Modify TTL for the archived devices. • Add assets audit settings. • Modify assets audit settings. • Duplicate assets audit settings. • Add the integration with Kaspersky EDR Expert settings. • Modify the integration with Kaspersky EDR Expert settings. • Modify the threshold settings to define the activity status of a device. Delete: • Delete categories. • Archive a device. • Delete asset custom fields. • Delete assets audit settings. • **IAM**: **Read users and roles** and **Lists users** • **Tenants**: **Read** • **Kaspersky integrations**: **Read** • **Third-party integrations**: **Read** • **Licenses**: **Read**

Role	Description
Approver	Grants the following rights in the EDR functional areas: • **Alerts and incidents**: **Read, Write, Close** • **Analysis and response**: **Read** • **Playbooks and response**: **Read** and **Response confirmation** • **Asset Management**: **Read** **Viewing the details** Read: • View the list of categories. • Add the list of devices in terms of categories. • Export devices in CSV format. • View devices that meet the criteria of active categorization. • View an asset card. • View the list of custom fields. • View TTL for the archived devices. • View assets audit settings. • View the integration with Kaspersky EDR Expert settings. • View the threshold settings to define the activity status of a device. Write: • Add categories. • Modify categories. • Add a device. • Modify a device, including the category. • Run forced synchronization of Kaspersky EDR Expert devices. • Run active categorization manually. • Add asset custom fields. • Modify asset custom fields. • Modify TTL for the archived devices. • Add assets audit settings. • Modify assets audit settings. • Duplicate assets audit settings. • Add the integration with Kaspersky EDR Expert settings. • Modify the integration with Kaspersky EDR Expert settings. • Modify the threshold settings to define the activity status of a device. Delete: • Delete categories. • Archive a device. • Delete asset custom fields. • Delete assets audit settings. • **IAM**: **Read users and roles and Lists users**. • **Tenants**: **Read** • **Kaspersky integrations**: **Read** • **Third-party integrations**: **Read** • **Licenses**: **Read**

Role	Description
Auditor	Grants the following rights in the EDR functional areas: • **Alerts and incidents**: **Read** • **Analysis and response**: **Read** • **Playbooks and response**: **Read** • **Asset Management**: **Read** **Viewing the details** Read: • View the list of categories. • Add the list of devices in terms of categories. • Export devices in CSV format. • View devices that meet the criteria of active categorization. • View an asset card. • View the list of custom fields. • View TTL for the archived devices. • View assets audit settings. • View the integration with Kaspersky EDR Expert settings. • View the threshold settings to define the activity status of a device. Write: • Add categories. • Modify categories. • Add a device. • Modify a device, including the category. • Run forced synchronization of Kaspersky EDR Expert devices. • Run active categorization manually. • Add asset custom fields. • Modify asset custom fields. • Modify TTL for the archived devices. • Add assets audit settings. • Modify assets audit settings. • Duplicate assets audit settings. • Add the integration with Kaspersky EDR Expert settings. • Modify the integration with Kaspersky EDR Expert settings. • Modify the threshold settings to define the activity status of a device. Delete: • Delete categories. • Archive a device. • Delete asset custom fields. • Delete assets audit settings. • **IAM**: **Read users and roles** and **Lists users** • **Tenants**: **Read** • **Kaspersky integrations**: **Read** • **Third-party integrations**: **Read** • **Licenses**: **Read**

Role	Description
Interaction with child incidents	Grants the following rights in the EDR functional areas: • **Child incidents**: **Read** and **Write** • **IAM**: **Read users and roles and Lists users**. In addition to this role, you must have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 2 analyst, Tier 1 analyst, SOC manager, Approver, Auditor.
Manage shared resources	Grants the right to edit access to shared resources located in the shared tenant. In addition to this role, you must have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 2 analyst, Tier 1 analyst, SOC manager, Approver.
Read shared resources	Grants the right to read access to shared resources located in the shared tenant. In addition to this role, you must have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 2 analyst, Tier 1 analyst, SOC manager, Approver.
SLA management	Grants the right to edit the remaining SLA time for incidents. In addition to this role, you must have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 2 analyst, Tier 1 analyst, SOC manager, Approver.
View universal dashboard layouts	Grants the right to view universal dashboard layouts. In addition to this role, you must have one of the following EDR roles: Main administrator, Tenant administrator, Junior analyst, Tier 2 analyst, Tier 1 analyst, SOC manager, Approver.
Service roles	
Automatic Threat Responder	Grants service accounts the right to respond to threats. Access rights are configured automatically in accordance with the role-based access control policies of Kaspersky Security Center Linux and managed Kaspersky applications. You can assign this role only to service accounts. This role cannot be edited.

Assigning access rights to specific objects

In addition to assigning access rights at the server level, you can configure access to specific objects, for example, to a specific task. The application allows you to specify access rights to the following object types:

- Administration groups
- Tasks
- Reports
- Device selections
- Event selections

To assign access rights to a specific object:

1. Depending on the object type, in the main menu, go to the corresponding section:
   - **Asset management → Hierarchy of groups**
   - **Tasks**
   - **Monitoring → Reports**
   - **Asset management → Device selections**
   - **Monitoring → Event selections**
2. Open the properties of the object to which you want to configure access rights.

   To open the properties window of an administration group or a task, click the object name. Properties of other objects can be opened by using the button on the toolbar.
3. In the properties window, open the **Access rights** section.

   The user list opens. The listed users and security groups have access rights to the object. By default, if you use a hierarchy of administration groups or Servers, the list and access rights are inherited from the parent administration group or primary Server.
4. To be able to modify the list, enable the **Use custom permissions** option.
5. Configure access rights:
   - Use the **Add** and **Delete** buttons to modify the list.
   - Specify access rights for a user or security group. Do one of the following:
     - If you want to specify access rights manually, select the user or security group, click the **Access rights** button, and then specify the access rights.
     - If you want to assign a user role to the user or security group, select the user or security group, click the **Roles** button, and then select the role to assign.
6. Click the **Save** button.

The access rights to the object are configured.

Assigning permissions to users and groups

You can give users and security groups access rights to use different features of Administration Server and of the Kaspersky applications for which you have management plug-ins, for example, Kaspersky Endpoint Security for Windows.

To assign permissions to a user or security group:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **Access rights** tab, select the check box next to the name of the user or the security group to whom to assign rights, and then click the **Access rights** button.

   You cannot select multiple users or security groups at the same time. If you select more than one item, the **Access rights** button will be disabled.

3. Configure the set of rights for the user or group:

   a. Expand the node with features of Administration Server or other Kaspersky application.

   b. Select the **Allow** or **Deny** check box next to the feature or the access right that you want.

      Example 1: Select the **Allow** check box next to the **Application integration** node to grant all available access rights to the Application integration feature (**Read**, **Write**, and **Execute**) for a user or group.

      Example 2: Expand the **Encryption key management** node, and then select the **Allow** check box next to the **Write** permission to grant the **Write** access right to the Encryption key management feature for a user or group.

4. After you configure the set of access rights, click **OK**.

The set of rights for the user or group of users will be configured.

The permissions of the Administration Server (or the administration group) are divided into the following areas:

- General features:
  - Managing administration groups
  - Access objects regardless of their ACLs
  - Basic functionality
  - Deleted objects
  - Encryption Key Management
  - Event processing
  - Operations with Administration Server
  - Device tags
  - Deploying Kaspersky applications
  - License key management
  - Managing reports
  - Hierarchy of Servers
  - User roles rights
  - Virtual Administration Servers

- Mobile Device Management:
  - General
- System Management:
  - Connectivity
  - Equipment inventory
  - Network Access Control
  - Operating system deployment
  - Manage vulnerabilities and patches
  - Remote installation
  - Software inventory

If neither **Allow** nor **Deny** is selected for a permission, then the permission is considered *undefined*: it is denied until it is explicitly denied or allowed for the user.

The rights of a user are the sum of the following:

- User's own rights
- Rights of all the roles assigned to this user
- Rights of all the security group to which the user belongs
- Rights of all the roles assigned to the security groups to which the user belongs

If at least one of these sets of rights has **Deny** for a permission, then the user is denied this permission, even if other sets allow it or leave it undefined.

You can also add users and security groups to the scope of a user role to use different features of Administration Server. Settings associated with a user role will only apply to devices that belong to users who have this role, and only if these devices belong to groups associated with this role, including child groups.

Adding an account of an internal user

To add a new internal user account to Kaspersky EDR Expert:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.
2. Click **Add**.
3. In the **Add user** window that opens, specify the settings of the new user account:
   - **Name**.
   - **Password** for the user connection to Kaspersky EDR Expert.

The password must comply with the following rules:

- The password must be 10 to 256 characters long.
- The password must contain characters from at least three of the groups listed below:
  - Uppercase letters (A–Z)
  - Lowercase letters (a-z)
  - Numbers (0–9)
  - Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)
- The password may not contain any whitespace, Unicode characters, or the combination of "." and "@" with the "." preceding the "@".

To see the characters that you entered, click and hold the **Show** button.

> The number of attempts for entering the password is limited. By default, the maximum number of allowed attempts to enter a password is 3. You can change the allowed number of attempts to enter a password, as described in "Changing the number of allowed password entry attempts".

> If the user enters an invalid password the specified number of times, the user account is blocked for one hour. You can unblock the user account only by changing the password.

4. Click **Save** to save changes.
5. If necessary, assign roles to a created internal user account in a tenant.

A new user account is added to the user list.

> To sign in with a created internal user account on the OSMP Console, you must assign a role to the account. Before signing in, make sure that the internal user account has a role. Otherwise, a login error will occur.

Creating a security group

To create a security group:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Groups** tab.
2. Click the **Add** button.

3. In the **Create security group** window that opens, specify the following settings for the new security group:

   - **Group name**
   - **Description**

4. Click **Save** to save changes.

A new security group is added to the group list.

Editing an account of an internal user

To edit an internal user account in Kaspersky EDR Expert:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.
2. Click the name of the user account that you want to edit.
3. In the user settings window that opens, on the **General** tab, change the settings of the user account:

   - **Description**
   - **Full name**
   - **Email address**
   - **Main phone**
   - **Set new password** for the user connection to Kaspersky EDR Expert.
     The password must comply with the following rules:

     - The password must be 10 to 256 characters long.
     - The password must contain characters from at least three of the groups listed below:

       - Uppercase letters (A–Z)
       - Lowercase letters (a-z)
       - Numbers (0–9)
       - Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ` ~ " ( ) ;)

     - The password must not contain any whitespaces, Unicode characters, or the combination of "." and "@", when "." is placed before "@".

     To see the entered password, click and hold the **Show** button for as long as you require.

The number of attempts for entering the password is limited. By default, the maximum number of allowed password entry attempts is 3. You can change the allowed number of attempts; however, for security reasons, we do not recommend that you decrease this number. If the user enters an invalid password the specified number of times, the user account is blocked for one hour. You can unblock the user account only by changing the password.

- If necessary, switch the toggle button to **Disabled** to prohibit the user from connecting to the application. You can disable an account, for example, after an employee leaves the company.

4. On the **Two-factor authentication** tab, you can specify the security settings for this account.
5. On the **Groups** tab, you can add the user to security groups.
6. On the **Devices** tab, you can assign devices to the user.
7. On the **Roles** tab, you can assign roles to the user.
8. Click **Save** to save changes.

The updated user account appears in the list of users.

Configuring Kerberos domain authentication

Kaspersky EDR Expert enables you to use domain authentication over the Kerberos protocol. Domain authentication allows you to enable secure authentication in OSMP Console without having to re-enter the password on the corporate network (single sign-on).

You must first configure your domain controller to use Kerberos and generate a keytab file. For more information, refer to the documentation for your domain controller.

SCRIL (Smart card is required for interactive logon) is supported for Microsoft Active Directory.

Generating a keytab file for FreeIPA and AldPro

To generate a keytab file:

1. Create a user account to be used by IAM to access the domain controller.
2. If the Administration Server is outside the FreeIPA/AldPro domain, add the DNS record entry and the host entry:

```
ipa dnsrecord-add <zoneName> <recordName> --a-rec <Administration Server IP address>
ipa host-add --password=<password> <Administration Server host address>
```

3. Specify the PAC type when creating the HTTP service for the Administration Server:

```
ipa service-add HTTP/<console_host>.<smp_domain>@<DOMAIN WRITTEN IN CAPITAL LETTERS> --ok-to-auth-as-
delegate=true --pac-type PAD
```

Here, `<console_host>` is the service host name, and `<smp_domain>` is the domain name. The service host name and domain name are parts of the service FQDN. For example, if the value of the `console_host` variable is `console`, and the value of the `smp_domain` variable is `smp.local`, then the full name of the service that provides access to the OSMP Console is `console.smp.local`.

4. Specify the user account for authentication:

```
ipa service-allow-retrieve-keytab HTTP/<Administration Server host address>@<DOMAIN WRITTEN IN CAPITAL LETTERS>
--user=<user>
```

5. Export the keytab file:

```
ipa-getkeytab -s <domain controller address> -p HTTP/<Administration Server host address>@<DOMAIN WRITTEN IN
CAPITAL LETTERS> -k /tmp/h.keytab
```

Generating a keytab file for Microsoft Active Directory

To generate a keytab file:

1. Create a user account to be used by IAM to communicate with the domain controller.
2. Enable the following options for the user account:
   - **User cannot change password**
   - **Kerberos AES 256-bit encryption**

   You can enable the **Password never expires** option to avoid reissuing the keytab file each time the password expires.
3. Add a Service Principal Name (SPN) to the user account:

```
setspn -S HTTP/<> <DOMAIN WRITTEN IN CAPITAL LETTERS>\<user>
```

4. Export the keytab file:

```
ktpass -out C:\<folder>\<keytab file name> -princ HTTP/<console_host>.<smp_domain>@<DOMAIN WRITTEN IN CAPITAL
LETTERS> -mapuser <user>@<DOMAIN WRITTEN IN CAPITAL LETTERS> -crypto AES256-SHA1 -ptype KRB5_NT_PRINCIPAL -pass
<user password> -mapop set
```

Here, `<console_host>` is the service host name, and `<smp_domain>` is the domain name. The service host name and domain name are parts of the service FQDN. For example, if the value of the `console_host` variable is `console`, and the value of the `smp_domain` variable is `smp.local`, then the full name of the service that provides access to the OSMP Console is `console.smp.local`.

Generating a keytab file for Samba

To generate a keytab file:

1. Create a user account to be used by IAM to communicate with the domain controller:

   ```
   samba-tool user add <user>
   ```

2. Add the SPN to the user account:

   ```
   samba-tool spn add HTTP/<console_host>.<smp_domain> <user>
   ```

   Here, `<console_host>` is the service host name, and `<smp_domain>` is the domain name. The service host name and domain name are parts of the service FQDN. For example, if the value of the `console_host` variable is `console`, and the value of the `smp_domain` variable is `smp.local`, then the full name of the service that provides access to the OSMP Console is `console.smp.local`.

3. Export the keytab file:

   ```
   samba-tool domain exportkeytab /tmp/file.keytab --principal=HTTP/<console_host>.<smp_domain>
   ```

Enabling Kerberos domain authentication

To enable Kerberos domain authentication:

1. Perform domain controller polling.
2. In the main menu, go to the **Settings** → **Single sign-on** section.
3. Enable the **Kerberos authentication** option.
4. Upload the keytab file.
5. Assign a role to domain users that gives access to OSMP Console.

