kaspersky

Kaspersky Industrial CyberSecurity for Networks

Contents

About Kaspersky Industrial CyberSecurity for Networks

Kaspersky Industrial CyberSecurity for Networks is an application designed to protect the infrastructure of industrial enterprises from information security threats, and to ensure uninterrupted process flows. Kaspersky Industrial CyberSecurity for Networks analyzes industrial network traffic to identify deviations in the values of process parameters, detect signs of network attacks, and monitor the operation and current device states on the network. The application is part of the solution known as Kaspersky Industrial CyberSecurity.

Kaspersky Industrial CyberSecurity for Networks performs the following functions:

- Protects company assets by monitoring its industrial network devices. Detects device activity and device information based on data received from network packet analysis and/or from Kaspersky applications that perform functions to protect workstations and servers.
- Scans communications between industrial network devices to check their compliance with defined Interaction Control rules. Interaction Control rules can be generated automatically by running the application in learning mode.
- Displays the network interactions between industrial network devices depicted as a network map. Displayed objects are visually distinguished based on various attributes (for example, objects with issues).
- Detects vulnerabilities of devices based on saved device information.
- Extracts the parameter values of the technological process controlled by the Industrial Control System (hereinafter referred to as the "ICS") from network packets and checks the acceptability of those values based on the defined Process Control rules. Process Control rules can be generated automatically by running the application in learning mode.
- Monitors traffic to detect system commands that are transmitted or received by devices involved in process automation. Provides notifications regarding detected unauthorized system commands or situations that could be signs of industrial network security violations.
- Monitors project read and write operations for programmable logic controllers, saves the obtained information about projects, and compares this information to previously obtained information.
- Analyzes industrial network traffic for signs of attacks without affecting the industrial network or drawing the attention of a potential attacker. Uses defined Intrusion Detection rules and embedded algorithms to scan for anomalies in network packets and detect signs of attacks.
- Registers events and relays information about them to recipient systems and to Kaspersky Security Center.
- Analyzes registered events and, upon detecting certain sequences of events, registers incidents based on embedded correlation rules. Incidents group events that have certain common traits or that are associated with the same process.
- Saves traffic associated with registered events in the database. Traffic can be saved automatically (if autosave is enabled for the traffic of events) or by requesting to download traffic.
- Can be used to work with both the GUI and API.
- Provides data for centralized monitoring of systems with Kaspersky Industrial CyberSecurity for Networks from the Kaspersky Security Center Web Console.

Distribution kit

The distribution kit of Kaspersky Industrial CyberSecurity for Networks includes the following files:

- Application components centralized installation script: kics4net-deploy-<application version number>.bundle.sh
- Script for local installation of application components: kics4net-install.sh.
- Script for local removal of application components: kics4net-remove.sh
- Packages for installing application components in the CentOS operating system:
  - Package for installing the Server and sensors: kics4net-<application version number>.x86_64.rpm.
  - Package for installing system connectors: kics4net-connectors-<application version number>.x86_64.rpm.
  - Package for installing the integration service: kics4net-epp-proxy-<application version number>.x86_64.rpm.
  - Package for installing the full-text search system: kics4net-fts-<application version number>.x86_64.rpm.
  - Package for installing the DBMS: kics4net-postgresql-<DBMS version number>.x86_64.rpm.
  - Package for installing the Intrusion Detection system: kics4net-suricata-<system version number>.x86_64.rpm.
  - Package for installing a web server for an application sensor: kics4net-websensor-<application version number>.x86_64.rpm
  - Package for installing a web server for the Application Server: kics4net-webserver-<application version number>.x86_64.rpm.
  - Package for installing Network Agent from the Kaspersky Security Center distribution kit: klnagent64-<Network Agent version number>.x86_64.rpm
- Packages for installing the Kaspersky Industrial CyberSecurity for Networks Administration Plug-in for Kaspersky Security Center: kics4net-sc-plugin_<plug-in version number>_<localization code>.msi
- Package of documentation describing requests for the Kaspersky Industrial CyberSecurity for Networks API: publicapi_doc.tar.gz
- Package of specifications for the Kaspersky Industrial CyberSecurity for Networks API: publicapi_swagger.tar.gz
- Files containing the text of the End User License Agreement in English and in Russian
- Files containing the text of the Privacy Policy in English and in Russian
- Files containing information about the version (Release Notes) in English and in Russian

Hardware and software requirements

Hardware requirements

Kaspersky Industrial CyberSecurity for Networks has the following minimum hardware requirements for computers on which application components will be installed:

- Computer that will perform Server functions:
  - CPU: Intel® Core™ i7.
  - RAM: 32 GB.
  - Free space on the hard drive: 750 GB and an additional 250 GB for each monitoring point on this computer.
- Computer that will perform sensor functions:
  - CPU: Intel Core i5 / i7.
  - RAM: 4 GB, and an additional 2 GB for each monitoring point on this computer.
  - Free space on the hard drive: 50 GB and 250 GB for each monitoring point on this computer.

It is recommended to use high-speed hard drives (for example, SSD drives).

When using sensors, the bandwidth of the dedicated Kaspersky Industrial CyberSecurity network between the Server and each sensor must be at least 50% of the cumulative incoming traffic at the sensor (for all monitoring points of the sensor).

Example:
A sensor has two monitoring points. One monitoring point receives 100 Mbit/s of traffic, while the other receives 200 Mbit/s. In this case, the bandwidth of the channel between the sensor and the Server must be at least 150 Mbit/s ((200+100)/2=150).

Software requirements

Kaspersky Industrial CyberSecurity for Networks has the following software requirements for computers on which application components will be installed:

- CentOS Linux version 8.3 or CentOS Stream 8 (you can migrate CentOS Linux version 8.3 to CentOS Stream 8 after Kaspersky Industrial CyberSecurity for Networks is already installed).

  When installing the operating system, it is recommended to allocate the entire hard drive (minus the minimum space required for the boot and swap partitions) to the system (root) partition. To improve the performance of software, you can also mount the /var/ folder to a high-speed hard drive (if you have an additional drive, such as an SSD drive). If you choose to do so, the /var/ folder must be completely mounted to the other drive. Subfolders within the /var/ folder (such as /var/opt/) cannot be mounted to different drives.

- The same version of operating system must be installed on all computers where application components are installed.
- To install application components in the CentOS operating system, the following conditions must be fulfilled:
  - **Chrony time synchronization package version 3.1 or later is installed.**

You can install the Chrony time synchronization package by using the following commands in the operating system console:

```
sudo dnf install chrony
sudo systemctl enable chronyd
sudo systemctl start chronyd
```

- The SELinux access control enforcement system is disabled.

  1. Open the system configuration file. To do so, enter the following command:

     ```
     sudo mcedit /etc/selinux/config
     ```

  2. Set the following parameter value:

     ```
     SELINUX=disabled
     ```

  3. Save and close the configuration file.

  4. Restart the computer.

- The dnf-utils package is installed.

  You can install the dnf-utils package by using the following command in the operating system console:

  ```
  sudo dnf install dnf-utils
  ```

- Python interpreter version 2.7 is installed.

  You can install python2 packages by using the following command in the operating system console:

  ```
  sudo dnf install python2 libnsl
  ```

- A symbolic link to the installed version of the python2 package is configured.

  You can configure a symbolic link to the installed version of a python2 package by using the following command in the operating system console:

  ```
  sudo alternatives --set python /usr/bin/python2
  ```

- The python2-pyyaml package is installed.

  You can install the python2-pyyaml package by using the following command in the operating system console:

  ```
  sudo dnf install python2-pyyaml
  ```

- To ensure proper functioning of application components on the computer that will perform Server functions, the following conditions must also be fulfilled in the CentOS operating system:

- Python interpreter version 3.6 or later is installed, as well as the following packages supporting the operation of connectors and data conversion scripts: python3-tqdm, python3-certifi, python3-dateutil, python3-pyyaml, python3-pytz, python3-urllib3, python3-psycopg2, python3-cffi (if connectors will also operate on other computers, the listed packages must also be installed on those computers).

  You can install packages for connectors and data conversion scripts by using the following command in the operating system console:

  ```
  sudo dnf install python3-tqdm python3-certifi python3-dateutil python3-pyyaml
  python3-pytz python3-urllib3 python3-psycopg2 python3-cffi
  ```

- A Postfix mail server (Mail Transfer Agent – MTA) for sending emails through the email connector is installed.

  You can install a Postfix mail server by using the following commands in the operating system console:

  ```
  sudo dnf -y install postfix
  sudo systemctl start postfix
  sudo systemctl enable postfix
  ```

- Perl interpreter version 5.10 or later is installed (if Kaspersky Security Center Network Agent is being installed).

For installation of application components, it is recommended to use separate computers on which only software from the operating system is installed. If third-party applications are installed on computers, the performance of components of Kaspersky Industrial CyberSecurity for Networks may be reduced.

To install the Kaspersky Industrial CyberSecurity for Networks Administration Plug-in for Kaspersky Security Center, the Windows® update KB2999226 must be installed on the computer hosting the Kaspersky Security Center Administration Server. Installation of this update is required if the problems fixed by this update are relevant for the installed version of the operating system and configuration of the installed software on the computer hosting the Administration Server (please refer to the description of the specific update).

You can use the following browsers to connect through the web interface:

- Google Chrome™ version 91 or later.
- Mozilla™ Firefox™ version 89 or later.
- Microsoft® Edge version 91 or later.

Kaspersky Industrial CyberSecurity for Networks is compatible with Kaspersky Security Center version 12 and 13.2. The Kaspersky Industrial CyberSecurity for Networks web management plug-in becomes available to use after you install Kaspersky Security Center Web Console version 13.2.571 and a patch for this application, which enables interaction with the Kaspersky Industrial CyberSecurity for Networks web management plug-in (patch version: 13.2.571.1). You can request the indicated versions of these programs from your technical account manager (TAM).

Kaspersky Industrial CyberSecurity for Networks supports joint operation with Kaspersky Industrial CyberSecurity for Nodes version 2.6 or later. It supports integration with Kaspersky Industrial CyberSecurity for Nodes version 3.0 (when integrated, Kaspersky Industrial CyberSecurity for Networks receives data from Kaspersky Industrial CyberSecurity for Nodes).

Overview of Kaspersky Industrial CyberSecurity for Networks functionality

Industrial network traffic analysis functionality

In Kaspersky Industrial CyberSecurity for Networks, industrial network traffic analysis is provided by the following functionality:

- **Asset Management**. This functionality lets you monitor the activity of devices and track changes to device information based on data received in network packets. To automatically receive information about devices, the application analyzes industrial network traffic according to the rules for identifying information about devices and the protocols of communication between devices. The application can also define device settings for Process Control. In conjunction with Process Control functionality, read/write operations for programmable logic controllers are also monitored. For the purpose of Asset Management, the application generates a table containing information that is received automatically from traffic or information that is manually provided.

- **Interaction Control**. This functionality lets you monitor interactions between devices of the industrial network. Detected interactions are checked to see if they match any Interaction Control allow rules. When the application detects an interaction that is described in an enabled rule, it considers this interaction to be allowed and does not register an event.

- **Deep Packet Inspection** (hereinafter also referred to as "Process Control"). This functionality lets you monitor traffic to detect the values of process parameters and the systems commands transmitted or received by devices. Values of industrial process parameters are tracked with the aid of Process Control rules that are used by the application to detect unacceptable values. Lists of monitored system commands are generated when you configure the settings of Process Control devices.

- **Intrusion Detection**. This functionality lets you monitor traffic to detect signs of attacks or unwanted network activity. Intrusion Detection rules and embedded network packet scan algorithms are used to detect such activity. When the conditions defined in an active Intrusion Detection rule are detected in traffic, the application registers a rule-triggering event. Using the embedded network packet scan algorithms, the application detects signs of falsified addresses in ARP packets and various anomalies in the TCP and IP protocols.

Only an application user with the Administrator role can configure industrial network traffic analysis functionality.

Functionality for performing common operator tasks

Application user accounts with the Operator role can be used to perform common tasks for monitoring the state of the industrial process and devices in Kaspersky Industrial CyberSecurity for Networks. These users can utilize the following functionality:

- **Display information for system monitoring in online mode**. This functionality lets you view the most significant changes to the system that have occurred up to the current moment. When the system is being monitored in online mode, you can monitor hardware resource consumption, various dynamic data, and the main information about devices and events.

- **Display data on the network map**. This functionality lets you visually display detected interactions between devices of the industrial network. When viewing the network map, you can quickly identify problematic objects or objects with other attributes and view information about these objects. To conveniently present information, you can automatically or manually arrange devices on the network map.

- **Display information about events and incidents**. This functionality lets you download registered events and incidents from the Server database and display this information as an events table or as interacting objects on

a network map. To provide the capability to monitor new events and incidents, by default the application loads events and incidents that occurred most recently. You can also load events and incidents for any period. When viewing the events table, you can change the statuses of events and incidents, copy and export data, load traffic, and perform other actions.

- **Display tag values in online mode**. This functionality lets you view the current values of process parameters detected in traffic at the current point in time. Information about received values is displayed in the tags table generated for Process Control.

- **Display information about detected vulnerabilities of devices**. This functionality lets you detect vulnerabilities in monitored devices on the industrial network. To detect vulnerabilities, the application compares the available device information to specific fields in the vulnerabilities database. Information about vulnerabilities can be viewed when managing devices or in the general vulnerabilities table.

- **Display information for centralized monitoring in the Kaspersky Security Center Web Console**. This functionality lets you view data on the security state of information systems that are running application components (including deployment scenarios involving multiple Servers of Kaspersky Industrial CyberSecurity for Networks). When working with the Kaspersky Security Center Web Console, you can view information in web widgets and on component deployment maps, search devices and events in Kaspersky Industrial CyberSecurity for Networks, and quickly navigate from the Kaspersky Security Center Web Console directly to the web interface pages of Servers.

Functionality for managing operation of the application

To manage the application for the purpose of general configuration and control of its use, an application user with the Administrator role can use the following functionality:

- **Manage technologies**. This functionality lets you enable and disable the use of technologies and methods for industrial network traffic analysis, and change the operating mode of technologies and methods. You can enable, disable, and change the operating mode of technologies and methods independently of each other.

- **Manage nodes and monitoring points**. This functionality lets you add sensor nodes and monitoring points to the application to receive traffic from the industrial network. You can also use this functionality to temporarily pause and resume monitoring of industrial network segments by disabling and enabling the corresponding monitoring points (for example, while conducting preventative maintenance and adjustment operations for the ICS).

- **Configure the receipt of data from EPP applications**. This functionality lets you select the nodes with installed application components that will receive and process data from other Kaspersky applications that perform functions to protect workstations and servers. These applications are included in the Endpoint Protection Platform (EPP) and are installed to endpoint devices within the enterprise IT infrastructure. When data is received from EPP applications, Kaspersky Industrial CyberSecurity for Networks can register events, add devices, and update device information.

- **Distribute access to application functions**. This functionality lets you restrict user access to application functions. Access is restricted based on the roles of application user accounts.

- **Monitor the state of the application**. This functionality lets you monitor the current state of Kaspersky Industrial CyberSecurity for Networks, and view application messages and user activity audit entries for any period. Users with the Operator role can also access the log containing application messages.

- **Update databases and application modules**. This functionality lets you download and install updates, thereby improving the effectiveness of traffic analysis and ensuring maximum protection of the industrial network against threats. Update functionality is available after a license key is added to Kaspersky Industrial CyberSecurity for Networks or to Kaspersky Security Center. You can manually start installation of updates, or enable automatic installation of updates according to a defined schedule.

- **Configure the types of registered events**. This functionality lets you generate and configure a list of event types for event registration in Kaspersky Industrial CyberSecurity for Networks, and for event transmission to recipient systems (for example, to a SIEM system) and to Kaspersky Security Center.

- **Manage logs**. This functionality lets you change the settings for saving data in application logs. You can configure the settings for saving entries in logs and the settings for saving traffic in the database. You can also change the logging levels for process logs.

- **Use the application programming interface**. This functionality lets you use the set of functions implemented through the Kaspersky Industrial CyberSecurity for Networks API in external applications. Using the Kaspersky Industrial CyberSecurity for Networks API, you can obtain data on events and tags, send events to Kaspersky Industrial CyberSecurity for Networks, and perform other actions.

Security recommendations for Kaspersky Industrial CyberSecurity for Networks

To ensure secure operation of the application at an enterprise after installation of Kaspersky Industrial CyberSecurity for Networks, it is recommended to reinforce the security of computers on which the Kaspersky Industrial CyberSecurity for Networks Server and sensors are installed. The required level of security ensuring safe operation of the application must be supported by the operating system and its protection tools. To maintain security of the application, it is recommended to regularly install updates for application modules and databases of Kaspersky Industrial CyberSecurity for Networks and security updates for the operating system.

It is recommended to restrict physical access to hardware on which the application is running to prevent the following potential security issues:

- Unauthorized shutdown of hardware (or disconnection from the network)

- Connection of tools that can intercept transmitted data

- Theft of hard drives containing data

- Use of other equipment to destroy or replace data on hard drives

When deploying Kaspersky Industrial CyberSecurity for Networks, you are advised to do the following:

- Restrict remote and local access to computers that have components of Kaspersky Industrial CyberSecurity for Networks installed.

- Regularly check and update password policies for active user accounts in operating systems on computers that have application components installed. Password policies must comply with the recommendations on ensuring the required level of security of the operating system.

- Ensure that the application interfaces can be accessed only by personnel who are authorized to install and configure the application, and by users (operators) who use the application to perform standard tasks.

- Use hardware or a security service to control physical access to the equipment running the application and to the utilized network equipment.

- Use video surveillance and alarm systems to monitor restricted rooms.

When application events are transmitted to recipient systems (other than Kaspersky Security Center), the application does not guarantee the security of the data transfer. We recommend that you use other means to secure the data transfer.

For use of application management tools, it is also recommended to take the following actions to ensure data security on the intranet:

- Protect traffic within the intranet.
- Protect connections to external networks.
- Use digital certificates published by trusted certificate authorities.
- Use account credentials that meet the requirements for user names and passwords of application user accounts.
- Ensure that passwords are confidential and unique.

  If there is a risk that the password was compromised, the application user must promptly change their password.
- Customized time synchronization on the Kaspersky Industrial CyberSecurity for Networks nodes.
- Terminate the web interface connection session before closing your browser.

  To force termination of a connection session, you need to use the **Log out** option in the user menu.

What's new

Kaspersky Industrial CyberSecurity for Networks 3.1 has the following new capabilities and refinements:

- Added functionality for centralized monitoring of the security state of information systems running the application – the Kaspersky Industrial CyberSecurity for Networks Administration web plug-in in the Kaspersky Security Center 13.2 Web Console provides the capability to monitor systems and Servers by using specialized web widgets, search events and devices, and map application components on geographic, schematic, or other images.

- Added support for Single Sign-On (SSO) technology for users who are allowed to work with the Kaspersky Security Center Web Console (including Active Directory® users) – these users can proceed from the Kaspersky Security Center Web Console page to the web interface page of the Kaspersky Industrial CyberSecurity for Networks Server and connect to the Server using their own account credentials. For user authentication, Kaspersky Security Center and Kaspersky Industrial CyberSecurity for Networks must be preconfigured to use Single Sign-On technology.

- Added capability for integration with an Endpoint Protection Platform (EPP) – Kaspersky Industrial CyberSecurity for Nodes. When configuring receipt of data from these applications, you must also install the Kaspersky Endpoint Agent application. When working in integration mode, Kaspersky Industrial CyberSecurity for Networks receives data from nodes that are protected by Kaspersky Industrial CyberSecurity for Nodes, and uses this data to update information about registered devices, security events, and network interactions. Data from EPP applications let you take inventory of the industrial network and track interactions between devices even if you are not using monitoring points on nodes that have application components installed (if integration servers for data acquisition were added to these nodes). Security events forwarded from Kaspersky Industrial CyberSecurity for Nodes expand the capabilities of Kaspersky Industrial CyberSecurity for Networks to detect incidents and help identify a larger number of attacks in all monitored segments of computer networks. System event types based on Endpoint Protection Platform and Asset Management are used to register events according to data from EPP applications. Data regarding EPP applications installed on devices is displayed in the devices table, on network map nodes, and on a widget in the **Dashboard** section.

- Augmented database for monitoring device vulnerabilities – the table in the **Vulnerabilities** section indicates the sources of information about detected vulnerabilities uploaded to the database. To detect vulnerabilities of only specific sources, you can select the relevant sources by enabling and disabling the use of various sources.

- Expanded functional capabilities of the application programming interface (API) – when working with events, you can change their statuses, add labels, and send requests to load traffic for events. When working with allow rules, you can send requests to receive a list of rules, and enable, disable, and delete rules. Added capabilities to receive data on the current states and operating modes of technologies. Added capability to receive information about an added license key.

- Expanded list of supported types of external projects that can be imported – various types of projects containing configurations of process control settings for devices can be imported into the application.

- Extended support for application layer protocols and devices for process control – there are now additional capabilities for analyzing traffic of supported protocols and devices, and new supported protocols and devices have been added.

Application architecture

Kaspersky Industrial CyberSecurity for Networks includes the following components:

- The *Server* is the main component that receives data, processes it, and provides it to users of the application. The received information (such as events and device information) is saved on the Server in the database. Only one Server can be used in each Kaspersky Industrial CyberSecurity for Networks deployment scenario.

- A *sensor* is a component that is managed by the Server and receives and analyzes data from computer networks that are connected to the network interfaces of the sensor's computer. A sensor forwards the data analysis results to the Server. Based on the specific requests from the Server, the sensor can forward data in the same format in which the data was received for analysis (for example, traffic related to registered events). Sensors are installed on separate computers. A sensor cannot be installed on a computer that performs Server functions. The application can have up to 32 sensors.

The connections between the Server and sensors are secured by using certificates. Use of certificates also ensures the security of other connections with application components (for example, a connection to a component through a web interface or connections of recipient systems through specialized application modules called *connectors*).

The Kaspersky Industrial CyberSecurity for Networks Server performs the following functions:

- Manages sensors and receives the results of their analysis of data received from computer networks.

- Processes and saves received information about devices and their interactions.

- Registers and saves events.

- Conducts an additional analysis of accumulated information to detect threats and incidents (for example, according to event correlation rules).

- Monitors application performance.

- Monitors the activities of application users.

- Processes incoming requests submitted through the web interface and connectors, and provides the requested data.

A Kaspersky Industrial CyberSecurity for Networks sensor performs the following functions:

- Analyzes industrial network traffic received by network interfaces of a computer hosting *monitoring points*:

  - Extracts information about device communications and process parameters from traffic.

  - Identifies signs of attacks in traffic.

- Uses connections to other computer networks to receive data from Kaspersky applications that perform functions to protect workstations and servers (EPP applications).

- Registers events based on the results of data analysis.

- Relays events, information about traffic, device information, and process parameters to the Kaspersky Industrial CyberSecurity for Networks Server.

Application components receive a copy of industrial network traffic from *monitoring points*. Monitoring points can be used on sensors as well as on the Server. You can add monitoring points to network interfaces detected on nodes that have application components installed. Monitoring points must be added to network interfaces that relay traffic from the industrial network.

You can add no more than 8 monitoring points on a sensor and no more than 4 monitoring points on the Server. You can use no more than 32 monitoring points total in the application.

All network interfaces with added monitoring points must be connected to the industrial network in such a way that excludes any possibility of impacting the industrial network. For example, you can connect using ports on industrial network switches configured to transmit mirrored traffic (Switched Port Analyzer, SPAN).

It is recommended to use a *dedicated* Kaspersky Industrial CyberSecurity network for connecting the Server to sensors and to other components of Kaspersky Industrial CyberSecurity (Kaspersky Industrial CyberSecurity for Nodes, Kaspersky Security Center). Network equipment used for interaction between components in the dedicated network must be installed separately from the industrial network. Normally, the following computers and devices should be connected to the dedicated network:

- Kaspersky Industrial CyberSecurity for Networks Server node.
- Kaspersky Industrial CyberSecurity for Networks sensor nodes.
- Computers for connecting to the Server and sensors through the web interface.
- Computers hosting Kaspersky Industrial CyberSecurity for Nodes.
- Computers hosting Kaspersky Endpoint Agent.
- Computer hosting Kaspersky Security Center.
- Network switch.

Common deployment scenarios

Kaspersky Industrial CyberSecurity for Networks supports the following scenarios for installing components:

- Installing a Server without external sensors
- Installing a Server and external sensors

If necessary, a data diode can be used to connect a Server and/or sensors to an industrial network.

Regardless of the installation method, it is recommended to use a special dedicated network for connecting Kaspersky Industrial CyberSecurity components (Kaspersky Industrial CyberSecurity for Networks, Kaspersky Industrial CyberSecurity for Nodes, Kaspersky Security Center). The dedicated network's minimum bandwidth requirements for installation of the Kaspersky Industrial CyberSecurity for Networks Server and sensors are provided in the Hardware and software requirements section.

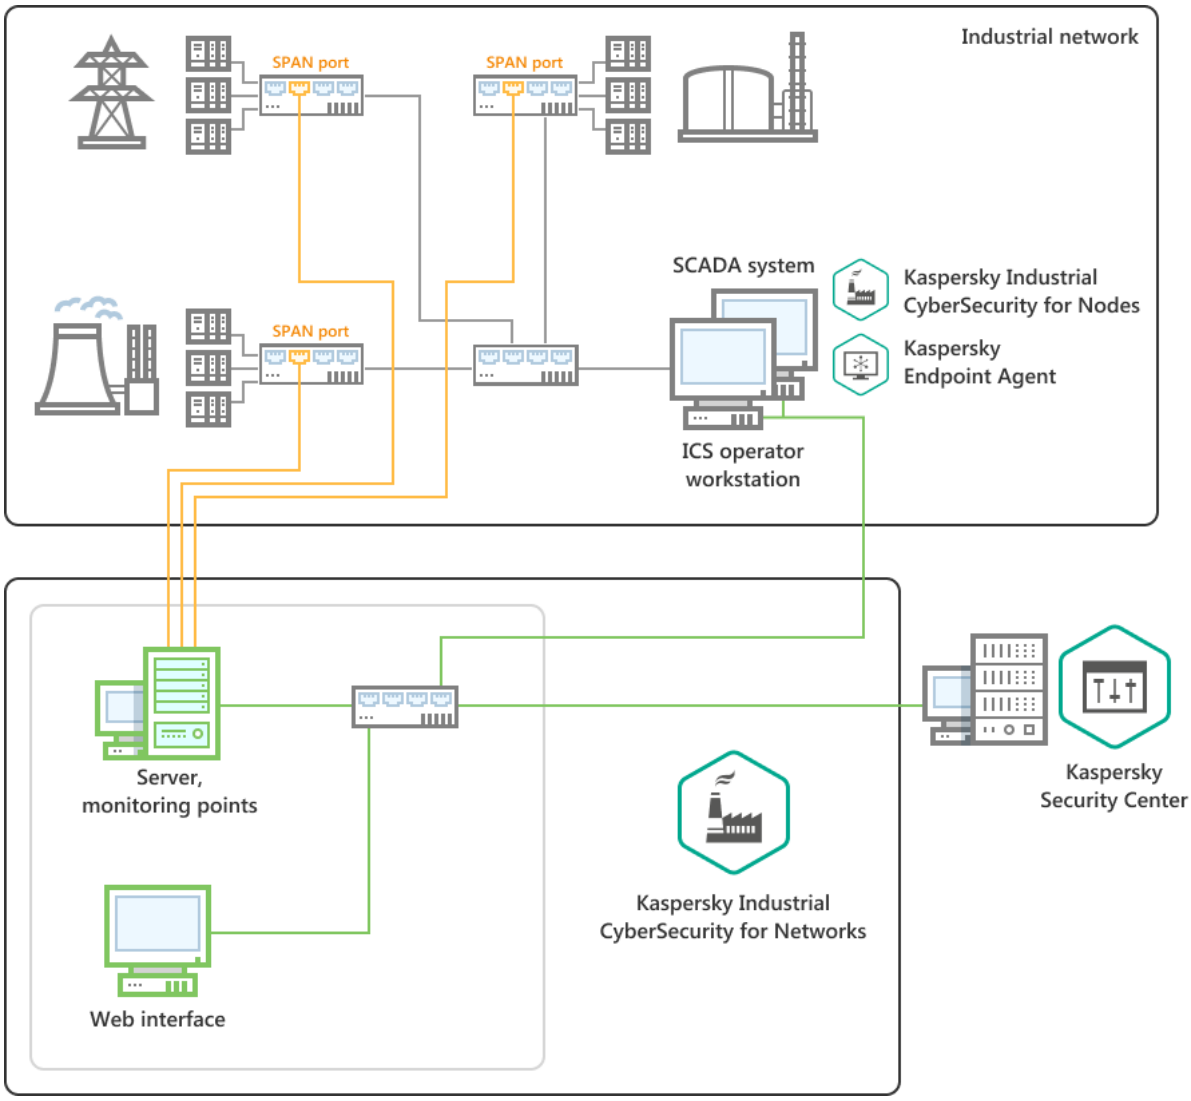
Installing a Server without external sensors

When installing a Server without external sensors, all data to be processed and analyzed is received only by the computer that performs Server functions. You can use this installation method if the computer has a sufficient number of network interfaces to receive data from various sources.

The computer must have network interfaces to receive traffic from all industrial network segments. Due to the limit on the number of monitoring points on the Server, there must be no more than four of these network interfaces.

The computer must also have one more network interface so that other computers can connect to the Server through the web interface. There must be no monitoring points on this network interface. This network interface can be used for connections through connectors and for receiving data from EPP applications.

The figure below shows an example scenario for deploying a Server without sensors. The network interfaces of the computer that performs Server functions are connected to the SPAN ports of network switches (SPAN ports and connections are marked in yellow) and receive a copy of traffic from three segments of the industrial network. The dedicated Kaspersky Industrial CyberSecurity network is designated by green lines.



Example deployment of a Server without sensors

Installing a Server and external sensors

When installing a Server with external sensors, at least 2 and up to 33 computers can be used for installing application components. The Server is installed on one of the computers. The sensors that will receive data from computer networks are installed on the other computers.

To receive traffic from the industrial network, you must add monitoring points to computers:

- No more than 8 monitoring points on a sensor
- No more than 4 monitoring points on the Server
- No more than 32 monitoring points in the application

Monitoring points are added to their corresponding network interfaces of computers. A computer must have one network interface per each monitoring point.

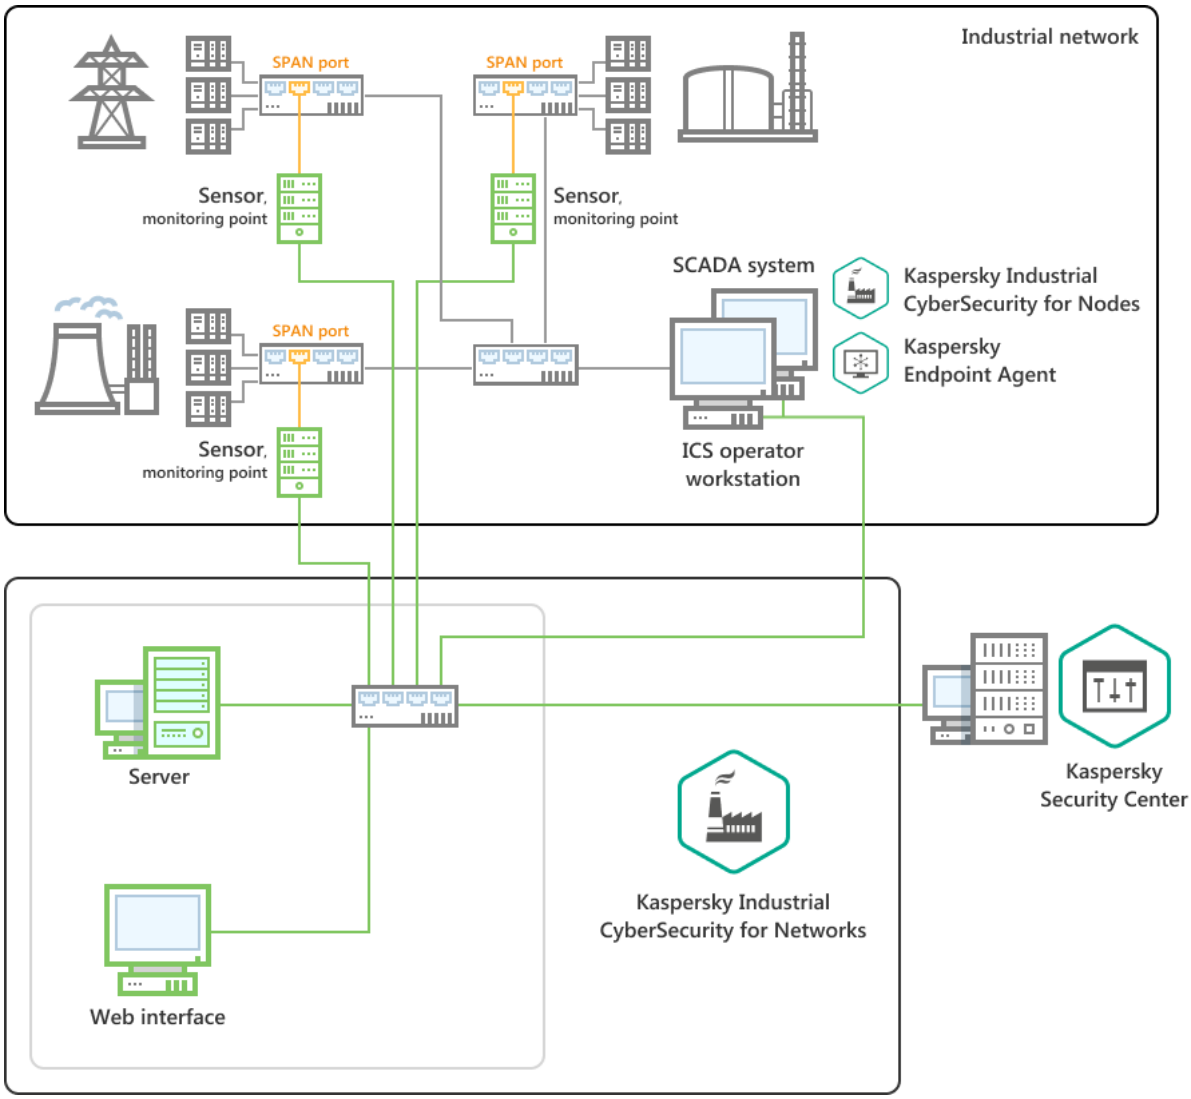
Computers must also have separate network interfaces that will be used for the following purposes:

- Connection with the Server (on computers that perform sensor functions)

- Connection with other computers through the web interface
- Receipt of data from EPP applications
- Connection through connectors (on the computer that performs Server functions)

For these purposes, each computer can use either multiple separate network interfaces or one shared network interface. There must be no monitoring points on these network interfaces.