   Kerberos domain authentication is enabled for domain users.

Changing a user work status

The user work status shows whether or not you can assign alerts and incidents to the user.

Users may have one of the following statuses:

- **Available**—The user is ready to work with alerts and incidents.
- **Busy**—The user is not ready to work with alerts and incidents. Alerts and incidents cannot be automatically assigned to the user.

By default, when a user signs in to OSMP Console or to KUMA Console, the user work status automatically updates to **Available**.

You can manually change your work status or the work status for the currently signed-in users.

Changing the work status for your own account

Your current work status is displayed in the main menu next to your account name as a green dot ( ) if the status is **Available**, or as a red dot ( ) if the status is **Busy**.

If you want to change your current work status, in the upper pane, go to your account settings, and then select the status to be assigned to your account.

Changing the work status for an internal user account

The **Work status** field is displayed in the user settings window only if the user is currently signed in to OSMP Console or to KUMA Console.
To change the work status for an internal user, you must have one of the following EDR roles: Main administrator, Tenant administrator, SOC administrator.

To change the work status of an internal user:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.

   The user list opens.

2. Click the name of the user account for which you want to change the status.

   The user settings window opens with the **General** tab selected.

3. In the **Work status** field, select the status that you want to assign: **Available** or **Busy**.

4. Click the **Save** button.

The window is closed, and the work status of the user is changed.

Editing a security group

To edit a security group:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Groups** tab.
2. Click the name of the security group that you want to edit.
3. In the group settings window that opens, change the settings of the security group:
   - On the **General** tab, you can change the **Name** and **Description** settings. These settings are available only for internal security groups.
   - On the **Users** tab, you can do the following:
     - View the table of the group users.
     - Add users to the security group. To do this, click the **Add** button, then in the **Add users** pane that opens, select the check boxes next to the user accounts that you want to add, and click **Save**.

       In the **Add users** pane, you can filter the users by tenant. To do this, set the **Tenant owner** filter criteria to the required value.

       > Adding users to the security group is available only for internal users and internal security groups.

     - Delete users from the security group. To do this, select the check box next to the user account name, click **Delete**, and then confirm the action.
   - On the **Roles** tab, you can assign a role to the security group.
4. Click **Save** to save changes.

The changes are applied to the security group.

Assigning a role to a user or a security group

To assign a role to a user or a security group:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** or the **Groups** tab.
2. Select the name of the user or the security group to whom to assign a role.

   You can select multiple names.
3. On the menu line, click the **Assign role** button.

   The Role assignment wizard starts.

4. Follow the instructions of the wizard: select the role that you want to assign to the selected users or security groups, and then select the scope of role.

   A *user role scope* is a combination of users and administration groups. Settings associated with a user role apply only to devices that belong to users who have this role, and only if these devices belong to groups associated with this role, including child groups.

The role with a set of rights for working with Administration Server is assigned to the user (or users, or the security group). In the list of users or security groups, a check box appears in the **Has assigned roles** column.

Adding user accounts to an internal security group

You can add only accounts of internal users to an internal security group.

To add user accounts to an internal security group:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.
2. Select check boxes next to user accounts that you want to add to a security group.
3. Click the **Assign group** button.
4. In the **Assign group** window that opens, select the security group to which you want to add user accounts.
5. Click **Save**.

The user accounts are added to the security group. You can also add internal users to a security group by using the group settings.

Assigning a user as a device owner

For information about assigning a user as a mobile device owner, see Kaspersky Secure Mobility Management Help.

To assign a user as a device owner:

1. If you want to assign an owner of a device connected to a virtual Administration Server, first switch to the virtual Administration Server:

   a. In the main menu, click the chevron icon (›) to the right of the current Administration Server name.

   b. Select the required Administration Server.

2. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.

   The user list opens. If you are currently connected to a virtual Administration Server, the list includes users from the current virtual Administration Server and the primary Administration Server.

3. Click the name of the user account that you want to assign as a device owner.
4. In the user settings window that opens, select the **Devices** tab.
5. Click the **Add** button.
6. From the device list, select the device that you want to assign to the user.
7. Click **OK**.

The selected device is added to the list of devices assigned to the user.

You can perform the same operation at **Asset management** → **Assets (Devices)**, by clicking the name of the device that you want to assign, and then clicking the **Manage device owner** link.

Configuring two-factor authentication

Starting with OSMP 2.0, two-factor authentication is enabled automatically. The global option to disable two-factor authentication is not supported. This scenario provides steps to configure two-step authentication at first sign-in and configure two-factor authentication settings on Administration Server.

Stages

Configuring two-factor authentication proceeds in stages:

1. **Installing an authenticator app on a device**

   You can install any application that supports the Time-Based One-Time Password algorithm (TOTP), such as:

   - Google Authenticator
   - Microsoft Authenticator
   - Bitrix24 OTP
   - Yandex ID
   - Avanpost Authenticator
   - Aladdin 2FA
   - Rutoken OTP

   To check if Kaspersky EDR Expert supports the authenticator app that you want to use, enable two-factor authentication for all users or for a particular user.

   One of the steps suggests that you specify the security code generated by the authenticator app. If it succeeds, then Kaspersky EDR Expert supports the selected authenticator.

We strongly do not recommend installing the authenticator app on the same device from which Administration Server is managed.

2. **Synchronizing the time on the device with the authenticator app with the time of the device on which Administration Server is installed**

   Ensure that the time on the device with the authenticator app and the time on the device with the Administration Server are synchronized to UTC. For better accuracy, we recommend using the same NTP servers throughout your infrastructure. Otherwise, failures may occur while configuring two-factor authentication.

3. **Configuring two-factor authentication for user accounts at sign-in to Web Console**

   Sign-in to Web Console and configure two-factor authentication.

   If two-factor authentication configuration is not available to you, contact a user who has the Modify object ACLs right of the **General features: User permissions** functional area and configured two-factor authentication to add your account to the two-factor authentication allow list.

4. **Configuring two-factor authentication settings on Administration Server**

   If you have configured two-factor authentication and the Modify object ACLs right of the **General features**: **User permissions** functional area, you can configure two-factor authentication settings on Administration Server as follows:

   1. Reviewing the list of users who can configure two-step authentication at sign-in:

      - For installing OSMP 2.0 from scratch: Add required users to the two-factor authentication allow list to enable them to configure two-factor authentication at his or her first sign-in.
      - For upgrading to OSMP 2.0: Review the two-factor authentication allow list and delete accounts that must not have access to Administration Server.

   2. Excluding user accounts for which you do not need to enable two-factor authentication (optional)

      Exclude user accounts from two-factor authentication to allow them to sign in to Administration Server even if they have not configured two-factor authentication. Excluding accounts from two-factor authentication may be necessary for integration accounts that cannot provide a security code during authentication. Integration accounts are used to run scripts through OpenAPI.

   3. Resetting or deleting a two-factor authentication secret key (optional)

      You can reset a two-factor authentication secret key when a user loses access to his or her two-factor authentication device, or needs to set up two-factor authentication on a new device. You can also reset a secret key for your own account.

      You can delete a secret key to completely block a user from signing in to Web Console and prevent the user from accessing Administration Server.

   4. Editing the name of a security code issuer (optional)

      If you have several Administration Servers with similar names, you may have to change the security code issuer names so there is better recognition of different Administration Servers.

Results

Upon completion of this scenario:

- Two-factor authentication is configured for your own account and for another user account who needs access to Administration Server.
- Integration accounts are excluded from two-factor authentication.

About two-factor authentication for an account

Kaspersky EDR Expert provides two-factor authentication for users of OSMP Console. Two-factor authentication is based on the RFC 6238 standard (TOTP: Time-Based One-Time Password algorithm).

Every time you log in to OSMP Console, you enter your user name, password, and an additional one-time security code. To receive a one-time security code, you must have an authenticator app on the mobile device or computer.

> Any authentication software that supports the Time-Based One-Time Password algorithm (TOTP) can be used as an authenticator app, for example, Google Authenticator. In order to generate the one-time security code, you must synchronize the time set on the device with the authenticator app with the time set on the Administration Server device. For better accuracy, we recommend using the same NTP servers throughout your infrastructure.

To check if Kaspersky EDR Expert supports the authenticator app that you want to use, try configuring two-factor authentication with this authenticator app.

One of the steps suggests that you specify the one-time security code generated by the authenticator app. If it succeeds, then Kaspersky EDR Expert supports the selected authenticator.

Generating a secret code by using an authentication app

An authenticator app generates the security code as follows:

1. Administration Server generates a special secret key and QR code.
2. You pass the generated secret key or QR code to the authenticator app.
3. The authenticator app generates a single-use security code that you pass to the authentication window of Administration Server.

A security code has an identifier referred to as *issuer name*. The security code issuer name is used as an identifier of the Administration Server in the authenticator app. You can change the name of the security code issuer name. The security code issuer name has a default value that is the same as the name of the Administration Server. A new security code issuer name is assigned to Administration Server after the next sign-in. A security code is single-use and valid for up to 30 seconds (the exact time may vary).

> We highly recommend that you save the secret key (or QR code) and keep it in a safe place. This will help you to restore access to OSMP Console in case you lose access to the device with the authenticator app.

Two-factor authentication has the following features:

- Starting with Kaspersky EDR Expert 8.0, two-factor authentication is enabled automatically and the option to configure two-factor authentication at sign-in is disabled by default. Configuring two-factor authentication at sign-in is available only to users who are included in the two-factor authentication allowlist.
- A user can configure two-factor authentication only for his or her own account.
- A user can exclude accounts from two-factor authentication. This can be necessary for integration accounts that cannot receive a one-time security code for authentication. Integration accounts are used to run scripts through OpenAPI and to run KUMA scripts.
- To regenerate a two-factor authentication secret key, a user must reset the secret key for his or her own account.
- To reset or delete a two-factor authentication secret key for account of another user, a user must have an account with configured two-factor authentication and with the Modify object ACLs right in the **General features**: **User permissions** functional area.
- To exclude accounts of other users from two-factor authentication or modify the two-factor authentication allowlist, a user must have an account with configured two-factor authentication and with the Modify object ACLs right in the **General features**: **User permissions** functional area.
- There should always be at least one user with configured two-factor authentication so that this user can manage the two-factor authentication allowlist and the exclusion list.
- Two-factor authentication is enabled automatically only for Kaspersky EDR Expert 8.0 or later. If other primary or secondary Administration Servers are running version 1.4 or earlier, their two-factor authentication settings will remain unchanged.
- A virtual Administration Server inherits two-factor authentication settings from the physical Administration Server so that if two-factor authentication is enabled on the physical Administration Server, it is also enabled on a virtual Administration Server. You cannot configure two-factor authentication settings on a virtual Administration Server.

To ensure comprehensive protection by using two-factor authentication, it is necessary to secure not only Administration Server but also the device on which it is installed. To do this, consider the Hardening guide recommendations.

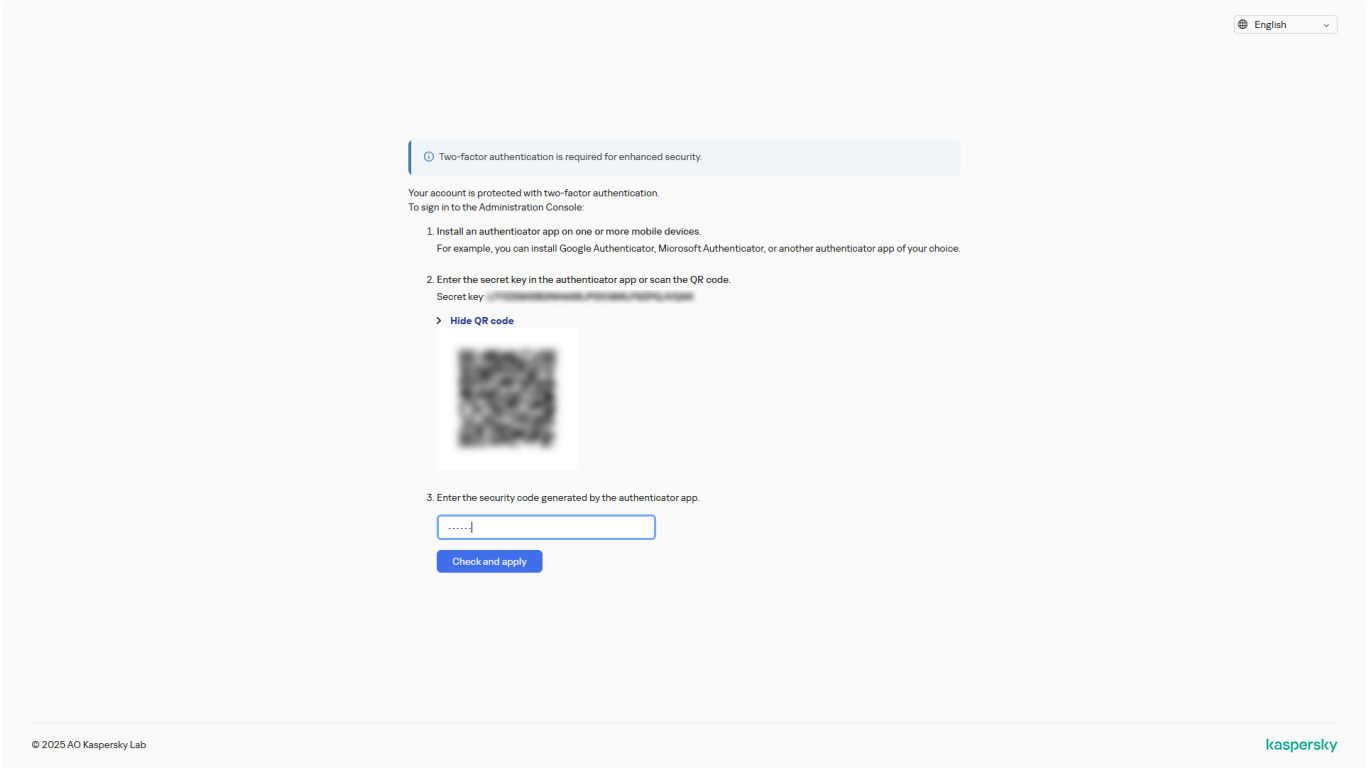
Configuring a two-factor authentication secret key at OSMP Console sign-in

The first time you sign in to OSMP 2.0 or later, the window for configuring two-factor authentication opens.

To configure two-factor authentication for your account:

1. Install any application that supports the Time-Based One-Time Password algorithm (TOTP) on the mobile device or computer, such as:
   - Google Authenticator
   - Microsoft Authenticator

- Bitrix24 OTP
- Yandex ID
- Avanpost Authenticator
- Aladdin 2FA
- Rutoken OTP



> We strongly do not recommend installing the authenticator app on the same device from which Administration Server is managed.

2. Ensure that the time on the device with the authenticator app and the time on the device with the Administration Server are synchronized to UTC. For better accuracy, we recommend using the same NTP servers throughout your infrastructure.

3. Generate a one-time security code by using the authenticator app on the mobile device or computer. To do so, follow one of these steps:

   - Enter the two-factor authentication secret key in the authenticator app manually.
   - Click **View QR code** and scan the QR code by using the authenticator app.

   A one-time security code of 6 digits will display on the mobile device.

Configuring a two-factor authentication secret key at OSMP Console sign-in

4. In the **Two-factor authentication** window, specify the one-time security code generated by the authenticator app, and then click the **Check and apply** button.

   Rutoken OTP configuration

If you use Rutoken OTP, you need an Android mobile device with the Rutoken OTP application installed. The Android mobile device must the following requirements:

- Operating system is Android 7 or newer.
- NFC module is available and enabled.

In the Rutoken OTP application, you have to configure the following parameters:

- Scan the QR code displayed in the two-step configuration wizard.
- Set the time interval to 30 seconds.
- Select SHA1 as the algorithm.

To configure Rutoken OTP:

1. Put the Rutoken OTP device next to the mobile device with the NFC module.
2. In the Rutoken OTP application, press **Connect token**.
3. In the Rutoken OTP application, press **Configure settings**, and then press **Save secret key.**

   If the token is successfully connected to the mobile device, the Rutoken OTP application shows the following status messages:

   - **Token is connected.**
   - **Settings are configured.**
   - **Secret key is saved.**
4. On the Rutoken OTP device, press the button.

   A security code is displayed on the device.
5. In OSMP Console, in the two-step verification window, enter the security code.

Two-factor authentication is configured for your account. You are able to access the Administration Server in accordance with your rights.

If two-factor authentication configuration is not available to you, contact a user who has the Modify object ACLs right in the **General features**: **User permissions** functional area and configured two-factor authentication to add your account to the two-factor authentication allowlist.

Allowing users to configure two-factor authentication

The two-factor authentication allowlist is a list of users who are permitted to initially configure two-factor authentication when signing in to Web Console. This list contains user accounts without configured two-factor authentication. By default, new user accounts are not included in the two-factor authentication allowlist and must be added to the list by an administrator. If a new account is an integration account used to run OpenAPI scripts, it must be excluded from two-factor authentication.

A user account will be automatically deleted from the two-factor authentication allowlist when it has configured two-factor authentication or is excluded from two-factor authentication.

Manual modifying the two-factor authentication allowlist is available for accounts that have configured two-factor authentication and that have the Modify object ACLs right in the **General features**: **User permissions** functional area.

To add a user account to the allow list manually:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **Two-factor authentication** tab of the properties window, in the **Users allowed to generate secret keys** table, click the **Add** button.

3. In the window that opens:

   a. Select the user account that you want to add.

      Only users who are not excluded from two-factor authentication and do not have a two-factor authentication secret key can be added to the allow list.

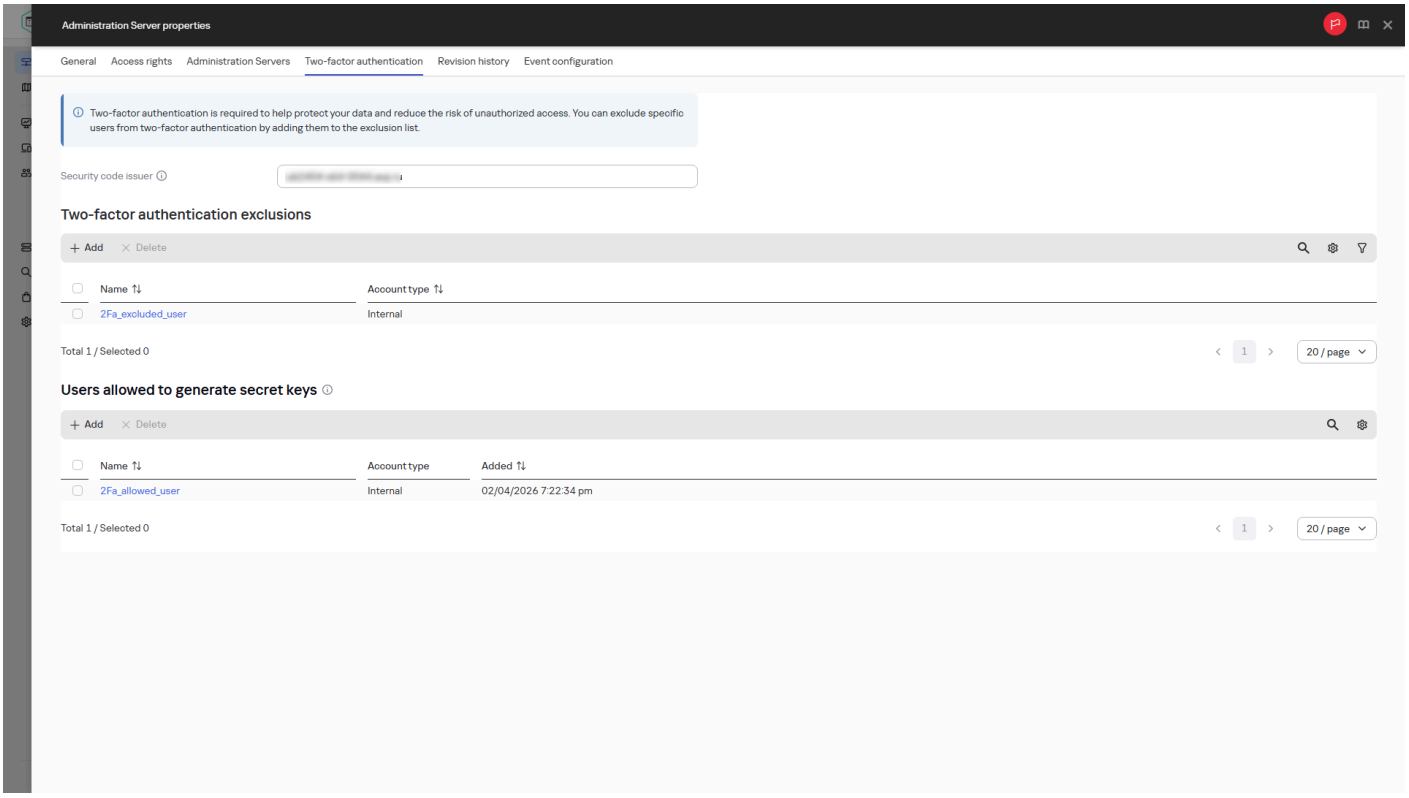
   b. If the account is protected against unauthorized modification, you must confirm that you have the permissions to change this account. In the **Account protection** window, specify the credentials of your own account and the one-time security code for two-factor authentication.

   c. Save your changes.

   The selected user account is added to the two-factor authentication allowlist. At the next sign-in, the user will be able to generate a secret key.

A user account can be deleted from the two-factor authentication allowlist until two-factor authentication is configured for that account.

To delete user accounts from the two-factor authentication allowlist manually:



1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **Two-factor authentication** tab of the properties window, in the **Users allowed to generate secret keys** table, select the user accounts that you want to delete, and then click **Delete**.

3. If the account is protected against unauthorized modification, you must confirm that you have the permissions to change this account. In the **Account protection** window, specify the credentials of your own account and the one-time security code for two-factor authentication.

The selected user accounts are deleted from the allow list.

Configuring the two-factor authentication allowlist

If, during an active session on Administration Server, your two-factor authentication secret key is deleted by another user or you reset the key yourself but do not create a new one, the ability to modify the allow list is blocked.

User accounts can also be automatically added and deleted from the two-factor authentication allowlist.

When resetting a two-factor authentication secret key for other accounts, their accounts are automatically added to the two-factor authentication allowlist so that they can generate a new secret key.

When upgrading Kaspersky EDR Expert from version 1.4 to version 2.0 or later, user accounts will be automatically added to the two-factor authentication allow list if all the following conditions are met:

- User has the Read permission in the functional area *General features: Basic functionality* assigned directly to the user (not through a security group). The scope of the user role with this permission must include all managed and unassigned devices, and must be set at the Administration Server level.
- User is not excluded from two-factor authentication.
- User does not have a two-factor authentication secret key.
- Two-factor authentication was not enabled for all users on Administration Server of the previous version.

Failure to meet even one condition will result in the user not being added to the two-factor authentication allowlist.

> After an upgrade or restore, we recommend ensuring that the allow list contains only the user accounts that must have access to Administration Server. Review the allow list and remove any other accounts from it. Add integration accounts used to run scripts through OpenAPI to the exclusion list to prevent script failures.

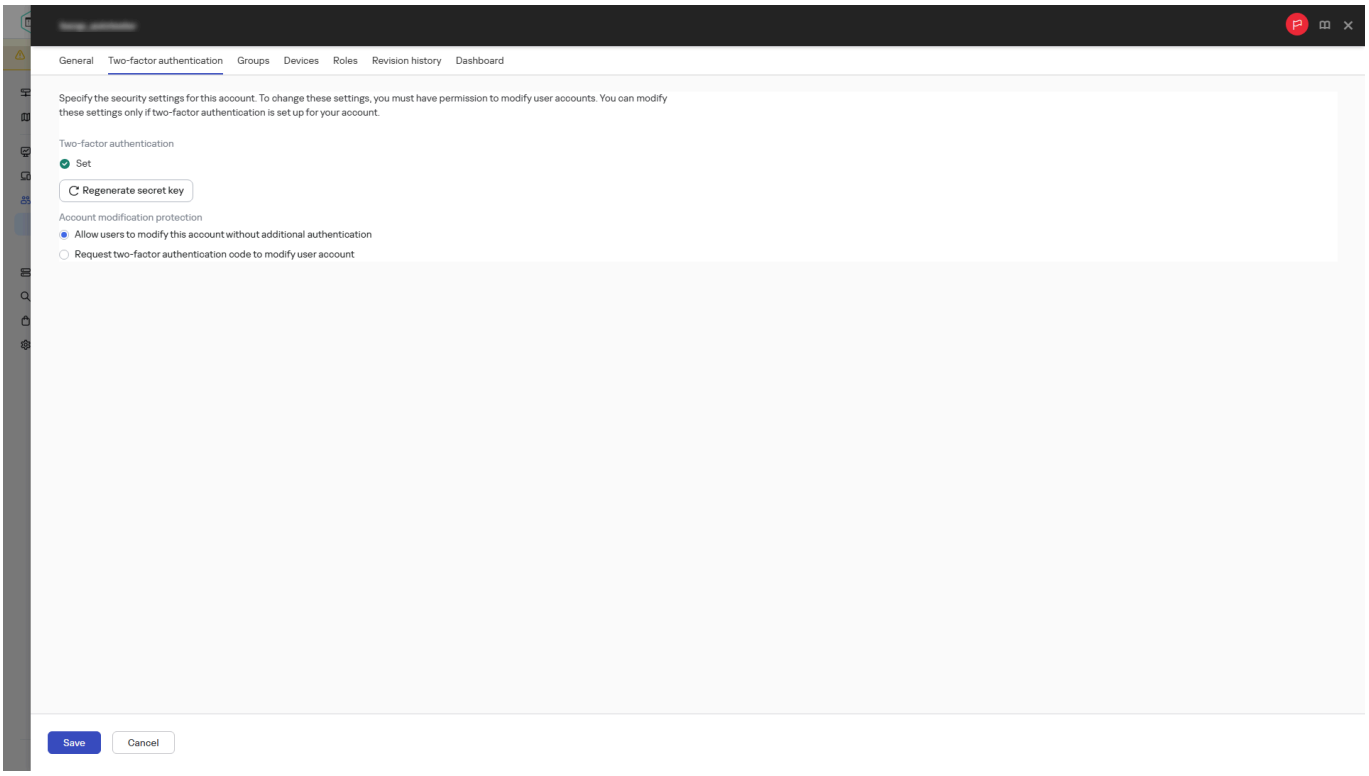
Accounts of the users will lose access to Administration Server after an upgrade or restore if all the following conditions are met:

- User has the Read permission in the functional area *General features: Basic functionality* assigned through a security group (not directly to the user) or does not have this permission at all.
- User is not excluded from two-factor authentication.
- User does not have a two-factor authentication secret key.
- Two-factor authentication was not enabled for all users on Administration Server of the previous version.

These accounts can be manually added to the two-factor authentication allowlist, if needed.

Resetting and deleting a two-factor authentication secret key

You can reset a secret key when a user loses access to his or her two-factor authentication device or needs to set up two-factor authentication on a new device. Resetting the secret key allows the user to sign in to Web Console again and generate a new secret key.



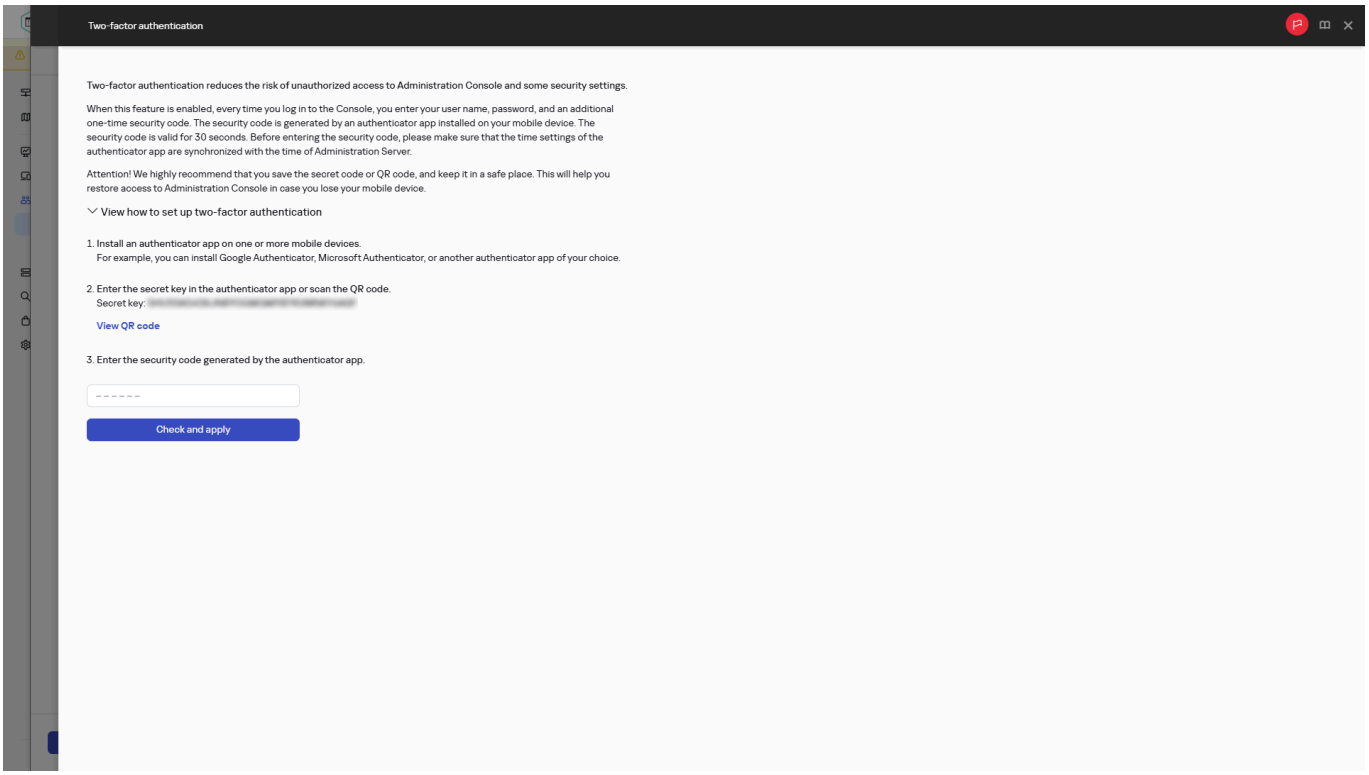
> You can reset or delete a two-factor authentication secret key for accounts of other users only if you have configured two-factor authentication and you have the Modify object ACLs right in the **General features**: **User permissions** functional area. You can also regenerate your own secret key.