The figure below shows an example scenario for deploying a Server and three sensors. The network interfaces of computers that perform sensor functions are connected to the SPAN ports of network switches (SPAN ports and connections are marked in yellow) and receive a copy of traffic from their respective segments of the industrial network. The dedicated Kaspersky Industrial CyberSecurity network is designated by green lines.

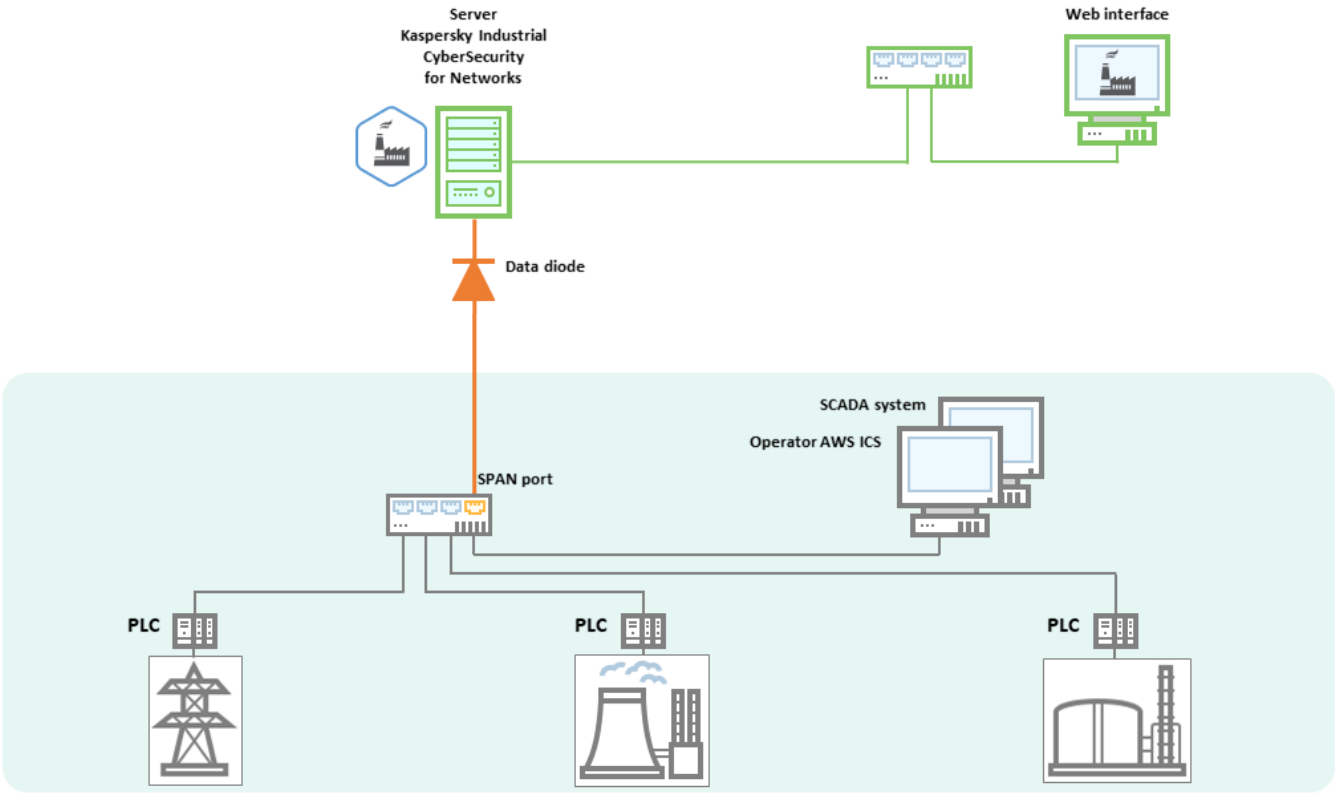


Example deployment of a Server and three sensors

Connecting Kaspersky Industrial CyberSecurity for Networks to an industrial network via data diode

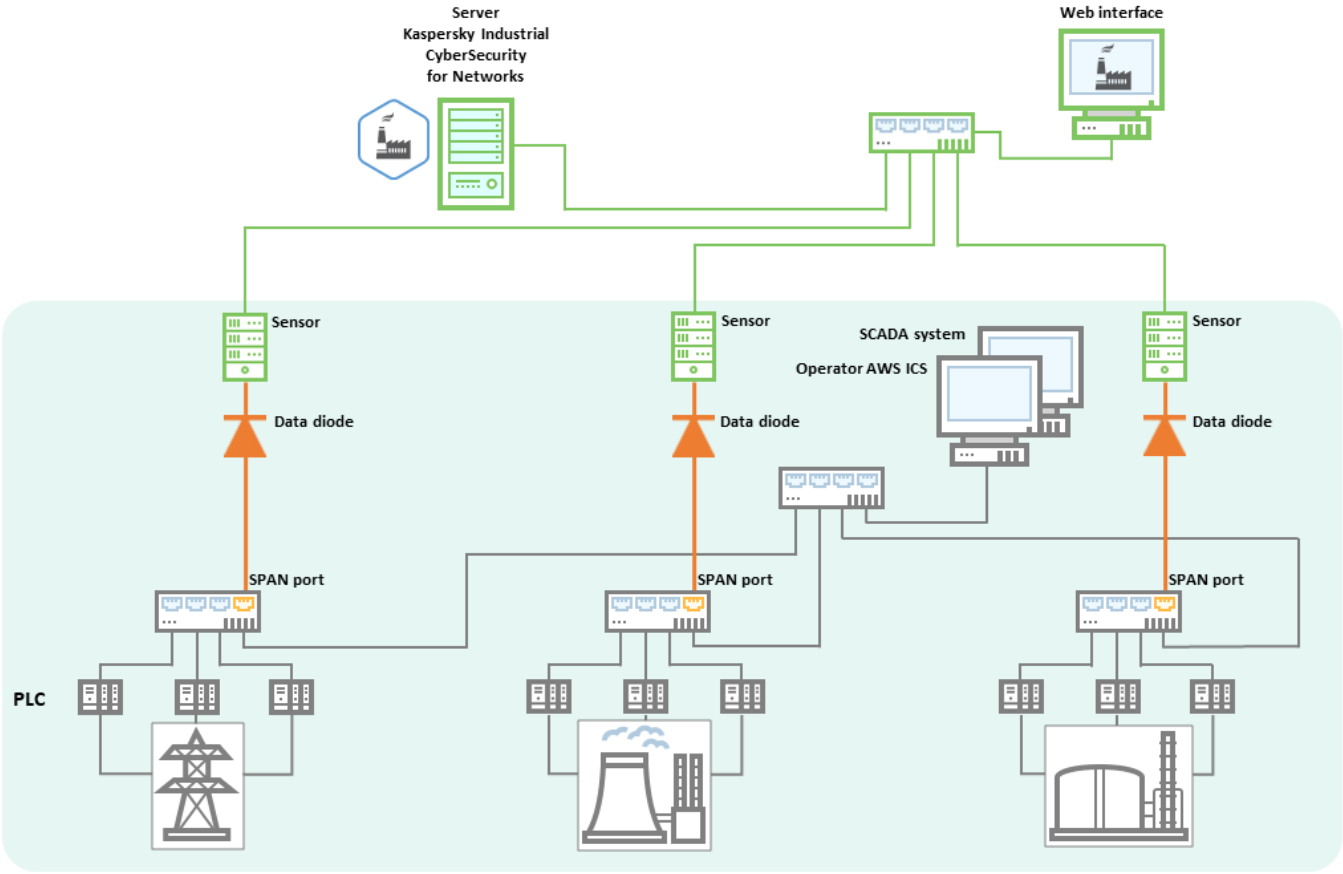
To connect Kaspersky Industrial CyberSecurity for Networks to an industrial network, you can additionally use special devices that provide unidirectional transmission of data from the industrial network. These devices are called *data diodes*. Data diodes can be installed on the connection links of monitoring points for Kaspersky Industrial CyberSecurity for Networks and on SPAN ports of network switches.

The figure below shows an example of connecting through a data diode to a monitoring point on the Server. In this deployment scenario, the Server is installed without external sensors.



Example Server connection via data diode

The example in the figure below shows the connection of multiple sensors of Kaspersky Industrial CyberSecurity for Networks via data diodes. In this deployment scenario, the Server is installed with three sensors.



Installing and removing the application

This section contains step-by-step instructions on installing and removing Kaspersky Industrial CyberSecurity for Networks.

Preparing for application installation

Before starting the installation of Kaspersky Industrial CyberSecurity for Networks, make sure that the computers meet the hardware and software requirements. Also make sure that the equipment, hardware, and software of the computers are compliant with all operational security recommendations.

> To ensure proper functioning of application components, it is recommended to use specially dedicated computers that only have software from the operating system installed. If third-party applications are installed on computers, the performance of components of Kaspersky Industrial CyberSecurity for Networks may be reduced.

To install application components, each computer must have a user account with root privileges that will be used to perform the installation. You can use the standard tools of the operating system to add the necessary user accounts.

Depending on the utilized application components installation script and on the type of application components being installed, you can do the following to prepare for application installation:

- **Preparing for centralized installation of components**

On the computers where components will be centrally installed, verify that the following conditions are fulfilled:

- The computers have network access, and access over SSH is configured and open.
- The computers have user accounts with root privileges (application components will be installed under these user accounts).
- The computers do not have any user accounts or groups with the following names that are reserved for interaction between application components (if these accounts exist, they could receive elevated access rights, even root privileges, after the application is installed):
  - kics4net
  - kics4net-postgresql
  - kics4net-webserver
  - kics4net-websensor
  - kics4net-connectors
  - kics4net-fts
  - kics4net-epp-proxy

To prepare computers for installation of application components:

1. On all computers on which application components will be installed, set the same password for the user account with root privileges (application components will be installed under this user account). By default, the root user account is used to perform the installation. Memorize the user names and password. You will need to provide this data while the application installation script is running.

   After application components are installed, you are advised to change the passwords for these users.

2. Find out and save the following information about the computers:
   - Name and IP address of the computer that will perform Server functions.
   - IP addresses of the computers that will perform sensor functions.
   - Name or IP address and SSL port of the computer with Kaspersky Security Center.

   To display the computer name, you can enter the `hostname` command in the command line. To display information about IP addresses and network interfaces, you can enter the `sudo ifconfig` command in the command line (in a Windows operating system, use the `ipconfig` command).

3. On the computer from which the centralized installation will be performed, use the SSH protocol to connect to each computer where the application components will be installed. A connection needs to be made to verify access over SSH.

   To connect:

   a. Enter the following command in the command line:

```
ssh <user name>@<computer IP address>
```

b. After entering this command, perform the necessary actions at the operating system prompts.

c. To terminate the connection session, use the following command:

```
exit
```

4. On the computer from which the installation will be performed, create a folder for storing the installation files.

5. Copy the following files from the Kaspersky Industrial CyberSecurity for Networks distribution kit to the folder you created:

   - Application components centralized installation script kics4net-deploy-<application version number>.bundle.sh.
   - Package for installing the Server and sensors: kics4net-<application version number>.x86_64.rpm.
   - Package for installing system connectors: kics4net-connectors-<application version number>.x86_64.rpm.
   - Package for installing the integration service: kics4net-epp-proxy-<application version number>.x86_64.rpm (this package is necessary if you want to add integration servers to nodes of the Server and/or sensors to receive data from EPP applications).
   - Package for installing the full-text search system: kics4net-fts-<application version number>.x86_64.rpm.
   - Package for installing the DBMS: kics4net-postgresql-<DBMS version number>.x86_64.rpm.
   - Package for installing the Intrusion Detection system: kics4net-suricata-<system version number>.x86_64.rpm.
   - Package for installing a web server for an application sensor: kics4net-websensor-<application version number>.x86_64.rpm (this package is required if you want to install the sensor component to one or more computers and connect to this component through the web interface).
   - Package for installing a web server for the Application Server: kics4net-webserver-<application version number>.x86_64.rpm.
   - Package for installing Network Agent from the Kaspersky Security Center distribution kit: klnagent64-<Network Agent version number>.x86_64.rpm (this package is required if you want to monitor the state of the application, receive a license key, and download application updates via Kaspersky Security Center).

   Network Agent is a Kaspersky Security Center component that enables interaction between the Kaspersky Security Center Administration Server and Kaspersky applications that are installed on a specific node (workstation or server). For detailed information on Network Agent, please refer to the Kaspersky Security Center Help system.

   The folder with the listed files will be required during installation, modification of installation settings, and centralized removal of application components.

- Preparing for local installation of the Server

On the computer where the Server will be installed, verify that the following conditions are fulfilled:

- There is network access to the computer.
- The computer has a user account with root privileges (the local installation script will be run under this user account).
- The computer does not have any user accounts or groups with the following names that are reserved for interaction between application components (if these accounts exist, they could receive elevated access rights, even root privileges, after the application is installed):
  - kics4net
  - kics4net-postgresql
  - kics4net-webserver
  - kics4net-connectors
  - kics4net-fts
  - kics4net-epp-proxy

To prepare the computer for local installation of the Server:

1. Find out and save the following information about the computer:
   - User account credentials for the account with root privileges that will be used to run the local installation script.
   - Name and IP address of the computer (for subsequent connection to this computer after installing the Server).

   To display the computer name, you can enter the `hostname` command in the command line. To display information about IP addresses and network interfaces, you can enter the `sudo ifconfig` command in the command line.
2. Create a folder for storing the installation files.
3. Copy the following files from the Kaspersky Industrial CyberSecurity for Networks distribution kit to the folder you created:
   - Script for local installation of application components: kics4net-install.sh.
   - Package for installing the Server and sensors: kics4net-<application version number>.x86_64.rpm.
   - Package for installing system connectors: kics4net-connectors-<application version number>.x86_64.rpm.
   - Package for installing the integration service: kics4net-epp-proxy-<application version number>.x86_64.rpm (this package is necessary if you want to add an integration server to the Server node to receive data from EPP applications).
   - Package for installing the full-text search system: kics4net-fts-<application version number>.x86_64.rpm.

- Package for installing the DBMS: kics4net-postgresql-<DBMS version number>.x86_64.rpm.
- Package for installing the Intrusion Detection system: kics4net-suricata-<system version number>.x86_64.rpm.
- Package for installing a web server for the Application Server: kics4net-webserver-<application version number>.x86_64.rpm.
- Package for installing Network Agent from the Kaspersky Security Center distribution kit: klnagent64-<Network Agent version number>.x86_64.rpm (this package is required if you want to monitor the state of the application, receive a license key, and download application updates via Kaspersky Security Center).

Network Agent is a Kaspersky Security Center component that enables interaction between the Kaspersky Security Center Administration Server and Kaspersky applications that are installed on a specific node (workstation or server). For detailed information on Network Agent, please refer to the Kaspersky Security Center Help system.

- Preparing for local installation of a sensor

On the computer where the sensor will be installed, verify that the following conditions are fulfilled:

- There is network access to the computer.
- The computer has a user account with root privileges (the local installation script will be run under this user account).
- The computer does not have any user accounts or groups with the following names that are reserved for interaction between application components (if these accounts exist, they could receive elevated access rights, even root privileges, after the application is installed):
  - kics4net
  - kics4net-websensor
  - kics4net-epp-proxy

To prepare the computer for local installation of the sensor:

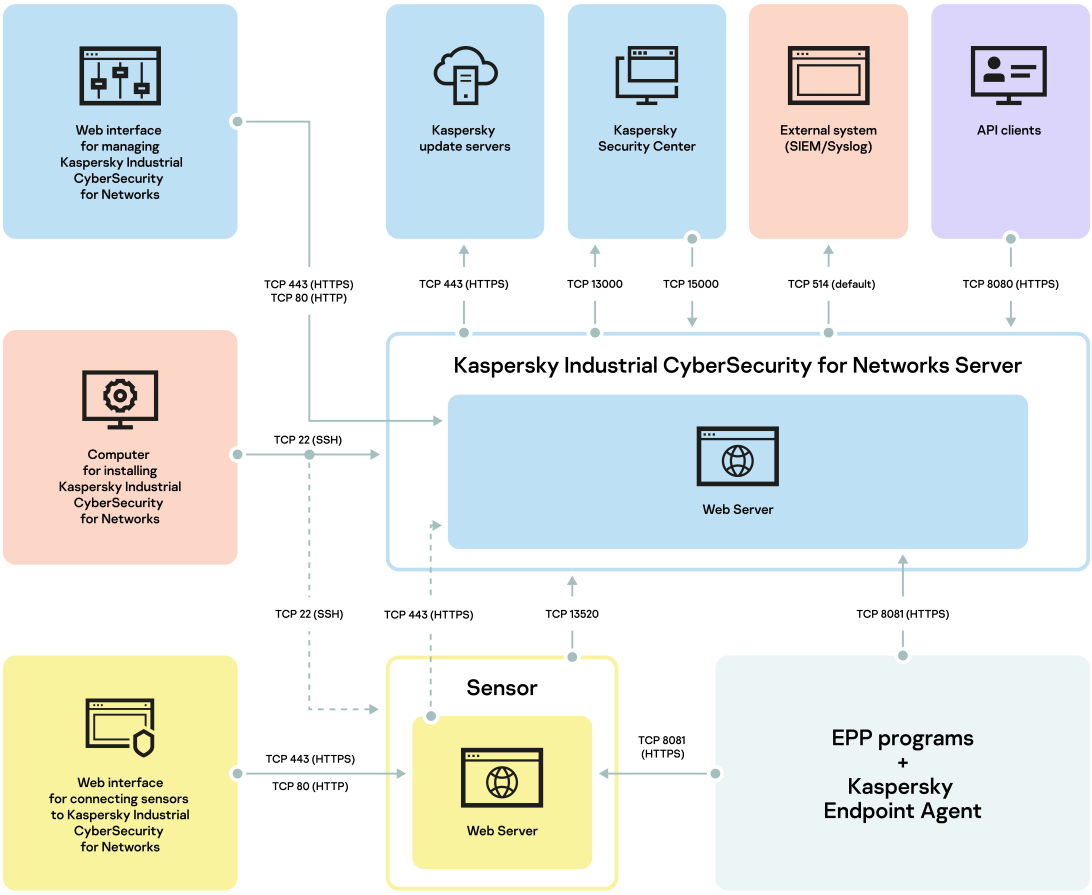
1. Find out and save the following information about the computer:
   - User account credentials for the account with root privileges that will be used to run the local installation script.
   - Name and IP address of the computer (for subsequent connection to this computer after installing the sensor).

   To display the computer name, you can enter the `hostname` command in the command line. To display information about IP addresses and network interfaces, you can enter the `sudo ifconfig` command in the command line.
2. Create a folder for storing the installation files.
3. Copy the following files from the Kaspersky Industrial CyberSecurity for Networks distribution kit to the folder you created:
   - Script for local installation of application components: kics4net-install.sh.
   - Package for installing the Server and sensors: kics4net-<application version number>.x86_64.rpm.
   - Package for installing the integration service: kics4net-epp-proxy-<application version number>.x86_64.rpm (this package is necessary if you want to add an integration server to a sensor node to receive data from EPP applications).
   - Package for installing the Intrusion Detection system: kics4net-suricata-<system version number>.x86_64.rpm.
   - Package for installing a web server for an application sensor: kics4net-websensor-<application version number>.x86_64.rpm.

Ports used for installation and operation of components

To ensure successful installation and operation of components of Kaspersky Industrial CyberSecurity for Networks, specific ports and protocols that will be used for data transfer must be available. You need to configure use of these ports and protocols in the settings of your network hardware or software that will be used to monitor network traffic.

The figure below shows the ports and protocols used by application components.



Utilized ports and protocols

The purpose of utilized ports is described in the table below.

Purpose of utilized ports

Port	Protocol	Description
Computer where application components are installed		
22	TCP (SSH)	This port is used to connect to nodes and to install Server and sensor components.
Computer that performs Server functions		
22	TCP (SSH)	This port is used for interaction with the computer where the application components are installed.
80	TCP (HTTP)	This port is used for connecting through the web interface.
443	TCP (HTTPS)	This port is used for the following purposes: • Connection through the web interface • Connection to Kaspersky update servers

		• Connection of a sensor through the web interface automatically over the network.
8080	TCP (HTTP)	This port is used to connect through the Kaspersky Industrial CyberSecurity for Networks API.
8081	TCP (HTTP)	This port is used to receive data from EPP applications (if an integration server was added to the Server node).
514	TCP	This port is used for connecting recipient systems through connectors.
13000	TCP	This port is used to connect to the Kaspersky Security Center Administration Server.
13520	TCP	This port is used for connections of sensors.
15000	UDP	This port is used for interaction between the application and Kaspersky Security Center.
Computer that performs sensor functions		
22	TCP (SSH)	This port is used for interaction with the computer where the application components are installed.
80	TCP (HTTP)	This port is used for connecting through the web interface.
8081	TCP (HTTP)	This port is used to receive data from EPP applications (if an integration server was added to the sensor node).

Using a script for centralized installation of application components

This section provides information on the capabilities for using the application components centralized installation script kics4net-deploy-<application version number>.bundle.sh. You can use this script for centralized installation and removal of the Server and sensors of Kaspersky Industrial CyberSecurity for Networks.

If installation or removal of application components is performed using the kics4net-deploy-<application version number>.bundle.sh script, you are not required to apply the local installation or local removal scripts that are included in the application distribution kit.

Centralized installation of application components

This section describes the procedure for centralized installation of application components when using the script named kics4net-deploy-<application version number>.bundle.sh.

Prior to centrally installing components, you must perform the necessary actions to prepare for application installation.

The application components centralized installation script uses data that was saved in the installation settings file. Running the script does not require root privileges for the current user account on the computer from which the installation will be performed.

During centralized installation of application components, by default the script verifies the checksums of packages in the folder containing the saved files from the distribution kit. This lets you verify the integrity of files from the application installation packages by comparing the calculated checksums of packages with their reference values. If a calculated checksum for even one package does not match the reference value, the installation script stops.

> It is recommended to centrally install application components with package checksum validation enabled. If necessary, you can disable validation of package checksums. However, correct installation of application components cannot be guaranteed if you do so.

To centrally install components of Kaspersky Industrial CyberSecurity for Networks on computers:

1. On the computer from which the installation will be performed, go to the folder containing the saved files from the distribution kit of Kaspersky Industrial CyberSecurity for Networks.

2. Enter the command for running the application components centralized installation script:

   ```
   bash kics4net-deploy-<application version number>.bundle.sh
   ```

   > If for some reason you need to enable validation of the checksums of packages used for application installation, you can enter the script startup command with the `--skip-checksum-validation` switch. This switch is intended only for testing and must not be used during normal installation of application components.

   The screen prompts you to choose the language of the installation menu.

3. Select the language that you want to use in the installation menu.

   > The choice of the installation menu language does not affect the localization of the Kaspersky Industrial CyberSecurity for Networks components. The capability to choose the localization language of application components is available during initial configuration of Kaspersky Industrial CyberSecurity for Networks after a Server is installed.

4. If the script was run without the `--skip-checksum-validation` switch, after selecting the language for the installation menu, the script runs a verification of the checksums of packages in the folder containing the saved files from the distribution kit. Wait for validation of the package checksums to complete.

   If a calculated checksum for even one package does not match the reference value, the installation script stops. In this case, replace the corrupted files with the original files from the distribution kit and run the application components centralized installation script again.

5. In the menu for selecting the installation option, select **Run new installation**.

   The main centralized installation menu appears on the screen.

6. Perform the following actions:

   a. Click the **Add Server** menu item to add the Kaspersky Industrial CyberSecurity for Networks Server node.

   b. If the Server is installed with sensors, use the **Add sensor** menu item to add nodes of sensors.

   c. Use the **Change the user running the installation** menu item to specify the user account with root privileges that will be used for centralized installation of application components. This user account will be used on those nodes for which no additional account was specified when configuring advanced settings.

7. When finished configuring the settings, select **Save settings and start installation**.

   You will be prompted to enter the password of the user running the installation.

8. Enter the password of the user running the installation. The password must be entered twice: first in the `SSH password` prompt and then in the `BECOME password` prompt.

   The installation script will begin the installation of components. During installation, the screen will display service messages regarding operations being completed.

Wait for completion of the script kics4net-deploy-<application version number>.bundle.sh.

After installation of Kaspersky Industrial CyberSecurity for Networks components is complete, the application is not yet ready to monitor your industrial network. To use the application, you need to perform the necessary actions to prepare the application for operation.

Centralized installation menu commands

This section provides information on the main commands in the centralized installation menu. The menu is displayed when you run the application components centralized installation script kics4net-deploy-<application version number>.bundle.sh. This file must be run in the folder that was created during preparations for application installation.

You can use the centralized installation menu to create or modify the application installation configuration and run the procedure for installing or removing components.

The installation menu has a hierarchical structure of items. The first level contains the items of the main menu. To select the necessary option, you must enter its number and press **ENTER**. If the selected item takes you to another group of items, a submenu will appear on the screen.

The menu items that define the values of settings may have default values or previously defined values. These values are displayed in brackets after the item name.

The main menu contains the following groups of commands:

- Server installation management commands

You can use the following installation menu commands to manage installation of the Server:

- **Add Server** – adds a new node that will be assigned Server functions. This item is available if the Server has not yet been added. If you select this option, you need to specify the main settings for the Server when the following prompts appear:

  - **Enter the IP address of the node for installation** – defines the IP address that will be used for connecting to the computer over the SSH protocol and installing the Server.

  - **Add the capability for application interaction with Kaspersky Security Center** – adds the functionality that allows use of the Kaspersky Security Center Administration Server to receive a license key and download updates, and to relay events and application state to Kaspersky Security Center. You do not have to add this functionality to relay events to other recipient systems.

    If the capability for application interaction with Kaspersky Security Center has been added, the Network Agent component of Kaspersky Security Center is installed when the application is installed. Kaspersky Security Center Network Agent is not installed if this component is being used by another Kaspersky application (to avoid disrupting the interaction between this application and the Kaspersky Security Center Administration Server). In addition, the functionality for interaction between Kaspersky Industrial CyberSecurity for Networks and Kaspersky Security Center may be limited if the version of the installed Network Agent differs from the version of this component provided in the distribution kit of Kaspersky Industrial CyberSecurity for Networks.

  - **Enable time synchronization between Server and sensors** – enables automatic time synchronization between the Server and nodes on which sensors are installed.

- **Change Server settings** – modifies the settings of the added Server. You can use this menu item to change the main component settings that can be edited and to configure advanced settings. After selecting this item, you will see a submenu in which you can change the following settings:

  - **Specify an additional user to run the installation** – defines an additional user account that will be used to run the installation on the Server node. An additional user account needs to be specified if the user name with root privileges on this node differs from the user name defined in the **Change the user running the installation** item. The passwords of all user accounts that will be used to run the installation must match.

  - **Enable hardware Watchdog** – enables use of the hardware Watchdog. The *hardware Watchdog* is a hardware-implemented system for controlling system hangs. If a node has a hardware Watchdog, you can enable its use in Kaspersky Industrial CyberSecurity for Networks. If the use of a hardware Watchdog is enabled, specify its path in the **Specify path to hardware Watchdog** item.

  - **Add the capability for application interaction with Kaspersky Security Center** – adds the functionality enabling the application to interact with Kaspersky Security Center (if this functionality was not already added). This menu item is analogous to the **Add the capability for application interaction with Kaspersky Security Center** item in the **Add Server** menu.

  - **Remove the capability for application interaction with Kaspersky Security Center** – removes the functionality that lets the application interact with Kaspersky Security Center.

  - **Create database again** – deletes the existing database and creates a new one during reinstallation of the application.

If you select this menu item, information in the existing database will be lost after Server installation.

- **Remove Server** – removes the Server node.

- Sensor installation management commands

  You can use the following installation menu commands to manage installation of sensors:

  - **Add sensor** – adds a new node that will be assigned sensor functions. If you select this option, you need to specify the main settings for the sensor when the **Enter the IP address of the node for installation** prompt appears. In this prompt, you can define the IP address that will be used for connecting to the computer over the SSH protocol and installing the sensor.

  - **Change sensor settings** – modifies the settings of the added sensor. You can use this menu item to change the main sensor settings that can be edited and to configure advanced settings. Selecting this menu item displays a list of nodes on which sensors have been added. After selecting a node, you will see a submenu in which you can change the following settings:

    - **Specify an additional user to run the installation** – defines an additional user account that will be used to run the centralized installation on the sensor node. An additional user account needs to be specified if the user name with root privileges on this node differs from the user name defined in the **Change the user running the installation** item. The passwords of all user accounts that will be used to run the installation must match.

    - **Enable hardware Watchdog** – enables use of the hardware Watchdog. The *hardware Watchdog* is a hardware-implemented system for controlling system hangs. If a node has a hardware Watchdog, you can enable its use in Kaspersky Industrial CyberSecurity for Networks. If the use of a hardware Watchdog is enabled, specify its path in the **Specify path to hardware Watchdog** item.

  - **Remove sensor** – removes the sensor node. Selecting this item displays a list of nodes on which sensors have been added.

- General installation commands

  General installation menu commands include the following commands:

  - **Change the user running the installation** – defines the user name with root privileges that runs the centralized installation of application components. The same password for the user accounts that will run the installation must be set on all computers. The password must be entered during installation of components.

  - **View application installation settings** – displays the list of installation settings and their values.

- Installation menu exit commands

You can use the following commands to exit the centralized installation menu:

- **Save settings and start installation** – install the Kaspersky Industrial CyberSecurity for Networks application components according to the defined installation settings. The defined settings are saved in the installation settings file. The application centralized installation script saves the installation settings file on each computer on which the script is run.
- **Save settings and exit without installing** – save changes to the installation settings file, terminate the application centralized installation script, and exit without installing components.
- **Exit without saving settings** – terminate the application centralized installation script without saving changes to the installation settings file.

Reconfiguration and centralized reinstallation of application components

You can centrally reinstall components of Kaspersky Industrial CyberSecurity for Networks. For example, reinstallation of components may be required in the following cases:

- To add a new sensor.
- To change settings that can be defined using the application components centralized installation script.

To centrally reinstall application components, the script named kics4net-deploy-<application version number>.bundle.sh uses the installation settings file that was saved on the computer. If the installation settings file on this computer is corrupt or missing from its original folder, the application centralized installation script searches for a copy of the file on the computer and on other computers that have application components installed.

To centrally reinstall components of Kaspersky Industrial CyberSecurity for Networks:

1. Run the application centralized installation script by completing steps 1–4 of the installation procedure.
2. In the menu for selecting the installation option, select **Edit settings of current installation**.

   The main centralized installation menu appears on the screen.
3. Depending on the necessary result, perform the following actions:

   - Using the **Change Server settings** menu item, specify the necessary settings for the Server.

     You cannot change the IP address of the Server. If you want to change the IP address, you need to first remove the existing Server and then add it again with the new IP address by using the **Add Server** menu item (this menu item appears if a Server has not been added).
   - If the Server was installed with sensors, use the **Change sensor settings** menu item to specify the necessary settings for the sensors.

     You cannot change the IP address of a previously added sensor. If you want to change the IP address, you need to first remove the existing sensor and then add it again with the new IP address by using the **Add sensor** menu item. You can also use this menu item to add new sensors.
   - Use the **Change the user running the installation** menu item to specify the user name of the account with root privileges that will be used to centrally install the application components on computers. This account

will be used on those nodes for which no additional account was specified when configuring advanced settings of the Server or sensors.

4. When finished configuring the settings, select **Save settings and start installation**.

   You will be prompted to enter the password of the user running the installation.

5. Enter the password of the user running the installation. The password must be entered twice: first in the `SSH password` prompt and then in the `BECOME password` prompt.

   The installation script will begin the installation of components. During installation, the screen will display service messages regarding operations being completed.

Wait for completion of the script kics4net-deploy-<application version number>.bundle.sh.

Centralized installation of application components in non-interactive mode

You can centrally install application components in non-interactive (silent) mode, which means without the interactive input of installation settings. For non-interactive centralized installation, you must use special settings when you run the application components centralized installation script kics4net-deploy-<application version number>.bundle.sh.

You must prepare an installation settings file for non-interactive centralized installation. You can prepare an installation settings file by using the script kics4net-deploy-<application version number>.bundle.sh.

To prepare a centralized installation settings file using the script:

1. Configure the centralized installation settings by completing steps 1-6 of the installation procedure.

2. Save the installation settings file by selecting the **Save settings and exit without installing** menu item.

   The installation settings file named inventory.json is saved in the /home/<user>/.config/kaspersky/kics4net-deploy/ folder (the application components will not be installed).

3. If necessary, copy the centralized installation settings file into a different folder.

After preparing the centralized installation settings file, you can centrally install the application components in non-interactive mode.

During centralized installation of application components in non-interactive mode, there is no validation of the checksums of packages in the folder containing the saved files from the distribution kit. You can verify the checksums of packages by completing steps 1–4 of the installation procedure prior to starting centralized installation of components in non-interactive mode.

To centrally install application components in non-interactive mode:

1. On the computer from which the centralized installation will be performed, go to the folder containing the saved files from the distribution kit of Kaspersky Industrial CyberSecurity for Networks.

2. Enter the following command:

   `bash kics4net-deploy-<application version number>.bundle.sh --silent-mode`

   `silent-mode` enables non-interactive installation mode (mandatory switch).

   In addition to the mandatory switch, you may also add the following switches for running the installation script:

- `-i <path to the installation settings file>` – indicates the full path and name of the centralized installation settings file. If the setting is not defined, the inventory.json file located in the /home/<user>/.config/kaspersky/kics4net-deploy/ folder is used.

- `--enable-debug-grpc-server` – installs a debug gRPC server. This gRPC server is used for testing purposes and is not required for normal use of the application.

  If the script is run with the `--enable-debug-grpc-server` switch, the application will lose its certified state.

After you enter a script run command, the screen will prompt you to enter the password of the user running the centralized installation.

3. Enter the password of the user running the centralized installation. The password must be entered twice: first in the `SSH password` prompt and then in the `BECOME password` prompt.

   The centralized installation script will begin the installation of components. During installation, the screen will display service messages regarding operations being completed.

Wait for completion of the script kics4net-deploy-<application version number>.bundle.sh.

Reinforcing the security of computers with application components installed

After installing Kaspersky Industrial CyberSecurity for Networks, it is recommended to reinforce the security of the operating systems on computers that have application components installed. To reinforce security, you can use the application components centralized installation script named kics4net-deploy-<application version number>.bundle.sh or locally run the kics4net-harden.sh script, which is located on the computer with the installed application component in the /opt/kaspersky/kics4net/sbin/ folder.

You can use the script to perform the following actions:

- Enable prevention of the startup of operating system services that are not required for the operation of application components (for example, avahi-daemon and cups).

- Change the network configuration settings that impact the security of the operating system (for example, enable prevention of redirected network packet processing over the ICMP protocol).

The centralized application components installation script performs actions that harden the security on all computers that have application components installed.

To reinforce security, this script uses the centralized installation settings file that was saved on the computer. If the centralized installation settings file on this computer is corrupt or missing from its original folder, the script searches for a copy of the file on the computer and on other computers that have application components installed.

To reinforce security of computers using the kics4net-deploy-<application version>.bundle.sh script:

1. On the computer from which the centralized installation was performed, go to the folder containing the saved files from the distribution kit of Kaspersky Industrial CyberSecurity for Networks.

2. Enter the following command:

`bash kics4net-deploy-<application version number>.bundle.sh --harden <parameter>`

where `<parameter>` is one of the following startup parameters:

- `-s` enables prevention of the startup of operating system services.
- `-n` modifies the network configuration settings.
- `-a` enables prevention of the startup of operating system services and modifies the network configuration settings.

3. In the `SSH password` and `BECOME password` prompts, enter the password for the user account that is running the centralized installation.

Wait for completion of the script kics4net-deploy-<application version number>.bundle.sh. If it completes successfully, the screen displays information about the actions performed on computers with application components installed.

Centralized removal of application components

Kaspersky Industrial CyberSecurity for Networks components can be removed centrally by using the application components centralized installation script. This script lets you remove application components from individual nodes of the Server or sensors or fully uninstall the current version of the application as well as previous versions (beginning with version 2.0).

For removal of components, the script kics4net-deploy-<application version number>.bundle.sh uses the centralized installation settings file that was saved on the computer. If the centralized installation settings file on this computer is corrupt or missing from its original folder, the application installation script searches for a copy of the file on the computer and on other computers that have application components installed.

To centrally remove application components from individual nodes:

1. Run the application components centralized installation script by completing steps 1–4 of the installation procedure.
2. In the menu for selecting the installation option, select **Edit settings of current installation**.

   The main centralized installation menu appears on the screen.
3. Depending on the necessary result, perform the following actions:
   - Use the **Remove Server** menu item to remove a Server node.

     After removing the Server node, you need to add a different Server node to ensure proper performance of the application.
   - Use the **Remove sensor** menu item to remove a sensor node (if multiple sensors have been added to the application, select the relevant node in the list of nodes that have added sensors).
4. When finished configuring the settings, select **Save settings and start installation**.
5. In the `SSH password` and `BECOME password` prompts, enter the password for the user account that is performing the centralized removal of application components.

Wait for completion of the script kics4net-deploy-<application version number>.bundle.sh.

To completely remove the application:

1. Run the application components centralized installation script by completing steps 1–4 of the installation procedure.
2. In the menu for selecting the installation option, select **Edit settings of current installation**.

   The main centralized installation menu appears on the screen.
3. Use the **Remove Server** menu item to remove a Server node.
4. If sensors have been added to the application, use the **Remove sensor** menu item to sequentially remove all nodes of sensors.
5. Use the **Removal settings** menu item to configure advanced settings for centralized removal. When this item is selected, the following prompts are displayed:

   - **Remove the application together with data**. If you want to delete all data saved by the application in the system, enter `y`. If you do not need to remove the data, enter `n`.
   - **Remove Network Agent**. If you want to remove the Kaspersky Security Center Network Agent component, enter `y`. If you do not need to remove this component, enter `n`. This prompt is displayed if an installed Network Agent is detected.
6. Select **Save settings and start installation**.
7. In the `SSH password` and `BECOME password` prompts, enter the password of the user account performing the centralized removal.

Wait for completion of the script kics4net-deploy-<application version number>.bundle.sh.

Removal of Kaspersky Industrial CyberSecurity for Networks does not automatically delete the additional files from the distribution kit that were manually copied to the computer (such as the package containing descriptions of specifications for the Kaspersky Industrial CyberSecurity for Networks API). If necessary, these files can be manually deleted.

Using a script for local installation of application components

This section describes the procedure for local installation of an application component (Server or sensor) on a computer by using the kics4net-install.sh script.

Prior to locally installing components, you must perform the necessary actions to prepare for application installation.

The application components local installation script can install only one of the components (Server or sensor) on a computer. If an application component (for example, the Server) is already installed on a computer, you cannot install a different type of component (in this case, a sensor) on this computer. If you attempt to install the same type of component on the computer, the local installation script will reinstall the component.

When installing the Server, the Kaspersky Security Center Network Agent component is automatically installed. Kaspersky Security Center Network Agent is not installed if this component is being used by another Kaspersky application (to avoid disrupting the interaction between this application and the Kaspersky Security Center Administration Server). In addition, the functionality for interaction between Kaspersky Industrial CyberSecurity for Networks and Kaspersky Security Center may be limited if the version of the installed Network Agent differs from the version of this component provided in the distribution kit of Kaspersky Industrial CyberSecurity for Networks.

To locally install a component of Kaspersky Industrial CyberSecurity for Networks on a computer:

1. Log in to the system using the account credentials of a user account with root privileges that you want to use to run the local installation script.

2. Go to the folder containing the saved files from the Kaspersky Industrial CyberSecurity for Networks distribution kit.

3. Enter the command for running the application components local installation script:

   `bash kics4net-install.sh --<component type>`

   where `<component type>` is one of the following startup parameters:

   - `server` – for installing the Server.
   - `sensor` – for installing a sensor.

   The script will begin installation of the component. During installation, the screen will display service messages regarding operations being completed.

Please wait for the kics4net-install.sh script to finish.

Using a script for local removal of application components

This section describes the procedure for local removal of an application component (Server or sensor) from a computer by using the kics4net-remove.sh script.

The application components local removal script deletes the files of the installed component from the computer, except for data that was saved by the application in the system.

To locally remove a component of Kaspersky Industrial CyberSecurity for Networks from a computer:

1. Log in to the system using the account credentials of a user account with root privileges that you want to use to run the local removal script.

2. Go to the folder containing the saved files from the Kaspersky Industrial CyberSecurity for Networks distribution kit.

3. Enter the command for running the application components local removal script:

   `bash kics4net-remove.sh`

   The script will begin removal of the component. During removal, the screen will display service messages regarding operations being completed.

Wait for the kics4net-remove.sh script to finish.

Installing the Kaspersky Industrial CyberSecurity for Networks Administration Plug-in for Kaspersky Security Center

The Kaspersky Industrial CyberSecurity for Networks Administration Plug-in for Kaspersky Security Center (hereinafter also referred to as the "administration plug-in") must be installed on the computer on which the Kaspersky Security Center Administration Server is installed. The administration plug-in needs to be installed using an account that belongs to the group of local administrators.

You can install the administration plug-in in one of the following ways:

- Using the Setup Wizard.
- From the command line.

After installation, the Kaspersky Industrial CyberSecurity for Networks Administration Plug-in for Kaspersky Security Center appears in the list of installed administration plug-ins in the properties of the Kaspersky Security Center Administration Server. For detailed information on working with the Kaspersky Security Center Administration Server, please refer to the Kaspersky Security Center Help system.

To install the administration plug-in using the Wizard:

1. On the computer where the Kaspersky Security Center Administration Server is installed, run the file named kics4net-sc-plugin_<plug-in version number>_<localization code>.msi from the Kaspersky Industrial CyberSecurity for Networks distribution kit.

   Run the file with the localization code that matches the localization language of Kaspersky Security Center.

2. Follow the instructions of the Setup Wizard.

To install the administration plug-in from the command line:

1. On the computer where the Kaspersky Security Center Administration Server is installed, open the command line interface.
2. Go to the folder that contains the file named kics4net-sc-plugin_<plug-in version number>_<localization code>.msi from the Kaspersky Industrial CyberSecurity for Networks distribution kit.
3. Enter the following command in the command line:

   ```
   kics4net-sc-plugin_<plug-in version number>_<localization code>.msi <settings for starting MSI files>
   ```

   where:

   - `<localization code>` – localization code of the administration plug-in. Run the file with the localization code that matches the localization language of Kaspersky Security Center.
   - `<settings for starting MSI files>` refers to one or several standard startup settings provided for Windows Installer. You can receive information about available settings by running a file with the `/help` setting.

Upgrading from a previous version of the application

You can upgrade a previous version of Kaspersky Industrial CyberSecurity for Networks (starting with version 3.0). You can use the following options for upgrading the application to the current version:

- Centrally on all nodes where the previous version of the application was installed.

  This option uses the application components centralized installation script to complete the procedure for centralized re-installation of components (without removing Server and sensor nodes where you want to upgrade the application).

- Locally at each node where a component from the previous version of the application is installed.

  This option uses the application components local installation script.

Getting started

After installing components of Kaspersky Industrial CyberSecurity for Networks, you need to prepare the application for operation. The preparation process consists of the following main steps:

1. **Initial configuration of the application**

   At this step, the main application settings are configured after Server installation. After this step is completed, the Server will be available for connection and for operations with the application through the web interface.

2. **Adding and connecting sensors**

   This step is necessary when you install external sensors along with the Server. After this step is completed, nodes that have sensors installed will be ready for further configuration.

3. **Adding monitoring points**

   At this step, monitoring points are added on nodes that have application components installed. After this step is completed, the application begins to analyze traffic coming from industrial network segments to network interfaces hosting monitoring points.

4. **Adding application users**

   At this step, application user accounts are created in addition to the user account that was created during initial configuration of the application. After this step is completed, the application will have multiple user accounts that you can use to restrict access to application functions and monitor activity based on audit entries.

5. **Adding a license key**

   This step adds a license key to the application to activate the update functionality. After this step is completed, you will be able to configure and utilize the functionality for updating application modules and databases.

6. **Configuring updates of application modules and databases**

   This step is necessary if a license key was added to the application. After this step is completed, you will be able to install updates for application modules and databases.

7. **Configuring Asset Management**

   At this step, lists of devices and subnets known to the application are generated. After this step is completed, the application will be configured to track the relevant devices in the industrial network.

8. **Configuring Process Control**

   At this step, the settings of devices are configured for proper industrial process control by the application. After this step is completed, you will be able to use the application to monitor industrial process parameters (including with the use of rules) and track the system commands that are transmitted.

9. **Configuring Interaction Control**

   At this step, rules are generated to identify network interactions that are authorized or unauthorized by the application. After this step is completed, rules allowing interactions between specific devices and authorized system commands will be configured (the application will not register events when these rules are triggered).

10. **Configuring Intrusion Detection**

    This step is necessary for configuring the application to implement Intrusion Detection functionality. After this step is completed, you will be able to use Intrusion Detection rules (already embedded rules and/or rules additionally uploaded to the application) and track traffic anomalies showing signs of an attack.

Initial configuration of the application after Server installation

After the Server is installed using the script for centralized installation or another method, the application awaits completion of initial configuration. Initial configuration can be completed by any user connected to the Server through the web interface.

To perform initial configuration of the application after a Server is installed:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface. Use the IP address of the Server computer for the connection.

2. Select **Initial configuration**.

3. In the **Application localization language** field, select the localization language for components of Kaspersky Industrial CyberSecurity for Networks (and for the data provided by these components).

4. In the **Administrator account** settings group, define the user account name and password for the first application user. The Administrator role will be assigned to this user. This user does not have to be registered as an operating system account on the Server computer or other computer.

   For the account name, you can enter any unique name using uppercase and lowercase letters of the English alphabet, numerals, dots, and the following special characters: _ and - (for example, Admin_1). The name must contain from 3 to 20 characters, must begin with a letter, and end with any supported character except a dot.

   The password must meet the following requirements:

   - Must contain between 8 and 256 ASCII characters.
   - Must contain one or more uppercase letters of the English alphabet.
   - Must contain one or more lowercase letters of the Latin alphabet.
   - Must contain one or more numerals.
   - Must contain no more than three consecutive repeated characters.

5. In the **Application Server** field, enter the name of the Server used in Kaspersky Industrial CyberSecurity.

   The Server name must be unique (not match the names of sensors on other nodes) and must contain no more than 100 characters. You can use letters of the English alphabet, numerals, a space, and the following special characters: _ and - (for example, `Server_1`). The Server name must begin and end with any permitted character except a space.

6. Please read the terms of the End User License Agreement and the Privacy Policy. To do so, open each document by using the corresponding links in the names of the following check boxes: **I confirm that I have fully read, understand, and accept the terms and conditions of this End User License Agreement** and **I am**

aware and agree that my data will be handled and transmitted (including to third countries) as described in the Privacy Policy. I confirm that I have fully read and understand the terms of the Privacy Policy.

7. If you fully agree to the terms of the End User License Agreement and the Privacy Policy, select both check boxes.

   If you do not agree to the terms of the End User License Agreement and/or the Privacy Policy, close the web interface page and remove the installed application components from your computers.

8. Click the **Continue** button.

   After the defined settings are applied, the web interface page will open to the normal operating mode of the application. The account credentials of the first application user will be used for the current connection session.

You can revert the Server to the initial state using the kics4net-reset-to-defaults.sh script. The script is located on the computer with the installed application component in the /opt/kaspersky/kics4net/sbin/ folder.

Starting and stopping the application

A component of the application installed on a computer is started automatically when the operating system of the computer is loaded. An application component must be configured so that it can work properly. Components are configured when the application is being prepared for operation.

The application performs industrial network traffic analysis functions if it receives traffic through monitoring points. You can disable or enable monitoring points to suspend or resume analysis of traffic received by these monitoring points.

Nodes with Kaspersky Industrial CyberSecurity for Networks components installed receive and process data from EPP applications if integration servers were added on these nodes. You can disable and enable integration servers to suspend and resume receipt of data from EPP applications, respectively.

To manage operation of the application and view information, you can connect to the Server through the web interface. When you are done working with the Server, you are advised to properly close the connection session.

To configure the connection between a sensor and the Server, and to view information about the connection state, you can connect to the sensor through the web interface. When connecting to a sensor, you are not required to enter your user account credentials. Therefore, you do not need to do anything to close the connection session.

Connecting to the Server through the web interface

You can use any supported browser to connect to the Server through the web interface. You can connect from any computer that has network access to the computer hosting the Kaspersky Industrial CyberSecurity for Networks Server.

To connect to the Kaspersky Industrial CyberSecurity for Networks Server:

1. Open your browser and enter the following in the address bar:
   `https://<Server name>:<port>`
   where:
   - `<Server name>` is the IP address or computer name used by the web server on the Server computer.
   - `<port>` is the port number specified for the web server.

   If a port number is not specified (prior to initial configuration of the application) or if the default port number (443) is specified for the web server, you only need to enter the IP address or computer name of the Server in the address bar. In this case, the HTTPS protocol and the port number will be automatically determined.

2. When the account credentials entry page opens, enter the application user name and password and click the **Log in** button.

   The Kaspersky Industrial CyberSecurity for Networks Server web interface page opens in the browser window. The name of the browser bookmark for the web interface page will show the Server name that was defined during initial configuration of the application after installation.

A Server connection session has a time limit. A session remains active for 10 hours. If 10 hours have passed since the connection was established, the current page of the application web interface switches to the page for entering account credentials. If this happens, to continue working you will need to re-enter your application user name and password.

Closing a Server connection session through the web interface

When you are done working with the Kaspersky Industrial CyberSecurity for Networks Server through the web interface, make sure you close the connection session in your browser.

If you close the browser window without first closing the connection session, the session will remain active. A session remains active for 10 hours. During this time, the application can grant access to the web interface of the Kaspersky Industrial CyberSecurity for Networks Server without prompting for user account credentials, provided that the connection is used by the same computer, browser, and operating system account.

To close the connection session with the Kaspersky Industrial CyberSecurity for Networks Server:

1. On the Kaspersky Industrial CyberSecurity for Networks Server web interface page, open the user menu:
   - If the menu is collapsed, click the button.
   - If the menu is expanded, click the button on the right of the name of the current user.
2. In the user menu, select **Log out**.

   The browser window shows the page for entering account credentials.

Connecting to a sensor through the web interface

You can connect to a Kaspersky Industrial CyberSecurity for Networks sensor through the web interface. You can do the following on the sensor web interface page:

- Download the communication data package for connecting the sensor to the Kaspersky Industrial CyberSecurity for Networks Server.
- View the fingerprint of the certificate signing request to compare it with the fingerprint on the Server web interface page if the sensor is being connected to the Server automatically over the network.
- View information about the status of the connection between the sensor and the Server.

You can use any supported browser to connect to the sensor through the web interface. This connection can be established from a computer that can access the sensor computer over the network.

To connect to a Kaspersky Industrial CyberSecurity for Networks sensor:

Open your browser and enter the following into the address bar:
`https://<sensor name>:<port>`

where:

- `<sensor name>` is the IP address or name of the sensor computer used by the web server of the sensor.

- <port> is the port number used by the web server of the sensor.

If the default port number (443) is used for the sensor web server, you only need to enter the IP address or computer name of the sensor into the address bar. In this case, the HTTPS protocol and the port number will be automatically determined.

The Kaspersky Industrial CyberSecurity for Networks sensor web interface page opens in the browser window. The name of the browser bookmark for the web interface page will show the sensor name that was defined when the sensor was added.

Application interface

This section describes the primary application interface elements.

Kaspersky Industrial CyberSecurity for Networks Server web interface

When you connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface, the Server web interface page opens in your browser. The contents of the web interface page depend on the application operating mode and on the specific role of the connected user account.

Depending on the application operating mode, the web interface page may contain the following management elements or messages:

- Initial configuration of the application – management elements for configuring the Server after its installation and for viewing and accepting the End User License Agreement and Privacy Policy.
- Normal operating mode of the application – management elements for configuring and utilizing application functionality.
- Application maintenance – message regarding an operation that must be completed before the Server will be available for connections.

When the application is running in its normal operating mode, its available functionality on the web interface page depends on the role of the connected user account. If the user role does not grant the permissions to utilize application management functions, the corresponding management elements are either not displayed on the web interface page or are unavailable.

About the Server web interface during initial configuration of the application

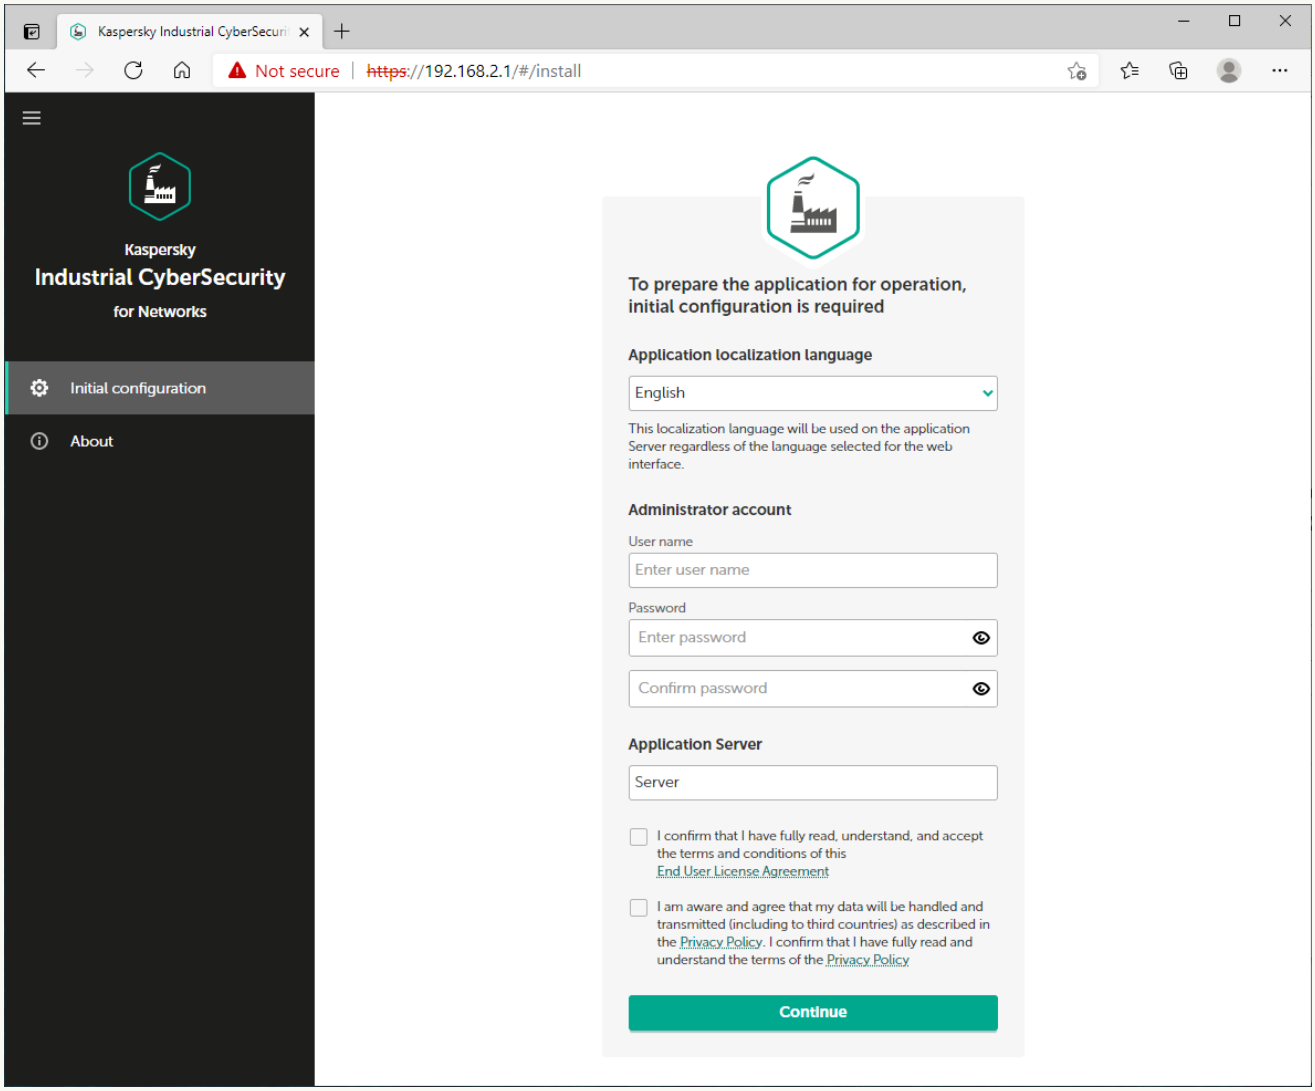
When connecting to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface for the first time after installing the application, you are not prompted to enter your user account credentials to log in. Instead of the account credentials entry page, you see a page containing management elements for configuring the Server and for viewing and accepting the End User License Agreement and Privacy Policy.

A menu is displayed in the left part of the web interface page. The contents of the selected section are displayed on the right.

The web interface menu contains the following items:

- – expands and collapses the menu. If the menu is collapsed, the items are displayed without text descriptions.
- – opens the **Initial configuration** section.

In the **Initial configuration** section of the Server web interface (see the figure below), you can configure the Application Server's main settings that are required before the application can begin operations after installation.



Initial configuration section

This section contains a window that you can use to configure the main settings of the Server, create the first user with the Administrator role, and carefully read and accept the terms of the End User License Agreement and Privacy Policy. After completing these actions, this web interface page will automatically close (along with other Server connection sessions through the web interface) and you will be taken to the Server web interface page for the normal operating mode of the application.

- – opens a section containing brief information about the application.

About the Server web interface during normal operation of the application

After connecting to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface while the application is running in normal operating mode, a web interface page opens to provide tools for working with the application. The available tools and their functionality depend on the role of the user who established the connection to the Server.

A menu is displayed in the left part of the web interface page. The contents of the selected section are displayed on the right.

The web interface menu contains the following items:

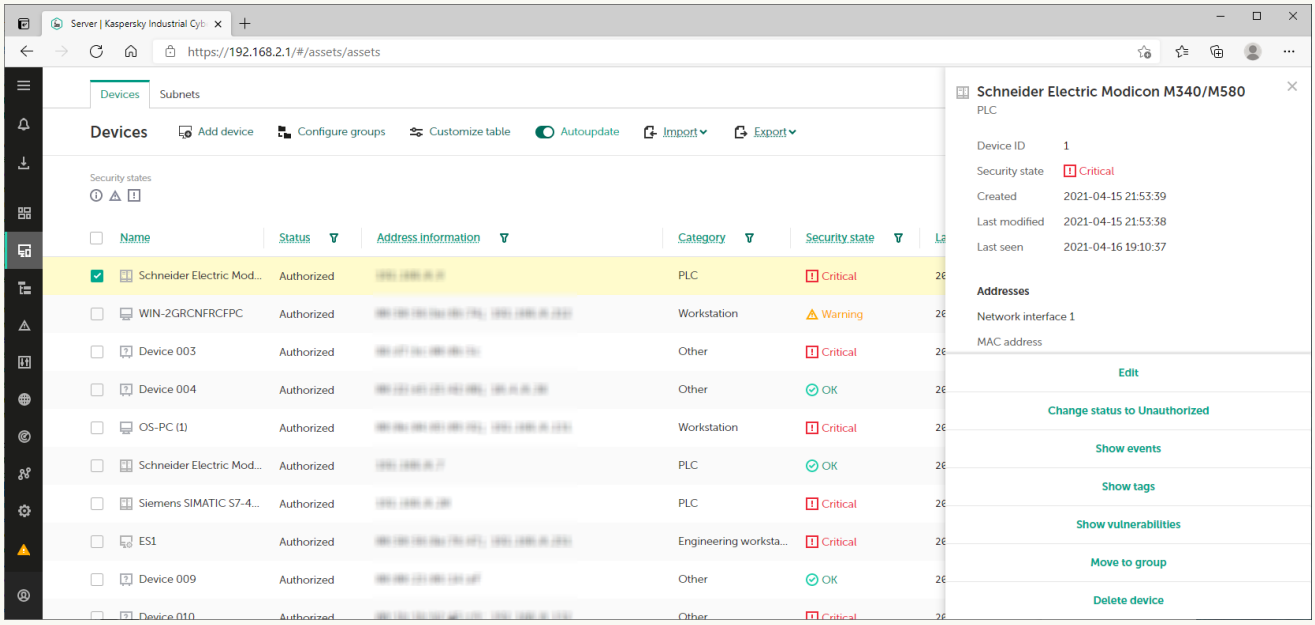
- – expands and collapses the menu. If the menu is collapsed, the items are displayed without text descriptions.
- – opens a list of notifications regarding application operating issues. The availability of notifications is indicated by an icon whose color corresponds to the status of the notifications.
- – opens a list of background operations. This list contains information about operations that take a long time (for example, creating a file when exporting a large number of events). The number of active background operations and their progress status are indicated by an icon. The icon is colored red if there are operations that resulted in errors.
- – opens the **Dashboard** section.

  In the **Dashboard** section of the Application Server web interface (see the figure below), you can view information about the current state of the system in online mode.

  
  Dashboard section

- – opens the **Assets** section.

In the **Assets** section of the Application Server web interface (see the figure below), you can view and edit information about known devices and settings of known subnets.



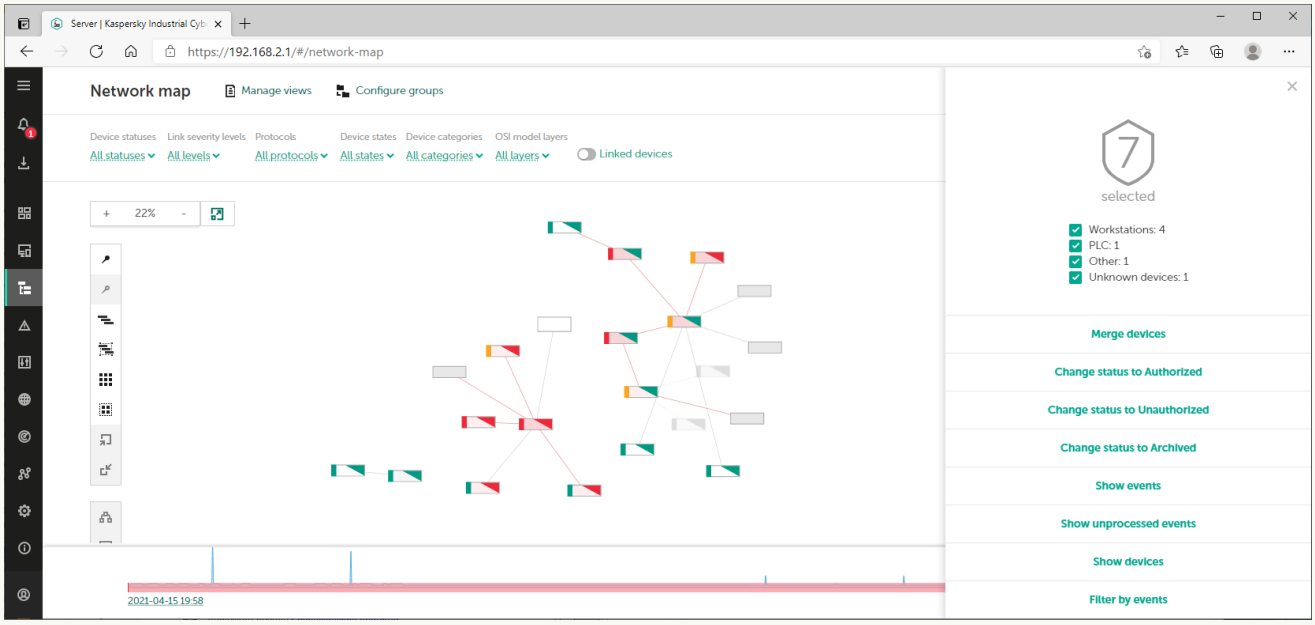
Assets section

The **Assets** section contains tabs with tables of devices and subnets.

When a device or subnet is selected, the details area opens in the right part of the section. The details area contains information about the selected elements and the tools for managing them.

- – opens the **Network map** section.

In the **Network map** section of the Application Server web interface (see the figure below), you can view information about the interactions of devices.



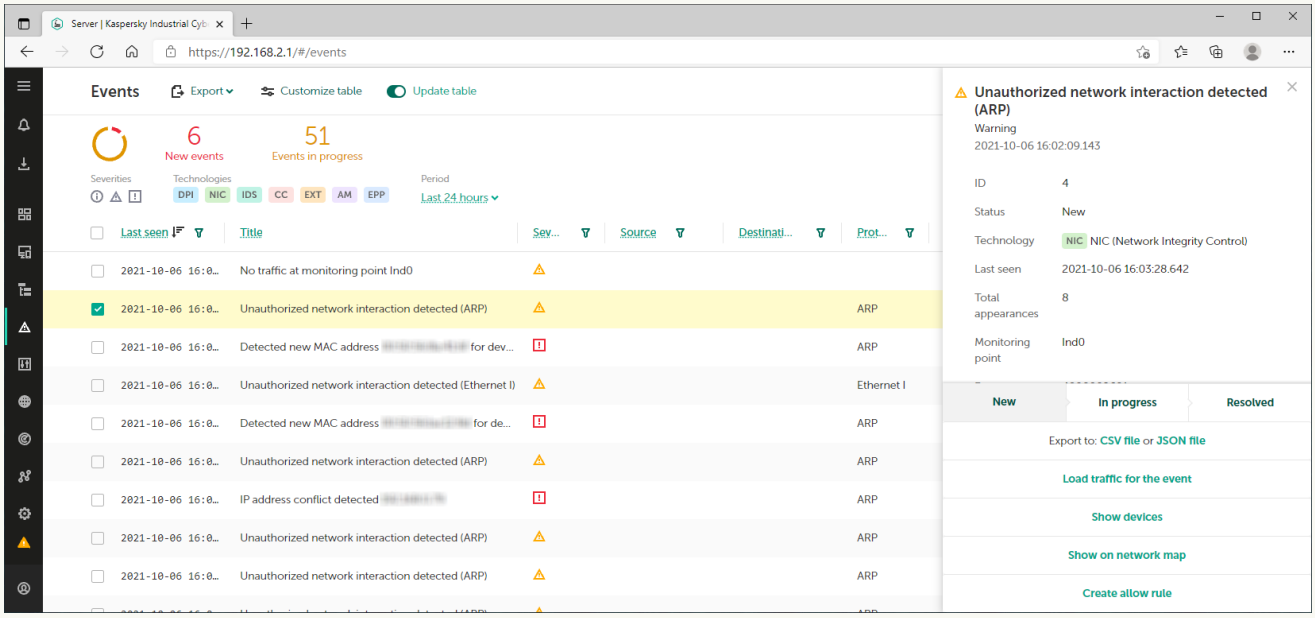
Network map section

The **Network map** section contains the main toolbar in the upper part, an area for displaying objects on the network map, and additional toolbars for managing the position of objects. The lower part of the section contains a time scale for filtering objects by time period.

When objects are selected, the details area opens in the right part of the section. The details area contains information about the selected objects and the tools for managing them.

- – opens the **Events** section.

In the **Events** section of the Application Server web interface (see the figure below), you can view and process events and incidents registered by the application.