To reset a secret key for an account:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.
2. Click the name of the user account for which you want to reset a secret key.

3. If you want to reset a secret key for your account:

   a. On the **Two-factor authentication** tab, click the **Regenerate secret key** button.



Regenerating the two-factor authentication secret key for the current user account

   a. If your account is protected against unauthorized modification, you must confirm that you have the permissions to change this account. In the **Account protection** window, specify the credentials of your own account and the two-factor authentication code.

   b. In the **Two-factor authentication** window, click **View how to set up two-factor authentication**, and then click **View QR code**.

   c. Use the authenticator app on the mobile device to scan the QR code and receive a one-time security code.

Configuring a new two-factor authentication secret key for the current user account

a. In the **Two-factor authentication** window, specify the one-time security code generated by the authenticator app, click the **Check and apply** button, and then save changes.

Rutoken OTP configuration

If you use Rutoken OTP, you need an Android mobile device with the Rutoken OTP application installed. The Android mobile device must the following requirements:

- Operating system is Android 7 or newer.
- NFC module is available and enabled.

In the Rutoken OTP application, you have to configure the following parameters:

- Scan the QR code displayed in the two-step configuration wizard.
- Set the time interval to 30 seconds.
- Select SHA1 as the algorithm.

To configure Rutoken OTP:

1. Put the Rutoken OTP device next to the mobile device with the NFC module.
2. In the Rutoken OTP application, press **Connect token**.
3. In the Rutoken OTP application, press **Configure settings**, and then press **Save secret key.**

If the token is successfully connected to the mobile device, the Rutoken OTP application shows the following status messages:

- **Token is connected.**
- **Settings are configured.**
- **Secret key is saved.**

4. On the Rutoken OTP device, press the button.

   A security code is displayed on the device.

5. In OSMP Console, in the two-step verification window, enter the security code.

The secret key for your account is changed.

4. If you want to reset a secret key for another account:

   a. On the **Two-factor authentication** tab, click the **Reset secret key** button.

Resetting the two-factor authentication secret key for another user account

   a. If the account is protected against unauthorized modification, you must confirm that you have the permissions to change this account. In the **Account protection** window, specify the credentials of your own account and the one-time security code for two-factor authentication.

   b. Confirm the reset of the secret key, and then save changes.

When you reset a secret key for another account, the existing secret key is deleted and the user account is added to the two-factor authentication allowlist in the Administration Server properties. At the next sign-in, the user will be able to generate a new secret key.

The secret key of a user account is reset.

You can delete a secret key to completely block a user from signing in to Web Console and prevent the user from accessing Administration Server.

To delete a secret key:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.
2. Click the name of the internal user account for which you want to delete a secret key.

   You cannot delete a secret key for your own account.

3. On the **Two-factor authentication** tab, click the **Delete secret key** button.
4. If the account is protected against unauthorized modification, you must confirm that you have the permissions to change this account. In the **Account protection** window, specify the credentials of your own account and the one-time security code for two-factor authentication.
5. Confirm the deletion of the secret key, and then save changes.

The secret key of a user account is deleted.

You can restore access by adding the user to the two-factor authentication allowlist in the Administration Server properties. In this case, at the next sign-in, the user will be able to generate a new secret key.

Excluding accounts from two-factor authentication

You can exclude user accounts from two-factor authentication to allow them to sign in to Administration Server even if they have not configured two-factor authentication. Excluding accounts from two-factor authentication may be necessary for integration accounts that cannot provide a one-time security code during authentication. Integration accounts are used to run scripts through OpenAPI and to run KUMA scripts.

You can modify the exclusion list if two-factor authentication is configured for your account and you have the Modify object ACLs right in the **General features**: **User permissions** functional area.

To exclude a user account from two-factor authentication:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **Two-factor authentication** tab of the properties window, in the **Two-factor authentication exclusions** table, click the **Add** button.

3. In the window that opens:

   a. Select the user account that you want to exclude.

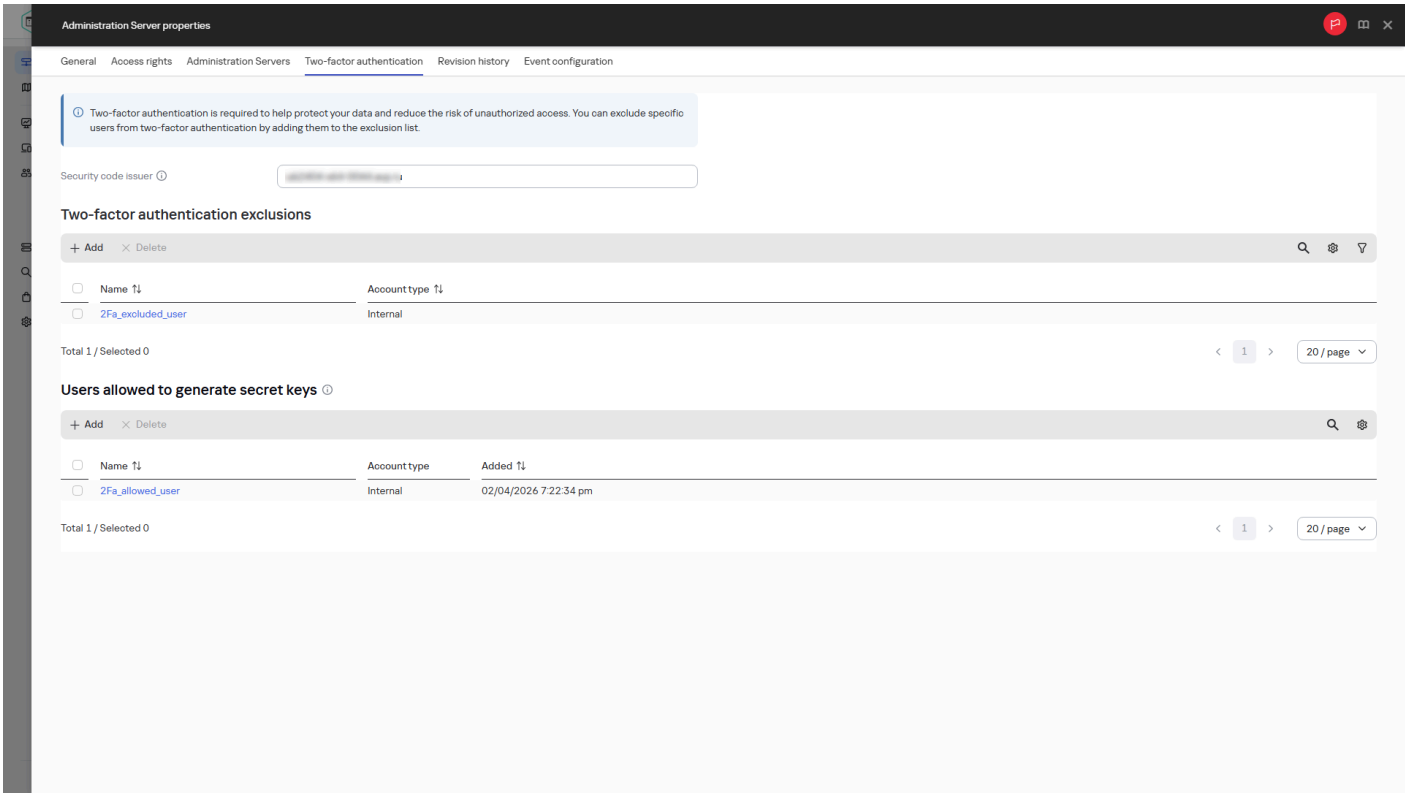
   b. If the account is protected against unauthorized modification, you must confirm that you have the permissions to change this account. In the **Account protection** window, specify the credentials of your own account and the one-time security code for two-factor authentication.

   c. Save your changes.

The selected user accounts are excluded from two-factor authentication, and their secret keys are deleted if they exist. The list of excluded accounts is not changed when you upgrade Kaspersky EDR Expert to version 8.0 or later. If the accounts from the exclusion list had secrets in the previous version of the Kaspersky EDR Expert, these secret keys will be deleted in 2.0.

You can delete user accounts from the exclusion list to completely block users from signing in to Web Console and to prevent users from accessing Administration Server.

To delete user accounts from the exclusion list:



1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **Two-factor authentication** tab of the properties window, in the **Two-factor authentication exclusions** table, select the user accounts that you want to delete, and then click **Delete**.

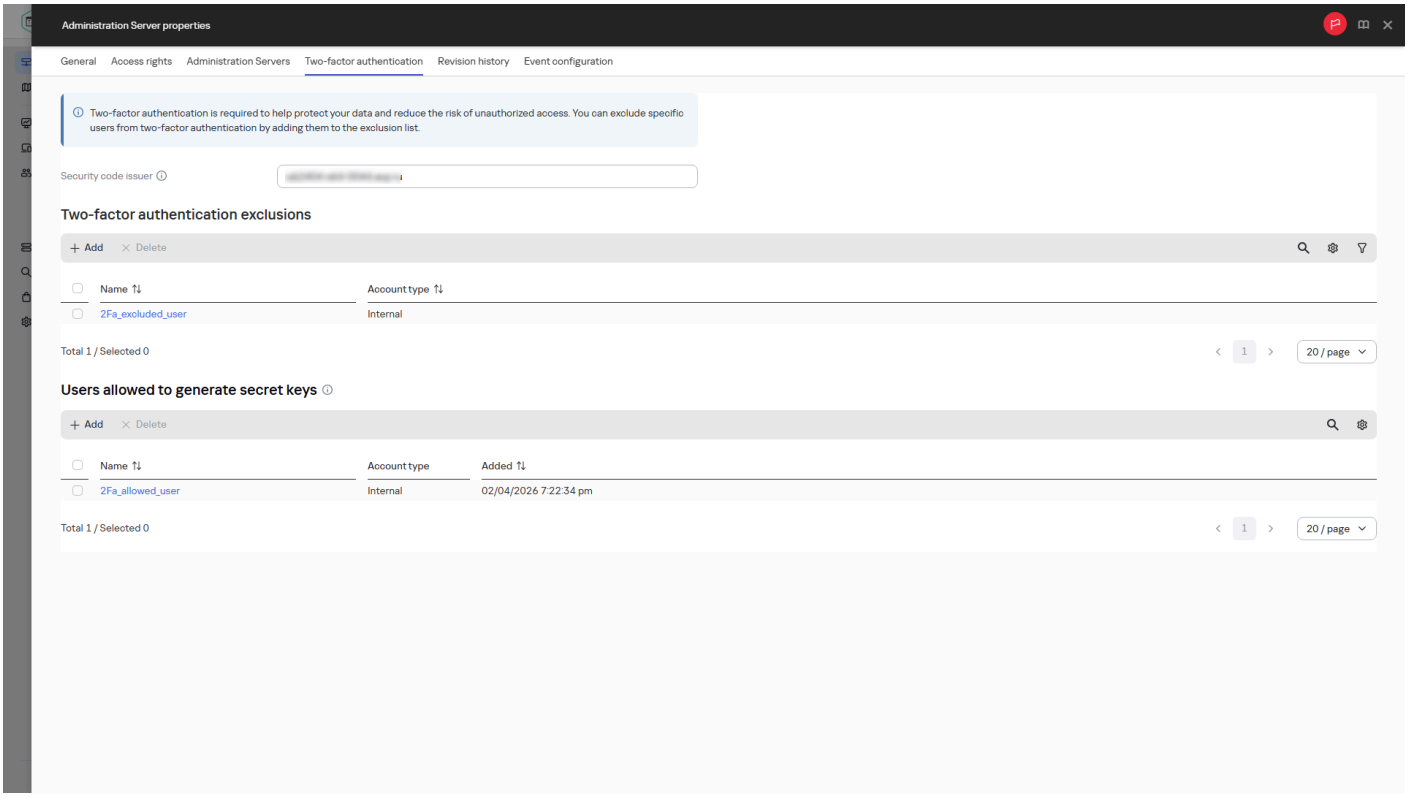
3. If the account is protected against unauthorized modification, you must confirm that you have the permissions to change this account. In the **Account protection** window, specify the credentials of your own account and the one-time security code for two-factor authentication.

The selected user accounts are deleted from the exclusion list.

Configuring the two-factor authentication exclusion list

Editing the name of a security code issuer

You can have several identifiers (called issuers) for different Administration Servers. You can change the name of a security code issuer in case, for example, the Administration Server already uses a similar name of the security code issuer for another Administration Server. By default, the name of a security code issuer is the same as the name of the Administration Server.



To specify a new name of a security code issuer:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **Two-factor authentication** tab of the properties window, enter a new name in the **Security code issuer** field, and then save changes.

A new security code issuer name is assigned to Administration Server after the next sign-in.

Specifying the name of a security code issuer

The number of allowed password entry attempts

The Kaspersky EDR Expert user can enter an invalid password a limited number of times. After the limit is reached, the user account is blocked for one hour.

By default, the maximum number of allowed password entry attempts is 3. This number is fixed and cannot be changed.

Configuring the lifetime of user SSO sessions and authentication tokens

Lifetime of a token (or a user session) is the period of time during which a token or a session remains valid and can be used for authentication. When that time period ends, the token or a session automatically expires, and requires renewal or re-login. Kaspersky EDR Expert lets you configure the lifetime of access tokens, refresh tokens used to refresh access tokens, and the lifetime of Single Sign-On (SSO) sessions when the user is idle. By configuring shorter lifetimes of a token or an SSO session, you reduce the risk of unauthorized access in the event of token compromise.

You can also configure the lifetime period for tokens and SSO session idle time before multi-node or single-node deployment of Kaspersky EDR Expert, by specifying the corresponding setttings (`tokenhub_access_token`, `tokenhub_refresh_token`, `credentials_session_ttl`) in the configuration file. If these settings were not specified during deployment, the default values are used:

- For access tokens (`tokenhub_access_token`)—1 hour
- For refresh tokens (`tokenhub_refresh_token`)—24 hours
- For idle SSO sessions (`credentials_session_ttl`), 1 hour.

To change settings in an already deployed solution, use the KDT commands.

To check the current lifetime period values:

On the administrator host, run the following command:

```
./kdt invoke iam -a getAuthTTLs
```

The current lifetime period values for access tokens, refresh tokens, and SSO session idle time are displayed in the command output as < `hours` >h< `minutes` >m< `seconds` >s, for example:

- `2h`
- `23h30m`
- `12h55m`

To configure the lifetime period of an access token:

On the administrator host, run the following command:

```
./kdt invoke iam -a setAuthTTLs --param tokenhub_access_token=< time period >
```

Where < `time_period` > is the required time period in hours, minutes, and seconds. For example, `1h` or `1h30m`. The minimum value for < `time_period` > for an access token is `5m`, and the maximum value is `2h`.

To configure the lifetime period of a refresh token:

On the administrator host, run the following command:

```
./kdt invoke iam -a setAuthTTLs --param tokenhub_refresh_token=<time_period>
```

Where `<time_period>` is the required time period in hours, minutes, and seconds. For example, `24h` or `720h30m`. The minimum value for `<time period>` for a refresh token is `12m`, and the maximum value is `4320h`.