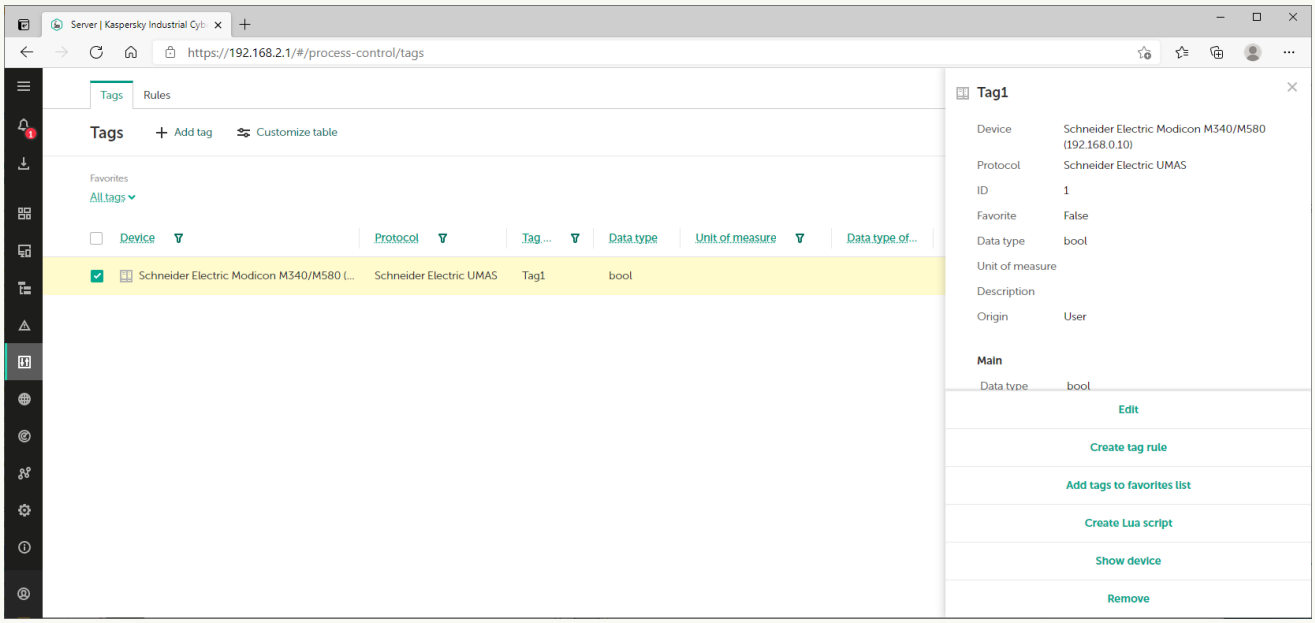
Events section

The **Events** section contains a toolbar and the events table.

When events are selected, the details area opens in the right part of the section. The details area contains information about the selected events and the tools for managing them.

- – opens the **Process control** section.

In the **Process control** section of the Application Server web interface (see the figure below), you can view and edit tags and Process Control rules.



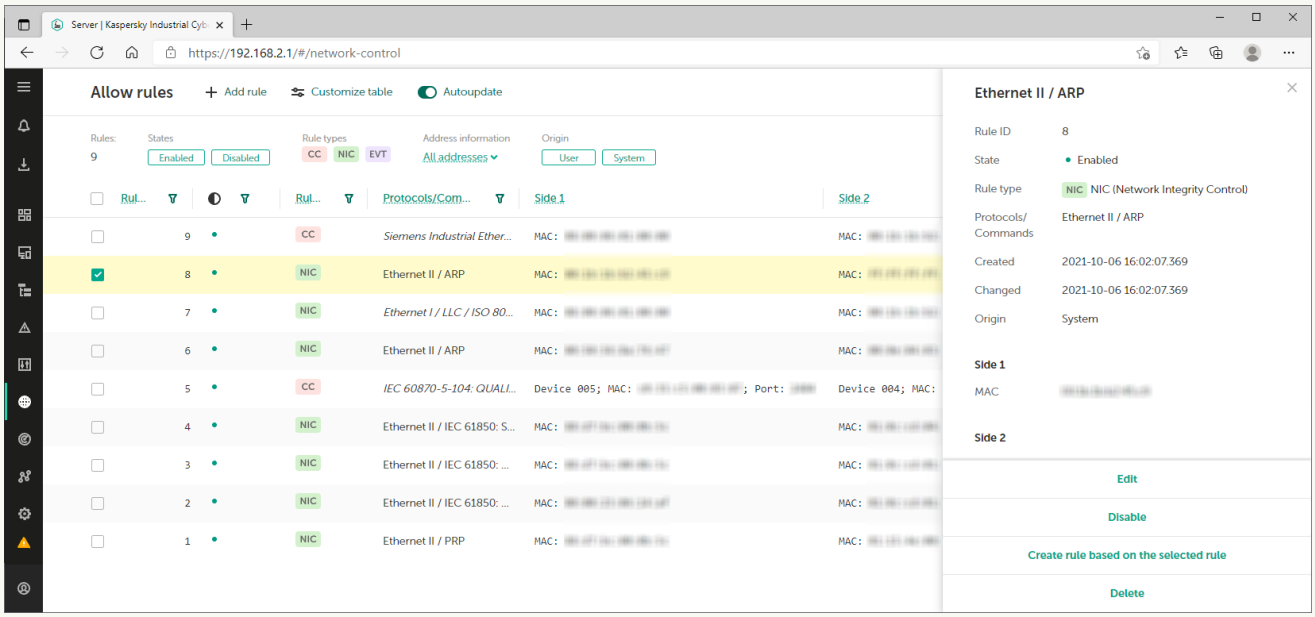
Process control section

The **Process control** section contains tabs with tables of tags and Process Control rules.

When tags or rules are selected, the details area opens in the right part of the section.

- – opens the **Allow rules** section.

  In the **Allow rules** section of the Application Server web interface (see the figure below), you can view and edit allow rules for the application.



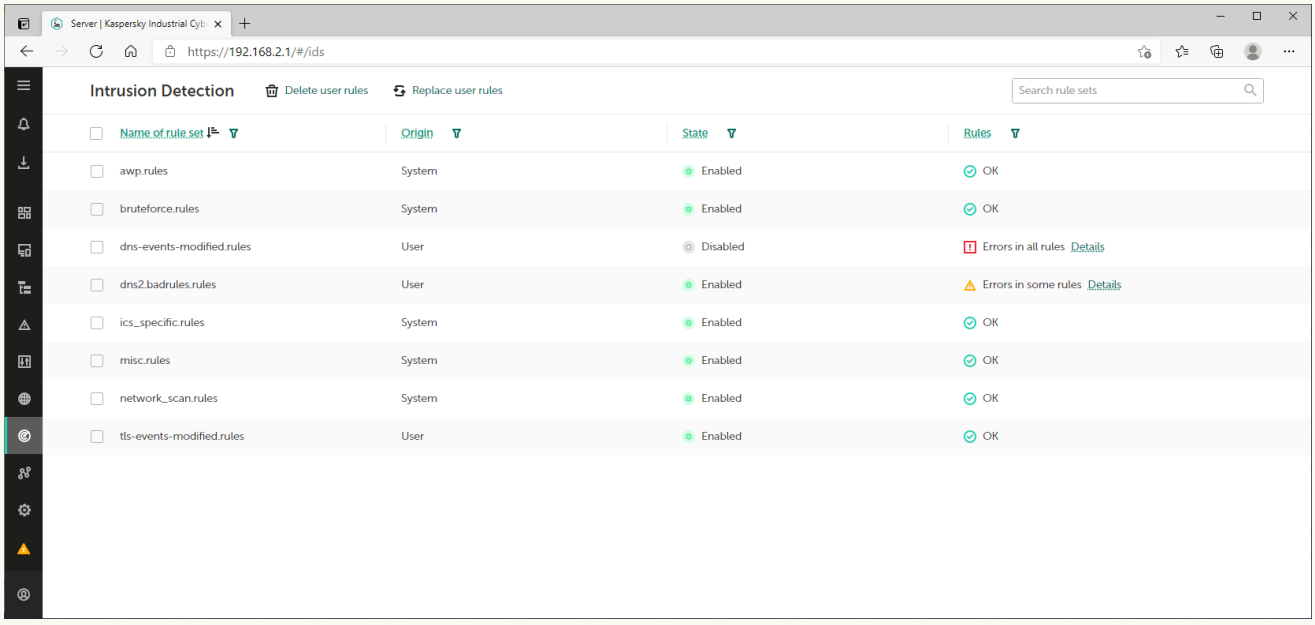
Allow rules section

The **Allow rules** section contains a toolbar and table of allow rules for Interaction Control and for events.

When rules are selected, the details area opens in the right part of the section. The details area contains information about the selected rules and the tools for managing them.

- – opens the **Intrusion detection** section.

  In the **Intrusion detection** section of the Application Server web interface (see the figure below), you can manage sets of Intrusion Detection rules.



Intrusion detection section

The **Intrusion detection** section contains a toolbar and a table containing sets of rules.

- – opens the **Vulnerabilities** section.

  In the **Vulnerabilities** section of the Application Server web interface (see the figure below), you can view and resolve vulnerabilities detected in devices.

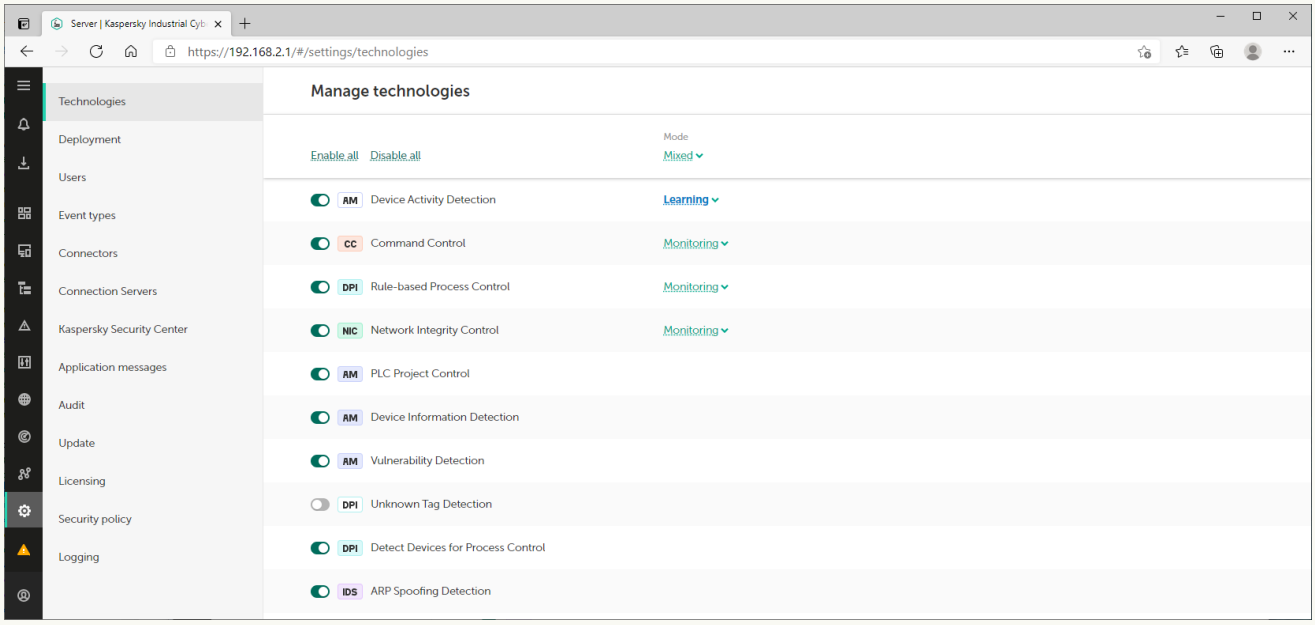
  
  Vulnerabilities section

  The **Vulnerabilities** section contains a toolbar and the vulnerabilities table.

  When vulnerabilities are selected, the details area opens in the right part of the section. The details area contains information about the selected vulnerabilities and the tools for managing them.

- – opens the **Settings** section.

In the **Settings** section of the Application Server web interface (see the figure below), you can view and edit application settings.



Settings section

When you select the **Settings** section, an additional menu appears on the web interface page. In this menu, you can go to the following subsections:

- **Technologies**.

  In this section, you can manage the technologies and methods used for analyzing traffic in Kaspersky Industrial CyberSecurity for Networks. The **Technologies** section is displayed if an Administrator account was used to connect to the Server.

- **Deployment**.

  In this section, you can view information about nodes that have application components installed, and information about monitoring points on nodes. If an Administrator account was used to connect to the Server, you can also manage nodes and manage monitoring points in this section.

- **Users**.

  In this section, you can manage application user accounts. The **Users** section is displayed if an Administrator account was used to connect to the Server.

- **Event types**.

  In this section, you can view and edit the parameters of event types.

- **Connectors**.

  In this section, you can manage connectors for the application.

- **Connection Servers**.

  In this section, you can view and edit the settings of the web server on the computer hosting the Server (for example, to use a trusted certificate), REST API server and integration servers on nodes.

- **Kaspersky Security Center**

  In this section, you can view and edit the settings for connecting to the Kaspersky Security Center Administration Server (if the capability for application interaction with Kaspersky Security Center has been added).

- **Application messages**.

  In this section, you can view application messages.

- **Audit**.

  In this section, you can view audit log entries and enable or disable the user activity audit. The **Audit** section is displayed if a user account with the Administrator role was used to connect to the Server.

- **Update**.

  In this section, you can configure and run updates of application modules and databases.

- **Licensing**.

  In this section, you can manage the license key for updating application modules and databases.

- **Security policy**.

  In this section, you can manage the application security policy.

- **Logging**.

  In this section, you can configure the logging levels for process logs.

- – opens a section containing brief information about the application.
- – displayed if some application functions are disabled or if learning mode is enabled for functions. If the menu is expanded, a message about disabled protection functions is displayed next to it. Clicking this icon or text opens a window containing information about disabled protection functions.
- **Connection Server** – displays the name of the Server to which the connection was established (the name defined during initial configuration of the application after installation).
- – opens and closes the user menu if the menu is collapsed. If the menu is expanded, nearby you will see the name of the current user and its role (in this case, you can use the button on the right to open and close the user menu). The user menu consists of the following sections:
  - **Language** – lets you select the language of the application web interface: English or Russian.

    The selected localization language of the application web interface does not affect the localization language of the Kaspersky Industrial CyberSecurity for Networks Server. This component uses the localization language that was defined during installation or reinstallation of Kaspersky Industrial CyberSecurity for Networks. Therefore, the localization language of data provided by the Server may differ from the selected localization language of the web interface. For example, events and messages received from the Server (including some error messages) are displayed in the localization language of the Server.

  - **Theme** – lets you select the color design theme for the web interface page:
    - **Light** – items are displayed on a white background.
    - **Dark** – items are displayed on a dark background.
  - **User account** – groups menu items for performing actions with the account of the current user:
    - **Change password** – opens the window for changing the password of the current user.

- **Log out** – ends the Server connection session and opens the page for entering the account credentials to connect.

- **Additional information** – contains the **Help** option for proceeding to the Online Help page of Kaspersky Industrial CyberSecurity for Networks.

Kaspersky Industrial CyberSecurity for Networks sensor web interface

When you connect to a Kaspersky Industrial CyberSecurity for Networks sensor through the web interface, the sensor web interface page opens in your browser. The contents of the web interface page depend on the state of the connection between the sensor and the Application Server.

Depending on the state of the connection between the sensor and the Application Server, the web interface page may contain the following management elements or data:

- Before connecting the sensor to the Server – management elements for selecting a communication data package and/or data for automatically connecting the sensor over the network.

- After connecting the sensor to the Server – data on the Server and sensor (including the capability to proceed to the Server web interface page) and the connection state.

Licensing the application

This section contains information about licensing Kaspersky Industrial CyberSecurity for Networks.

About the End User License Agreement

The *End User License Agreement* is a binding agreement between you and AO Kaspersky Lab, stipulating the terms on which you may use the application.

Please carefully read and accept the terms of the End User License Agreement before you start using the application.

You can view the terms of the End User License Agreement in the following ways:

- During initial configuration of the application.
- By opening the license_en.txt, that is a part of application distribution kit (the copy of this document is also saved in the application installation folder).

Please read and accept the terms of the End User License Agreement during initial configuration of the application. If you do not accept the terms of the End User License Agreement, you must cancel the initial configuration of the application and must not use the application.

About the Privacy Policy

The *Privacy Policy* is a document that informs you about how your data is processed.

Please carefully read and accept the terms of the Privacy Policy before you start using the application.

You can view the terms of the Privacy Policy as follows:

- During initial configuration of the application.
- By opening the privacy_policy_en.txt, that is a part of application distribution kit (the copy of this document is also saved in the application installation folder).

Please read and accept the terms of the Privacy Policy during initial configuration of the application. If you do not accept the terms of the Privacy Policy, you must cancel the initial configuration of the application and must not use the application.

About the license

The *license* entitles you to use the application under the End User License Agreement. You can use the application functionality if you purchase a license certificate.

The following types of licenses are available:

- Base – for use of all functionality of the Server and sensors, except update functionality for databases and application modules.

  This type of license has no time limit and does not require you to add a license key to the application.

- Limited Updates – for use of update functionality for databases and application modules on the Server and sensors.

  This type of license has a time limit. To activate update functionality, you need to add a license key to the application. When this type of license expires, the application continues to work, but update functionality becomes unavailable. In this case, to continue to use the application with available update functionality, you need to add a new license key.

  You can view information about the added license key when connected to the Server through the web interface.

UPDATES FUNCTIONALITY (INCLUDING PROVIDING ANTI-VIRUS SIGNATURE UPDATES AND CODEBASE UPDATES) WILL NOT BE AVAILABLE IN THE SOFTWARE IN THE U.S. TERRITORY FROM 12:00AM EASTERN DAYLIGHT TIME (EDT) ON SEPTEMBER 10, 2024 IN ACCORDANCE WITH THE RESTRICTIVE MEASURES.

Technical support services are provided if you have an active Technical Support Agreement. To receive technical support services, you must appoint contact persons who are authorized to open requests for technical support services.

About the license certificate

The *license certificate* is a document that confirms your right to use the application. This document is provided to you when you purchase a license.

A license certificate for Kaspersky Industrial CyberSecurity for Networks contains the following information:

- License key or order number
- Information about the user who is granted the license
- Information about the application and the component covered by the license
- Restriction on the number of licensing units (for example, the number of sensors)
- Start date of the license term
- License expiration date or license term
- License type

About the license key used for activating update functionality

A *license key* (hereinafter also referred to as simply the "key") is a sequence of bits that you can apply to activate and then use the functionality for updating databases and application modules in accordance with the terms of the End User License Agreement. The license key is generated by Kaspersky experts.

You can add a license key to the application by using a *license key file*. After you add a license key to the application, the license key is displayed in the application interface as a unique alphanumeric sequence.

Kaspersky can block a license key over violations of the End User License Agreement. If a license key has been blocked, you must add a different license key to use the functionality for updating databases and application modules.

About the license key file used for activating update functionality

A *license key file* is a file with the KEY extension that you receive from Kaspersky. A license key file is intended for adding a license key that activates the functionality for updating databases and application modules.

You receive a license key file after you purchase Kaspersky Industrial CyberSecurity for Networks. The method used to receive a license key file is determined by the Kaspersky distributor from whom you purchased the application (for example, the license key file may be sent to the email address you specify).

You can also add a license key from a license key file that was received when purchasing a previous version of Kaspersky Industrial CyberSecurity for Networks. A license key can be added to the application before its expiration date.

You do not have to connect to Kaspersky activation servers to activate the functionality for updating databases and application modules using a license key file.

Adding a license key when connected to the Server through the web interface

You can add a license key to Kaspersky Industrial CyberSecurity for Networks when connected to the Server through the web interface or by using the functionality for automatic distribution of license keys to Kaspersky Security Center.

Only users with the Administrator role can add a license key.

To add a license key:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Licensing**.
3. Click the **Add license key** button. This button is absent if a license key has already been added to the application.

   This opens the standard browser window for selecting a license key file.
4. Specify the path to the license key file with the KEY extension.
5. Click the button for opening the file.

The license key from the selected key file will be loaded into the application.

Viewing information about an added license key

You can view information about the added license key when connected to the Server through the web interface. Information about the license key is displayed under **Settings** → **Licensing**. The list of notifications about application operating issues may also display warnings about the license key status.

To view information about the license key:

Select **Settings** → **Licensing**.

The following information is displayed for an added license key:

- **Key** – unique alphanumeric sequence.
- **Description** – information about available functionality.
- **Activation date** – date when the license key was first added to the application.
- **Validity term** – expiration date of the license key.
- **Expires** – number of days remaining until expiration.
- Information about the key status or warning about a problem.

Removing a license key

When connected to the Server through the web interface, you can remove an added license key from the application (for example, if you need to replace the current license key with a different key). After the license key is removed, the application does not provide the functionality for updating databases and application modules. This functionality will be re-activated the next time you add a license key.

Only users with the Administrator role can delete a license key.

To remove an added license key:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Licensing**.
3. Click the **Remove** button.

   A window with a confirmation prompt opens.
4. Confirm deletion of the license key.

The license key will be removed from the application.

Data provision

By accepting the terms of the End User License Agreement and the Privacy Policy, you consent to the automatic processing of personal data for the purposes of supporting the operation of the application. For information about how personal data is obtained, processed, and stored, please read the End User License Agreement and the Privacy Policy.

The application does not send users' personal data to Kaspersky. Users' personal data is processed on the computers on which the application components are installed.

The application processes and saves the following data related to users' personal data:

- Names of user accounts that were created in the application (application users).
- IP addresses or names of computers with application components installed.
- IP addresses, MAC addresses, and other device information received by the application.
- IP address or name of the computer hosting Kaspersky Security Center.
- IP addresses or names of computers that connect to the application through connectors.
- Email addresses of recipients indicated in email connectors.
- Data in industrial network traffic transmitted between devices and containing users' personal data (this data is processed by the application together with other data when analyzing industrial network traffic).
- Data on possibly infected objects or potential threats received from EPP applications and containing IP addresses, web addresses, and email addresses.

The listed data is processed for the purpose of analyzing process violations and for detecting network traffic anomalies and other threats that may be signs of attacks.

The application saves the received data in logs.

If the application administrator has configured forwarding of application data to recipient systems, the received data is processed and stored in the recipient system in accordance with its functionality and purpose.

If the application centralized installation script was used to create files for the purpose of providing information to Kaspersky Technical Support, the following data is saved in these files:

- Contents of folders used for storing application data:
  - Files of process logs for application components, the DBMS, and the Intrusion Detection system.
  - Files of working data of the Server and sensors.
  - Installation settings file created by the application centralized installation script.
  - Application message log and audit log.
- Security policy applied on the Server.
- Information about the current status of services that support the operation of application components:
  - kics4net

- kics4net-postgresql
- kics4net-webserver
- kics4net-websensor
- kics4net-epp-proxy
- klnagent

- Information about the version and distribution package of the operating system on computers that have application components installed (the `uname -a` command is used for receiving information).
- Information about the network interfaces on computers that have application components installed (the `ifconfig` command is used for receiving information).
- Entries saved by the auditd service in the file /var/log/audit/audit.log.
- Settings, status, and operating mode of the firewall in the operating system.
- If the corresponding settings are defined, the following files and data are also saved when running the application centralized installation script:
  - Traffic dump files.
  - Data on the Intrusion Detection system configuration.
  - Data on the certificates used in Kaspersky Industrial CyberSecurity for Networks (except certificates that were published by trusted certificate authorities).

The application does not monitor access to the installation settings file created by the application centralized installation script. However, the application does track startups of application components and other connections to the Server that involve verification of user credentials.

When receiving updates from Kaspersky servers, the application transmits data necessary for automatic selection of relevant updates. Transmitted data does not contain any personal data of users. The application transmits the following data:

- Version of Kaspersky Industrial CyberSecurity for Networks.
- Localization language code of components of Kaspersky Industrial CyberSecurity for Networks.
- IDs of updated elements.
- Kaspersky Industrial CyberSecurity for Networks installation ID.
- ID of the type, version and bit rate of the operating system.

Any received information is protected by Kaspersky in accordance with the requirements established by law and in accordance with current regulations of Kaspersky. Data is transmitted over encrypted communication channels.

Folders for storing application data

Deleting or modifying any file in these folders can affect the operation of the application.

The Kaspersky Industrial CyberSecurity for Networks Server uses the following folders and subfolders for storing data:

- Main folders of the Server:
  - /opt/kaspersky/kics4net/ – Server installation folder.
  - /var/opt/kaspersky/kics4net/ – folder for storing certificates and operational data of Kaspersky Industrial CyberSecurity for Networks.
  - /var/log/kaspersky/kics4net/ – folder for storing process logs related to the Server.
  - /etc/opt/kaspersky/kics4net/ – folder for storing files containing passwords to external systems.
- DBMS folders:
  - /opt/kaspersky/kics4net-postgresql/ – folder for DBMS installation.
  - /var/opt/kaspersky/kics4net-postgresql/ – folder for storing operational data of the DBMS (DBMS configuration, databases and other data).
  - /var/log/kaspersky/kics4net-postgresql/ – folder for storing DBMS process logs.
  - /etc/opt/kaspersky/kics4net-postgresql/ – folder for storing additional files.
- Folders of the Intrusion Detection system:
  - /opt/kaspersky/kics4net-suricata/ – folder for installation of the Intrusion Detection system.
  - /opt/kaspersky/kics4net/share/ids/ – folder for storing operational data of the Intrusion Detection system (Intrusion Detection system configuration, rules and other data).
  - /var/log/kaspersky/kics4net-suricata/ – folder for storing process logs related to the Intrusion Detection system.
- Web server folders:
  - /opt/kaspersky/kics4net-webserver/ – folder for web server installation.
  - /var/opt/kaspersky/kics4net-webserver/ – folder for storing operational data of the web server (files of certificates and other data).
  - /var/log/kaspersky/kics4net-webserver/ – folder for storing process logs of the web server (the web server also saves process data in the system log of the operating system).
  - /etc/opt/kaspersky/kics4net-webserver/ – folder for storing files containing passwords to external systems and configuration files.
- Folders of the full-text search system:
  - /opt/kaspersky/kics4net-fts/ – folder for installation of the full-text search system.

- /var/opt/kaspersky/kics4net-fts/ – folder for storing operational data of the full-text search system (configuration of the full-text search system and other information).
- /var/log/kaspersky/kics4net-fts/ – folder for storing process logs related to the full-text search system.
- /etc/opt/kaspersky/kics4net-fts/ – folder for storing files containing passwords to external systems and configuration files.

- Folders of the integration service:
  - /opt/kaspersky/kics4net-epp-proxy/ – folder for installing the integration service.
  - /var/opt/kaspersky/kics4net-epp-proxy/ – folder for storing operational data of the integration service (files of certificates and other data).
  - /var/log/kaspersky/kics4net-epp-proxy/ – folder for storing process logs related to the integration service.
  - /etc/opt/kaspersky/kics4net-epp-proxy/ – folder for storing configuration files.
- Folders of system connectors:
  - /opt/kaspersky/kics4net-connectors/ – folder for installing system connectors.
  - /var/opt/kaspersky/kics4net-connectors/ – folder for storing operational data of system connectors (files of certificates and other data).
- Folders containing files for centralized installation of application components:
  - /home/<user>/.config/kaspersky/kics4net-deploy/ – folder for storing installation process logs and the installation settings file (if application components were centrally installed from this computer).
  - /var/opt/kaspersky/kics4net-deploy/ – folder for storing a copy of the installation settings file created during centralized installation of the application.
- Network Agent folders:
  - /opt/kaspersky/klnagent64/ – Network Agent installation folder.
  - /var/opt/kaspersky/klnagent/ – folder for storing operational data of Network Agent.
  - /var/log/kaspersky/klnagent64/ – folder for storing process logs of Network Agent.
  - /etc/opt/kaspersky/klnagent/ – folder for storing Network Agent configuration files.
- Standard folders of the operating system:
  - /usr/lib/systemd/system/ – folder for storing configuration files for services (for example, kics4net.service).
  - /var/run/ – folder for storing variables of data on system health after loading. Application components may store files in the folder itself (for example, the file klnagent.pid) or in subfolders (for example, in the subfolder /kics4net/).

A Kaspersky Industrial CyberSecurity for Networks sensor uses the following folders and subfolders for storing data:

- Main folders of a sensor:

- /opt/kaspersky/kics4net/ – sensor installation folder.
- /var/opt/kaspersky/kics4net/ – folder for storing certificates and operational data of Kaspersky Industrial CyberSecurity for Networks.
- /var/log/kaspersky/kics4net/ – folder for storing process logs related to a sensor.

- Folders of the Intrusion Detection system:
  - /opt/kaspersky/kics4net-suricata/ – folder for installation of the Intrusion Detection system.
  - /opt/kaspersky/kics4net/share/ids/ – folder for storing operational data of the Intrusion Detection system (Intrusion Detection system configuration, rules and other data).
  - /var/log/kaspersky/kics4net-suricata/ – folder for storing process logs related to the Intrusion Detection system.
- Web server folders:
  - /opt/kaspersky/kics4net-websensor/ – folder for web server installation.
  - /var/opt/kaspersky/kics4net-websensor/ – folder for storing operational data of the web server (files of certificates and other data).
  - /var/log/kaspersky/kics4net-websensor/ – folder for storing process logs of the web server (the web server also saves process data in the system log of the operating system).
  - /etc/opt/kaspersky/kics4net-websensor/ – folder for storing files containing passwords to external systems and configuration files.
- Folders of the integration service:
  - /opt/kaspersky/kics4net-epp-proxy/ – folder for installing the integration service.
  - /var/opt/kaspersky/kics4net-epp-proxy/ – folder for storing operational data of the integration service (files of certificates and other data).
  - /var/log/kaspersky/kics4net-epp-proxy/ – folder for storing process logs related to the integration service.
  - /etc/opt/kaspersky/kics4net-epp-proxy/ – folder for storing configuration files.
- Folders containing files for centralized installation of application components:
  - /home/<user>/.config/kaspersky/kics4net-deploy/ – folder for storing installation process logs and the installation settings file (if application components were centrally installed from this computer).
  - /var/opt/kaspersky/kics4net-deploy/ – folder for storing a copy of the installation settings file created during centralized installation of the application.
- Standard folders of the operating system:
  - /usr/lib/systemd/system/ – folder for storing configuration files for services (for example, kics4net.service).
  - /var/run/ – folder for storing variables of data on system health after loading. Application components may place files in the folder itself or in subfolders.

Root privileges in the operating system are required for modifying the application files.

About logs

Kaspersky Industrial CyberSecurity for Networks saves data on its operation in logs. Depending on the type of log, the application saves data in the Server database or in files in local folders on the node of the Server or sensor.

Logs saved in the Server database

The application saves the following logs in the Server database:

- Log of events and incidents
- Audit log
- Application message log

You can view the contents of the listed logs when connected to the Server through the web interface.

If necessary, you can also configure data transfer from these logs to recipient systems through connectors.

Logs saved in files

Information about application processes is saved as files in local folders. Process log files may contain the following information:

- Data on the starting and stopping of Kaspersky Industrial CyberSecurity for Networks processes.
- Diagnostic messages that may be required when contacting Technical Support.
- Error messages.

Information about processes is stored according to the defined logging levels for processes.

You can use a text editor to view files containing process logs. Root privileges in the operating system are required for providing access to logs.

Files containing process logs are stored in non-encrypted form. You are advised to ensure protection against unauthorized access to information.

Administration of Kaspersky Industrial CyberSecurity for Networks

This section contains information about the actions performed for administration of Kaspersky Industrial CyberSecurity for Networks.

Managing nodes that have application components installed

This section contains information about managing nodes that host components of Kaspersky Industrial CyberSecurity for Networks (Server or sensor). When managing nodes, you can add and remove sensors, and modify various settings of the nodes.

Only users with the Administrator role can manage nodes that have application components installed.

To monitor the state of Kaspersky Industrial CyberSecurity for Networks, you can view information about nodes and the network interfaces on nodes.

Adding and connecting a sensor using the sensor web interface

After installation and initial configuration of the Kaspersky Industrial CyberSecurity for Networks Server, you can add sensors to the application. Sensors are added on the Server web interface page.

To add a sensor on a computer, the corresponding packages must be installed from the application distribution kit. You can use the application components centralized installation script or local installation script to install these packages.

When adding a sensor, a configuration package containing a certificate and configuration data for the sensor is generated on the Server. The added sensor is connected by using the sensor web interface. The sensor web interface lets you download the configuration package and connect the sensor using the following methods:

- Use a communication data package. When using this method, the configuration package is saved a file with password-protected certificate. This file is known as the *communication data package*. The communication data package must be securely delivered to a computer that can access the sensor computer over the network, and must then be downloaded on the sensor web interface page. After the communication data package is downloaded, the sensor is automatically connected to the Server on which this file was created.

  Using a communication data package to add and connect a sensor

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Deployment**.

3. Click the **Add sensor** button.

   The details area appears in the right part of the web interface window.

4. On the **Use a file** tab:

   a. Enter the sensor name that will represent the sensor within Kaspersky Industrial CyberSecurity for Networks.

      The sensor name must be unique (not match the names of other sensors or the Server) and must contain no more than 100 characters. You can use letters of the English alphabet, numerals, a space, and the following special characters: `_` and `-` (for example, `Sensor_1`). The sensor name must begin and end with any permitted character except a space.

   b. Enter the Server IP address that the sensor will use to connect to the Server.

   c. Enter the IP address used by the web server on the sensor computer.

   d. Enter password for protecting the certificate in the communication data package.

      The password must meet the following requirements:

      - Must contain between 8 and 256 ASCII characters.
      - Must contain one or more uppercase letters of the English alphabet.
      - Must contain one or more lowercase letters of the Latin alphabet.
      - Must contain one or more numerals.
      - Must contain no more than three consecutive repeated characters.

5. Click the **Create communication data package** button.

   Your browser will save the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

6. Connect to the sensor through the web interface.

7. On the sensor web interface page, click the **Select file** button.

   This opens the standard browser window for selecting a file.

8. Specify the path to the communication data package.

9. Click the button for opening the file.

10. After downloading the contents of the file, enter the password for accessing the sensor certificate in the communication data package.

The sensor will connect to the Server, then information about the connection will be displayed on the Server and sensor web interface pages.

- Automatically over the network. This method lets you forward a configuration package over the network to the specified IP address of the sensor computer. The sensor processes the configuration package, uses it to generate a certificate signing request (CSR), and sends this request to the Server. After receiving the request, the Server web interface page displays the fingerprint of the received request as a sequence of characters. This same request fingerprint is also displayed on the sensor web interface page at the same time. You must make sure that these fingerprints are identical before completing the addition of the sensor.

  Adding and connecting a sensor automatically over the network

  1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
  2. Select **Settings** → **Deployment**.
  3. Click the **Add sensor** button.

     The details area appears in the right part of the web interface window.
  4. On the **Automatically over the network** tab:

     a. Enter the sensor name that will represent the sensor within Kaspersky Industrial CyberSecurity for Networks.

        The sensor name must be unique (not match the names of other sensors or the Server) and must contain no more than 100 characters. You can use letters of the English alphabet, numerals, a space, and the following special characters: `_` and `-` (for example, `Sensor_1`). The sensor name must begin and end with any permitted character except a space.

     b. Enter the Server IP address that the sensor will use to connect to the Server.

     c. Enter the IP address used by the web server on the sensor computer.
  5. Click the **Connect and add sensor** button.

     The application will establish a connection with the sensor computer, then the Server web interface page will show a prompt to confirm the received fingerprint for the certificate signing request.
  6. Connect to the sensor through the web interface.

     The sensor web interface page will show a message containing information about the certificate request fingerprint that was sent to the Server.
  7. Make sure that the sequences of characters representing the certificate request fingerprint are identical on the web interface pages of the sensor and Server.
  8. On the Server web interface page, click the button to confirm the received certificate request fingerprint.

  The sensor will connect to the Server, then information about the connection will be displayed on the Server and sensor web interface pages.

Renaming a node that has application components installed

You can change the defined name of a node hosting the installed application component (Server or sensor).

To change the node name:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Deployment**.
3. Select the tile of the relevant node.

   The details area appears in the right part of the web interface window.
4. Click the **Edit** button.
5. In the field containing the current name of the node, enter a new name.

   The node name must be unique (must not match the names of other nodes) and must contain no more than 100 characters. You can use letters of the English alphabet, numerals, a space, and the special characters _ and - (for example, Server_1). The node name must begin and end with any permitted character except a space.
6. Click **Save**.

Changing the application data storage settings on a node

You can change the defined limits on the maximum space used for storing application data on a node.

To change the maximum space limits:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Deployment**.
3. Select the tile of the relevant node.

   The details area appears in the right part of the web interface window.
4. Click the **Edit** button.
5. In the **Storage settings** section, define the maximum space limits for application data. The set of data types available for configuration depends on the type of node (Server or sensor).

   You can select the unit of measure for the space limit: **MB** or **GB**.

   For some data types (such as events), you can define a storage time limit in days.
6. Click **Save**.

Creating a new communication data package for a sensor

If necessary, you can create a new communication data package for a sensor (for example, if you need to update the certificate used for connecting the sensor to the Server).

To create a new communication data package for a sensor:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Deployment**.

3. Select the node tile of the sensor for which you want to create a new communication data package.

   The details area appears in the right part of the web interface window.

4. Click the **Get new communication data package** button.

   A window with a confirmation prompt opens.

5. In the prompt window, click **OK**.

   The Server generates a new communication data package for the selected sensor, then the browser saves the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

6. On the sensor computer return the sensor to the initial state using the kics4net-reset-to-defaults.sh script that reverts the node to the initial state. The script is located on the computer with the installed application component in the /opt/kaspersky/kics4net/sbin/ folder.

7. Connect to the sensor through the web interface.

8. On the sensor web interface page, upload the new communication data package.

   The new communication data package is uploaded the same way it is uploaded when adding a sensor using a communication data package.

Removing a sensor

You can remove a sensor from the application. When a sensor is removed, the registration data of this sensor is deleted from the Application Server, which will make it impossible to connect the sensor to this Server.

However, the sensor component files will remain on this node after the sensor is removed. You can later add this node as a sensor again without having to install the corresponding packages. You can add the sensor to the current Server or to any other Kaspersky Industrial CyberSecurity for Networks Server that you can connect to.

To remove a sensor:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Deployment**.

3. Select the node tile of the sensor that you want to delete.

   The details area appears in the right part of the web interface window.

4. Click the **Remove** button.

   A window with a confirmation prompt opens.

5. In the prompt window, click **OK**.

Managing monitoring points on nodes

Monitoring points are used for receiving and processing industrial network traffic in Kaspersky Industrial CyberSecurity for Networks. Monitoring points can be added or removed on any node that has application components installed (including on a node that performs Server functions). When adding or removing them, you do not need to restart the computer on which the application components are installed or reinstall components on the computer.

Each monitoring point must be associated with a network interface that receives a copy of traffic from a specific industrial network segment. To add monitoring points, you can use network interfaces that meet the following conditions:

- Type of network interface: Ethernet.
- MAC address: different from 00:00:00:00:00:00.
- The network interface is intended for receiving a copy of industrial network traffic, and this network interface is not used for other purposes (for example, to connect nodes that have application components installed).

You can add monitoring points to not only physical network interfaces but also to logical interfaces that combine multiple physical interfaces (bonded interfaces). However, you cannot add a monitoring point to a physical network interface that is one of the interfaces of a logical bonded interface.

Monitoring points can be enabled and disabled. You can disable a monitoring point to temporarily stop monitoring an industrial network segment relaying a copy of traffic to a network interface. When you need to resume monitoring of the industrial network segment, you can enable the monitoring point.

> After disabling or removing a monitoring point, the application may still register events associated with this monitoring point for some time. This is due to a possible delay in processing incoming traffic when the Server is experiencing high loads.

You can manage monitoring points and view information about monitoring points, network interfaces, and nodes in the **Settings** → **Deployment** section of the Kaspersky Industrial CyberSecurity for Networks web interface.

Adding a monitoring point

To receive and process traffic flowing from the industrial network to the network interface of a node, you need to add a monitoring point to this network interface.

Only users with the Administrator role can add monitoring points to network interfaces.

To add a monitoring point to a network interface:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Deployment**.
3. Open the details area by clicking the **Add monitoring point** link in the tile of the relevant network interface. The link is displayed if a monitoring point has not been added to the network interface.

   The details area appears in the right part of the web interface window.
4. In the entry field in the upper part of the details area, enter the name of the monitoring point.

   You can use uppercase and lowercase letters of the English alphabet, numerals, and the _ and - characters.

The monitoring point name must meet the following requirements:

- Must be unique (not assigned to another monitoring point).
- Contains from 1 to 100 characters.

5. Click the ✓ icon on the right of the entry field.

Enabling monitoring points

The application does not receive and does not process traffic transmitted through the network interface of a disabled monitoring point. You need to enable the monitoring point if you want to resume receiving and processing traffic.

You can enable monitoring points individually, or all of them on one node or all nodes simultaneously.

Only users with the Administrator role can enable monitoring points.

To enable monitoring points:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Deployment**.
3. Do one of the following:
   - If you want to enable one monitoring point, click the **Enable** button in the network interface tile containing the monitoring point. The button is available if the monitoring point is disabled.
   - If you want to enable all monitoring points on a node, click the **Enable all** button in the node tile hosting the disabled monitoring points. The button is available if the node has network interfaces with disabled monitoring points.
   - If you want to enable all monitoring points on all nodes, use the **Enable on all nodes** link in the toolbar.
4. Wait for the changes to be applied.

Disabling monitoring points

You can disable a monitoring point if you need to temporarily pause the receipt and processing of traffic on the network interface of this monitoring point.

You can disable monitoring points individually, or all of them on one node or all nodes simultaneously.

Only users with the Administrator role can disable monitoring points.

To disable monitoring points:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Deployment**.

3. Do one of the following:

   - If you want to disable one monitoring point, click the **Disable** button in the network interface tile containing the monitoring point. The button is available if the monitoring point is enabled.

   - If you want to disable all monitoring points on a node, click the **Disable all** button in the node tile hosting the enabled monitoring points. The button is available if the node has network interfaces with enabled monitoring points.

   - If you want to disable all monitoring points on all nodes, use the **Disable on all nodes** link in the toolbar.

4. Wait for the changes to be applied.

Renaming a monitoring point

You can rename a monitoring point linked to a network interface.

> The new name of the monitoring point will appear in events that are registered after its renaming. The old name of the monitoring point is displayed in previously registered events.

Only users with the Administrator role can rename a monitoring point.

To rename a monitoring point:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Deployment**.

3. Select the network interface tile containing the monitoring point that you want to rename.

   The details area appears in the right part of the web interface window.

4. Click the icon located on the right of the current name of the monitoring point, and enter the new name in the field that appears.

   You can use uppercase and lowercase letters of the English alphabet, numerals, and the _ and - characters.

   The monitoring point name must meet the following requirements:

   - Must be unique (not assigned to another monitoring point).

   - Contains from 1 to 100 characters.

5. Click the icon on the right of the entry field.

Deleting a monitoring point

You can delete a monitoring point linked to a network interface. Deletion of a monitoring point may be required if this network interface will no longer be used for receiving industrial network traffic.

If it becomes necessary to temporary pause the receipt of traffic at a network interface of a monitoring point (for example, while performing preventative maintenance and adjustment operations), you can disable the monitoring point without deleting it.

The traffic received from a monitoring point prior to its deletion is not deleted from the database. Information about this monitoring point is also saved in the table of registered events.

Only users with the Administrator role can delete a monitoring point.

To remove a monitoring point:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Deployment**.
3. Select the network interface tile containing the monitoring point that you want to delete.

   The details area appears in the right part of the web interface window.
4. In the details area, click **Remove**.

   A window with a confirmation prompt opens. If the monitoring point is enabled, the application will prompt you to disable the monitoring point.
5. In the prompt window, confirm deletion of the monitoring point.

Identifying the Ethernet port associated with a network interface

A computer on which application components are installed may have multiple Ethernet ports used for connecting to the local area network. You can use the application to enable blink mode for a network interface and identify which Ethernet port is associated with this interface. When blink mode is enabled, the LED indicator next to the Ethernet port blinks for 15 seconds.

If the network interface does not support LED blink mode (for example, there is no LED indicator next to the Ethernet port or the network interface is a logical bonded interface), an error occurs when blink mode is enabled.

Only users with the Administrator role can enable Ethernet port blink mode.

To determine which Ethernet port is linked to a network interface:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Deployment**.
3. Click the **Blink** button on the network interface tile.

   If the network interface supports an LED indicator, the network cable connection icon begins to blink on the network interface tile. At the same time, the LED indicator next to the Ethernet port begins to blink on the corresponding network adapter of the computer.

While blink mode is enabled for one network interface, you cannot enable blink mode for another network interface on the same node.

Monitoring the state of Kaspersky Industrial CyberSecurity for Networks

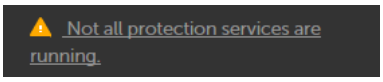
This section contains instructions on monitoring the state of the application.

Monitoring the application state when connected through the web interface

You can view information about the current state of the application when connected to the Server through the web interface. The application state is monitored by using the corresponding widgets in the **Dashboard** section.

Information about disabled protection functions

In the browser window, the lower part of the menu shows the ⚠ icon and a notification if some protection functions are disabled (see the figure below).



Message about disabled protection functions in the browser window

The ⚠ icon is displayed in the following cases:

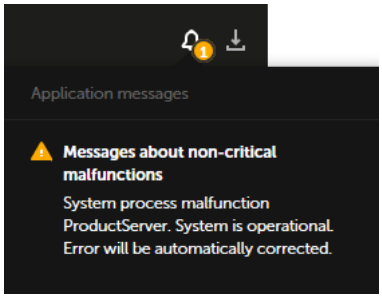
- One or more monitoring points are disabled.
- One or more protection functions are disabled (for example, rule-based Intrusion Detection).
- Learning mode is enabled for one or multiple protection functions (for example, for Network Integrity Control technology).

To view information about disabled protection functions:

Click the ⚠ icon or the text of the message about disabled protection functions.

Notifications about application operation problems

The upper part of the web interface menu contains a button for opening the list of notifications about problems in application operation (see the figure below).



List of notifications about problems in application operation in the browser window

If the list contains notifications about critical problems (for example, messages about disruption of application operation), a red icon is displayed. If the list contains only notifications about non-critical problems, a yellow icon is displayed.

The list contains only up-to-date notifications. If a problem has been resolved (for example, a lost connection with the Server has been restored), the corresponding notification is automatically removed from the list.

You can view detailed information about notifications (except notifications regarding unavailability of the Server or database).

To view information about a notification:

1. In the menu, click the button.
2. In the list of notifications, click the text of the notification.

   The browser window will show the section containing information pertaining to the notification (for example, under **Settings** → **Application messages**).

Viewing application messages

The application message log stores information about errors in application operation and about errors in operations performed by system processes of Kaspersky Industrial CyberSecurity for Networks.

You can view application messages when connected to the Server through the web interface. If necessary, you can also configure forwarding of application messages to recipient systems via connectors.

To view application messages:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface.
2. Select **Settings** → **Application messages**.

   The table will display application messages that match the defined filter and search settings.

The columns of the application messages table contain the following information:

- **Date and time** – date and time of registration of the application message.
- **Status** – name of the message status. The following statuses are available for messages:
  - *Getting started*, *Normal operation* – for informational messages.
  - *State unknown*, *Malfunction* – for messages about non-critical malfunctions in application operation.
  - *Moderate malfunction, Critical malfunction*, *Fatal malfunction* – for messages about disruption of application operation.
- **Node** – name or IP address of the node from which the message originated.
- **System process** – application process that invoked message registration.
- **Message** – numerical identifier and text of the message.

When viewing the application messages table, you can use the following functions:

- Filtering based on standard periods

  When filtering based on a standard period, the application messages table is updated in online mode.

  To configure application message filtering based on a standard period:

  1. Under **Settings** → **Application messages**, do one of the following:
     - Open the **Period** drop-down list in the toolbar.
     - Click the filtering icon in the **Date and time** column.
  2. In the drop-down list, select one of the standard periods:
     - **Last hour**
     - **Last 12 hours**
     - **Last 24 hours**.
     - **Last 48 hours**
  3. If table updates are disabled, in the opened window confirm that you agree to resume table updates.

  The table will display application messages for the period you specified.

- Filtering based on a specified period

When filtering by a defined period, the table will no longer be updated. The table displays only the messages that were registered during the specified period.

To configure application message filtering based on a specified period:

1. Under **Settings** → **Application messages**, do one of the following:
   - Open the **Period** drop-down list in the toolbar.
   - Click the filtering icon in the **Date and time** column.
2. In the drop-down list, select **Specify a period**.
3. If table updates are enabled, in the opened window confirm that you agree to suspend table updates.

   The start and end date and time of the filtering period are displayed on the right of the drop-down list.
4. Click the date of the start or end of the period.

   The calendar opens.
5. In the calendar, specify the date for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YYYY hh:mm:ss. If you don't need to specify the date and time of the filtering period end boundary, you can choose not to select a date or you can delete the current value.
6. Click **OK**.

The table will display application messages for the period you specified.

- Filtering based on table columns

When filtering by the **Date and time** column, you can use one of the standard periods or define a specific period.

*To filter the application messages table by the **Status** or **System process** column:*

1. Under **Settings** → **Application messages**, click the filtering icon in the relevant column.

   When filtering by status, you can also use the **Statuses** drop-down list in the toolbar.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events.

3. Click **OK**.

*To filter the application messages table by the **Node** or **Message** column:*

1. Under **Settings** → **Application messages**, click the filtering icon in the relevant column.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values for application messages that you want to include in the filter and/or exclude from the filter.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the column click the **Add condition** button and enter the condition in the opened field.

4. If you want to delete one of the created filter conditions, in the filter window of the column click the icon.

5. Click **OK**.

- Searching application messages

  You can find relevant application messages by using the **Search messages** field under **Settings** → **Application messages**.

  The search is performed based on the **Node** and **Message** columns.

- Resetting the defined filter and search settings

  You can reset the defined filter and search settings in the application messages table by using the **Default filter** button in the toolbar under **Settings** → **Application messages**. The button is displayed if search and/or filter settings are defined.

- Sorting application messages

1. Under **Settings** → **Application messages**, click the header of the column by which you want to sort.
2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

Viewing user activity audit entries

Kaspersky Industrial CyberSecurity for Networks can save information about actions performed by users in the application. Information is saved in the audit log if user activity audit is enabled.

You can view audit entries when connected to the Server through the web interface. If necessary, you can also configure forwarding of application messages to recipient systems via connectors.

Only users with the Administrator role can view audit entries.

To view audit entries:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Audit**.

The table will display the audit entries that match the defined filter and search settings.

The columns of the audit entries table contain the following information:

- **Date and time** – date and time when the user activity data was registered.
- **Action** – registered action performed by the user.
- **Result** – result of the registered action (successful or unsuccessful).
- **User** – name of the user that performed the registered action.
- **User node** – IP address of the node on which the registered action was performed.
- **Description** – additional information about the registered action.

When viewing the audit entries table, you can use the following functions:

- Configure the display and order of columns in the audit entries table

1. Under **Settings** → **Audit**, click the **Customize table** link to open a window for configuring how the table is displayed.
2. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.
3. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

The selected columns will be displayed in the audit entries table in the order you specified.

- Filtering based on standard periods

When filtering based on a standard period, the audit entries table is updated in online mode.

To configure filtering of audit entries based on a standard period:

1. Under **Settings** → **Audit**, do one of the following:
   - Open the **Period** drop-down list in the toolbar.
   - Click the filtering icon in the **Date and time** column.
2. In the drop-down list, select one of the standard periods:
   - **Last hour**
   - **Last 12 hours**
   - **Last 24 hours**.
   - **Last 48 hours**
3. If table updates are disabled, in the opened window confirm that you agree to resume table updates.

The table will display audit entries for the period you specified.

- Filtering based on a specified period

When filtering by a defined period, the table will no longer be updated. The table displays only the entries that were registered during the specified period.

To configure filtering of audit entries based on a specified period:

1. Under **Settings** → **Audit**, do one of the following:
   - Open the **Period** drop-down list in the toolbar.
   - Click the filtering icon in the **Date and time** column.
2. In the drop-down list, select **Specify a period**.
3. If table updates are enabled, in the opened window confirm that you agree to suspend table updates.

   The start and end date and time of the filtering period are displayed on the right of the drop-down list.
4. Click the date of the start or end of the period.

   The calendar opens.
5. In the calendar, specify the date for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YYYY hh:mm:ss. If you don't need to specify the date and time of the filtering period end boundary, you can choose not to select a date or you can delete the current value.
6. Click **OK**.

The table will display audit entries for the period you specified.

- Filtering based on table columns

You can filter the audit entries table based on the values in all columns except the **Description** column.

When filtering by the **Date and time** column, you can use one of the standard periods or define a specific period.

*To filter the audit entries table by the **Action** column:*

1. Under **Settings** → **Audit**, click the filtering icon in the **Action** column.

   The filtering window opens.

2. In the **Actions** field, choose the necessary action from the available audit actions. To do so, start entering the name of the action and select it in the drop-down list (the list of appropriate actions is automatically expanded when the value in the **Actions** field is changed).

   You can sort the opened list of actions by clicking the **Sort** link.

3. If you want to add another action, click the **Add action** button and specify another action in the opened field.

4. If you want to delete one of the specified actions, click the icon in the filter window. You can also delete all indicated actions by clicking the **Default filter** link in the filter window.

5. Click **OK**.

*To filter the audit entries table by the **Result** column:*

1. Under **Settings** → **Audit**, click the filtering icon in the **Result** column.

   To filter by the results of actions, you can also use the corresponding buttons in the toolbar.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events.

3. Click **OK**.

*To filter the audit entries table by the **User** or **User node** column:*

1. Under **Settings** → **Audit**, click the filtering icon in the relevant column.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values for audit entries that you want to include in the filter and/or exclude from the filter.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the column click the **Add condition** button and enter the condition in the opened field.

4. If you want to delete one of the created filter conditions, in the filter window of the column click the icon.

5. Click **OK**.

- Searching for audit entries

You can find relevant audit entries by using the **Search records** field under **Settings** → **Audit**.

A search is performed in all columns except the **Date and time** and **Result** columns.

- Resetting the defined filter and search settings

  You can reset the defined filter and search settings in the audit entries table by using the **Default filter** button in the toolbar under **Settings** → **Audit**. The button is displayed if search or filter settings are defined.

- Sorting audit entries

  1. Under **Settings** → **Audit**, click the header of the column by which you want to sort.

     You can filter the audit entries table based on the values of any column except the **Description** column.

  2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

  The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

Viewing information about nodes with application components installed and about network interfaces on nodes

Users with the Administrator role and users with the Operator role can both view information about nodes with application components installed and about network interfaces on nodes.

To view information about nodes and network interfaces:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface.
2. Select **Settings** → **Deployment**.

   The web interface window displays node tiles (on the left) and network interface tiles detected on these nodes (on the right of each node).
3. If you want to view detailed information about a node or network interface, select the tile of the relevant node or network interface.

   The details area appears in the right part of the web interface window.

Displayed information about nodes with application components installed

A node tile displays the following information:

- Defined node name.

- Current state of the node indicated by an icon and text description. Possible states:
  - *OK*. The node is available, and no application messages about non-critical malfunctions or disrupted operation were received from this node.
  - *Non-critical malfunction*. The node is available, and application messages with the *State unknown* or *Malfunction* status were received from this node.
  - *Operation disrupted*. The node is available, and application messages with the *Moderate malfunction*, *Critical malfunction* or *Fatal malfunction* status were received from this node.
  - *No connection*. The node is unavailable.
- Application component installed on the node: **Server** or **Sensor**.

[Detailed information about the node is displayed in the details area.]

The details area displays the following information for the selected node:

- Defined node name.
- **State** – current state of the node indicated by an icon and text description (like in the node tile).
- **Node type** – application component installed on the node: **Server** or **Sensor**.
- **Disk space currently used by the application** – disk space occupied by application files. This includes the installed files and files that are created while the application is running.
- **Maximum disk space that can be used by the application** – disk space that can be occupied by application files. This includes the installed files and the sum of all volume limits defined in data storage rules. This value cannot exceed the available disk space.
- **Occupied on disk** – disk space occupied by all files. This includes application files and files of the operating system and other applications. This volume of space is calculated on the drive that contains the /var/ folder in the file system of the node.
- **Free disk space** – disk space that is not occupied by files. This volume of space is calculated on the drive that contains the /var/ folder in the file system of the node.
- **Available disk space** – total volume of disk space on the drive that contains the /var/ folder in the file system of the node.
- **Retention rules** – settings for storing data that is saved for application functions.

Displayed information about network interfaces

A network interface tile displays the following information:

- Icon showing if a network cable is connected to the Ethernet port of the network interface. The following icons are provided:
  - – the network cable is connected.
  - – the network cable is disconnected.

The icon blinks when Ethernet port blink mode is enabled.

- Network interface name in the operating system.
- MAC address.
- IP address. If multiple IP addresses are detected on a network interface, the network interface tile displays only one of them.
- Rate of incoming traffic received by the network interface.
- Information about the monitoring point (if one was added):
  - Monitoring point name.
  - Current state of the monitoring point indicated by an icon and text description. Possible states:
    - *OK*. The monitoring point is available.
    - *Switchover*. The operating mode of the monitoring point is being changed.
    - *Error*. An error was detected when switching over the operating mode of the monitoring point.
  - Current operating mode of the monitoring point. The following modes are provided:
    - *Enabled*.
    - *Disabled*.

Detailed information about the network interface is displayed in the details area.

The details area displays the following information for the selected network interface:

- Icon showing if a network cable is connected to the Ethernet port of the network interface (it is displayed in the **Connection** field in the details area). The following icons are provided:
  - – the network cable is connected.
  - – the network cable is disconnected.

  The icon blinks when Ethernet port blink mode is enabled.
- Name of the network interface in the operating system (it is displayed in the **Network interface** field in the details area).
- MAC address (it is displayed in the **MAC address** field in the details area).
- IP address. If multiple IP addresses are detected on a network interface, the network interface tile displays only one of them and the details area displays no more than 16 IP addresses.
- Rate of incoming traffic received by the network interface.

If a monitoring point has been added to the network interface, the following additional information is displayed.

- Monitoring point name.
- Current state of the monitoring point indicated as an icon and text description (in the details area, the icon and text description are displayed in the **State** field). Possible states:
  - *OK*. The monitoring point is available.
  - *Switchover*. The operating mode of the monitoring point is being changed.
  - *Error*. An error was detected when switching over the operating mode of the monitoring point.
- Current operating mode of the monitoring point. In the network interface tile, information about the current mode is displayed next to the current status field (except the *Switchover* state). In the details area, information about the current state is displayed in the **Mode** field. The following modes are provided:
  - *Enabled*.
  - *Disabled*.

Viewing the status of services supporting operation of application components

You can view the status of services that support the operation of application components. If the service is active, this means that it was successfully started.

To view the status of a service:

1. On the computer on which the application component is installed, open the operating system console.

2. Enter the following command:

   `sudo service <service name> status`

   where `<service name>` is the name of the service, whose information you want to view. You can specify the following services:

   - `kics4net` – main service (runs on a computer that performs Server functions or sensor functions)
   - `kics4net-epp-proxy` – integration service (runs on a computer that performs Server functions or sensor functions)
   - `kics4net-postgresql` – DBMS service (runs only on a computer that performs Server functions)
   - `kics4net-fts` – full-text search system service (runs only on a computer that performs Server functions).
   - `kics4net-webserver` – web server service (runs only on a computer that performs Server functions).
   - `kics4net-websensor` – web server service (runs only on a computer that performs sensor functions).

     Example:
     `sudo service kics4net status`

If the service is not active, you can restart the computer or restart the service.

Restarting a computer that has application components installed

When restarting a computer that performs Server or sensor functions, application components are automatically started. A restart does not affect the subsequent operation of these components (except in some situations when there is a malfunction after an unexpected restart).

A restart may be required in the following cases:

- There is not enough free space on the computer hard drive.
- The computer was unexpectedly restarted, after which the operation of application components was not restored.
- One of the application services is not active.
- A lost connection between the Server and a sensor is not being restored. In this case, you should restart the computer that performs sensor functions.

You can use the standard commands of the operating system to restart a computer that has application components installed.

If the computer cannot be restarted for some reason, you can restart the services that support operation of application components.

To restart services:

1. Open the operating system console.
2. Depending on which functions are performed by the computer, do the following:
   - If the computer performs Server functions, enter the following sequence of commands:

```
sudo service kics4net-epp-proxy restart
sudo service kics4net-fts restart
sudo service kics4net-postgresql restart
sudo service kics4net restart
sudo service kics4net-webserver restart
```

- If the computer performs sensor functions, enter the following command:

```
sudo service kics4net-epp-proxy restart
sudo service kics4net restart
sudo service kics4net-websensor restart
```

Using a test network packet to verify event registration

To verify the registration of events in Kaspersky Industrial CyberSecurity for Networks, you can use a test network packet. When this type of packet is detected in traffic, the application registers test events based on the following technologies:

- Deep Packet Inspection. An event is registered regardless of whether or not there are Process Control rules or tags.
- Network Integrity Control An event is registered regardless of whether or not there are Interaction Control rules. Use of Network Integrity Control technology must be enabled.
- Intrusion Detection. An event is registered regardless of whether or not there are Intrusion Detection rules. Use of Rule-based Intrusion Detection must be enabled.
- Asset Management. An event is registered regardless of whether or not there are known devices in the devices table. Use of device activity detection must be enabled.

Events are registered with system event types that are assigned the following codes:

- 4000000001 for an event based on Deep Packet Inspection technology.
- 4000000002 for an event based on Network Integrity Control technology.
- 4000000003 for an event based on Intrusion Detection technology.
- 4000000004 for an event based on Asset Management technology.

You can view test events in the table of registered events.

To verify audit functions, Kaspersky Industrial CyberSecurity for Networks saves information about the registration of test events in the audit log. An audit entry is created for each registered event, and this entry specifies the technology used to register the test event.

A test network packet is a UDP protocol packet with certain parameter values. The parameters are defined in such a way as to exclude the probability of receiving such a packet in normal industrial network traffic.

The following data must be defined in the parameters of a test network packet:

- Ethernet II header:

- Source MAC address: `00:00:00:00:00:00`
- Destination MAC address: `ff:ff:ff:ff:ff:ff`
- EtherType: `0x0800 (IPv4)`

- IP header:
  - Source IP address: `127.0.20.20`
  - Destination IP address: `127.0.20.20`
  - ID: `20`
  - TTL: `20`
  - Protocol type: `17 (UDP)`
  - Flags: `0x00`
- UDP header:
  - Source port: `20`
  - Destination port: `20`
- Packet contents:
  - Length of packet contents, in bytes: `20`
  - Packet contents: "`KICS4Net Sentinel 20`"

To generate and send a test network packet, you can use a network packet generator program such as Scapy. You need to send the test network packet from a node whose traffic is controlled by Kaspersky Industrial CyberSecurity for Networks.

Example:

To send a test network packet using the program Scapy in a Linux operating system:

1. In the operating system console of the computer, enter the command to run Scapy in interactive mode:

   ```
   sudo scapy
   ```

2. Enter the command to send the test network packet:

   ```
   sendp(
   Ether(src='00:00:00:00:00:00', dst='ff:ff:ff:ff:ff:ff')/
   IP(src='127.0.20.20', dst='127.0.20.20', id=20, ttl=20)/
   UDP(sport=20, dport=20)/
   "KICS4Net Sentinel 20",
   iface="< interface name >"
   )
   ```

   where < `interface name` > is the name of the network interface connected to the industrial network (for example, `eth0`).

After the packet is detected in traffic, Kaspersky Industrial CyberSecurity for Networks registers test events.

Synchronizing the time on nodes of Kaspersky Industrial CyberSecurity for Networks with the time source used for industrial network devices

To correctly correlate the time of registration of events with the time when events occurred in the industrial network, time must be synchronized in the system. The time on nodes with Kaspersky Industrial CyberSecurity for Networks components installed must be synchronized with a common source of time used by industrial network devices.

When centrally installing Kaspersky Industrial CyberSecurity for Networks, you can enable automatic time synchronization between the Server and nodes where sensors are installed. In this case, the node with the Server installed will serve as the time source for nodes that have sensors installed. It is recommended to use the software tools from the operating system of the computer performing Server functions to configure time synchronization between the Server and the common time source used by devices in the industrial network. For Server time synchronization, you can use the standard protocols known as Network Time Protocol (NTP) and Precision Time Protocol (PTP).

NTP is used for automatic time synchronization between the Server and other nodes. In this case, you cannot configure synchronization with other time sources or use the PTP protocol on nodes that have sensors installed.

If a sensor was installed locally using the kics4net-install.sh script, automatic time synchronization with the Server is not performed on this node. If this is the case, you must configure time synchronization on the Server and on all nodes containing sensors that were installed locally.

For example sequences of operations for configuring time synchronization, please refer to the Appendices.

Updating SSL connection certificates

Kaspersky Industrial CyberSecurity for Networks can use the following certificates:

- Certificates for connections between nodes of Kaspersky Industrial CyberSecurity for Networks.
- Certificates for connecting to Kaspersky Industrial CyberSecurity for Networks through the web interface.
- Certificates for connecting through the Kaspersky Industrial CyberSecurity for Networks API.
- Certificates for connecting connectors.
- Certificates for connections with Kaspersky Endpoint Agent.

It is recommended to update certificates in the following cases:

- Current certificates have been compromised.
- Certificates have expired.
- Certificates need to be regularly updated in accordance with the information security requirements at the enterprise.

Updating certificates for connections between nodes of Kaspersky Industrial CyberSecurity for Networks

During installation of Kaspersky Industrial CyberSecurity for Networks, certificates for connections between nodes of Kaspersky Industrial CyberSecurity for Networks are automatically updated. You can manually update these certificates without reinstalling application components.

To update certificates for connections between nodes of Kaspersky Industrial CyberSecurity for Networks:

1. On the Server computer, go to the /opt/kaspersky/kics4net/sbin/ folder and enter the command to launch the script for local certificate update:

   ```
   sudo bash kics4net-update-certs.sh
   ```

2. After the script finishes, return all sensors to the initial state using the kics4net-reset-to-defaults.sh script that reverts the node to the initial state. The script is located on the computer with the installed application component in the /opt/kaspersky/kics4net/sbin/ folder.

3. Add and connect sensors again.

Updating the certificate for connecting to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface

To update the certificate for connecting to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface, you need to replace the certificate used by the web server. You can specify a new web server certificate under **Settings** → **Connection Servers** on the **Web server** tab.

Updating the certificate for connecting to the Server through the Kaspersky Industrial CyberSecurity for Networks API

To update the certificate for connecting to the Server through the Kaspersky Industrial CyberSecurity for Networks API, you need to replace the certificate used by the REST API server. You can specify a new REST API server certificate under **Settings** → **Connection Servers** on the **REST API server** tab.

Updating certificates for connecting connectors

You can update the certificates used for connecting connectors when creating new communication data packages for connectors.

Updating certificates for connections with Kaspersky Endpoint Agent

You can update the certificates used for connections with Kaspersky Endpoint Agent when changing the settings of integration servers.

Updating databases and application modules

Kaspersky Industrial CyberSecurity for Networks provides the capability to update the following databases and application modules:

- System Intrusion Detection rules.

- Rules for obtaining information about devices and communication protocols.
- Event correlation rules for registering incidents.
- Modules for processing application-layer protocols for industrial process control purposes.
- Database of known vulnerabilities.
- Methods for identifying techniques of potential attacks based on system command detection events.

Application modules and databases are updated after installing updates released by Kaspersky.

Timely installation of updates ensures maximum protection of an industrial network using Kaspersky Industrial CyberSecurity for Networks. In addition, these updates can augment and update application modules involved in providing security for the application. Failure to regularly install updates over time will increase the risks to application security due to the emergence of new threats. You must also install security updates for your particular operating system.

It is recommended to manually start installing updates immediately after you install components of Kaspersky Industrial CyberSecurity for Networks. You can configure automatic scheduled start settings for regular installation of updates.

You can use the following update sources:

- Kaspersky update servers.
- Kaspersky Security Center Administration Server.

For an update source, you can also use files from a local resource if installation of updates is started manually.

You can configure the settings and start the installation of updates when connected to the Server through the web interface.

Updates of databases and application modules are subject to the following limitations and special considerations:

- Update functionality is available after a license key is added.

  UPDATES FUNCTIONALITY (INCLUDING PROVIDING ANTI-VIRUS SIGNATURE UPDATES AND CODEBASE UPDATES) WILL NOT BE AVAILABLE IN THE SOFTWARE IN THE U.S. TERRITORY FROM 12:00AM EASTERN DAYLIGHT TIME (EDT) ON SEPTEMBER 10, 2024 IN ACCORDANCE WITH THE RESTRICTIVE MEASURES.

- To download updates from Kaspersky update servers, you must have Internet access. When connected to update servers from a computer that performs functions of the Kaspersky Industrial CyberSecurity for Networks Server, the connection is established over the HTTPS protocol (connection through a proxy server is not supported).
- To download updates from the Kaspersky Security Center Administration Server to Kaspersky Industrial CyberSecurity for Networks, the capability for application interaction with Kaspersky Security Center must be added. You can add this functionality during installation or reinstallation of Kaspersky Industrial CyberSecurity for Networks. Updates are downloaded from the Administration Server repository, which obtains its updates through the corresponding task in Kaspersky Security Center.