To configure the lifetime of an idle Single Sign-On session:

On the administrator host, run the following command:

```
./kdt invoke iam -a setAuthTTLs --param credentials_session_ttl=<time_period>
```

Where `<time_period>` is the required time period in hours, minutes, and seconds. For example, `2h` or `1h30m`. The minimum value for `<time period>` for an idle SSO session is `5m`, and the maximum value is `96h`.

To configure the lifetime period for all parameters at once:

On the administrator host, run the following command:

```
./kdt invoke iam -a setAuthTTLs --param tokenhub_access_token=<time_period> --param
tokenhub_refresh_token=<time_period> --param credentials_session_ttl=<time_period>
```

Where `<time_period>` is the required time period in hours, minutes, and seconds.

The lifetime period for authentication tokens and SSO sessions is configured. If you enter a value outside the minimum and maximum limits, it is replaced by the default value.

A newly configured lifetime period applies only to tokens and sessions created after the changes are saved. Active tokens and sessions will expire based on the lifetime parameter values that were in effect when they were issued.

Deleting a user or a security group

You can delete only internal users or internal security groups.

To delete a user or a security group:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** or the **Groups** tab.
2. Select the check box next to the user or the security group that you want to delete.

   There should always be at least one user with configured two-factor authentication so that this user can manage the two-factor authentication allowlist and the exclusion list.

3. Then click the **Delete** button.

4. In the window that opens, click **OK**.

   The user or the security group is deleted.

Changing a user account password

You may need to change the password for a user account if the current password is about to expire or you want to change it to a more secure one.

The password must comply with the following rules:

- The password must be 10 to 256 characters long.
- The password must contain characters from the groups listed below:
  - Uppercase letters (A–Z)
  - Lowercase letters (a-z)
  - Numbers (0–9)
  - Special characters (@ # $ % ^ & * - _ ! + = [ ] { } | : ' , . ? / \ ~ " ( ) < > ;)
- The password must not contain any whitespaces or Unicode characters.

Changing the password for an internal user account

To edit the password for an internal user account:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** tab.
2. Click the name of the user account that you want to edit.
3. In the user settings window that opens, on the **General** tab, click the **Change password** button.
4. Set a new password for the user connection to Open Single Management Platform.

   To see the entered password, click .
5. If the user account is protected against unauthorized modification, you must confirm that you have the permissions to change this account. In the **Account protection** window, specify the credentials of the account that has the Modify object ACLs right in the General features: User permissions functional area.
6. Enter the one-time security code generated by the authenticator app on the mobile device.

Enforcing password change at first sign-in

You can require that users change their password the first time they sign in to Open Single Management Platform Console. This option is recommended if the same temporary password was set for multiple new accounts, as it ensures each user sets their own password upon first sign-in.

To enforce password change at first sign-in:

1. In the main menu, go to **Settings** → **Authentication policies**, and then enable the **Enforce password change at first sign-in** option.

2. Save your changes.

Enforced password change at first sign-in is enabled.

The enforcement of password change is determined at the time of user account creation and does not apply retroactively:

- Accounts created with this option enabled will always require a password change after the first sign-in, even if this option was disabled later.

- Accounts created with this option disabled will not require a password change after the first sign-in, even if this option was enabled later.

Configuring the password lifetime period

You can configure the password lifetime for user accounts, to ensure more frequent password changes. By default, the option is enabled.

To change the password lifetime period:

1. In the main menu, go to **Settings** → **Authentication policies**, and then enable the **Enforce regular password changes** option.

2. In the **Password lifetime (days)** entry field, specify the time period after which the password will expire. The default password lifetime is 365 days.

3. Save your changes.

The password lifetime period is changed.

Adding a custom banner to the login page

You can add a custom banner to the login page to display important information to users before authorization. For example, you can notify users about the measures taken to ensure information security.

To add a custom banner:

1. **Create a banner string**.

   To create a banner string:

   1. Write the HTML code for your banner, for example:

      ```
      <div>
       <h4>YourCompany Secure System</h4>
       <p>Only authorized employees are allowed to use the system.</p>
      </div>
      ```

      Adding images is not supported.

      Save this code in a file, for example, markup.html.

   2. Encode your HTML in Base64. In Linux, the command for encoding is the following:

      ```
      base64 -w 0 markup.html > banner.b64
      ```

      The command returns an encoded string, such as:

      ```
      PGRpdj4KPGg0PtCX0LDRidC40YnQtdC90L3QsNGPINGB0LjRgdGC0LXQvNCwINCe0J7QniDCq9Cg0L7QvNCw0YjQutCwwrs8aDQ+CjxwPtCaIN(
      ```

2. Add the string to the Kaspersky EDR Expert configuration. You can add the banner string to the configuration in different ways:

   - **Adding the banner during initial setup**

     To add the banner during initial setup:

     1. Before running the Kaspersky EDR Expert installation, add the following lines to the `parameters` section of the param.yaml file:

        ```
        - name: login_markup_b64
          source:
          value: "<your banner string encoded in Base64>"
        ```

     2. Run the Kaspersky EDR Expert installation.

   - **Adding the banner during upgrade**

     To add the banner during upgrade:

     1. On the administrator host, export the current configuration file by using the following command:

        ```
        ./kdt ec -e <configuration_file_name_with_path>
        ```

        The current version of the configuration file is saved to the specified directory with the specified name.

2. In the `parameters` section of the exported configuration file, add the following lines:

```
- name: login_markup_b64
 source:
 value: "<your banner string encoded in Base64>"
```

3. Upgrade Kaspersky EDR Expert and the Bootstrap component. When running the upgrade command, specify the full path to the exported configuration file from step 1 using the `-i` flag:

```
./kdt apply -k <full_path_to_XDR_updates_archive> --force --accept-eula -i
<configuration_file_name_with_path>
```

- **Adding the banner via a command line**

To add the banner via a command line:

1. Export the ConfigMap to a file:

```
kubectl get configmap credentials -n iam -o yaml > credentials.yaml
```

The credentials.yaml file contains the initial configuration that you need to modify.

2. Insert your encoded banner string into credentials.yaml:

```
sed -i 's|public:\\n|public:\\n login_markup_b64: \\"'"$(sed 's|[\/&\\]|\\&|g' banner.b64)"'\\"\\n|'
credentials.yaml
```

This command finds the line containing 'public:\n' and inserts the `login_markup_b64` field immediately after it.

3. Using any text editor, ensure that there are exactly six space characters before and after the `login_markup_b64` parameter, and that the quotes are properly escaped. Example:

```
6 space characters before login_markup_b64:
\"PGRpdj4KICA8aDQ+WW91ckNvbXBhbnkgU2VjdXJlIFN5c3RlbTwvaDQ+CiAgPHA+T25seSBhdXRob3JpemVkIGVtcGxveWVlcyBhcmUgY
6 space characters after
```

4. Apply your local changes to the Kubernetes cluster:

```
kubectl apply -f credentials.yaml
kubectl -n iam rollout restart deployment credentials
```

If you want to edit or delete the banner later:

1. Run the following command:

```
kubectl edit configmap credentials -n iam
```

2. Change the value of the `login_markup_b64` parameter or delete the parameter.

3. Apply your local changes to the Kubernetes cluster:

```
kubectl apply -f credentials.yaml
kubectl -n iam rollout restart deployment credentials
```

- **Adding the banner via IDE Lens**

  To add the banner via IDE Lens:

  1. Download and install IDE Lens.
  2. Copy the contents of the `~/.kdt/cluster.config` file.
  3. In Lens IDE, go to the **Local Kubeconfigs** → **+** → **Add kubeconfig by pasting** section and paste the contents of the `cluster.config` file.
  4. Open the added namespace (`iam`), then go to **Config** → **Config Maps**, and locate the `credentials` ConfigMap.
  5. Open the `credentials` ConfigMap and add the following line at the end (without indentation):

     ```
     credentials.server.public.login_markup_b64: "<your banner string encoded in Base64>"
     ```

     Example:

     ```
     credentials.server.public.login_markup_b64:
     "PGRpdiBzdHlsZT0idGV4dC1hbGlnbjogY2VudGVyOyI+CiAgPGltZyBzcmM9ImZpbGU6Ly8vaG9tZS90b29yLzUwLmpwZyIgYWx0PSJTZW
     ```

  6. Click **Save**.
  7. Reload the pod:

     ```
     kubectl -n iam rollout restart deployment credentials
     ```

  To edit or delete the banner later:

  1. Repeat steps 1 to 4 above.
  2. Open the `credentials` ConfigMap and edit or delete the `login_markup_b64` parameter.
  3. Click **Save**.
  4. Reload the pod:

     ```
     kubectl -n iam rollout restart deployment credentials
     ```

Once the new configuration is applied, your custom banner will be displayed on the login page.

Creating a user role

To create a user role:

1. In the main menu, go to **Users & roles** → **Roles**.
2. Click the **Add** button.
3. In the **New role name** window that opens, enter the name of the new role.
4. Click **OK** to apply the changes.
5. In the role properties window that opens, change the settings of the role:
   - On the **General** tab, edit the role name.
     You cannot edit the name of a predefined role.
   - On the **Settings** tab, edit the role scope and policies and profiles associated with the role.
   - On the **Access rights** tab, edit the rights for access to Kaspersky applications.
6. Click **Save** to save changes.

The new role appears in the list of user roles.

Editing a user role

To edit a user role:

1. In the main menu, go to **Users & roles** → **Roles**.
2. Click the name of the role that you want to edit.
3. In the role properties window that opens, change the settings of the role:
   - On the **General** tab, edit the role name.
     You cannot edit the name of a predefined role.
   - On the **Settings** tab, edit the role scope and policies and profiles associated with the role.
   - On the **Access rights** tab, edit the rights for access to Kaspersky applications.
4. Click **Save** to save changes.

The updated role appears in the list of user roles.

Editing the scope of a user role

A *user role scope* is a combination of users and administration groups. Settings associated with a user role apply only to devices that belong to users who have this role, and only if these devices belong to groups associated with this role, including child groups.

To add users, security groups, and administration groups to the scope of a user role, you can use either of the following methods:

Method 1:

1. In the main menu, go to **Users & roles** → **Users & groups**, and then select the **Users** or the **Groups** tab.
2. Select check boxes next to the users or security groups that you want to add to the user role scope.
3. Click the **Assign role** button.

   The Role assignment wizard starts. Proceed through the wizard by using the **Next** button.
4. On the **Select role** step, select the user role that you want to assign.
5. On the **Define scope** step, select the administration group that you want to add to the user role scope.
6. Click the **Assign role** button to close the window.

The selected users or security groups and the selected administration group are added to the scope of the user role.

Method 2:

1. In the main menu, go to **Users & roles** → **Roles**.
2. Click the name of the role for which you want to define the scope.
3. In the role properties window that opens, select the **Settings** tab.
4. In the **Role scope** section, click **Add**.

   The Role assignment wizard starts. Proceed through the wizard by using the **Next** button.
5. On the **Define scope** step, select the administration group that you want to add to the user role scope.
6. On the **Select users** step, select users and security groups that you want to add to the user role scope.
7. Click the **Assign role** button to close the window.
8. Click the **Close** button (×) to close the role properties window.

The selected users or security groups and the selected administration group are added to the scope of the user role.

Method 3:

1. In the main menu, click the Administration Server name.

   The Administration Server properties window opens.

2. On the **Access rights** tab, select the check box next to the name of the user or the security group that you want to add to the user role scope, and then click the **Roles** button.

   You cannot select multiple users or security groups at the same time. If you select more than one item, the **Roles** button will be disabled.

3. In the **Roles** window, select the user role that you want to assign, and then apply and save changes.

   The selected users or security groups are added to the scope of the user role.

Deleting a user role

To delete a user role:

1. In the main menu, go to **Users & roles** → **Roles**.
2. Select the check box next to the name of the role that you want to delete.
3. Then click the **Delete** button.
4. In the window that opens, click **OK**.

The user role is deleted.

Associating policy profiles with roles

You can associate user roles with policy profiles. In this case, the activation rule for this policy profile is based on the role: the policy profile becomes active for a user that has the specified role.

For example, the policy bars any GPS navigation software on all devices in an administration group. GPS navigation software is necessary only on a single device in the Users administration group—the device owned by a courier. In this case, you can assign a "Courier" role to its owner, and then create a policy profile allowing GPS navigation software to run only on the devices whose owners are assigned the "Courier" role. All the other policy settings are preserved. Only the user with the role "Courier" will be allowed to run GPS navigation software. Later, if another worker is assigned the "Courier" role, the new worker also can run navigation software on your organization's device. Running GPS navigation software will still be prohibited on other devices in the same administration group.

To associate a role with a policy profile:

1. In the main menu, go to **Users & roles** → **Roles**.
2. Click the name of the role that you want to associate with a policy profile.

   The role properties window opens with the **General** tab selected.

3. Select the **Settings** tab, and scroll down to the **Policies** section.

4. Click **Edit**.

5. To associate the role with:

   - **An existing policy profile**—Click the chevron icon (>) next to the required policy name, and then select the check box next to the profile with which you want to associate the role.

   - **A new policy profile**:

     a. Select the check box next to the policy for which you want to create a profile.

     b. Click **New policy profile**.

     c. Specify a name for the new profile and configure the profile settings.

     d. Click the **Save** button.

     e. Select the check box next to the new profile.

6. Click **Assign to role**.

The profile is associated with the role and appears in the role properties. The profile applies automatically to any device whose owner is assigned the role.

Multitenancy

Kaspersky EDR Expert supports a multitenancy mode. This mode enables the main administrator to provide the Kaspersky EDR Expert functionality to multiple clients independently, or to separate assets, application settings, and objects for different offices. Each client or office is isolated from others and is called a tenant.

Typically, the multitenancy mode is used in the following cases:

- A service provider has a number of client organizations and wants to provide the Kaspersky EDR Expert functionality to each client organization independently. To do this, the service provider administrator can create a tenant for each client organization.
- An administrator of a large enterprise might want to isolate assets, application settings, and objects for the offices or organization units and manage the offices or organization units independently. To do this, the administrator can create a tenant for each office or organization unit.

The multitenancy mode has the following features:

- Tenant isolation
- Cross-tenant scenarios

Tenant isolation

A tenant is isolated and managed independently from other tenants. Only users that have access rights to a tenant can work with and manage this tenant. An administrator of another tenant cannot gain access to the data, resources, and assets of a tenant, unless the main administrator explicitly grants the relevant access rights to such administrator.

For each tenant, you define a number of objects, including the following ones:

- Assets

  The asset list is unique for each tenant. Each asset can belong to one tenant only.
- Users and their access rights
- Events, alerts, and incidents
- Playbooks
- Integration with other Kaspersky applications, services, and third-party solutions

Cross-tenant scenarios

All tenants are arranged into a tenant hierarchy. By default, the tenant hierarchy contains a pre-created Root tenant at the top of the hierarchy. No other tenants can be created at the same level as the Root tenant. You create a new tenant as a child to any existing tenant, including the Root tenant. The tenant hierarchy can have any number of nesting levels.

The tenant hierarchy is used to provide cross-tenant scenarios, including the following ones:

- Inheritance and copying

  A child tenant receives the following objects from the parent tenant:

  - Users and their access rights

    Access rights are inherited down by the hierarchy and cannot be revoked on a lower level of the hierarchy.

  - Tenant settings, including integration settings

    Tenant settings are copied from a parent tenant to its child tenant. After the child tenant is created, you can reconfigure the copied settings to meet the requirements of the new tenant.

  > Aggregation and segmentation rules are inherited one level down the tenant hierarchy only. For example, a rule created in the Root tenant is inherited by the first-level child tenants, but not by their child tenants.

- Licensing

  A license key for Kaspersky EDR Expert is applied at the level of the primary Administration Server that is bound to the Root tenant. Then, the license key is automatically applied to all of the tenants in the hierarchy.

User role

Kaspersky EDR Expert provides you a predefined set of user roles. You grant user rights to manage tenants by assigning user roles to the users.

User role	User roles rights		
	Read	Write	Delete
Main administrator	✓	✓	✓
Tenant administrator	✓	✓	✓
SOC administrator	✓	✓	—
Tier 1 analyst	✓	—	—
Tier 2 analyst	✓	—	—
Junior analyst	✓	—	—
SOC manager	✓	—	—
Approver	✓	—	—
Auditor	✓	—	—
Interaction with child incidents	✓	—	—

Tenants and Administration Servers

You can bind only physical Administration Servers to tenants. A link between a tenant and an Administration Server allows you to combine features of both solutions—Kaspersky EDR Expert and Open Single Management Platform.

Tenant filter in the application interface

In the Kaspersky EDR Expert interface, you can configure object lists to display only those objects that relate to the tenants that you select. The tenant filter applies to the following objects:

- Alerts in the **Alerts** section
- Incidents in the **Incidents** section
- Events in the **Threat hunting** section
- Playbooks in the **Playbooks** section

When you apply the tenant filter, the new settings are applied to all of the object types across the interface of Console that you use (OSMP Console or KUMA Console).

About binding Administration Servers to tenants

You can bind Administration Servers to tenants. A link between a tenant and an Administration Server allows you to relate the assets managed by the Administration Server to the tenant.

> You cannot bind virtual Administration Servers to tenants, only physical ones.

Tenants can have subtenants; therefore they are arranged into a tenant hierarchy. Administration Servers can have secondary Administration Servers; therefore they are arranged into a Server hierarchy. You cannot bind an arbitrary Server to an arbitrary tenant because this may lead to an illegal binding. For example, a user may not have access rights to a tenant in the tenant hierarchy, but the same user may have access rights to the devices of this tenant. This might happen if this user has access rights to the Administration Server 2 which is primary to the Administration Server 1 bound to the tenant. Therefore, by default, this user has inherited access rights to the Administration Server 1 and its managed devices. To eliminate such a situation, tenants and Administration Servers can only be bound to each other according to the binding rules.

There are two types of bindings:

- Explicit binding

  This binding type is established when you select an Administration Server that you want to bind to a tenant.

- Inherited binding

  When you establish explicit binding for an Administration Server that has secondary Administration Servers, the secondary Administration Servers are bound to the tenant through the inherited binding type. Therefore several Administration Servers may be bound to a tenant.

Binding rules:

- The Root Administration Server is always bound to the root tenant. You cannot unbind it.
- A tenant may not have a bound Administration Server. Such a tenant can have subtenants, and Administration Servers can be bound to these subtenants.
- You can bind two Administration Servers which are arranged into a hierarchy only to two tenants which are arranged into a hierarchy too, and only if the hierarchy of Administration Servers matches the hierarchy of tenants.
- An Administration Server may be bound only to one tenant, explicitly or through the inherited binding type.
- When you bind an Administration Server to a tenant explicitly:
  - If the Administration Server was bound to another tenant explicitly, this binding is automatically removed.
  - If the Administration Server has secondary Administration Servers, the secondary Administration Servers are bound to the new tenant through the inherited binding type excluding those Administration Servers that were bound to their tenants explicitly. Before this operation, Kaspersky EDR Expert checks whether or not all of the new bindings are legal. If they are not, the binding cannot be established.
- When you remove an explicit binding between a tenant and an Administration Server (unbind Administration Server), the Administration Server and all of its secondary Administration Servers (if any) are automatically bound through the inherited binding type to the tenant to which the primary Administration Server of the selected Administration Server is bound. If some of the secondary Administration Servers are bound to their tenants explicitly, those Administration Servers keep their bindings.
- When you add a new Administration Server to the hierarchy, the Administration Server is automatically bound through the inherited binding type to the tenant to which the Server's primary Administration Server is bound.
- When you remove an Administration Server from the hierarchy and the Administration Server has an explicit binding to a tenant, this binding is removed.

Configuring integration with Open Single Management Platform

You can bind Administration Servers to tenants. A link between an Administration Server and a tenant allows you to relate the assets managed by the Administration Server to the tenant.

You cannot bind virtual Administration Servers to tenants, only physical ones.

Prerequisites:

- Make sure that you are familiar with the binding rules.
- You have created the tenant to which you want to bind an Administration Server.
- If required, you have added the secondary Administration Server that you want to bind to the tenant.

To bind an Administration Server to a tenant or unbind it from the tenant, you must have a role that grants the **Write** access right to the Tenants and Integrations functional areas.

Binding an Administration Server to a tenant

To bind an Administration Server to a tenant:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. On the **Settings** tab, in the **Kaspersky integrations** section, select **KSC**.

4. Click the **Bind Administration Server** button, and then in the window that opens, select an Administration Server that you want to bind to the tenant.

   If you want to add a new Server to the hierarchy or delete an existing one, you can do it in the Administration Server properties.

5. Click the **Bind** button.

The binding process may take a while. You can track this process in the **Binding status** column of the Administration Server list in the tenant properties window.

Unbinding an Administration Server from a tenant

To unbind an Administration Server from a tenant:

1. In the main menu, go to **Settings** → **Tenants**.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. On the **Settings** tab, select the check box next to the Administration Server that you want to unbind from the tenant, and then click the **Unbind** button.

Viewing and editing tenants

You can use tenants to provide the Kaspersky EDR Expert functionality to a client organization independently, or to separate assets, application settings, and objects for different offices.

To view or edit a tenant's properties:

1. In the main application window, go to the **Settings** → **Tenants** section.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Click the name of the required tenant.

   The tenant's properties window opens. If you have only **Read** access right to this tenant, the properties will be opened in read-only mode. If you have the **Write** access right, you will be able to modify the tenant's properties.

3. Modify the tenant's properties, and then click the **Save** button.

   You can click the **Save and Close** button to save changes and close the tenant's properties window.

The tenant's properties are modified and saved.

Common

The **General** tab contains general information about the tenant. You can modify the tenant's name and description.

Settings

The **Settings** tab contains the following sections:

- **Kaspersky integrations**

  This section allows you to configure integration settings for the Kaspersky applications that you want to integrate into Kaspersky EDR Expert for the current tenant.

- **Third-party integrations**

  This section allows you to configure integration settings for third-party applications that you want to integrate into Kaspersky EDR Expert for the current tenant.

- **Analysis and response**

  This section allows you to configure settings and objects related to threat detection and response:

  - Segmentation rules
  - Aggregation rules
  - Mail server connection

- Asset audit
- Network Share Credentials
- Email templates
- Scanning settings
- Assets settings
  - Retention period for archived assets
  - Custom asset fields
  - **KSC assets import**

    All assets that are protected by this program are registered in Kaspersky Security Center. Information about assets protected by Kaspersky Security Center can be imported into KUMA. To do so, you need to configure integration between the applications in advance.

    KUMA imports the following device information received from Kaspersky Security Center Network Agents:

    - Basic information about the asset: name, address, time of connection to Kaspersky Security Center, hardware information, protection status, anti-virus database versions
    - Information about asset attributes: vulnerabilities; software, including the operating system; owners of the asset

    To import information about the Kaspersky Security Center assets:

    1. In the main menu, navigate to **Asset management** → **Assets (Devices)** → **Analysis and response**.
    2. Click **Import**, and then select one of the following actions:
       - To import information about the basic attributes of assets, click **Import KSC assets**.

         This opens the **Import KSC assets** window.
       - To import information about other attributes of assets, click **Import KSC assets attributes**.

         This opens the **Import KSC assets attributes** window.
    3. In the drop-down list, select the tenant for which you want to perform the import.

       In this case, the program downloads information about all assets of all Kaspersky Security Center servers that have been configured to connect to the selected tenant.

       If you want to import information about all assets of all Kaspersky Security Center servers for all tenants, select **All**.
    4. Click the **Import** button.

    The asset information will be imported.

Also, in a tenant properties window, you can schedule regular import of asset information or run import manually.

- KICS/KATA assets import

- KPSN reputation database
- Retention period

  Retention periods for alerts and incidents depend on the Kaspersky EDR Expert license that you use.
- Incident management

You do not need to configure the settings of the shared tenant.

Roles

The **Roles** tab lists the users who have access rights to the tenant. You can change this list and assign user roles to the users.

Adding tenants

Prerequisites, read general information about tenants.

To add child tenants, you must have the **Read** and **Write** rights in the **Tenants** functional area on the parent tenant or on a tenant of a higher level in the tenant hierarchy.

To add a new tenant:

1. In the main application window, go to the **Settings** → **Tenants** section.
2. Select the check box next to the parent tenant. The new tenant will be created as a child to the selected tenant.
3. Click **Add**.
4. In the **Add tenant** window that opens, enter the name of the new tenant.
5. If necessary, add a description for the new tenant.
6. Click **Add**.

The new tenant appears in the tenant list.

A child tenant inherits the following objects from the parent tenant:

- Users and their access rights
- Integration settings

After a tenant is created, you can reconfigure the inherited objects to meet the requirements of the new tenant.

Assigning roles to users and groups in a tenant

You can assign EDR roles to the Kaspersky EDR Expert users and domain groups to provide them with sets of access rights in a tenant.

To do this, you must have one of the following EDR roles in the tenant in which you want to assign roles to users: Main administrator, SOC Administrator, or Tenant Administrator.

Since tenants are isolated and managed independently from other tenants, only users who have assigned access rights to the tenant can work within this tenant and manage it.

Access rights are inherited down in the hierarchy and cannot be revoked on a lower level of the hierarchy.

New internal user accounts in the OSMP Console become available for addition and role assignment in the tenant within five minutes after the account is created.

The rights of a user are the sum of the user's own rights and the rights of the domain groups to which the user belongs, if any. This is true when the user is included in a group directly or indirectly through the membership in a nested group. For example, if a user is a member of group A and this group is nested inside group B, then the user's rights amount to the set of rights assigned to this user and the rights assigned to groups A and B. This means that if you assign rights to group B, its nested groups and users belonging to group B inherit these rights.

However, in the case of circular group nesting, the members of the circle as well as their child groups do not inherit the rights assigned to their parent groups.

To assign roles to a user or a domain group in a tenant:

1. In the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed on the screen.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Go to the **Access rights** tab, and then select **Users** or **Groups**, depending on to whom you want to assign roles.

   The table of users or domain groups is displayed.

4. If necessary, configure the table:

   - Click the filter icon ( ), and then specify and apply the filter criterion in the invoked menu.

     You cannot apply a filter to the **Group roles** and **Parent group roles** columns.

   - Click the settings icon (⚙) to configure the columns display.

5. Click the **Add user** button or the **Add group** button, depending on the tab you selected at step 3.

6. In the window that opens, do one of the following:

   a. If at step 3 you selected the **Users** tab, in the **User** field, enter the user name or email address. If at step 3 you selected the **Groups** tab, in the **Group** field, specify the group name.

   b. Select the check boxes next to the roles that you want to assign to the user or the domain group.

      You can select several roles, if necessary.

   c. Click **Add**.

   The window is closed, and the user or the domain group is displayed in the list.

7. Click the **Save** button.

   The user or the domain group is added to the tenant and assigned roles. If necessary, you can edit the roles by clicking the user or the domain group name, and then performing the actions described at steps 6–7.

Deleting tenants

You can delete only one tenant at a time. However, if the selected tenant has child tenants, they will be deleted as well. The playbooks related to the tenant will be deleted, and information about alerts and incidents related to the tenant will become unavailable.

When you delete a tenant in OSMP Console, the following changes occur in KUMA Console:

- Tenant and its resources are deleted. Assets of the deleted tenant are archived and removed when the TTL term of the archived asset expires.
- Storage partitions related to the tenant are deleted.
- Raw events become unavailable.
- Services status of the deleted tenants change to **Gray**.

To delete a tenant, you must have the **Read** and **Write** rights in the **Tenants** functional area on the selected tenant.

You cannot delete the Root tenant and the Shared tenant that was migrated from Kaspersky Unified Monitoring and Analysis Platform.

To delete a tenant:

1. In the main application window, go to the **Settings** → **Tenants** section.

   The tenant filter opens. The list contains only the tenants to which you have at least the **Read** access right.

2. Select the check box next to the tenant that you want to delete. If the selected tenant has child tenants, they will be selected automatically and you cannot unselect them.

3. Click the **Delete** button.

4. Confirm the operation by typing the name of the tenant that you want to delete. If the tenant has child tenants, they are listed as tenants to be deleted as well.

The selected tenant, its child tenants (if any), and related objects are deleted.

Configuring email notifications

You can configure email notifications about events occurring in Kaspersky EDR Expert via Kaspersky Security Center Administration Server and an external SMTP server. To do this, you must configure connection settings to an SMTP server.

To configure SMTP server connection:

1. In the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed on the screen.

2. Click the name of the required tenant.

   This opens the tenant properties window.

3. Go to the **Settings** tab and click **Mail server connection**.

4. In the right pane, click the **View properties** button.

   The Administration Server properties window opens with the **General** tab selected.

   > The window displays properties of the primary Administration Server and SMTP settings for the primary Administration Server, no matter to which Administration Server the tenant is bound.

5. Configure the parameters, as described at step 2 in Configuring notifications delivery.

After you configure connection to an SMTP server, the users will start receiving email messages from Kaspersky EDR Expert.

You can create email notifications templates that are sent to users when triggered by the specific alerts, incidents, or events. These templates can also be edited and deleted.

Creating a notification template

After you configure email notifications about events occurring in Kaspersky EDR Expert, you can create custom templates for these email notifications.

To create notifications templates, you must have one of the following EDR roles: Main administrator, Tenant administrator, or SOC administrator.

When you deploy Kaspersky EDR Expert, you have the templates for email notifications in the Root tenant. If you create a child tenant, it automatically copies the settings from the parent tenant. Since child and parent settings are not related, the changes you make in a child tenant settings do not affect the settings in the parent tenant, and vice versa.

To create an email notification template:

1. In the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Go to the **Settings** tab, and then in the **Analysis and response** section, click **Email templates**.

   The table of the event types for which you can configure notifications templates is displayed.

4. If at step 2 you selected the Root tenant, in the **Administration Server display name** field, enter the address to be used in links to alerts and incidents in the email messages.

5. Click the **Create** button and in the drop-down list that opens, select the event type for which you need to create an email notification template.

6. In the **Create email template** panel that opens, specify the following settings:

   The available fields vary depending on the selected event type.

   - In the **Name** field, specify the name of the email notification template.
   - If you want to change the event type of the email notification template, select a new one in the **Event type** field.
   - If you want to enable an email notification for the selected event type, move the toggle button to the **Enabled** position in the **Status** field.

     You can also enable email notifications from the table of the event types. By default, email notifications are disabled.

- In the **Subject** field, specify the subject of the email notification. Required field.