Manually starting an update

You can run an update at any time. The capability to run an update is available after a license key is added.

Only users with the Administrator role can manually start an update.

To manually start an update:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Update**.
3. In the **Source for manual update** settings block, select one of the following options for update sources:
   - Local update source – lets you download updates from files via a specific local path. You can use the **Browse** button to specify the local path to files.
   - **Kaspersky update servers** – for downloading updates from Kaspersky update servers.
   - **Kaspersky Security Center Administration Server** – for downloading updates from the Kaspersky Security Center Administration Server (this option is available if the capability for application interaction with Kaspersky Security Center has been added).
4. Click the **Update now** button.

Configuring automatic updates

After adding a license key, you can configure automatic updates by schedule.

Only users with the Administrator role can configure automatic updates by schedule.

To enable and configure automatic updates by schedule:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Update**.
3. Use the **Scheduled update** toggle to enable automatic updates.
4. In the **Source for scheduled update** settings block, select one of the following options for update sources:
   - **Kaspersky update servers** – for downloading updates from Kaspersky update servers.
   - **Kaspersky Security Center Administration Server** – for downloading updates from the Kaspersky Security Center Administration Server (this option is available if the capability for application interaction with Kaspersky Security Center has been added).
5. Define the update schedule settings. To do so:

a. In the **Frequency** drop-down list, indicate when the update will occur. Select one of the following options: **Hourly**, **Daily**, **Weekly**, **Monthly**.

b. Depending on the selected option, specify the values for the settings defining the precise update run schedule.

6. Click the **Save settings** button.

Viewing information about update installation

You can view general and detailed information about update installation.

General information about installed updates

General information provides the dates and times when the updated application modules and databases were released.

To view general information about installed updates:

On the application web interface page, select the **About** section.

Detailed information about update installation

Detailed information contains information about update installation processes that are started. The application saves the following detailed information:

- Date and time when the update process was started
- Update run mode
- Date and time of release of the databases and application modules installed during the update process (if the update was successful)
- Error information (if the update failed)
- List of updated databases and application modules

Detailed information about update installation is saved in the application message log.

Distributing access to application functions

In Kaspersky Industrial CyberSecurity for Networks, you can restrict users' access to application functions depending on the tasks of specific users.

The following user accounts may be used to access the application:

- User accounts created in the application.
- Kaspersky Security Center user accounts that are configured for Single Sign-On (SSO).

It is not possible to connect to the Server under other user accounts or using anonymous connections.

User accounts that have access to the application do not have to be registered as operating system user accounts on the Server computer.

The first application user account must be created during initial configuration of Kaspersky Industrial CyberSecurity for Networks. Then you can create additional user accounts that will be used to perform actions in the application.

Depending on which component you are connected to through the web interface, the following sets of functions are available:

- Application functions when connected to the Server
- Application functions when connected to a sensor

When connected to the Server, the application provides access to functions depending on the role of the user that established the connection.

About application user accounts

Role-based access control (RBAC) is used to restrict access to application functions. The role of an application user account determines the set of actions available to the user. The following roles are provided for application user accounts:

- Administrator.

  A user with the Administrator role has access privileges that enable use of all functions for application management, monitoring, and viewing information. This user can also access functions for managing user accounts created in the application.

- Operator.

  A user with the Operator role has access privileges only for monitoring and viewing information.

The Administrator role is assigned to the first user account that is created during initial configuration of the application.

When adding subsequent user accounts, you can assign the appropriate roles to them. You can create up to 100 user accounts for users of the application (not counting users that are configured for Single Sign-On from Kaspersky Security Center).

When connected to the Server, users receive the access privileges corresponding to the role of their user account. If the role of an application user is changed by another user (who has been assigned the Administrator role) while the user is working, the access rights of the connected user are updated in online mode. For example, a user that has connected to the Server with the Administrator role will lose the rights to access application management functions after the Operator role is assigned to their user account.

You can manage user accounts that were created in the application under **Settings** → **Users** in the Kaspersky Industrial CyberSecurity for Networks web interface.

Application functions that are available when connected to the Server through the web interface

This section presents the application functions that are available to users when connected to the Server through the web interface (see the table below).

Available application functions depending on the user role

Application function	Administrator	Operator
Monitoring the application state when connected through the web interface	✓	✓
Viewing application messages	✓	✓
Enabling and disabling the user activity audit	✓	
Viewing user activity audit entries	✓	
Viewing information about nodes with application components installed and about network interfaces on nodes	✓	✓
Managing nodes that have application components installed	✓	
Managing monitoring points on nodes	✓	
Viewing information about an added license key	✓	✓
Adding a license key	✓	
Removing a license key	✓	
Configuring automatic updates	✓	
Manually starting an update	✓	
Viewing information about update installation	✓	✓
Viewing information about application user accounts	✓	
Creating an application user account	✓	
Changing the role of an application user account	✓	
Deleting an application user account	✓	
Changing a user account password	✓	✓
Viewing the devices table	✓	✓
Viewing subnets for asset management	✓	✓
Viewing information about devices with IP addresses from the selected subnets	✓	✓
Exporting devices to a file	✓	✓
Exporting subnets to a file	✓	✓
Viewing device information	✓	✓
Viewing events associated with devices	✓	✓
Selecting sources for device vulnerability monitoring	✓	
Manually adding devices	✓	
Merging devices	✓	
Deleting devices	✓	
Changing the statuses of devices	✓	
Generating a list of subnets for asset management	✓	
Creating a device group tree	✓	
Automatic grouping of devices based on a specific criterion	✓	
Manually arranging devices into groups	✓	
Adding and removing labels for devices	✓	
Editing device information	✓	
Adding, editing and deleting custom fields for a device	✓	

Configuring Process Control	✓	
Viewing information about devices associated with tags	✓	✓
Viewing Process Control rules associated with tags	✓	✓
Viewing information about devices associated with Process Control rules	✓	✓
Monitoring process parameter values	✓	✓
Viewing Interaction Control rules in the table of allow rules	✓	✓
Manually creating Interaction Control rules	✓	
Editing Interaction Control rule settings	✓	
Enabling and disabling Interaction Control rules	✓	
Deleting Interaction Control rules	✓	
Viewing the table containing sets of Intrusion Detection rules	✓	✓
Enabling and disabling sets of Intrusion Detection rules	✓	
Loading and replacing custom sets of Intrusion Detection rules	✓	
Removing custom sets of Intrusion Detection rules	✓	
Managing the settings for storing log entries in the database	✓	
Managing the settings for saving traffic in the database	✓	
Changing the logging level for processes	✓	
Managing technologies	✓	
Configuring the receipt of data from EPP applications	✓	
Enabling and configuring interaction with Kaspersky Security Center	✓	
Managing connectors	✓	
Configuring event types	✓	
Exporting a security policy to a file	✓	✓
Importing a security policy from a file	✓	
Clearing the current security policy	✓	
System monitoring in online mode	✓	✓
Working with the network map	✓	✓
Moving nodes and groups to other groups on the network map	✓	
Monitoring events and incidents	✓	✓
Monitoring vulnerabilities of devices	✓	✓

Viewing information about application user accounts

When connected to the Server through the web interface, you can view information about user accounts that were created in the application. The application does not display information about Kaspersky Security Center user accounts that are configured for Single Sign-On (SSO).

Only users with the Administrator role can view information about user accounts.

To view information about application user accounts:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Users**.

The **Users** tab displays user tiles containing the names and roles of application users.

Creating an application user account

Only users with the Administrator role can create an application user account.

To create an application user account:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Users**.
3. Add a new user tile. To do so, click the tile with the + icon.

   You will see a new user tile showing fields for entering account credentials and selecting a role for the new user account.
4. In the user name entry field, enter a user name for the account you want to create.

   You can use uppercase and lowercase letters of the English alphabet, numerals, dots, and the _ and - characters.

   The user account name must meet the following requirements:

   - Must be unique within the list of application user names (not case-sensitive).
   - Must contain 3-20 characters.
   - Must begin with a letter.
   - Must end with any supported character except a dot.
5. In the password entry fields, enter the password that you want to set for the user account.

   The password must meet the following requirements:

   - Must contain between 8 and 256 ASCII characters.
   - Must contain one or more uppercase letters of the English alphabet.
   - Must contain one or more lowercase letters of the Latin alphabet.
   - Must contain one or more numerals.
   - Must contain no more than three consecutive repeated characters.
6. In the drop-down list, select the necessary user role: **Administrator** or **Operator**.
7. Click **Save**.

The user tile displays an icon containing the name of the user account and the role assigned to it.

Changing the role of an application user account

When connected to the Server through the web interface, you can change the roles of user accounts that were created in the application. This role modification method is not available for Kaspersky Security Center user accounts that are configured for Single Sign-On (SSO).

Only users with the Administrator role can change the roles of user accounts.

Users with the Administrator role can change the role of any user account except the role of their own user account.

To change the role of an application user account:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Users**.
3. Click the **Change** button in the user tile of the user whose role you want to change.

   The user tile will switch to account settings editing mode.
4. In the drop-down list, select the necessary user account role: **Administrator** or **Operator**.
5. Click **Save**.

The user tile displays an icon containing the user name and role assigned to this user account.

Deleting an application user account

When connected to the Server through the web interface, you can delete user accounts that were created in the application. This deletion method is not available for Kaspersky Security Center user accounts that are configured for Single Sign-On (SSO).

Only users with the Administrator role can delete an application user account.

A user with the Administrator role can delete any user account except their own user account.

To delete an application user account:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Users**.
3. Click the **Delete** button in the user tile that you want to delete.

   A window with a confirmation prompt opens.
4. In the prompt window, click **OK**.

Changing a user account password

After connecting to the Server through the web interface, you can change the password of your user account that you used to establish the connection. Only a user account that was created in the application can change a user password on the Kaspersky Industrial CyberSecurity for Networks web interface page. This password change method is not available for Kaspersky Security Center user accounts that are configured for Single Sign-On (SSO).

You are advised to change the password in the following cases:

- You are connecting for the first time after the user account was created in the application.
- The current password has been compromised.
- The password must be changed regularly in accordance with the information security requirements at the enterprise.

To change the password of your own user account:

1. On the Kaspersky Industrial CyberSecurity for Networks web interface page, open the user menu.
   - If the menu is collapsed, click the button.
   - If the menu is expanded, click the button on the right of the name of the current user.
2. In the user menu, select **Change password**.
   The **Change password** window appears.
3. In the **Current password** field, enter your current password.
4. In the **New password** and **Repeat new password** fields, enter the new password.
   The new password must meet the conditions listed in the **Change password** window. The conditions you fulfill are automatically marked while you are entering your password.
5. Click the **Edit** button. This button is available after entering the current password and new password and after fulfilling all requirements for the new password.

The new password will be required the next time you connect to the Server through the web interface.

Configuring Asset Management

Kaspersky Industrial CyberSecurity for Networks lets you monitor the assets of a company as represented by its industrial network devices. Devices are identified by the application based on their MAC- and/or IP addresses. The application can receive device data when doing the following:

- Processing traffic arriving through monitoring points
- Processing data received from EPP applications

For asset management purposes, the application generates a devices table and subnets table. The devices table contains device information that was manually provided or obtained automatically by the application.

Subnets that are known to the application are used to verify IP addresses detected by the application. Depending on the type of subnet that a detected IP address belongs to, the application may take different actions for asset management and device interaction control.

Only information that can be identified by the application may be automatically obtained and updated (for example, address information of a device).

Subnets are automatically added only based on data received from EPP applications. The application automatically adds detected subnets to the subnets table if they are nested within a subnet for which automatic addition of subnets is enabled.

For device activity detection and automatic update of information, the corresponding Asset Management methods must be enabled. If necessary, you can manually specify the values of specific data and disable their automatic update to lock the current values (for example, you can lock the device category if the currently defined category differs from the one that is determined automatically).

Some device information must be specified manually because it cannot be automatically updated. For example, you can save specific device information in the device table, and add any absent criteria for sorting and filtering devices. You can also use manually defined information to arrange devices in various groups in the group tree, or filter and search for devices based on device labels.

You can configure asset management and edit device information on the Server web interface page in the **Assets** section. You can also view information about the interactions between devices and perform various actions with devices when working with the network map. To conveniently present information about interactions between devices and to enable automatic grouping of devices by subnet, you can generate lists of subnets in the application and indicate the subnet structure of your company's network.

Asset Management methods and modes

The following methods are used for asset management in Kaspersky Industrial CyberSecurity for Networks:

- Device activity detection This method lets you monitor the activity of devices in industrial network traffic based on the obtained MAC- and/or IP addresses of devices.
- Device Information Detection This method lets you automatically obtain and update device information based on data received from traffic or from EPP applications.
- PLC Project Control This method lets you detect information about PLC projects in traffic, save this information in the application, and compare it to previously obtained information.
- Vulnerability Detection This method lets you detect vulnerabilities in devices based on the saved information about the devices.

You can enable and disable the use of individual asset management methods.

The following modes are available for asset management methods:

- Learning mode. This mode is intended for temporary use. In this mode, all devices whose activity is detected in traffic are considered to be authorized by the application. You can enable learning mode only for the device activity detection method. The device activity detection method can be applied together with other asset management methods.
- Monitoring mode. This mode is intended for continual use. In this mode, when activity of devices is detected, the application considers only those devices that have been assigned the *Authorized* status as authorized.

Depending on the selected mode, the application automatically assigns statuses to devices.

In learning mode, the application does not register events when it detects activity of devices or when device information is automatically updated.

Asset management learning mode must be enabled for a sufficient amount of time to detect the activity of relevant devices. This amount of time depends on the number of devices in the industrial network and how frequently they operate and are serviced. We recommend that you enable learning mode for at least one hour. In large industrial networks, learning mode can be enabled for a period ranging from one to several days to detect the activity of all new devices.

The received MAC- and IP addresses of devices are processed with the following special considerations:

- A router indicator must be set for devices that perform functions of a network switch between industrial network segments. If this indicator is not defined automatically, it must be manually set. Otherwise, before the router indicator is set, the application may fail to populate the devices table with devices that interact through this routing device in different industrial network segments. After the indicator is set, interacting devices will be added to the devices table when there is corresponding traffic involving them.

- If only the device IP address is detected in traffic (the IP address cannot be matched to a specific MAC address), this IP address is checked against the list of subnets known to the application. For the device activity detection method, IP addresses that belong only to **Public** subnets are not taken into account.

When the device information detection method is enabled, the application automatically updates information about devices. For example, the application can automatically update the name of the operating system installed on a device as it detects updated data in the traffic of the device. The application updates data for which automatic updates are enabled in the settings of devices.

To automatically receive information about devices, the application analyzes industrial network traffic according to the *rules for identifying information about devices and the protocols of communication between devices*. These rules are built in to the application.

After installation, the application uses the default rules for identifying information about devices and the protocols of communication between devices. In most cases, these rules generate correct results. However, there can be situations when information is incorrectly identified due to the technical specifics of devices (for example, when identifying the category of some devices). To increase the accuracy of identifying information, Kaspersky experts regularly update the databases containing the sets of rules. You can update rules by installing updates.

In monitoring mode, the application registers the corresponding events based on Asset Management technology. Depending on the applied methods, events may be registered in the following cases:

- Detection of activity of unknown devices or devices with the *Archived* status.

- Automatic change of device information.

- Detection of read/write operations with projects and PLC project blocks.

- Detection of vulnerabilities and modifications associated with vulnerabilities.

When PLC Project Control is enabled, the application may register a large number of events associated with the detection of read/write operations with projects or blocks. Normally, a large number of events are registered at the initial stage when this method is used. To reduce the total number of registered events, the PLC Project Control method is disabled by default after the application is installed. You can enable this method at any time.

Selecting the applied methods and changing the Asset Management mode

Only users with the Administrator role can manage asset management methods and modes.

To enable or disable the use of asset management methods:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Technologies**.
3. Enable or disable the use of asset management methods by using the following toggle buttons:
   - **Device Activity Detection**
   - **Device Information Detection**
   - **PLC Project Control**
   - **Vulnerability Detection**
4. After a method is enabled or disabled, wait for the toggle switch to change to the necessary position (*Enabled* or *Disabled*).

   The process may take some time, during which the toggle switch will be unavailable. Wait for the method to be enabled or disabled.
5. If the Device Activity Detection method is enabled, select the necessary asset management mode to be applied with the method. To do so, in the drop-down list on the right of the method name, select one of the following values:
   - **Learning** – to apply the method in learning mode.
   - **Monitoring** – to apply the method in monitoring mode.
6. After the mode is selected, wait for the name of this mode to appear in the field of the drop-down list.

   This process may take some time, during which the drop-down list displays the *Changing* status. Wait for the selected mode to be enabled.

Selecting sources for device vulnerability monitoring

When monitoring device vulnerabilities, the application detects vulnerabilities whose information has been uploaded to the vulnerabilities database from various sources. You can select specific sources of vulnerability information for the purpose of detecting vulnerabilities from only those selected sources.

Only users with the Administrator role can select sources for device vulnerability detection.

To enable or disable use of sources of vulnerability information:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Vulnerabilities** section, click the **Sources** link to open the window for selecting sources.
3. Enable or disable the use of specific sources. The list contains all sources available in the database of known vulnerabilities.
4. Click the **Apply** button.

Manually adding devices

You can manually add a new device to the devices table. For an added asset, you must specify a unique MAC address and/or IP address.

Only users with the Administrator role can manually add devices.

You can add devices in the following ways:

- **Adding a device when working with the devices table**

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. On the **Devices** tab in the **Assets** section, open the details area by clicking the **Add device** link.
3. On the **Addresses** tab in the details area, specify unique MAC- and/or IP addresses for the device.
4. You can specify multiple IP addresses for the same network interface of the device. To generate a list of IP addresses, perform one of the following actions:
   - If you want to add an IP address, click the **Add IP address** button.
   - If you want to remove an IP address, click the icon located on the right of the field containing the IP address.
5. If the device has multiple network interfaces, generate a list of network interfaces of the device and specify the corresponding MAC- and/or IP addresses for them.

   To do so, perform one of the following actions:
   - If you want to add a network interface, click the **Add interface** button located under the group of settings of the last network interface of the device.
   - If you want to delete a network interface, click the **Delete interface** button located on the right of the name of the network interface of the device (if there are two or more network interfaces).
   - If you want to define a different name for a network interface, click the icon located on the right of the current name and enter the new name for the network interface in the field that opens.
6. On the **Settings** tab in the details area, specify the relevant values in the fields that identify the device information.
7. On the **Addresses** and **Settings** tabs in the details area, enable or disable automatic updates for the relevant information about the device. To do so, use the **Autoupdate** toggle buttons located above the fields that have automatic update capability. For the **Status** field, the autoupdate toggle switch is named **Automatically change to Archived status** due to the specific features of automatically changing the statuses of devices.
8. On the **Custom fields** tab in the details area, create a list of custom fields if necessary.
9. Click **Save**.

   This button is unavailable if not all required information is specified in the device settings or if invalid values have been defined. The tab containing settings requiring corrected values is marked by the icon.

The devices table will show the new device with the *Authorized* status.

- Adding a device based on a node on the network map

When working with the network map, you can add a new device to the devices table using a node representing a device that is unknown to the application.

To add a node of an unknown device to the devices table:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select the relevant node representing a device that is unknown to the application.

   The details area appears in the right part of the web interface window.
3. Click the **Add to the Device table** button.

   The details area will show the tabs for configuring the settings of the new device.
4. Configure the settings of the new device without changing the MAC- and/or IP address that are specified for the node.

   For a description of how to configure these settings, please refer to the procedure for manually adding a device when working with the devices table.
5. Click **Save**.

The devices table will show the new device with the *Authorized* status. The node that previously represented a device that was unknown to the application will now represent a device on the network map.

After adding a device, you can add Process Control settings for the device.

Merging devices

If one device is represented by multiple devices in the table for some reason, these devices can be merged into one device. Devices can be merged automatically when the device activity detection method is enabled in learning mode. You can also manually merge devices.

Devices are automatically merged if the application identifies a connection between the MAC address of one device and the IP address of a different device. If conflicts arise between defined values in device information, the merged device will retain the values that were defined for the device with the IP address. For this reason, prior to enabling learning mode (and while working in this mode), it is not recommended to change information about devices for which only a MAC address is defined if they could be automatically merged with devices that have defined IP addresses.

When devices are merged, some information from the merged devices might not be saved in the new device (for example, the contents of dynamic fields). In addition, to merge devices, the total number of network interfaces in the new device must not be more than 64.

Only a user with the Administrator role can manually merge devices.

You can merge devices in the following ways:

- **Merging devices when working with the devices table**

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Assets** section.
3. On the **Devices** tab, select the devices that you want to merge.

   The details area appears in the right part of the web interface window.
4. Click the **Merge devices** button.

   The details area will show the tabs for configuring the settings of the new device.
5. Check the settings of the new device and edit them if necessary:

   - On the **Addresses** tab in the details area, the MAC- and IP addresses of the selected devices are distributed among individual network interfaces. If necessary, change the values of addresses and the names of network interfaces.
   - On the **Settings** tab in the details area, all fields containing conflicting values in the selected devices are marked by messages regarding the conflicting values. The conflicting values are merged into one value in text fields.
   - On the **Custom fields** tab in the details area, the list contains all custom fields of the selected devices.
6. Click the **Merge** button.

   A window with a confirmation prompt opens.
7. In the prompt window, click **OK**.

The devices table will show the new device with the *Authorized* status.

- Merging devices when working with the network map

When working with the network map, you can merge multiple nodes on the network map into one new device for the devices table.

You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

WAN nodes cannot be merged.

To merge devices represented by nodes on the network map:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. In the **Network map** section, select multiple objects representing nodes and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.

   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.

3. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.

4. Click the **Merge devices** button.

   The details area will show the tabs for configuring the settings of the new device.

5. Check the settings of the new device and edit them if necessary:

   - On the **Addresses** tab in the details area, the MAC- and IP addresses of the selected devices are distributed among individual network interfaces. If necessary, change the values of addresses and the names of network interfaces.

   - On the **Settings** tab in the details area, all fields containing conflicting values in the selected devices are marked by messages regarding the conflicting values. The conflicting values are merged into one value in text fields.

   - On the **Custom fields** tab in the details area, the list contains all custom fields of the selected devices.

6. Click the **Merge** button.

   A window with a confirmation prompt opens.

7. In the prompt window, click **OK**.

The devices table will show the new device with the *Authorized* status. The network map will show one merged node instead of the previously selected multiple nodes.

Deleting devices

You can delete one or multiple devices from the devices table.

Only a user with the Administrator role can delete devices.

Information about deleted devices is not saved in the application. If deleted devices start displaying activity in the industrial network again, the application will add them to the devices table as new devices (with the *Authorized* or *Unauthorized* status depending on the current asset management mode).

You can delete devices in the following ways:

- **Deleting devices when working with the devices table**

  1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
  2. Select the **Assets** section.
  3. On the **Devices** tab, select the devices that you want to delete.

     The details area appears in the right part of the web interface window.
  4. Click **Delete device** (if one device is selected) or **Delete devices** (if multiple devices are selected).

     A window with a confirmation prompt opens.
  5. In the prompt window, click **OK**.

- **Deleting devices when working with the network map**

When working with the network map, you can remove devices from the devices table by using the nodes representing those devices on the network map.

To remove a device when working with the network map:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select one or multiple nodes representing devices.

   To select multiple nodes, perform one of the following actions:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant nodes.
   - Hold down the **CTRL** key and use your mouse to select the relevant nodes.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes while also indicating how many of the devices belong to each category.
3. If there are devices with various categories among the selected nodes, you can exclude devices from one of the categories. To do so, clear the check box next to the name of this category. The category name will disappear from the list.
4. Click **Delete device** (if one node is selected) or **Delete devices** (if multiple nodes are selected).

   A window with a confirmation prompt opens.
5. In the prompt window, click **OK**.

Manually changing the statuses of devices

Only a user with the Administrator role can change the statuses of devices.

You can change the status (select either the *Authorized*, *Unauthorized* or *Archived* status) for one selected device or for multiple selected devices simultaneously. If you are changing the status of one selected device, you can enable or disable automatic status changes for this device. If you are changing the status of multiple selected devices, you will be able to enable or disable automatic status changes when editing the information of each of these devices individually.

The application automatically changes the status of an *Archived* device if it displays activity. Depending on the current asset management mode, the application assigns either the *Authorized* or *Unauthorized* status to the detected device.

You can change the statuses of devices in the following ways:

- **Changing the statuses of devices when working with the devices table**

To change the status of one device when working with the devices table:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. On the **Devices** tab in the **Assets** section, select the relevant device.

   The details area appears in the right part of the web interface window.
3. Click the **Edit** button.

   The details area will show the following tabs for viewing and editing device information: **Addresses**, **Settings** and **Custom fields**.
4. Select the **Settings** tab.
5. In the **Status** drop-down list, select the necessary status of the device.
6. Enable or disable automatic status changes. To do so, use the **Automatically change to Archived status** toggle switch located above the **Status** drop-down list.

   You may need to disable automatic status changes if, for example, you want to prevent the *Authorized* status from changing to the *Archived* status for a rarely connected device.
7. Click **Save**.

To change the status of multiple devices when working with the table:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Devices** section.
3. In the devices table, select the devices whose status you want to change.

   The details area appears in the right part of the web interface window.
4. Click the button with the name of the relevant status.

   A window with a confirmation prompt opens.
5. In the prompt window, click **OK**.

- **Changing the statuses of devices when working with the network map**

When working with the network map, you can change the statuses of known devices represented by nodes on the network map.

You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

To change the status of one device when working with the network map:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select the node of the relevant device.

   The details area appears in the right part of the web interface window.
3. Click the **Edit** button.

   The details area will show the following tabs for viewing and editing device information: **Addresses**, **Settings** and **Custom fields**.
4. Select the **Settings** tab.
5. In the **Status** drop-down list, select the necessary status of the device.
6. Enable or disable automatic status changes. To do so, use the **Automatically change to Archived status** toggle switch located above the **Status** drop-down list.

   You may need to disable automatic status changes if, for example, you want to prevent the *Authorized* status from changing to the *Archived* status for a rarely connected device.
7. Click **Save**.

To change the status of multiple devices when working with the network map:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select the objects representing the nodes of known devices and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.
3. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.
4. Click the button with the name of the relevant status.

   A window with a confirmation prompt opens.

5. In the prompt window, click **OK**.

Generating a list of subnets for asset management

You can generate a list of known subnets while taking into account the specific addressing of devices within the network of your organization. The list of subnets can be generated manually.

If Kaspersky Industrial CyberSecurity for Networks receives data from EPP applications, the application can use this data to automatically add subnets. If this is the case, the application automatically adds detected subnets if they are nested within a subnet for which automatic addition of subnets is enabled.

Only users with the Administrator role can generate a list of subnets.

You can use the following functions to generate a list of subnets:

- **Adding a subnet**

  1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
  2. Select the **Assets** section.
  3. On the **Subnets** tab, open the details area by clicking the **Add subnet** link.
  4. In the **Subnet** field, enter the subnet address in CIDR format: `<base address of subnet>/<number of bits in mask>`.
  5. In the **Type** drop-down list, select the type of subnet according to its purpose.
  6. Set the following toggle buttons to the necessary positions:
     - **Ignore MAC addresses for NIC rules** – enables and disables the mode for skipping detected MAC addresses when creating allow rules based on Network Integrity Control technology.

       If this option is enabled, the MAC addresses detected together with IP addresses from the subnet will not be added to Network Integrity Control rules in learning mode.
     - **Automatically add subnets** – enables and disables automatic addition of nested subnets according to data received from EPP applications.

       If this mode is enabled, the application adds nested subnets within this subnet based on data received from EPP applications. By default, the type selected for the current subnet is indicated for these nested subnets.
  7. Click **Save**.

  The list of subnets will show the new subnet at its corresponding level of the hierarchy within the tree.

- **Editing subnet settings**

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Assets** section.
3. On the **Subnets** tab, select the relevant subnet.

   The details area appears in the right part of the web interface window.
4. Click the **Edit** button.
5. Depending on the necessary result, perform the following actions:

   - In the **Subnet** field, enter the subnet address in CIDR format: `<base address of subnet>/<number of bits in mask>`.

     The address of the root subnet cannot be edited.
   - In the **Type** drop-down list, select the type of subnet according to its purpose.

     When changing the subnet type, keep in mind that a new type of subnet may affect the accessible operations that the application can perform with IP addresses from this subnet. For example, if you select the **Public** type, the network map will no longer display links to devices that were assigned IP addresses from this subnet.
   - Set the following toggle buttons to the necessary positions:

     - **Ignore MAC addresses for NIC rules** – enables and disables the mode for skipping detected MAC addresses when creating allow rules based on Network Integrity Control technology.

       If this option is enabled, the MAC addresses detected together with IP addresses from the subnet will not be added to Network Integrity Control rules in learning mode.
     - **Automatically add subnets** – enables and disables automatic addition of nested subnets according to data received from EPP applications.

       If this mode is enabled, the application adds nested subnets within this subnet based on data received from EPP applications. By default, the type selected for the current subnet is indicated for these nested subnets.
6. Click **Save**.

If the **Subnet** parameter is changed, the tree hierarchy level may be changed for a subnet.

- Deleting subnets

You can delete any subnet except the root subnet in the tree (subnet 0.0.0.0/0).

To delete subnets:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Assets** section.
3. On the **Subnets** tab, select the subnets that you want to delete.

   The details area appears in the right part of the web interface window.
4. Click the **Remove** button.

   A window with a confirmation prompt opens.
5. In the prompt window, confirm deletion of the subnets.

Deleted subnets will no longer be displayed in the list of subnets. If a deleted subnet contained nested subnets, these subnets will remain in the list (but the tree hierarchy level of these subnets will change).

Viewing information about devices with IP addresses from the selected subnets

You can view information about devices with assigned IP addresses from the selected subnets. Information about devices is displayed in the devices table. The devices table automatically applies a filter based on the addresses of subnets.

To view information about devices in the devices table:

1. Select the **Assets** section.
2. On the **Subnets** tab, select the subnets for which you want to view information about devices.

   The details area appears in the right part of the web interface window.
3. Click the **Show devices** button.

The **Devices** tab opens in the **Assets** section. The devices table will be filtered based on the IP addresses in the address information of devices.

About arranging devices into groups

You can use the device group tree to arrange devices into groups. The device group tree supports up to six nesting levels.

Devices can be put into groups at any level of the hierarchy. However, each device can be added to only one of the groups in the tree.

The tree also has a limit of no more than 1000 groups.

Until a device is added to a specific group, information about this device does not contain any information about the specific location of the device. This device is assigned to the top level of the hierarchy within the group tree. After a device is added to a group, the application saves the location of this device as the full path to the group in the group tree.

Devices can be arranged into groups in the following ways:

- Automatically group devices based on a specific criterion.

  Using this type of device grouping, the application can automatically add groups to the device group tree. Groups are added when the application detects devices whose information matches the selected grouping criterion. The names of groups are assigned from a range of specific values for the selected criterion (for example, from the names of device categories when grouping by category).

- Manually arrange devices into groups.

  You can manually arrange devices into groups, including by adding devices into relevant groups and excluding them from other groups. When necessary, you can make changes to the device group tree by utilizing the available functions for manually forming the device group tree.

Automatic grouping of devices based on a specific criterion

You can automatically group devices in the device group tree based on one of the following criteria:

- Affiliation of IP addresses with subnets that are known to the application
- Device categories
- Device vendors

Only users with the Administrator role can automatically group devices.

To automatically group devices based on a specific criterion beginning with the top level of the hierarchy in the group tree:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, click one of the following buttons for selecting a grouping criterion in the toolbar located in the left part of the network map display area:

   - – for grouping devices by subnet.
   - – for grouping devices by category.
   - – for grouping devices by vendor.

   A window opens with a prompt for you to select a grouping option.

3. In the prompt window, click one of the following buttons depending on your desired result:

   - If you want to group devices based on the selected criterion in all groups of the device group tree, click the **With child groups** button.

- If you want to group devices based on the selected criterion only at the top level of the device group tree hierarchy, click the **Selected only** button.

The application will identify the devices that match the selected grouping criterion, create groups for these devices, and place the devices into these groups.

To automatically group devices in a selected device group:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select the group in which you want to automatically group devices.
3. Right-click to open the context menu.
4. In the context menu, select one of the following options:
   - **Group by subnet**.
   - **Group by category**.
   - **Group by vendor**.

   A window opens with a prompt for you to select a grouping option.
5. In the prompt window, click one of the following buttons depending on your desired result:
   - If you want to group devices based on the selected criterion in all child groups of the selected group, click the **With child groups** button.
   - If you want to group devices based on the selected criterion only in the selected group, click the **Selected only** button.

   The application will identify the devices that match the selected grouping criterion, create groups for these devices, and place the devices into these groups (however, devices that are already in other groups will not be put into the new groups).

Manually arranging devices into groups

Only users with the Administrator role can manage the location of devices within the group tree.

To manage the arrangement of devices in the group tree, you can use the following functions:

- Add one device to a group

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the device in the **Assets** section on the **Devices** tab or in the **Network map** section.

   The details area appears in the right part of the web interface window.
3. Click the **Edit** button.
4. In the details area, go to the **Settings** tab.
5. Click the icon in the right part of the **Group** field.

   The **Select group in tree** window appears.
6. In the device group tree, select the relevant group.

   If the relevant group is not in the tree, you can add it in the currently open **Select group in tree** window.
7. Click the **Select** button.

   The path to the selected group will appear in the **Group** field.
8. Click **Save** in the details area.

   This button is unavailable if not all required information is specified in the device settings or if invalid values have been defined. The tab containing settings requiring corrected values is marked by the icon.

- Add multiple devices to a group

You can add multiple devices to a group when working with the devices table.

When working with the network map, you can also add multiple known devices represented by nodes on the network map to a group. You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

To add multiple devices to a group when working with the table:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Assets** section.
3. On the **Devices** tab, select the devices that you want to add to a group.

   The details area appears in the right part of the web interface window.
4. Right-click to open the context menu.
5. In the context menu, select the **Move to group** option.

   The **Select group in tree** window appears.
6. In the device group tree, select the relevant group.

   If the relevant group is not in the tree, you can add it in the currently open **Select group in tree** window.
7. Click the **Select** button.

   The path to the selected group will appear in the **Group** column.