  You can also use the alert fields, incident fields, and KUMA normalized event fields in the **Subject** field, for example, `New incident in OSMP: {{ .InternalID }}, {{ .Name }}`.

- In the **Template** field, write an email notification message.

  Example of an email notification message

  ```
  Hello,<br>
  <br>
  Alert {{ .InternalID }}{{ with escapeHTML .Rules.Names }} "{{ . }}"{{ else }}{{ end }} was registered at {{
  .CreatedAt }}.<br>
  <br>
  Details on alert:<br>
  <br>
  Tenant: {{ .TenantID }}<br>
  Alert severity: {{ .Severity }}<br>
  Alert first seen: {{ .FirstEventTime }}<br>
  Alert last seen: {{ .LastEventTime }}<br>
  Full information about the alert is available in OSMP web-interface: {{ link_alert . }}<br>
  <br>
  Open Single Management Platform
  ```

  You can also use alert fields, incident fields, KUMA normalized event fields, and HTML tags.

  When writing a template, you can use the following functions:

  - `date`—Defines the date and time format. The function takes the time in milliseconds (UNIX time) as the first parameter. The second parameter can be used to pass the time in the RFC standard format. The time zone cannot be changed.

    ```
    {{range .Events }}
    Service name: {{.Event.ServiceName}}
    Device host name: {{.Event.DeviceHostName}}
    Message: {{.Event.Message}}
    {{end}}
    ```

    Nested objects can have their own nested objects. You can access them using nested range functions.

  - `limit`—Limits the number of objects returned by the `range` function.

  - `link_alert`—Generates a link to the alert, with the URL specified in the **Administration Server display name** field.

  - `link_incident`—Generates a link to the incident, with the URL specified in the **Administration Server display name** field.

  - `link`—Takes the form of a link that the user can open when he/she receives the notification email.

- In the **Recipients** field, specify or select one or more email addresses for sending notifications.

- In the **Correlation rules** drop-down list, select one or more correlation rules according to which the email notification will be sent.

- In the **Notify based on severity level** field, select the minimum severity of the alert that triggers the email notification. Alerts with a severity below the specified level will not trigger an email notification.

- In the **Detection technologies** drop-down list, select one or several detection technologies that will trigger an email notification.
- If necessary, in the **Description** field, write a description of notification template.

7. Click the **Create** button.

   The **Create email template** window is closed.

8. In the tenant's properties window, save the changes.

The email notification template is created and saved. When the selected types of events occur in Kaspersky EDR Expert, email notifications are sent to the email addresses that you specified.

Editing and deleting a notification template

You can edit or delete an email notification template about events occurring in Kaspersky EDR Expert.

To edit or delete a notification template, you must have one of the following EDR roles: Main administrator, Tenant administrator, or SOC administrator.

When you deploy Kaspersky EDR Expert, you have the templates for email notifications in the Root tenant. If you create a child tenant, it automatically copies the settings from the parent tenant. Since child and parent settings are not related, the changes you make in a child tenant settings do not affect the settings in the parent tenant, and vice versa.

To edit an email notification template:

1. In the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Go to the **Settings** tab and click **Email templates**.

4. In the **Event type** column of the table, click the event type of the notifications template that you want to edit.

5. In the **Edit email template** window that opens, change the necessary settings.

6. Save your changes.

   The **Edit email template** window is closed.

7. Save your changes.

The email notification template is edited and saved. When the selected types of events occur in Kaspersky EDR Expert, the template notification is sent to the email addresses that you specified.

To delete an email notification template:

1. In the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Go to the **Settings** tab and click **Email templates**.

4. Select the check box next to the notification template that you want to delete.

5. Click the **Delete** button.

6. In the window that opens, confirm the deletion.

The email notification template is deleted.

Configuring automatic rotation of files in the Files repository

Automatic rotation of files is ensured by limiting the space of the **Files** repository: upon reaching the limit, the oldest files in the repository are deleted. If you do not specify the limit, you will not be able to upload new files to the **Files** repository after you run out of the space allocated for the repository when deploying Kaspersky EDR Expert.

For example, during the deployment procedure 20 GB of disk space was allocated for the **Files** repository. Then, in the tenant settings you specified 10 GB as a limit at which the oldest files in the **Files** repository will be deleted. If you didn't specify any limit, you will not be able to upload files to the **Files** repository upon reaching 20 GB.

To configure automatic rotation of files in the Files repository:

1. In the main menu, go to **Settings** → **Tenants**.

   The list of tenants is displayed on the screen.

2. Click the name of the required tenant.

   The tenant's properties window opens.

3. Go to the **Settings** tab, and then in the **File rotation** section, do the following:

   a. In the **Automatic file rotation** field, switch the toggle button to the **Enabled** position.

   b. In the Maximum storage limit field, specify the files volume at which the oldest files will be deleted from the **Files** repository.

      The minimum value is 1 GB.

   c. Click **Save** or **Save and close** to save the settings.

The automatic file rotation is enabled and configured.

Backup copying and restoration of Kaspersky EDR Expert data

Data backup allows you to save a full copy of Kaspersky EDR Expert data. During the backup process, the operation of Kaspersky EDR Expert components are temporarily suspended to ensure data consistency. After the backup is created, it is saved in the network folder on a separate server, and then the solution resumes its functioning. You can create a backup manually or according to the specified schedule.

Following this scenario, you can configure the backup storage, set up the scheduled backup or create a backup manually, manage your backups, and restore Kaspersky EDR Expert data from the backup.

Limitations:

- During the backup process, the operation of Kaspersky EDR Expert components are temporarily suspended to ensure data consistency.
- The backup includes all Kaspersky EDR Expert data. Creating a backup or restoring data of an individual component are not supported.
- Restoring Kaspersky EDR Expert data from the backup must be performed by using the same version of Kaspersky EDR Expert in which the backup was created.
- Backing up and restoring Kaspersky EDR Expert data is supported only if the DBMS is not included in the Kubernetes cluster. Configuration where the DBMS is installed into the Kubernetes cluster is used only to get acquainted with the solution, not to solve standard work tasks.
- Free space for a backup is not checked automatically. You have to make sure that you have enough free space in the network folder.

Stages

The backup copying and restoration of Kaspersky EDR Expert data proceeds in stages:

1. **Configure the backup storage**

   Specify the path to the network folder for storing backups. This network folder must be located on a separate server and must be available from the Kubernetes cluster by using the CIFS or NFS protocol.

   To prevent an overload of the network folder, the maximum number of backups that can be stored in the network folder is limited. By default, you can create up to 10 backups. You can set the maximum number of backups by using the `backup_retain` parameter when creating a backup manually or when configuring a backup schedule. If the network folder already contains the maximum number of backups, the next backup will overwrite the oldest one.

   Because the available space in the network folder isn't checked automatically, we recommend regularly monitoring the free space in this folder to prevent backup failures.

2. **Create a backup copy of Kaspersky EDR Expert data**

Use one of the following ways to create a backup:

- Scheduled backup

  If you want to create backups according to a schedule, you have to configure the schedule by using KDT. You can specify only one backup schedule. Creating a new schedule will replace the existing one. Additionally, you can view the current schedule, and pause or resume automatic backups.

  Before using the automatic scheduled backup, we recommend creating a backup manually to ensure that the network folder for storing backups is configured correctly and is accessible.

- Manual backup

  If you need to save a backup without waiting for the next automatic backup, you can create a manual backup.

A backup is saved to the specified network folder. You can view the list of available backups and details of each backup.

KDT logs provide detailed information about the results of the backup operation, including its success or failure, the date and time of execution, and the name and location of the backup copy.

3. **Restore Kaspersky EDR Expert data from the backup copy**

   Restore the backup copy to roll back Kaspersky EDR Expert to a saved state.

Configuring the storage for a Kaspersky EDR Expert backup copy

All created backups are stored in the network folder on a separate server. This folder must be available from the Kubernetes cluster by using the CIFS or NFS protocol.

> Free space for a backup is not checked automatically. You have to make sure that you have enough free space on the network resource.

To prevent an overload of the network folder, the maximum number of backups that can be stored in the network folder is limited. By default, you can create up to 10 backups. You can set the maximum number of backups by using the `backup_retain` parameter when creating a backup manually or when configuring a backup schedule. If the network folder already contains the maximum number of backups, the next backup will overwrite the oldest one.

Specifying the path to the network folder for backup storage

To specify the backup storage path accessible via the CIFS/SMB protocol,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a setBackupStore \
--param backup_target_url="cifs://<host>/<path>" \
--param cifs_username="<username>" \
--param cifs_password="<password>"
```

where:

- < host > is the address of the network storage server.
- < path > is the path to the backup network folder.
- < username > is the user name for accessing the network folder.
- < password > is the password for accessing the network folder.

  If the password contains double quotes, escape them with backslashes (\").

To specify the backup storage path accessible via the NFS protocol,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a setBackupStore --param backup_target_url="nfs://<host>:/<path>"
```

where:

- < host > is the address of the network storage server.
- < path > is the path to the backup network folder.

The path to the network folder for backup storage is specified.

Viewing the path to the network folder for backup storage

To view the current backup storage path,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a getBackupStore
```

The current backup storage path is displayed.

Configuring and managing the backup schedule

Kaspersky EDR Expert allows you to create backups according to a schedule, view the current schedule, pause or resume scheduled backups, and delete the schedule.

You can configure only one backup schedule. Creating a new schedule will replace the existing one.

Before using the scheduled backup, we recommend creating a backup manually to ensure that the network folder for storing backups is configured correctly and is accessible.

Configuring the backup schedule

To configure the backup schedule,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a updateSchedule \
--param schedule='<schedule>' \
--param schedule_paused=<schedule_is_paused> \
--param backup_retain=<max_number_of_backups>
```

where:

- `<schedule>` is a line in the UNIX cron format that specifies the frequency of backups. For example, if you want to create a backup at 9:30 AM on the 1st and 15th of each month, and every Monday, use the following command:

  `./kdt invoke backup-operator -a updateSchedule --param schedule='30 9 1,15 * 1' --param schedule_paused=false --param backup_retain=5`

  The format correctness is validated: if you enter an incorrect parameter, an error message is displayed.

- `<schedule_is_paused>` is a parameter that specifies the state of the scheduled backup after the schedule is created:

  - `<schedule_is_paused>=false`—Scheduled backup is active and will run as configured.
  - `<schedule_is_paused>=true`—Scheduled backup is paused and will not run.

- `<max_number_of_backups>` is the maximum number of backups that can be stored in a network folder. The default value is 10. If the network folder already contains the maximum number of backups, the next backup will overwrite the oldest one. If you reduce the parameter value (for example, set `<max_number_of_backups>` to `3` when creating a backup manually or when configuring a backup schedule), KDT will delete all backups except the three most recent ones.

The backup schedule is configured.

View the details of the backup schedule

To view the details of the backup schedule,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a getBackupSchedule
```

The configured backup schedule details are displayed, including the schedule name shown in the `NAME` column.

Pausing the scheduled backup

To pause the scheduled backup,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a updateSchedule --param schedule_paused=true
```

The scheduled backup is paused.

Resuming the scheduled backup

To resume the scheduled backup,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a updateSchedule --param schedule_paused=false
```

The scheduled backup is resumed.

Create a backup copy of Kaspersky EDR Expert data

If you need to save a backup without waiting for the next automatic backup, or ensure that the network folder for storing backups is configured correctly and is accessible, you can create a manual backup. During the backup process, the operation of Kaspersky EDR Expert components are temporarily suspended to ensure data consistency.

To create a backup manually,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a createBackup --param backup_retain=
<max_number_of_backups>
```

where `<max_number_of_backups>` is the maximum number of backups that can be stored in a network folder. The default value is 10. If the network folder already contains the maximum number of backups, the next backup will overwrite the oldest one. If you reduce the parameter value (for example, set `<max_number_of_backups>` to `3` when creating a backup manually or when configuring a backup schedule), KDT will delete all backups except the three most recent ones.

The created backup copy is saved to the configured network folder. KDT logs provide detailed information about the results of the backup operation, including its success or failure, the date and time of execution, and the name and location of the backup copy.

Viewing the backups of Kaspersky EDR Expert data

View the list of backups

To view the list of backups,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a listBackups
```

The list of backups is displayed. The list shows the backup size, status, date and time of backup execution, as well as the backup name shown in the `NAME` column and the unique backup identifier shown in the `BACKUPID` column.

View the details of the backup

To view the details of the backup,

On the administrator host, run the following command:

```
./kdt invoke backup-operator -a describeBackup --param backup_id='<backup_name>'
```

where `<backup_name>` is the backup name that is displayed in the `NAME` column in the list of the backups.

The details of the backup are displayed.

If necessary, you can delete backups by using a custom action. To do this, on the administrator host where the KDT utility is located, run the following command:

```
./kdt invoke backup-operator -a deleteBackup --param
backup_id='01kp2qkprmwaajpd8cgy3zeqbt'
```

Restore Kaspersky EDR Expert data from the backup copy

Before restoring data, ensure that you use the same version of Kaspersky EDR Expert in which the backup was created.

Backing up and restoring Kaspersky EDR Expert data is supported only if the DBMS is not included in the Kubernetes cluster. Configuration where the DBMS is installed into the Kubernetes cluster is used only to get acquainted with the solution, not to solve standard work tasks.

To restore the Kaspersky EDR Expert data from the backup copy,

On the administrator host, run the command:

```
./kdt invoke backup-operator -a restoreFromBackup --param backup_id='<backup_id>'
```

where `<backup_id>` is the unique backup identifier that is displayed in the `BACKUPID` column in the list of the created backups.

Kaspersky EDR Expert data is restored from the backup. In log files, KDT outputs information about the success or failure of the restore operation and its total duration time.

To view the status of Kaspersky EDR Expert data restoration from a backup copy,

On the administrator host, run the command:

```
./kdt invoke backup-operator -a restoreStatus
```

Kaspersky EDR Expert API

Kaspersky EDR Expert allows you to work with REST API and OpenAPI.

Working with REST API

By using the API, you can access Kaspersky EDR Expert from third-party solutions. REST API operates over HTTP and consists of a set of request/response methods.

REST API Help Swagger: EDR

REST API Help Swagger: KUMA

On the Swagger page, use the **Select a definition** drop-down list to switch between KUMA and EDR (OSMP) API sets.

REST API requests must be sent to the following address:

https://<api_host>.<smp_domain>/xdr/api/v1/<request>

https://<api_host>.<smp_domain>/xdr/api/v3/kuma/<request> (for KUMA-specific API)

Where the <smp_domain> parameter is the service domain name specified in the configuration file during the Kaspersky EDR Expert deployment.

Example:

https://api.example.com/xdr/api/v1/

https://api.example.com/xdr/api/v3/kuma/ (for KUMA-specific API)

Since REST API requests must be authorized, you have to create a token.

Working with OpenAPI

OpenAPI allows you to automate and customize the management of Administration Server by using scripts. OpenAPI can also be used to develop custom client applications that interact with Kaspersky EDR Expert over HTTP by using JSON-based synchronous requests and responses.

OpenAPI requests must be sent to the following address:

https://api.<smp_domain>:13299

Where the <smp_domain> parameter is the service domain name specified in the configuration file during the Kaspersky EDR Expert deployment.

Example:

https://api.example.com:13299

API methods unavailable under the EDR license

The following methods are unavailable under the EDR license:

- Methods for managing assets:
  - `GET /xdr/api/v3/kuma/assets`
  - `POST /xdr/api/v3/kuma/assets/import`
  - `POST /xdr/api/v3/kuma/assets/delete`
- Methods for managing settings:
  - `GET /xdr/api/v3/kuma/settings/id/{id}`
  - `GET /xdr/api/v3/kuma/settings/extendedFields/export`
  - `POST /xdr/api/v3/kuma/settings/extendedFields/import`
- Methods for managing services:
  - `POST /xdr/api/v3/kuma/services/create`
- Methods for managing incidents:
  - `GET /xdr/api/v1/incident/workflows/tenants`
  - `GET /xdr/api/v1/incidents/types/usage`

Creating a token

To generate a user API token:

1. In the main menu, go to **Settings** → **API Tokens**.
2. Click the **Add token** button.
3. In the **Add token** panel, configure the token options:
   a. Click **Expiration date** and use the calendar to specify the expiration date. If you want to disable automatic expiration for the token, select the **No expiration date** check box.

The maximum expiration date range is 365 days.

> We recommend that you enable automatic expiration for tokens that have access to POST methods.

b. Select check boxes next to the API methods you want to allow access to.

In addition to API methods, you can select the purpose of creating a token:

- POST:DynamicClientRegistration for dynamic registration of OAuth clients.
- POST:KSCOpenAPI for OpenAPI authentication using API tokens.

4. Click the **Generate** button.
5. Click **Copy and close**.

> You will not be able to copy the token later.

The token is created and copied to the clipboard. Save the token in any convenient way.

Authorizing API requests

Each API request must include token-based authorization. The user whose token is used to make the API request must have the permissions to perform this type of request.

Each request must be accompanied by the following header:

```
Authorization: Bearer <token>
```

Possible errors

HTTP code	Description	`message` field value
400	Invalid header	invalid authorization header
403	The token does not exist or the owner user is disabled	access denied

Contact Technical Support

This section describes how to get technical support and the terms on which it is available.

How to get technical support

If you did not find a solution to your problem in the documentation or other sources of information about Open Single Management Platform, we recommend contacting Technical Support. Technical Support specialists will answer all your questions about installing and using Open Single Management Platform.

Kaspersky provides support of Open Single Management Platform during its lifecycle (see the application support lifecycle page). Before contacting Technical Support, please read the support rules.

You can contact Technical Support in one of the following ways:

- By visiting the Technical Support website
- By submitting a request to Kaspersky Technical Support from the Kaspersky CompanyAccount portal.

Technical support via Kaspersky CompanyAccount

Kaspersky CompanyAccount is a portal for companies that use Kaspersky applications. The Kaspersky CompanyAccount portal is designed to facilitate interaction between users and Kaspersky specialists through online requests. On the Kaspersky CompanyAccount portal, you can track the status of online requests of Kaspersky specialists and store a history of them.

You can register all of your organization's employees under a single account on Kaspersky CompanyAccount. A single account lets you centrally manage electronic requests from registered employees to Kaspersky and also manage the privileges of these employees via Kaspersky CompanyAccount.

The Kaspersky CompanyAccount portal is available in the following languages:

- English
- Spanish
- Italian
- German
- Polish
- Portuguese
- Russian

- French
- Japanese

To learn more about Kaspersky CompanyAccount, visit the Technical Support website.

Known issues and limitations

Minimum hardware requirements have been increased compared to the previous version of Kaspersky EDR Expert. The solution requires at least 12 CPU cores and at least 32 GB RAM.

OSMP limitations

OSMP has the following limitations:

- 10721464: When EDR is disabled and an asset is moved to KATA, the asset keeps the "EDR" value in the **Asset source** column of the asset table (**Assets (Devices)** → **Analysis and response**). This may prevent KATA responses from being enacted.
- 9495472: If you plan to use multiple tenants in your infrastructure, create a separate collector for each tenant.
- 9792316: In the Administration Server properties window, the **Two-factor authentication** tab displays the **Users allowed to generate secret keys** table. Since all users are allowed to generate secret keys, the table is unreasonable.
- 7208621: When you import the *Download updates to the repositories of distribution points* or *Update verification* task the **Select devices to which the task will be assigned** option is enabled. These tasks cannot be assigned to a device selection or specific devices. If you assign the *Download updates to the repositories of distribution points* or *Update verification* task to specific devices, the task will be imported incorrectly.
- 6822204: The notifications about new versions of web plug-ins that are available to download are disabled. You can update the plug-ins by using Kaspersky Deployment Toolkit.
- 6919635: After creating a new tenant, the alerts related to the tenant are sent to the server, but not displayed in the alert table. You may need to refresh the webpage to update the table data.
- The Get NTFS metafiles response action does not return alternate streams of the requested metafiles if their primary stream is missing.
- The Run program response action, when run on Linux devices, does not allow the use of wildcards (in particular, the '*' character) in the file path.
- To deploy the application on the KVM virtual platform, you need to install the KVM hypervisor based on the Debian GNU/Linux 12 operating system using QEMU 8.0.2.
- Data migration directly from Kaspersky EDR Expert 7.1 to version 8.2 is not supported. It is required to migrate data to Kaspersky EDR Expert 8.1, and then upgrade the solution to version 8.2.
- 10419403: Up to 1000 threat hunting events can be obtained and exported via Kaspersky EDR Expert web interface or API.
- 10079501: When using a hierarchy of instances, permissions assigned in Kaspersky Security Center are not replicated from the parent instance to child instances. To ensure correct operation, manually assign the required permissions to replicated users on each child instance.

- 10042351: When you get a memory dump for a process with a memory footprint of 3 GB or more, the response action is launched but does not complete.
- 10421874: Raw logs are disabled in all normalizers to reduce storage size, so queries cannot search across every event field.
- 10420850: After Active Directory synchronization, logging into the OSMP Console may display a message about incorrect configuration, and a subsequent reboot can result in a `no healthy upstream` error.
- 10420739: Issues with free space in the Administration Server database may occur due to a cyclical dependence of domain groups.
- 10419715: KUMA within OSMP does not support Kaspersky Smart II license. To use this license, deploy KUMA as a standalone component and Kaspersky EDR Expert separately.
- 10408974: When using the KIAkOAPI package, Bearer token authentication is not included in the request headers, which can cause API calls to fail with a `401 Unauthorized` error. A custom Bearer token must be added manually to the Authorization header.
- 10408469: Integration with Kaspersky Endpoint Agent 3.16 and 4.0 is not supported.
- 10404511: If a playbook includes an action that is not covered by the current license, the playbook will be marked as unavailable.
- 10403607: When integration with Kaspersky Security Center is enabled, occasional connectivity interruptions may prevent the secondary Administration server from reaching the primary Administration server. Additionally, in the **Assets (Devices)** section, only the **General** tab is available while other tabs remain unavailable. It is recommended to verify that the connection settings are correct, the certificates on each Administration servers are valid, and the hierarchy is configured correctly.
- 10360014: If raw events cannot be accessed, you can view field values in the web interface. The raw event field names are identical to those shown in the web interface. Detailed field descriptions are available in the Help.
- A collector cannot be created without a Kaspersky Next XDR Expert license.
- Without a Kaspersky Next XDR Expert license, the export of raw telemetry data is performed incorrectly.

Sandbox limitations

The Sandbox component has the following limitations:

- By default, the maximum size of a file scanned by the Sandbox module is 100 MB. You can configure scan settings in the administrator menu of the application management console.
- The maximum level of nesting for scanned archives is 32.
- The maximum number of objects that can be in queue to be scanned by the Sandbox component per day is 20,000 objects. When this limit is reached, the application deletes 10% of the objects that have been queued for scanning the longest and replaces them with new objects queued for scanning. The deleted objects are saved in the application with the NOT_SCANNED status.

Glossary

Administrator device

A physical or virtual machine that is used to deploy and manage the Kubernetes cluster and Kaspersky EDR Expert by using KDT. KDT runs on the administrator host. If the administrator host is not included in the Kubernetes cluster, it will be used only for deployment. If the administrator host is included in the cluster, it will also act as a target host that is used for operation of Kaspersky EDR Expert components.

Alert

An event in the organization's IT infrastructure that was marked by Open Single Management Platform as unusual or suspicious, and that may pose a threat to the security of the organization's IT infrastructure.

Anti-Malware Engine

Components that scans files and objects for viruses and other threats using anti-virus databases. After scanning, Anti-Malware Engine may send an object for additional analysis to Sandbox and YARA module.

Asset

A device or user of the infrastructure to be protected. If an alert or incident is detected on an asset, you can perform response actions for this asset.

Bootstrap

The basic execution environment that includes the Kubernetes cluster and infrastructure components for the function of Kaspersky EDR Expert. Bootstrap is included in the transport archive and it is automatically installed the during deployment of Kaspersky EDR Expert.

Collector

A KUMA service that receives messages from event sources, processes them, and then transmits them to a storage, correlator, and/or third-party services to identify alerts.

Configuration file

A file in the YAML format that contains the list of target hosts for the Kaspersky EDR Expert deployment and a set of installation parameters of the Kaspersky EDR Expert components. Configuration file is used by KDT.

Context

A set of access parameters that define the Kubernetes cluster that the user can select to interact with. The context also includes data for connecting to the cluster by using KDT.

Correlation rule

A KUMA resource used to recognize the defined sequences of processed events and perform specific actions after recognition.

Correlator

A KUMA service that analyzes normalized events.

Custom actions

KDT commands that allows you to perform additional operations specific to the Kaspersky EDR Expert components.

Distribution package

An archive that contains the transport archive with Kaspersky EDR Expert components and End User License Agreements for Kaspersky EDR Expert and KDT, as well as the archive with the KDT utility and templates of the configuration file and KUMA inventory file.

EPP application

An application included in a protection system for endpoint devices (Endpoint Protection Platform, or EPP). EPP applications are installed to endpoint devices within an enterprise IT infrastructure (such as mobile devices, computers or laptops). One example of an EPP application is Kaspersky Endpoint Security for Windows included in the EPP solution known as Kaspersky Endpoint Security for Business.

Event

Information security events registered on the monitored elements of the organization's IT infrastructure. For example, events include login attempts, interactions with a database, and sensor information broadcasts. Each separate event may seem uninformative, but when considered together they form a bigger picture of network activities to help identify security threats.

Incident

A container of alerts that normally indicates a true positive issue in the organization's IT infrastructure. An incident may contain a single or several alerts. By using incidents, analysts can investigate multiple alerts as a single issue.

Investigation graph

A visual analysis tool that shows the relationships between events, alerts, incidents, observables, and assets (devices). Also, the investigation graph displays the details for an incident: the corresponding alerts, users, assets and their common properties.

Kaspersky Deployment Toolkit

A utility used to deploy and manage a Kubernetes cluster, Kaspersky EDR Expert components, and management web plug-ins. KDT runs on the administrator host and connects to target hosts via SSH.

Kubernetes cluster

A set of hosts combined by means of Kubernetes into one computing resource. The Kubernetes cluster is used for the function of Kaspersky EDR Expert components (except for KUMA services). The Kubernetes cluster can include both target hosts and the administrator host.

KUMA inventory file

A file in the YAML format that contains the parameters for installation of the KUMA services that are not included in the Kubernetes cluster. The path to the KUMA inventory file is included in the configuration file that is used by KDT for the Kaspersky EDR Expert deployment.

KUMA services

The main components of KUMA that help the system to manage events. Services allow you to receive events from event sources and subsequently bring them to a common form that is convenient for finding correlation, as well as for storage and manual analysis. KUMA services are collectors, correlators, and storages.

Lightweight Nagent (LWNGT)

A protocol for interaction with Kaspersky Endpoint Security on mobile devices. The LWNGT (also called Mobile protocol) functions as Network Agent without actually installing Network Agent on mobile devices.

Multitenancy

A mode that enables the main administrator to provide the Kaspersky EDR Expert functionality to multiple clients independently, or to separate assets, application settings, and objects for different offices. Also the multitenancy mode allows you to copy and inherit tenant settings and objects from the parent tenant and automatically apply a license key for Kaspersky EDR Expert to all of the tenants in the hierarchy.

Network Agent

An Open Single Management Platform component that enables interaction between the Administration Server and Kaspersky applications that are installed on a specific network node (workstation or server). This component is common to all of the company's applications for Microsoft® Windows®. Separate versions of Network Agent exist for Kaspersky applications developed for Unix-like OS and macOS.

Network Location Awareness (NLA)

A Windows service that helps an operating system identify the current network. NLA detects network changes and adjusts the security configuration of the device.

Node

A physical or virtual machine on which Kaspersky EDR Expert is deployed. There are primary and worker nodes. The primary node is intended for managing the cluster, storing metadata, and distributing of the workload. The worker nodes are intended for performing the workload of the Kaspersky EDR Expert components.

Normalized event

An event that is processed in accordance with the KUMA normalized event data model.

Observables

Objects related to the alert and incident, such as MD5 and SHA256 hashes, IP address, URL, Domain name, UserName, or HostName.

Playbook

An object that responds to alerts or incidents according to the specified algorithm (playbook algorithm). Playbooks allow you to automate workflows and reduce the time it takes to process alerts and incidents.

Playbook algorithm

An algorithm that includes a sequence of response actions that help analyze and handle alerts or incidents.

Registry

Infrastructure component that stores the application containers and is used for the installation and storing of the Kaspersky EDR Expert components.

Response actions

Actions that are launched within playbooks.

Sandbox

Application component. Starts virtual images of operating systems. Starts files in these operating systems and tracks the behavior of files in each operating system to detect malicious activity and signs of targeted attacks to the corporate IT infrastructure.

Segmentation rules

Rules that allow you to automatically split related alerts into different incidents based on specified conditions.

Storage

A KUMA service that is used to store normalized events so that they can be quickly and continually accessed from KUMA for the purpose of extracting analytical data.

Target hosts

Physical or virtual machines that are used to deploy Kaspersky EDR Expert. Target hosts are included in the Kubernetes cluster. Kaspersky EDR Expert components work on these hosts.

Tenant

A logical entity that corresponds to an organization unit (a client or an office) to which the Kaspersky EDR Expert functionality is provided. Each tenant can include assets, users and their access rights, events, alerts, incidents, playbooks, and integration with other Kaspersky applications, services, and third-party solutions. Also a tenant defines a set of available operations on the included objects.

Threat development chain

A series of steps that trace the stages of a cyber attack. Threat development chain allows you to analyze the reasons of the threat. To create a threat development chain, the managed application transfers data from the device to Administration Server through Network Agent.

Transport archive

An archive that contains Kaspersky EDR Expert components, management web plug-ins, and End User License Agreements for Kaspersky EDR Expert and KDT. The transport archive is included in the distribution package.

Information about third-party code

Information about third-party code is contained in the files legal_notices_ksmp.txt and legal_notices_kuma.txt on the device that acts as an operator node. The files are located in the `~/kaspersky_eula` directory of the user that runs the installation of Kaspersky EDR Expert.

Trademark notices

Registered trademarks and service marks are the property of their respective owners.

Adobe and Flash are either registered trademarks or trademarks of Adobe in the United States and/or other countries.

AMD and AMD64 are trademarks or registered trademarks of Advanced Micro Devices, Inc.

Apache and Apache Cassandra are either registered trademarks or trademarks of the Apache Software Foundation in the United States and/or other countries.