To add multiple devices to a group when working with the network map:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select the relevant nodes of known devices and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.
3. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.
4. Right-click to open the context menu.
5. In the context menu, select the **Move to group** option.

   The **Select group in tree** window appears.

6. In the device group tree, select the relevant group.

   If the relevant group is not in the tree, you can add it in the currently open **Select group in tree** window.

7. Click the **Select** button.

   The selected nodes representing known devices will be displayed within the selected group.

- Remove one device from a group

  1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
  2. Select the device in the **Assets** section on the **Devices** tab or in the **Network map** section.

     The details area appears in the right part of the web interface window.
  3. Click the **Edit** button.
  4. In the details area, go to the **Settings** tab.
  5. In the **Group** field, delete the path to the group by clicking the **Clear** link above the field (the link is displayed if a group is defined).
  6. Click **Save**.

     This button is unavailable if not all required information is specified in the device settings or if invalid values have been defined. The tab containing settings requiring corrected values is marked by the ⚠ icon.

  After saving the changes for the device, the **Group** parameter is cleared and the device will be assigned to the top level of the hierarchy within the group tree.

- Remove multiple devices from groups

You can remove multiple devices from groups when working with the devices table. The devices selected for removal from groups may be part of the same group or in different groups.

When working with the network map, you can also remove multiple known devices represented by nodes on the network map from groups. You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

To remove multiple devices from groups when working with the table:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Assets** section.
3. On the **Devices** tab, select the devices that you want to remove from groups.

   The details area appears in the right part of the web interface window.
4. Right-click to open the context menu.
5. In the context menu, select the **Remove from group** option.

   A window with a confirmation prompt opens.
6. In the prompt window, confirm removal of the devices from groups.

For all selected devices, the **Group** parameter is cleared and these devices will be assigned to the top level of the hierarchy within the group tree.

To remove multiple devices from groups when working with the network map:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select the nodes in expanded groups and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.
3. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.
4. Right-click to open the context menu.
5. In the context menu, select the **Remove from group** option.

   A window with a confirmation prompt opens.

6. In the prompt window, confirm removal of the devices from groups.

   For all selected devices, the **Group** parameter is cleared and these devices will be displayed outside of groups.

Moving nodes and groups to other groups on the network map

You can change the location of nodes and groups in the device group tree by dragging objects on the network map. After being moved, nodes and groups change their location in the device group tree just as when adding devices to a group and removing devices from groups.

Only users with the Administrator role can move nodes and groups to other groups.

To move nodes and/or groups to other groups:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select the relevant nodes of known devices and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.
3. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.
4. Move the cursor over one of the selected objects (group or node representing a known device).
5. Press the **CTRL** key and hold it down while dragging the selected objects to the relevant group (or to any place outside of groups if you want to move the selected objects to the top level of the hierarchy within the group tree).

   A window with a confirmation prompt opens.
6. In the prompt window, confirm movement of the selected objects.

Manually creating a device group tree

You can create a device group tree when working with the devices table or network map. Tree creation functions are available in the **Create group tree** or **Select group in tree** window.

Only users with the Administrator role can create a device group tree.

To utilize the functions for creating a device group tree:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. In the **Assets** section on the **Devices** tab or in the **Network map** section, do one of the following:

   - Open the **Create group tree** window by clicking the **Configure groups** link.

   - Open the **Select group in tree** window by adding devices to groups. You can also open this window when filtering the devices table by the **Group** column.

Any changes made to the device group tree in the **Create group tree** or **Select group in tree** window are applied immediately.

To create the device group tree, you can use the following functions:

- Add group

  1. In the **Create group tree** or **Select group in tree** window, add a new group in one of the following ways:

     - If the tree is empty and you want to add the first group, click the **Add** button or press either the **INSERT** or **ENTER** key.

     - If you want to add a group on the same hierarchical level as an existing group, select this group and press **ENTER**.

     - If you want to add a child group to an existing group, select this group and click the **Add** button or press the **INSERT** key.

  2. In the entry field, enter the group name.

     You can use letters, numerals, a space, and the following special characters: `! @ # № $ % ^ & ( ) [ ] { } ' , . - _ /`.

     The group name must meet the following requirements:

     - Must begin and end with any permitted character except a space.

     - Must contain 255 characters or less.

     - Must not match the name of any other group included under the same parent group (not case-sensitive).

  3. Click the ✓ icon on the right of the entry field.

- Rename group

1. In the **Create group tree** or **Select group in tree** window, select the group that you want to rename.
2. Click the **Rename** button or press **F2**.
3. In the entry field, enter the new name of the group.

   You can use letters, numerals, a space, and the following special characters: `! @ # № $ % ^ & ( ) [ ] { } ' , . - _ /`.

   The group name must meet the following requirements:

   - Must begin and end with any permitted character except a space.
   - Must contain 255 characters or less.
   - Must not match the name of any other group included under the same parent group (not case-sensitive).
4. Click the ✓ icon on the right of the entry field.

The new group name will appear in the information about devices that are added to this group or to its child groups.

- Deleting groups

When a group is deleted, the devices that were added to that group are not deleted. Instead, the devices from the deleted group are moved to the same level in the device tree hierarchy where the deleted group had been.

To delete a group from the device group tree:

1. In the **Create group tree** or **Select group in tree** window, select the group that you want to delete.
2. Click the 🗑 icon.

   This opens a window prompting you to select a deletion option.
3. In the prompt window, click one of the following buttons depending on your desired result:

   - If you want to delete only the selected group and leave its child groups, click the **Selected only** button.
   - If you want to delete the selected group together with all of its child groups, click the **With child groups** button.

- Move group

1. In the **Create group tree** or **Select group in tree** window, select the group that you want to move.
2. Use the arrow icons or their corresponding key combinations **ALT+↓**, **ALT+↑**, **ALT+←**, or **ALT+→** to move the group relative to other elements of the tree. If an operation cannot be performed, the icon for the operation is not available.

- Search groups

  You can find relevant groups in the device group tree by using the **Search groups** field in the **Create group tree** or **Select group in tree** window. Groups that meet the search criteria are displayed in the device group tree. For groups that are child groups, their parent groups are also displayed.

- Update the tree

  The composition of groups in the device group tree could be changed on the Server while you are working with the tree (for example, it could be changed by another user who is connected to the Server).

  You can manually update the tree by using the icon in the **Create group tree** or **Select group in tree** window.

Adding and removing labels for devices

You can assign any user-defined labels to devices.

A *device label* contains a text description that helps you quickly find or filter devices in the table. Any convenient text descriptions can be saved as labels. You can assign up to 16 labels for a device. Each device can have its own set of labels.

Lists of device labels are displayed in the devices table in the **Labels** column. Labels in a cell are sorted in alphabetical order.

Only users with the Administrator role can add or remove labels for devices.

Labels can be added or removed in the following ways:

- Adding labels for one device

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the device in the **Assets** section on the **Devices** tab or in the **Network map** section.

   The details area appears in the right part of the web interface window.

3. Click the **Edit** button.

   In the details area, go to the **Settings** tab.

4. In the **Labels** field, enter the text descriptions that you want to use as labels. To separate labels, you can use the **ENTER** key or the `;` character.

   You can use uppercase and lowercase letters, numerals, a space, and the following special characters: `! @ # № $ % ^ & ( ) [ ] { } ' , . - _`.

   A label name must meet the following requirements:

   - Must begin and end with any permitted character except a space.
   - Unique in the list of device labels (not case-sensitive).
   - Contains from 1 to 255 characters.

5. If necessary, use the **Copy labels** link to copy the list of labels. The link is displayed if the list of labels is not empty.

6. Click **Save**.

   This button is unavailable if not all required information is specified in the device settings or if invalid values have been defined. The tab containing settings requiring corrected values is marked by the ⚠ icon.

- Adding labels for multiple devices

You can add labels for multiple devices when working with the devices table.

When working with the network map, you can also add labels for known devices that are represented by nodes on the network map. You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

To add labels for multiple devices when working with the table:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Assets** section.
3. On the **Devices** tab, select the devices for which you want to add labels.
4. Right-click to open the context menu of one of the selected devices.
5. In context menu select **Add labels**.

   The **Add labels** window opens.
6. In the **Labels** field, enter the text descriptions that you want to use as labels. To separate labels, you can use the **ENTER** key or the **;** character.

   You can use uppercase and lowercase letters, numerals, a space, and the following special characters: **!** **@ # № $ % ^ & ( ) [ ] { } ' , . - _**.

   A label name must meet the following requirements:

   - Must begin and end with any permitted character except a space.
   - Unique in the list of device labels (not case-sensitive).
   - Contains from 1 to 255 characters.
7. If necessary, use the **Copy labels** link to copy the list of labels. The link is displayed if the list of labels is not empty.
8. If you want to clear the current lists of labels for selected devices and provide only new labels for these devices, select the **Delete existing** check box.

   If the **Delete existing** check box is cleared, the current list of labels will remain on each device. The new labels will be added to the lists of labels on all selected devices. In this case, the total number of labels for some of the selected devices may exceed the limit (up to 16 labels for each device). The application checks this limit before adding new labels.
9. Click **OK**.

   The button is not available if the names of entered labels do not meet the requirements, or if the list of labels is empty while the **Delete existing** check box is cleared.

To add labels for multiple devices when working with the network map:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. In the **Network map** section, select the relevant nodes of known devices and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.

3. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.

4. Right-click to open the context menu of one of the selected objects.

5. In context menu select **Add labels**.

   The **Add labels** window opens.

6. In the **Labels** field, enter the text descriptions that you want to use as labels. To separate labels, you can use the **ENTER** key or the **;** character.

   You can use uppercase and lowercase letters, numerals, a space, and the following special characters: **!** **@ # № $ % ^ & ( ) [ ] { } ' , . - _**.

   A label name must meet the following requirements:

   - Must begin and end with any permitted character except a space.
   - Unique in the list of device labels (not case-sensitive).
   - Contains from 1 to 255 characters.

7. If necessary, use the **Copy labels** link to copy the list of labels. The link is displayed if the list of labels is not empty.

8. If you want to clear the current lists of labels for selected devices and provide only new labels for these devices, select the **Delete existing** check box.

   If the **Delete existing** check box is cleared, the current list of labels will remain on each device. The new labels will be added to the lists of labels on all selected devices. In this case, the total number of labels for some of the selected devices may exceed the limit (up to 16 labels for each device). The application checks this limit before adding new labels.

9. Click **OK**.

   The button is not available if the names of entered labels do not meet the requirements, or if the list of labels is empty while the **Delete existing** check box is cleared.

- Removing labels from one device

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the device in the **Assets** section on the **Devices** tab or in the **Network map** section.

   The details area appears in the right part of the web interface window.
3. Click the **Edit** button.

   In the details area, go to the **Settings** tab.
4. In the **Labels** field, delete the unnecessary labels:

   - If you want to delete specific labels, use the × icon next to the names of the labels.
   - Click the **Clear** link above the list of labels if you want to remove all labels.
5. Click **Save**.

   This button is unavailable if not all required information is specified in the device settings or if invalid values have been defined. The tab containing settings requiring corrected values is marked by the ⚠ icon.

- Clearing lists of labels for multiple devices

You can clear the lists of labels for multiple devices when working with the devices table.

When working with the network map, you can also clear the lists of labels for known devices that are represented by nodes on the network map. You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

To clear the lists of labels for multiple devices when working with the table:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Assets** section.
3. On the **Devices** tab, select the devices for which you want to clear the lists of labels.
4. Right-click to open the context menu of one of the selected devices.
5. In context menu select **Add labels**.

   The **Add labels** window opens.
6. Select the **Delete existing** check box.
7. Click **OK**.

To clear the lists of labels for multiple devices when working with the network map:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, select the relevant nodes of known devices and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.
3. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.
4. Right-click to open the context menu of one of the selected objects.
5. In context menu select **Add labels**.

   The **Add labels** window opens.
6. Select the **Delete existing** check box.
7. Click **OK**.

Editing device information

Only users with the Administrator role can change device information.

To manually edit device information:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. On the **Devices** tab in the **Assets** section, select the relevant device.

   The details area appears in the right part of the web interface window.

3. Click the **Edit** button.

   The details area will show the following tabs for viewing and editing device information: **Addresses**, **Settings** and **Custom fields**.

4. On the **Addresses** tab in the details area, specify the MAC- and/or IP addresses of the device.

   You can specify multiple IP addresses for the same network interface of the device. To generate a list of IP addresses, perform one of the following actions:

   - If you want to add an IP address, click the **Add IP address** button.
   - If you want to remove an IP address, click the icon located on the right of the field containing the IP address.

5. If the device has multiple network interfaces, generate a list of network interfaces of the device and specify the corresponding MAC- and/or IP addresses for them.

   To generate a list of network interfaces of a device, perform one of the following actions:

   - If you want to add a network interface, click the **Add interface** button located under the group of settings of the last network interface of the device.
   - If you want to delete a network interface, click the **Delete interface** button located on the right of the name of the network interface of the device (if there are two or more network interfaces).
   - If you want to define a different name for a network interface, click the icon located on the right of the current name and enter the new name for the network interface in the field that opens.

6. On the **Settings** tab in the details area, specify the relevant values in the fields that identify the device information.

7. On the **Addresses** and **Settings** tabs in the details area, enable or disable automatic updates for the relevant information about the device. To do so, use the **Autoupdate** toggle buttons located above the fields that have automatic update capability. For the status field, the autoupdate toggle button is named **Automatically change to Archived status** due to the specific features of automatically changing the statuses of devices.

8. On the **Custom fields** tab in the details area, create a list of custom fields and their values if necessary.

9. Click **Save**.

   This button is unavailable if not all required information is specified in the device settings or if invalid values have been defined. The tab containing settings requiring corrected values is marked by the icon.

After saving changes to device information, you can add or edit the Process Control settings for a device.

Adding, editing and deleting custom fields for a device

You can add, edit and delete custom fields containing information about devices. Custom fields are displayed in the details area when a device is selected.

For custom fields, the following limitations apply:

- The number of custom fields for one device shall not exceed 16.
- The number of characters in the field name can be no more than 100.
- The number of characters in the field value can be no more than 1024.

Only users with the Administrator role can add, edit, or delete custom fields.

To add, edit, or delete a custom field:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. On the **Devices** tab in the **Assets** section, select the relevant device.

   The details area appears in the right part of the web interface window.
3. Click the **Edit** button.

   The details area will show the following tabs for viewing and editing device information: **Addresses**, **Settings** and **Custom fields**.
4. Go to the **Custom fields** tab and perform one of the following actions:
   - If you want to add a custom field, click the **Add custom field** button and in the opened fields enter the name and value for the custom field.
   - If you want to edit a custom field, enter the new name and/or value of the relevant custom field.
   - If you want to delete a custom field, click the × icon located on the right of the custom field name.
5. Click **Save**.

Configuring Process Control

Kaspersky Industrial CyberSecurity for Networks can monitor an industrial process by tracking process parameters and system commands transmitted in industrial network traffic. The application tracks this data for devices that are displayed in the devices table and that have defined Process Control settings.

Process Control settings can be configured for the types of devices and protocols that are supported by the application.

For automated control of the industrial process, you can employ Process Control rules and system command monitoring functionality. You can also track process parameters in online mode.

A *Process Control rule* is a group of settings that define a condition for the values of a tag. Process Control rules contain descriptions of situations that must be detected in industrial network traffic (for example, when a tag exceeds the specified value).

When the condition defined in a rule is fulfilled, an event is registered by Kaspersky Industrial CyberSecurity for Networks. You can define the relevant event registration settings (for example, headers of events) when configuring Process Control rules.

Monitoring system commands ensures registration of events when transmitted system commands are detected in traffic. When configuring Process Control settings for devices, you can select the relevant system commands to monitor. This functionality can be used regardless of Process Control rules.

Only users with the Administrator role can configure Process Control settings for devices and generate lists of monitored tags and Process Control rules. However, data can be viewed and exported by users with the Administrator or Operator roles.

You can generate lists of monitored tags and Process Control rules on the Server web interface page in the **Process control** section. You can configure Process Control settings for devices when working with the devices in the **Assets** section and **Network map** section.

Supported devices and protocols

Kaspersky Industrial CyberSecurity for Networks analyzes traffic of the following types of devices used for process automation:

- Programmable Logic Controllers (PLC):
  - ABB™ AC 700F, 800M
  - Allen-Bradley® ControlLogix®, CompactLogix™ series
  - AutomationDirect DirectLOGIC
  - BECKHOFF® CX series
  - Emerson DeltaV MD, MD Plus, MQ
  - Emerson ControlWave series
  - General Electric RX3i
  - Honeywell C300 for Experion PKS / PlantCruise control systems
  - Honeywell ControlEDGE 900 series
  - IPU950
  - Mitsubishi System Q E71
  - OMRON CJ2M

- Schneider Electric Foxboro FCP270, FCP280
- Schneider Electric Modicon: M580, M340, Momentum
- Siemens™ SIMATIC™ S7-200, S7-300, S7-400, S7-1200, S7-1500
- YCU and ELC supporting the YARD protocol
- Yokogawa CENTUM
- Yokogawa ProSafe-RS
- OWEN PLC100 series
- Prosoft-Systems Regul R500
- Devices in Valmet DNA control systems
- Devices that support the Allen-Bradley EtherNet/IP protocol
- Devices supporting the COS protocol
- Devices supporting the FEU protocol
- Devices supporting the CODESYS V2 and V3 protocols
- Devices that support the Siemens S7comm™ and S7comm-plus protocols
- Devices that support PROFINET IO standard protocols

- Intelligent electronic devices (hereinafter referred to as IED):
  - ABB Relion™ series: REF615, RED670, REL670, RET670
  - General Electric Multilin series: B30, C60
  - MiCOM C264
  - Schneider Electric P545
  - Schneider Electric Sepam 80 NPP series
  - Siemens SIPROTEC™ 4: 6MD66, 7SA52, 7SJ64, 7SS52, 7UM62, 7UT63
  - Relematika TOR 300
  - EKRA 200 series, BE2502, BE2704
  - Devices supporting the DNP3 protocol
  - Devices supporting the Schneider Electric UMAS protocol
  - Devices supporting protocols of the IEC 60870 standard: IEC 60870-5-101, IEC 60870-5-104
  - Devices supporting protocols of the IEC 61850 standard: IEC 61850-8-1 (GOOSE, MMS), IEC 61850-9-2 (Sampled Values)

    - Devices supporting the Modbus TCP protocol
- Devices with server software installed:
    - FTP server
    - OPC DA server
    - OPC UA server
    - TASE.2 server
    - Server with encryption support
- Devices categorized as network equipment:
    - Moxa NPort series
    - I/O devices that support the following protocols: BACnet™, FTP, IEC 60870-5-101, IEC 60870-5-104, Modbus TCP, OPC DA, WMI device interaction protocol, and OPC UA Binary.

Kaspersky Industrial CyberSecurity for Networks also has *generic types* of devices for process control: **Generic PLC**, **Generic IED** and **Generic Gateway**. Using these types of devices, you can configure Kaspersky Industrial CyberSecurity for Networks to analyze traffic for those devices that are not on the list of supported types. For generic types of devices, you can specify any combination of application-level protocols from the list of supported protocols on devices related to programmable logic controllers, intelligent electronic devices and network gateways.

For the supported types of devices, Kaspersky Industrial CyberSecurity for Networks analyzes communications over the following application-level protocols:

- ABB SPA-Bus
- Allen-Bradley EtherNet/IP
- BECKHOFF ADS/AMS
- CODESYS V2 and V3 Gateway over TCP and V3 Gateway over UDP
- COS
- DMS for ABB AC 700F devices
- DNP3
- Emerson ControlWave Designer
- Emerson DeltaV, including the protocol for updating embedded software (firmware)
- FTP
- General Electric SRTP
- IEC 60870: IEC 60870-5-101, IEC 60870-5-104
- IEC 61850: GOOSE, MMS (including MMS Reports), Sampled Values

- Mitsubishi MELSEC System Q
- Modbus TCP
- OMRON FINS
- OPC DA, protocol for interaction of devices over WMI technology
- OPC UA Binary
- PROFINET IO and RPC for PROFINET IO
- Schneider Electric UMAS
- Siemens Industrial Ethernet
- Siemens S7comm, S7comm-plus
- TASE.2
- YARD
- Yokogawa Vnet/IP
- Relematika BDUBus
- Modification of the Modbus TCP protocol for devices of Ekra 200 series
- AutomationDirect DirectLOGIC device interaction protocol
- Protocol for interaction of Foxboro FCP270, FCP280 devices
- IPU-FEU device interaction protocol
- MiCOM C264 device interaction protocol
- Valmet DNA device interaction protocol
- Protocol for initial setup of Prosoft-Systems devices
- Protocol for data exchange with Emerson ControlWave series devices
- Protocol of devices with Siemens DIGSI 4 system software
- Protocols for interaction of devices in Honeywell Experion PKS / PlantCruise control systems
- Protocols for initial configuration and interaction of Moxa NPort series devices
- Protocols for detection and interaction of Honeywell ControlEDGE 900 series devices

To analyze traffic and interactions of devices, the application uses specialized modules for processing application-level protocols. The modules included in packages from the Kaspersky Industrial CyberSecurity for Networks distribution kit provide support for the listed types of devices and application-level protocols. You can update protocol processing modules by installing updates. When installing updates to the application, new modules that support additional types of devices and/or application-layer protocols may be added.

Process Control devices

For industrial process control purposes, you can use devices from the devices table that have Process Control settings defined.

Kaspersky Industrial CyberSecurity for Networks supports the use of various types of devices and application-layer protocols for Process Control.

You can view and edit Process Control settings in the details area of the device selected in the **Assets** section or in the **Network map** section of the Kaspersky Industrial CyberSecurity for Networks web interface.

Process Control settings for devices

Process Control settings for devices are displayed in the details area when a device is selected in the devices table or on the network map. If Process Control settings are defined for a device, the details area contains a separate block containing the following settings:

- **Device type** – type of device from the list of device types supported for Process Control.
- **Protocol** – name of the utilized protocol. The following information is displayed for each protocol:
  - **System commands** – main settings for tracking system commands for a protocol. This field shows the total number of system commands for the protocol and the number of monitored system commands that will cause the application to register events if detected.
  - **Address** – depending on the selected protocol, this field contains the IP address and port, MAC address or domain ID (for the IEC 61850: GOOSE protocol).
  - Additional settings depending on the selected protocol. Additional settings are displayed if the application lets you configure more than system commands and address information for this protocol.

    Examples:
    When the Modbus TCP protocol is selected, the additional setting **Reverse order of registers** is also displayed. This setting lets you enable or disable support for an inverted sequence of registers (machine words) in 32-bit data values.

    When the IEC 60870-5-101 protocol is selected, the following additional parameters are displayed:

    - **Two-byte ASDU address** – lets you enable or disable two-byte addressing mode for application service data units (ASDU). If this mode is disabled, one-byte addressing is used.
    - **Originator** – lets you enable or disable the use of an additional byte for the originator's address in the data block ID.
    - **Channel address block (bytes)** – number of bytes in a data link layer address block.
    - **Object address block (bytes)** – number of bytes in an information object address block.

You can add Process Control settings for devices in the following ways:

- Automatically
- Manually
- Import from external projects

About automatic detection of Process Control settings for devices

Kaspersky Industrial CyberSecurity for Networks can automatically identify the Process Control settings for devices and save these settings in the device information. Settings are identified by analyzing traffic to detect the protocol commands for devices involved in the industrial process.

The application automatically adds or edits Process Control settings for devices that have been added to the devices table. Devices can also be automatically added to the devices table if the Device Activity Detection method is enabled for Asset Management.

Automatically added Process Control settings are considered to be *system* settings. The application can change these settings if protocol commands with updated parameter information are detected in traffic.

Process Control settings that are manually added by a user are considered to be *custom settings*. The application does not change custom Process Control settings. If a user manually changes system settings for Process Control, these settings will also become custom settings.

Process Control settings for devices are automatically detected when the application is running in a mode known as Device Discovery for Process Control. You can enable and disable this mode.

To automatically detect Process Control settings, the application employs modules for processing application-layer protocols. The application is installed with built-in modules that can determine the main settings for a number of devices and protocols that are indicated on the list of types of devices and protocols supported by the application. You can update protocol processing modules by installing updates.

Enabling and disabling automatic detection of Process Control settings for devices

When automatic detection of Process Control settings for devices is enabled, the application can add and edit settings only for devices that have been added to the devices table. If you want devices to be automatically added to the devices table when their settings are detected, you need to enable device activity detection.

Only users with the Administrator role can enable or disable automatic detection of Process Control settings for devices.

To enable or disable automatic detection of Process Control settings for devices:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Technologies**.
3. Use the **Device Discovery for Process Control** toggle to enable or disable automatic detection of Process Control settings.
4. After you enable or disable this detection mode, wait for the toggle switch to change to the necessary position (*Enabled* or *Disabled*).

   This process takes some time. The toggle switch will be unavailable during this time.

Manually adding Process Control settings for a device

You can manually add Process Control settings for a device when working with the devices table or network map. Process Control settings that were added for a device are considered to be custom settings. Custom settings are not changed when Process Control settings are automatically detected for devices.

Only users with the Administrator role can add Process Control settings.

To add Process Control settings for a device:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the relevant asset in the **Assets** section on the **Devices** tab or in the **Network map** section.

   The details area appears in the right part of the web interface window.
3. Click the **Edit** button.

   The details area will show the following tabs for viewing and editing device information: **Addresses**, **Settings** and **Custom fields**.
4. On the **Addresses** tab in the details area, click the **Add process control settings** button (the button is displayed if Process Control settings have not been defined).

   The **Add Process Control settings** window appears.
5. Configure the Process Control settings:

   a. Select the device type.

   b. Select the protocol used for interaction with the device within the industrial process.

   c. If necessary, edit the settings for monitoring system commands over the selected protocol. By default, the application monitors all system commands except those that are frequently encountered during normal operation of the device.

   d. If you need to configure other settings for the selected protocol (such as address information for interaction with the device), specify the relevant values in the fields that appear.

   e. If you want to additionally specify a different protocol (that is supported for the selected device type) or a different combination of parameters for a previously selected protocol (when using multiple connected modules within one device), add the parameters for this protocol by clicking the **Add protocol** link.
6. Click **Save**.

   This button is unavailable if not all required values are specified or if there are invalid values in the settings.

A separate block containing the defined settings appears in the details area in the lower part of the **Addresses** tab.

Editing Process Control settings for a device

If Process Control settings were added for a device, you can manually edit these settings when working with the devices table or network map. After saving the changes, Process Control settings for a device are considered to be custom settings. Custom settings are not changed when Process Control settings are automatically detected for devices.

Only users with the Administrator role can edit Process Control settings.

To edit Process Control settings for a device:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the relevant asset in the **Assets** section on the **Devices** tab or in the **Network map** section.

   The details area appears in the right part of the web interface window.
3. Click the **Edit** button.

   The details area will show the following tabs for viewing and editing device information: **Addresses**, **Settings** and **Custom fields**.
4. On the **Addresses** tab in the details area, click the icon in the block containing the defined Process Control settings (this block is displayed if Process Control settings have been defined).

   The **Edit Process Control settings** window appears.
5. Configure the Process Control settings. You can edit individual settings (for example, edit the settings for tracking system commands for a specific protocol) or reconfigure all settings in the same order as you would when adding Process Control settings.

   When you edit settings that were used in previously created tags, the application automatically deletes these tags and their associated Process Control rules. For example, if you delete a protocol, after saving the settings the application will delete all tags containing the device and deleted protocol (the Process Control rules associated with these tags will also be deleted).
6. Click **Save**.

   This button is unavailable if not all required values are specified or if there are invalid values in the settings.

Information in the block containing the defined settings is updated in the lower part of the **Addresses** tab in the details area.

Selecting the monitored system commands

You can configure traffic monitoring of system commands that are transmitted and received by process control devices. In Kaspersky Industrial CyberSecurity for Networks, system commands include device management commands (for example, START PLC) as well as system messages related to the operation of devices or containing packet analysis results (for example, REQUEST NOT FOUND).

When a monitored system command is detected, Kaspersky Industrial CyberSecurity for Networks registers an event for Command Control technology. The event is registered using the system event type that is assigned the code 4000002602. You can configure the settings for this type of event.

Only users with the Administrator role can configure monitoring of system commands for devices.

To configure monitoring of system commands for a device:

1. In the **Assets** section on the **Devices** tab or in the **Network map** section, select the relevant device with defined Process Control settings.

   If Process Control settings are not defined for a device, add the settings.

2. On the **Addresses** tab in the details area, click the icon in the block containing the defined Process Control settings.

   The **Edit Process Control settings** window appears.

3. Specify the relevant system commands for the first protocol. To do so, expand the **System commands** list under the **Protocol** field and select the check boxes of the system commands that you want to monitor. After selecting system commands, click **OK**.

4. If a different protocol is additionally indicated in the Process Control settings, or if it is the same protocol but with different address information, select the system commands that will be monitored during communications over this protocol. To do so, use the **System commands** drop-down list under the field containing the name of this protocol. Likewise, configure monitoring of system commands for all other specified protocols of the device.

5. Click **Save**.

   This button is unavailable if not all required values are specified or if there are invalid values in the settings.

Information in the block containing the defined settings is updated in the lower part of the **Addresses** tab in the details area.

Clearing Process Control settings defined for a device

You can clear Process Control settings defined for a device when working with the devices table or the network map.

When clearing Process Control settings defined for a device, the application automatically deletes all tags that were created for this device. In addition to the tags, all of their associated Process Control rules are also deleted.

Only users with the Administrator role can clear Process Control settings for a device.

To clear Process Control settings for a device:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the relevant asset in the **Assets** section on the **Devices** tab or in the **Network map** section.

   The details area appears in the right part of the web interface window.

3. Click the **Edit** button.

   The details area will show the following tabs for viewing and editing device information: **Addresses**, **Settings** and **Custom fields**.

4. On the **Addresses** tab in the details area, click the icon in the block containing the defined Process Control settings (this block is displayed if Process Control settings have been defined).

   A window with a confirmation prompt opens.

5. In the prompt window, confirm deletion of the settings.

The **Add Process Control settings** button appears in the lower part of the **Addresses** tab.

Importing configurations of devices and tags from external projects

Configurations of Process Control settings for devices and tags can be imported into Kaspersky Industrial CyberSecurity for Networks from external project files. In the context of Kaspersky Industrial CyberSecurity for Networks, *external projects* are projects that contain data on devices and tags saved by other systems (such as a SCADA system).

To import files of external projects, the files must be packed into a ZIP archive (except for files of certain projects whose contents consist of a ZIP archive).

Configurations of devices and tags can be imported from data files comprising the following types of projects:

- Universal-format project.

  This type of project can be obtained from any source by converting and saving its data in text files with delimiters in CSV format. For information about files in a universal project, please refer to the Appendices.

- AC 800M configuration file for OPC server.

  This type of project can be obtained via ABB AC 800M device management software.

- Control Builder M project.

  This type of project can be obtained via ABB Control Builder M software.

- COS device configuration archive.

  This type of project can be obtained via device management software for devices supporting the COS protocol.

  > Configuration files of devices do not contain the network IP addresses that are used by these devices. After adding devices from configuration files, you will need to verify the information about devices in the application and manually define the correct IP addresses for these devices if necessary.

- DeltaV project.

  This type of project can be obtained via Emerson DeltaV device management software.

- DirectSOFT6 project.

  This type of project can be obtained via DirectLOGIC device management software.

- ABB Freelance 2016 Engineering tag list.

  This type of project can be obtained via ABB Freelance 2016 Engineering software.

- Project for IEC 61850 devices.

  This type of project can be obtained via device management software for devices supporting IEC 61850 standard protocols.

- RSLogix 5000® project (provided as a CSV- or ACD file).

  This type of project can be obtained via RSLogix 5000 device management software.

When importing a CSV file containing an RSLogix 5000 project, the application ignores structural and custom types of tags in this project. If you want to add these tags to the application, you can import an ACD file containing the RSLogix 5000 project or enable Unknown Tag Detection to add tags from traffic.

- SICAM PAS V7 description file.

  This type of project can be obtained via Siemens SICAM PAS version 7 software.

- TIA Portal V12/V13 project.

  This type of project can be obtained via Siemens TIA Portal version 12 or 13 software.

- Schneider Electric Unity project.

  This type of project can be obtained via Schneider Electric Modicon device management software. A project can be provided as ZEF- or XEF files (if a project is provided as a ZEF file, this file does not need to be packed into a ZIP archive for import).

  When a Schneider Electric Unity project is imported, the added devices are assigned the names of the files from which they were imported. You can manually define names for these devices when editing device information.

- WinCC® project (including WinCC OA).

  This type of project can be obtained via Siemens SIMATIC WinCC or WinCC OA software.

- YARD configuration file.

  This type of project can be obtained via device management software for devices supporting the YARD protocol.

- CIMPLICITY export CSV file.

  This type of project can be obtained via CIMPLICITY software.

- Valmet DNA configuration file.

  This type of project can be obtained via Valmet DNA software.

You can update and expand the supported types of projects by installing updates.

To import configurations of devices and tags from an external project:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Assets** section.
3. Click the **Import** link in the toolbar on the **Devices** tab to open the menu for selecting the type of project to be imported.
4. In the opened window, select the option with the relevant project type.

   The **Importing <project type>** window will appear on the screen.
5. In the **Project name** field, enter the local path to the project. You can use the **Browse** button to specify the local path.

6. Select the relevant option for your existing configurations of devices and tags. To do so, click one of the following buttons:

   - **Add** means that the imported configurations of devices and tags will be added to the existing configurations of devices and tags.

   - **Replace** means that the existing configurations of devices and tags, associated with those devices for which new configurations and tags are imported, are deleted (tags with custom process control rules are not deleted).

7. Confirm the import by clicking **Continue**.

   The data import process starts. Information about the running import operation is displayed in the list of background operations. When the process completes, the imported configurations of devices and tags will be available for upload in the devices table and tags table.

8. If you want to view a report on the results of the import:

   a. Click the button in the menu of the application web interface.

      The list of background operations appears.

   b. Please wait while the import operation completes.

   c. Click the **Show report** button.

Tags

A *tag* is a process parameter transmitted in the industrial network (for example, a controlled temperature). The values of tags are transmitted and received by devices over specific protocols.

You can add tags to the application in the following ways:

- Manually
- Automatically when unknown tags are detected
- Importing from external projects

A tag can be added under the following conditions:

- The devices table contains a device associated with the tag being added.
- A device has defined Process Control settings in which the protocol of the added tag is indicated.

After adding a tag to the application, this tag can be used in Process Control rules. In accordance with the conditions defined in Process Control rules, the application will register the corresponding events in which the received tag values may be saved.

You do not need to add this tag to Process Control rules to control tag values when monitoring process parameters.

You can view and edit tags on the **Tags** tab in the **Process Control** section of the Kaspersky Industrial CyberSecurity for Networks web interface.

About Unknown Tag Detection

Kaspersky Industrial CyberSecurity for Networks can analyze traffic to detect and save information about unknown tags. Unknown tags are tags that are absent from the tags table.

The application adds a detected tag to the tags table if the conditions for adding a tag are fulfilled. If one of the conditions is not fulfilled, the detected tag is ignored (for example, if the tag has no associated protocol specified for the device in the Process Control settings).

Information about unknown tags is obtained from traffic when the application is operating in Unknown Tag Detection mode. You can enable and disable this mode.

When the application is operating in Unknown Tag Detection mode, the performance of application-layer protocol processing modules may be slightly reduced. For this reason, Unknown Tag Detection is disabled by default after the application is installed. It is recommended to enable Unknown Tag Detection mode for a sufficient amount of time to detect all tags that may be associated with devices that have defined Process Control rules. It is recommended to disable this mode after you have added detected tags to the table.

Unknown Tag Detection is supported for the following protocols:

- Allen-Bradley EtherNet/IP
- BACnet
- CODESYS V3 Gateway
- DMS for ABB AC 700F devices
- DNP3
- Emerson DeltaV
- IEC 60870: IEC 60870-5-101, IEC 60870-5-104
- OPC DA
- OPC UA Binary
- Schneider Electric UMAS
- TASE.2
- Yokogawa Vnet/IP
- Protocol for interaction of Foxboro FCP270, FCP280 devices
- Protocol for data exchange with Emerson ControlWave series devices

Enabling and disabling Unknown Tag Detection

Unknown Tag Detection is disabled by default after the application is installed. It is recommended to enable Unknown Tag Detection after first preparing the application. For preliminary preparation of the application, you need to add Process Control settings for all devices whose tags you want to detect in traffic.

Only users with the Administrator role can enable and disable Unknown Tag Detection.

To enable or disable Unknown Tag Detection:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Technologies**.
3. Use the **Unknown Tag Detection** toggle switch to enable or disable Unknown Tag Detection.
4. After you enable or disable this detection mode, wait for the toggle switch to change to the necessary position (*Enabled* or *Disabled*).

   This process takes some time. The toggle switch will be unavailable during this time.

Selecting tags in the table

In the tags table, you can select tags to view their information and to manage these tags. When tags are selected, the details area appears in the right part of the web interface window.

To select the relevant tags in the table, perform one of the following actions:

- If you want to select one tag, select the check box next to the tag or use your mouse to select the tag.
- If you want to select multiple tags, select the check boxes next to the relevant tags or select them while holding down the **CTRL** or **SHIFT** key.
- If you want to select all tags that satisfy the current filter and search settings, perform one of the following actions:
  - Select any tag in the table and press the key combination **CTRL+A**.
  - Select the check box in the title of the left-most column of the table.

When multiple tags are selected, the details area shows the total number of selected tags. If you selected all tags that satisfy the current filter and search settings, one of the following values appears in the details area:

- The precise number is displayed if you selected 1000 tags or less. In this case, the application checks whether the tags are on the favorites list just like when using other methods for selecting multiple tags.
- If more than 1000 tags are selected, the number **1000+** is displayed. In this case, the application does not check whether the tags are on the favorites list.

The title of the left-most column of the table shows the tag selection check box. Depending on the number of selected tags, the check box can have one of the following states:

- ☐ – all tags that satisfy the current filter and search settings were not selected in the table. However, one tag or multiple tags may be selected in the table by using the check boxes next to the tags or by using the **CTRL** or **SHIFT** key.

- ☑ – all tags that satisfy the current filter and search settings were selected in the table.
- ▣ – all tags that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of the tags were cleared. This state is also retained if the check boxes were cleared for all tags selected in this way (because the number of selected tags may change).

If all tags that satisfy the filter and search settings are selected, the number of selected tags may be automatically changed. For example, the specific set of tags in the table may be changed by an application user in a different connection session or when detected tags are automatically added. It is recommended to configure the filter and search settings in such a way that ensures that only the relevant tags end up in the selection (for example, you can filter tags by their IDs before selecting all tags).

Manually adding a tag

Only users with the Administrator role can manually add tags.

To manually add a new tag:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Process Control** section.
3. On the **Tags** tab, open the details area by clicking the **Add tag** link.
4. Click the **Select device** link to open the device selection window.
5. In the device selection window, select the device for which you want to create a tag and click **OK**.

   The device selection window contains a table in which you can configure the layout and order of columns, and filter, search, and sort similarly to the devices table in the **Assets** section.
6. Select the protocol that is indicated in the Process Control settings for the selected device. You must select a protocol that supports the transmission of tags.

   If the necessary protocol is not available, you can configure the Process Control settings and specify the necessary protocol. To open the settings window, use the button on the right of the protocol selection field. Process Control settings are configured the same as when adding or editing settings while working with the devices table.
7. Change the tag name if necessary. The default name according to the template is **Tag <value of the device tag counter>**.

   You can use letters of the English alphabet, numerals, and the following special characters: `( ) . , : ; ? ! * + % - < > @ [ ] { } / \ _ $ #`. The tag name must begin and end with any permitted character except a space.
8. Configure other tag parameters.

   The mandatory parameters (such as the tag name and data type) must be specified for a tag. Depending on the selected protocol and data type, additional parameters (such as the unit of measure and scaling limits) may be available for configuration.
9. Click **Save**.

   This button is unavailable if not all required values are specified or if there are invalid values in the settings.

The new tag appears in the tags table.

Editing tag parameters

Only users with the Administrator role can edit tag parameters.

To edit tag settings:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Process Control** section.
3. On the **Tags** tab, select the relevant tag.

   The details area appears in the right part of the web interface window.
4. Click the **Edit** button.
5. Change the tag name if necessary.

   You can use letters of the English alphabet, numerals, and the following special characters: `( ) . , : ; ? ! * + % - < > @ [ ] { } / \ _ $ #`. The tag name must begin and end with any permitted character except a space.
6. Configure other tag parameters.

   The mandatory parameters (such as the tag name and data type) must be specified for a tag. Depending on the selected protocol and data type, additional parameters (such as the unit of measure and scaling limits) may be available for configuration.
7. Click **Save**.

   This button is unavailable if not all required values are specified or if there are invalid values in the settings.

Adding tags to the favorites list

If you want to create a list of the most important tags and quickly navigate to this list (for example, to view the current values of these tags), you can add tags to the favorites list. Tags can be added to the favorites list and deleted from it at your own discretion. The number of tags on the favorites list is unlimited.

To display the list of favorite tags, you can filter by the **Favorites** column when viewing the tags table.

A created tag is not add to the favorites list by default.

To add a tag to the favorites list or to delete it from the list:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Process Control** section.
3. On the **Tags** tab, select the tag that you want to either add to the favorites list or delete from the list.

   The details area appears in the right part of the web interface window.

4. Click the **Edit** button.
5. Set the **Favorites** toggle button to the necessary position.
6. Click **Save**.

Depending on the selected state of the toggle button, the tags table shows either **Yes** or **No** in the **Favorites** column for the specific tag.

To add multiple tags to the favorites list or to delete multiple tags from the list:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Process Control** section.
3. On the **Tags** tab, select the tags that you want to either add to the favorites list or delete from the list.

   The details area appears in the right part of the web interface window.
4. Use the **Add tags to favorites list** or **Remove tags from favorites list** button depending on whether you want to add tags to the favorites list or delete them from the list. The buttons that are displayed depend on whether their corresponding operations are relevant for one or more of the selected tags.

   If all tags that satisfy the current filter and search settings are selected, and the number of selected tags is more than 1000, the application does not check whether the tags are on the favorites list. If this is the case, the details area displays both buttons for adding and deleting tags.

Depending on which button was clicked, the tags table shows either **Yes** or **No** in the **Favorites** column for all selected tags.

Deleting tags

Only users with the Administrator role can delete tags.

To delete tags:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Process Control** section.
3. On the **Tags** tab, select the tags that you want to delete.

   The details area appears in the right part of the web interface window.
4. Click the **Remove** button.

   A window with a confirmation prompt opens.
5. In the prompt window, confirm deletion of the tags.

Viewing Process Control rules associated with tags

When working with the tags table, you can view information about the Process Control rules associated with the selected tags. The following options are available for viewing information:

- View the main information about associated rules in the details window of the selected tag. The main information is displayed for the first five rules associated with the selected tag.
- View detailed information about associated rules in the Process Control rules table. The rules table automatically applies a filter based on the IDs of selected tags. Information about rules in the rules table can be loaded if no more than 200 tags are selected.

To view the main information about Process Control rules associated with a tag:

1. Select the **Process Control** section.
2. On the **Tags** tab, select the tag for which you want to view the main information about Process Control rules.

   The details area appears in the right part of the web interface window. The main information about linked Process Control rules is displayed in the **Linked Process Control rules** section (this section is absent if no rule is linked to the tag).

The blocks containing the main information show the names of rules and their current states. If necessary, you can use the **Show details** button to view detailed information about a rule. Detailed information about a rule will be displayed in the details area on the **Rules** tab of the **Process Control** section.

Users with the Administrator role can also change the states of rules and delete rules by using the corresponding interface elements in the blocks containing the main information about rules.

To view detailed information about Process Control rules associated with tags:

1. Select the **Process Control** section.
2. On the **Tags** tab, select the tags for which you want to view information about Process Control rules.

   The details area appears in the right part of the web interface window.
3. Depending on the number of selected tags, click one of the following buttons:

   - **Show rules (<number of rules>) in table** – displayed for one selected tag in the lower part of the **Linked Process Control rules** section.
   - **Show Process Control rules** – displayed for multiple selected tags in the lower part of the details area. This button is not available if the number of selected tags exceeds 200.

   The **Rules** tab of the **Process Control** section opens. The rules table will be filtered based on the IDs of selected tags.

Process Control rules

The application can employ the following Process Control rules to monitor the values of tags:

- Rules with defined conditions. These rules contain conditions for tracking the values of tags. Each rule can contain one of the provided types of conditions. If a condition defined in a rule is fulfilled, the application registers an event. The settings of a registered event are also defined in the rule.

- Rules with Lua scripts. These rules contain descriptions of algorithms used for checking the values of tags. The algorithms are compiled in the Lua programming language using functions and variables for Lua scripts. When an algorithm in a rule containing a Lua script is triggered, the application registers an event (the settings of a registered event are defined in the rule). If you are using Lua scripts for Process Control rules, you can use a *global Lua script* in which the global Lua variables and functions are initialized. You can use these global variables and functions in a Lua script of any rule. By default, the global Lua script is empty and does not contain executable code. The application can have only one global Lua script at one time.

Process Control rules can be enabled or disabled. Enabled rules are applied during traffic analysis. Disabled rules are not applied and are not taken into account.

The application can automatically create Process Control rules with defined conditions when Process Control is running in learning mode.

You can view and edit Process Control rules on the **Rules** tab in the **Process Control** section of the Kaspersky Industrial CyberSecurity for Networks web interface.

Rules with defined conditions for tag values

To monitor the values of tags, you can employ Process Control rules in which conditions are defined for the values of tags. Each rule can contain one of the provided types of conditions. A rule can be bound to only one tag. However, you can create up to 20 rules with different types of conditions for one tag.

Rules with defined conditions can be created automatically by the application when Process Control is running in learning mode. You can also manually create and edit rules with defined conditions for the values of tags.

For a Process Control rule, you can select one of the following types of conditions:

- **Value changed** – the value of the controlled tag was either completely changed or was changed in a specific bit.

  If a particular bit of a value is not being specifically monitored, you can use this condition to monitor the value of any type of tag. You can also specify the number of saved (allowed) values of a tag whose detection will not result in the registration of an event. For a rule, you can specify a number of saved values from 1 to 10 (the saved values will be updated as new values are detected). By default, only the latest value is saved.

  If a particular bit of a value is being specifically monitored, you can use this condition to monitor only int and unsigned int tags. For monitoring purposes, you need to specify the sequence number of the monitored bit in the tag (integer within the range corresponding to the data type of the selected tag: from 1 to 8, 16, 32 or 64).

- **Tag missing** – the controlled tag was not detected in monitored traffic during the defined time period.

  You can use this condition to monitor any type of tag.

- **Detection** – the controlled tag was detected in the traffic being monitored.

  You can use this condition to monitor any type of tag.

- **In range** – the value of the controlled tag is inside the specified range.

  You can use this condition to monitor only int and float tags.

  You can define values for the lower and/or upper limit of the range. The defined values for limits can be included in the range or excluded from it.

- **Out of range** – the value of the controlled tag is outside of the specified range.

  You can use this condition to monitor only int and float tags.

  You can define values for the lower and/or upper limit of the range. The defined values for limits can be included in the range or excluded from it.

- **Equals** – the value of the controlled tag is equal to one of the defined values, either completely or in a specific bit.

  If a particular bit of a value is not being specifically monitored, you can use this condition to monitor the value of int, bool and string tags. You can define from 1 to 10 values for comparison.

  If a particular bit of a value is being specifically monitored, you can use this condition to monitor only int and unsigned int tags. For monitoring purposes, you need to specify the sequence number of the monitored bit in the tag (integer within the range corresponding to the data type of the selected tag: from 1 to 8, 16, 32 or 64) and the value of the bit for comparison (indicated as one of two integers: zero or one).

- **Does not equal** – the value of the controlled tag is not equal to one of the defined values, neither completely nor in a specific bit.

  If a particular bit of a value is not being specifically monitored, you can use this condition to monitor the value of int, bool and string tags. You can define from 1 to 10 values for comparison.

  If a particular bit of a value is being specifically monitored, you can use this condition to monitor only int and unsigned int tags. For monitoring purposes, you need to specify the sequence number of the monitored bit in the tag (integer within the range corresponding to the data type of the selected tag: from 1 to 8, 16, 32 or 64) and the value of the bit for comparison (indicated as one of two integers: zero or one).

- **Monotonic change violation** – the value of a controlled tag violates the sequence of monotonic increase or reduction of values.

  You can use this condition to monitor only int and float tags.

For rules that monitor the values of tags, you need to take into account how the application processes values represented by denormalized numbers (low-order numbers approaching zero – for example, 2.22507e-308 if this value is represented with double precision). The application converts denormalized numbers into zero values.

For any condition, you can select the operations for which the application will monitor the values of a tag. The following monitoring options are available depending on operations performed with the tag:

- **Monitor when reading tag** – the value is checked when reading a tag from a device.
- **Monitor when writing tag** – the value is checked when writing a tag to a device.

Rules with Lua scripts

Scripts written in the Lua programming language can be used to describe the algorithms for checking the values of tags in Process Control rules. Lua scripts provide the capabilities to not only check the values of tags but also to add various information to registered events and process logs.

A Lua script must consist of one or more functions. The names of the functions must be unique among all rules with Lua scripts. A function that is used to track the values of tags is called a *trigger function*. A trigger function must return a value of `true` to register an event.

If a variable is indicated in a script, the variable must be initialized either in that specific script (to be applied only in that script) or in a separate global script (to be applied in all rules with Lua scripts). A global script can also contain auxiliary functions that can be used in rules with Lua scripts.

A trigger function is called whenever the value of any tag used in the function is changed. The function is first called when all values of tags used in the function are received.

To obtain the values of a tag, the code of a function contains an entry that looks as follows:

```
tag'main_tag_parameters[:field_name][@modifier]'[.transmission_direction]
```

where:

- `main_tag_parameters` are the mandatory parameters that identify the tag in the application. Parameters are separated by a colon. The main parameters consist of the following parameters from the tags table:
  - **Device**
  - **Tag name**
  - **Tag ID**
- `field_name` is the name of the field within the tag field structure represented by the **Structural values** parameter in the tags table. If a field is embedded into other fields, its name is indicated together with the names of all parent fields separated by a colon. If the `field_name` parameter is not specified, the main value within the tag field structure is checked.
- `modifier` defines how the obtained value is presented. The following modifiers are available:
  - `str` means that the obtained value is converted into a string value.
  - `type` means that the name of the data type from the obtained value is passed as the value.
  - `loc` means that the passed value is the assigned localized name for the obtained value (if there is no localized named, the obtained value is converted into a string value).

  If a modifier is not specified, the actual obtained value is used. In this case, the data type of the value is not changed.
- `transmission_direction` defines the direction in which the obtained value is transmitted. The transmission direction can be defined by one of the following parameters:
  - `R` means that the value was received when it was read from a device.
  - `W` means that the value was received when it was written to a device.
  - `RW` refers to any direction of the obtained value.

  If the transmission direction is not defined, the value obtained from any direction is used.

Records for obtaining the values of tags can be used in expressions (for example, assigning values to variables or comparing values).

To perform various operations with a Lua script, you can use *auxiliary functions* supported by the Server. The names of auxiliary functions begin with an underscore (_).

The main auxiliary functions for adding information via Lua scripts are as follows:

- Function for adding parameters to use as additional variables in events:

  `_AddEventParam('parameter_name', parameter_value)`

  Any name and value can be defined for a parameter. To use a parameter and its value in events, this parameter must be specified in event type parameters as follows: `$extra.<parameter_name>`.

- Functions for adding entries to the process log in which the Lua script is executed (this is normally a process whose name starts with the word `Filter`). A record defined by an argument of the function (variable or constant) is added to the log:

  - To create a record with the *Errors* level:

    `_WriteErrorLog(function_argument)`

  - To create a record with the *Warning* level:

    `_WriteWarningLog(function_argument)`

  - To create a record with the *Info* level:

    `_WriteInfoLog(function_argument)`

  - To create a record with the *Debug* level:

    `_WriteDebugLog(function_argument)`

  - To create a record with the *Debug* level that may contain multiple arguments of the function:

    `print(function_argument1, function_argument2,…)`

    Variables or constants defined by function arguments are separated by a tab character in a log record.

  Records are not created in the log if the level of the record is lower than the logging level set for the process.

Process Control rules learning mode

In Process Control rules learning mode, the application automatically generates Process Control rules with conditions for the values of tags. To generate rules, the application analyzes traffic to monitor the values of only those tags that have been added to the tags table.

Process Control rules that were automatically added in learning mode are called *system* rules. For these rules, the **Origin** parameter contains the **System** value.

Rules that were manually created are called *User* rules. For these rules, the **Origin** parameter contains the **User** value. If a system rule is manually changed, this rule also becomes a user rule.

Rules that are added in learning mode are in the *Disabled* state by default. If a system rule is updated in learning mode, it remains in the same state it was in before the update.

When adding or updating Process Control rules in learning mode, the application defines one of the following conditions for each of them:

- **Does not equal**.

  This condition is defined when a rule is added (if no other system rule is found for the detected tag value) or when ten or less different tag values are received (except for tags with the bool or float data type).

- **Out of range**.

  This condition replaces the previous condition in a rule if a new value for a tag with the float data type is received or if more than ten different values for a tag with the int data type are received.

- **Monotonic change violation**.

  This condition replaces the previous condition in a rule if the detected tag values have only increased or only decreased, without any other variation. This condition replaces the previous condition in rules for tags with the int or float data type when learning mode ends.

In learning mode, the application also deletes system Process Control rules in the following cases:

- The rule was created for a tag with the bool data type, and the detected and saved values do not match (comparisons are conducted only for the first ten detected values, and all other values are ignored).

- The rule was created for a tag with the string data type, and more than ten different values are received.

Process Control rules learning mode must be enabled for a sufficient amount of time to detect all possible values of relevant tags. This amount of time depends on how frequently tags are circulated in traffic, how often devices are running in the industrial network, and other specifics of the industrial process. We recommend that you enable learning mode for at least one hour. In large industrial networks, learning mode can be enabled for a period ranging from one to several days to accumulate the maximum amount of data.

Enabling and disabling rule-based Process Control

Only users with the Administrator role can enable and disable rule-based Process Control.

To enable or disable rule-based Process Control:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Technologies**.

3. Use the **Rule-based Process Control** toggle switch to enable or disable rule-based Process Control.

4. After a method is enabled or disabled, wait for the toggle switch to change to the necessary position (*Enabled* or *Disabled*).

   This process takes some time. The toggle switch will be unavailable during this time.

5. Select the necessary operating mode for rule-based Process Control. To do so, in the drop-down list on the right of the method name, select one of the following values:

   - **Learning** – to apply the method in learning mode.

   - **Monitoring** – to apply the method in monitoring mode.

6. After the mode is selected, wait for the name of this mode to appear in the field of the drop-down list.

   This process may take some time, during which the drop-down list displays the *Changing* status. Wait for the selected mode to be enabled.

Viewing the table of Process Control rules

The Process Control rules table is displayed on the **Rules** tab in the **Process Control** section of the application web interface. The table provides the general settings of rules and of the tags and devices associated with the rules.

When viewing the rules table, you can use the following functions:

- Configure the display and order of columns in the rules table

1. On the **Rules** tab, in the **Process Control** section, click the **Customize table** link to open the window for configuring how the table is displayed.
2. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.

   The following settings are available for selection:

   - **Rule ID** – unique ID of the rule.
   - **Device group** – name of the group containing the device associated with the tag (contains the name of the group and the names of all its parent groups in the device group tree).
   - **Device** – name of the device associated with the tag.
   - **Protocol** – name of the protocol used to transmit the tag.
   - **Tag name** – defined name of the tag for which the rule was created.
   - **Rule** – defined name of the rule.
   - **State** – current state of the rule (*Enabled* or *Disabled*).
   - **Rule description** – defined description of the rule.
   - **Condition type** – name of the selected type of condition for the rule.
   - **Created** – date and time when the rule was created.
   - **Changed** – date and time of the most recent change in the rule.
   - **Event title** – header of the event that was registered when the rule was triggered.
   - **Event severity** – severity of the event that was registered when the rule was triggered.
   - **Event description** – description of the event that was registered when the rule was triggered.
   - **Origin** – information about the source of the rule.
3. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

The selected columns will be displayed in the tags table in the order you specified.

- Filtering based on table columns

*To filter rules by the **Rule ID**, **Device**, **Tag name** or **Rule** column:*

1. On the **Rules** tab in the **Process Control** section, click the filtering icon in the relevant column of the table.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values for rules that you want to include in the filter and/or exclude from the filter.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the selected column click the **Add condition** button and enter the condition in the opened field.

4. If you want to delete one of the created filter conditions, in the filter window of the selected column click the icon.

5. Click **OK**.

*To filter rules by the **Device group** column:*

1. On the **Rules** tab in the **Process Control** section, click the filtering icon in the **Device group** column.

   The filtering window opens.

2. Click the icon in the right part of the field for indicating the device group.

   The **Select group in tree** window appears.

3. In the device group tree, select the relevant group and click the **Select** button.

   The path to the selected group will appear in the field in the filter window.

4. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window click the **Add condition (OR)** button and specify a different group in the opened field.

5. If you want to delete one of the created filter conditions, in the filter window click the icon.

6. Click **OK**.

*To filter rules by the **Protocol** column:*

1. On the **Rules** tab in the **Process Control** section, click the filtering icon in the **Protocol** column.

   The filtering window opens.

2. In the **Protocols** field, choose the relevant protocol from the supported application-layer protocols. To do so, start entering the name of the protocol and select the relevant protocol from the drop-down list (the list of suitable protocols is automatically expanded when the value in the **Protocols** field is changed).

   You can sort the opened list of protocols by clicking the **Sort** link.

3. If you want add another protocol, click the **Add protocol** button and specify the other protocol in the opened field.

4. If you want to delete one of the specified protocols, click the icon in the filter window. You can also delete all specified protocols by clicking the **Default filter** link in the filter window.

5. Click **OK**.

*To filter rules by the **State**, **Event severity** or **Origin** column:*

1. On the **Rules** tab in the **Process Control** section, click the filtering icon in the relevant column.

   When filtering based on the states or sources of Process Control rules, you can also use the corresponding buttons in the toolbar.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events.

3. Click **OK**.

*To filter rules by the **Created** or **Changed** column:*

1. On the **Rules** tab in the **Process Control** section, click the filtering icon in the relevant column.

   The calendar opens.

2. In the calendar, specify the date for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YYYY hh:mm:ss. If you don't need to specify the date and time of the filtering period boundary, you can choose not to select a date or you can delete the current value.

3. Click **OK**.

- Rule search

  You can find relevant rules by using the **Rule search** field on the **Rules** tab in the **Process control** section.

  A search is performed in all columns except the **State**, **Condition type**, **Created**, **Changed**, **Event title**, **Event severity**, **Event description** and **Origin** columns.

- Resetting the defined filter and search settings

  You can reset the defined filter and search settings in the Process Control rules table by using the **Default filter** button in the toolbar on the **Rules** tab in the **Process control** section. The button is displayed if search or filter settings are defined.

- Sorting rules

  1. On the **Rules** tab in the **Process Control** section, click the header of the column by which you want to sort.

  2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

  The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

- Updating the rules table

Process Control rules could be changed on the Server while you are viewing the rules table. For example, the Process Control rules table becomes outdated if an application user in a different connection session modifies rules or if the application converts rules while in learning mode.

To keep the Process Control rules table up to date, you can enable automatic update of the rules.

To enable or disable automatic update of the Process Control rules table:

On the **Rules** tab in the **Process Control** section, use the **Autoupdate** toggle button.

Selecting Process Control rules

In the Process Control rules table, you can select rules to view their information and manage these rules. When rules are selected, the details area appears in the right part of the web interface window.

To select the relevant Process Control rules, perform one of the following actions:

- If you want to select one rule, select the check box next to the rule or use your mouse to select the rule.
- If you want to select multiple rules, select the check boxes next to the relevant rules or select the rules while holding down the **CTRL** or **SHIFT** key.
- If you want to select all rules that satisfy the current filter and search settings, perform one of the following actions:
  - Select any rule in the table and press the key combination **CTRL+A**.
  - Select the check box in the title of the left-most column of the table.

When multiple rules are selected, the details area shows the total number of selected rules.

The title of the left-most column of the table shows the rule selection check box. Depending on the number of selected rules, the check box can have one of the following states:

- ☐ – all rules that satisfy the current filter and search settings were not selected in the table. However, one rule or multiple rules may be selected in the table by using the check boxes next to the rules or by using the **CTRL** or **SHIFT** key.
- ☑ – all rules that satisfy the current filter and search settings were selected in the table.
- ▣ – all rules that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of the rules were cleared. This state is also retained if the check boxes were cleared for all rules selected in this way (due to the fact that the number of selected rules may change).

If all rules that satisfy the filter and search settings are selected, the number of selected rules may be automatically changed. For example, the specific set of rules in the table may be changed by an application user in a different connection session or when rules are converted in learning mode. It is recommended to configure the filter and search settings in such a way that ensures that only the relevant rules end up in the selection (for example, you can filter rules by their IDs before selecting all rules).

Creating a Process Control rule with settings of conditions

The following options are provided for creating Process Control rules with settings of conditions:

- Create a new rule for a tag.
- Create an additional rule based on an existing rule.

To create a new rule for a tag:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Process Control** section.
3. On the **Tags** tab, select the tag for which you want to create a Process Control rule.

   The details area appears in the right part of the web interface window.
4. Click the **Create rule for tag** button.

   This opens the **Rules** tab containing the details area for the created Process Control rule.
5. Perform the following actions:

   a. Use the **Enable** toggle to define the status of the rule: *Enabled* or *Disabled*.

   b. Enter the rule name and description.

   You can use letters of the English alphabet, numerals, and the following special characters: `( ) . , : ; ? ! * + % - < > @ [ ] { } / \ _ $ #`. The rule name must begin and end with any permitted character except a space.

   c. Select the type of condition and configure the settings depending on the selected type.

   d. Configure the settings for registering an event when the rule is triggered (event title and description, severity, and settings for saving traffic).
6. Click **Save**.

To create an additional Process Control rule based on an existing rule:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select the **Process Control** section.
3. On the **Rules** tab, select the rule that you want to use as the basis for creating another rule for the same tag.

   The details area appears in the right part of the web interface window.
4. Click the **Create another rule for tag** button.

   You will see the details area for the created Process Control rule. For the new rule, you will see information about the device, protocol and tag received from the settings of the selected rule.
5. Perform the following actions:

a. Use the **Enable** toggle to define the status of the rule: *Enabled* or *Disabled*.

b. Enter the rule name and description.

c. Select the type of condition and configure the settings depending on the selected type.

d. Configure the settings for registering an event when the rule is triggered (event title and description, severity, and settings for saving traffic).

6. Click **Save**.

Creating a Process Control rule with a Lua script

To create a rule with a Lua script:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the **Process Control** section.

3. On the **Rules** tab, open the details area by clicking the **Add Lua script** link.

4. Perform the following actions:

   a. Use the **Enable** toggle to define the status of the rule: *Enabled* or *Disabled*.

   b. Enter the rule name and description.

   c. If you want to define the script from a template, in the details area click the **Use Lua template** button, select the necessary template in the opened window and click **Apply**.

   d. In the **Lua script for rule** field, enter the code of the script in the Lua language.

   The script input field displays the names of functions and comments loaded from template. You can create a script by editing and augmenting template strings. When entering text, suggestions or available values automatically appear near the cursor (for example, relevant names of devices and tags when entering settings that identify a tag).

   If the script code does not fit into the **Lua script for rule** field, you can use the button to open a separate window for displaying the code.

   e. Configure the settings for registering an event when the rule is triggered (event title and description, severity, and settings for saving traffic).

5. Click **Save**.

Editing Process Control rule settings

To edit Process Control rule settings:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the **Process Control** section.

3. On the **Rules** tab, select the rule that you want to edit.

   The details area appears in the right part of the web interface window.

4. Click the **Edit** button.

5. Change the settings as necessary. You can edit the settings by using the same operations that were available when creating Process Control rules with conditions or Lua scripts.

Creating, viewing and editing a global Lua script

Variables and functions defined in a global Lua script can be used in rules with Lua scripts.

Only users with the Administrator role can create or edit a global Lua script for Process Control rules. However, users with the Administrator role and users with the Operator role can both view the contents of a global Lua script.

To create or edit a global Lua script:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the **Process Control** section.

3. On the **Rules** tab, open the global Lua script editing window by clicking the **Global Lua script** link.

4. Enter the code of the script in the Lua language.

5. Click **Save**.

Deleting Process Control rules

To delete Process Control rules:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the **Process Control** section.

3. On the **Rules** tab, select the rules that you want to delete.

   The details area appears in the right part of the web interface window.

4. Click the **Remove** button.

   A window with a confirmation prompt opens.

5. In the prompt window, confirm deletion of the rules.

Viewing information about devices associated with Process Control rules

You can view information about devices that are associated with Process Control rules (Process Control rules are linked to devices via tags). Information about devices is displayed in the devices table. The devices table is automatically filtered based on the IDs of devices that are indicated in tags.

Information can be loaded if no more than 200 rules are selected.

To view information about devices in the devices table:

1. Select the **Process Control** section.
2. On the **Rules** tab, select the rules for which you want to view information about devices.

   The details area appears in the right part of the web interface window.
3. Click **Show device** (if one rule is selected) or **Show devices** (if multiple rules are selected).

   The **Show devices** button is not available if the number of selected rules exceeds 200.

The **Assets** section opens. The devices table on the **Devices** tab will be filtered based on the IDs of devices associated with the selected rules.

Viewing tags associated with Process Control rules

You can view information about tags associated with the selected Process Control rules. The tags table automatically applies a filter based on the IDs of tags indicated in rules.

Information can be loaded if no more than 200 rules are selected.

To view information about tags associated with Process Control rules:

1. Select the **Process Control** section.
2. On the **Rules** tab, select the rules for which you want to view information about tags.

   The details area appears in the right part of the web interface window.
3. Click the **Show tag** button (if one rule is selected) or the **Show tags** button (if multiple rules are selected).

   The **Show tags** button is not available if the number of selected rules exceeds 200.

The **Tags** tab of the **Process Control** section opens. The tags table will be filtered based on the IDs of tags.

Configuring Interaction Control

Kaspersky Industrial CyberSecurity for Networks can monitor the network interactions of devices in the industrial network. *Interaction Control rules* are used to define authorized and unauthorized network interactions. All detected network interactions that do not satisfy the active Interaction Control rules are considered to be unauthorized. The application registers the corresponding events when unauthorized interactions are detected.

An Interaction Control rule can be applied by one of the following technologies:

- Network Integrity Control – the rule describes network interaction between devices using a specific set of protocols and connection settings.
- Command Control – the rule describes the monitored system commands during communications between devices over one of the supported protocols for Process Control.

An Interaction Control rule contains the following information about interactions/communications:

- Sides participating in network interactions.
- Allowed protocol or system commands.

Network interactions between devices are identified based on the MAC- and/or IP addresses of the devices.

When analyzing network interactions for Network Integrity Control, the application also checks the IP addresses in these interactions to see if they belong to known subnets. The application checks the IP addresses for those interactions in which the MAC addresses of network packet sources and destinations could not be identified. If only the IP address is identified for one of the sides of network interaction, the application checks this interaction against the table of subnets for Interaction Control. The application then checks this interaction against Network Integrity Control rules (and registers the corresponding event if necessary) only if this interaction must be controlled according to the table.

Table of subnets for Interaction Control based on Network Integrity Control technology

Subnets of IP addresses whose interactions are controlled

Source subnet	Destination subnet				
	Private, IT	Private, OT	Private, DMZ	Public	Link-local
Private, IT	no	yes	no	no	yes
Private, OT	yes	yes	yes	yes	yes
Private, DMZ	no	yes	no	no	yes
Public	no	yes	no	no	yes
Link-local	yes	yes	yes	yes	no

Example
When controlling interactions based on Network Integrity Control technology, the application checks all interactions in which the sources or destinations of network packets have IP addresses from **Private, OT** subnets. The application does not check interactions in which the destinations of network packets have IP addresses from **Private, DMZ** subnets while the network packet sources have IP addresses from **Private, IT** subnets.

Command Control technology is applied regardless of the specific subnet of the IP addresses of the sources and destinations of network packets containing system commands.

Interaction Control rules can be enabled or disabled.

By default, a rule is enabled after it is created and is applied to allow the described communications. The application does not register events when it detects interactions that are described in enabled rules.

Disabled rules are intended for describing unwanted network interactions. In learning mode for Interaction Control technologies, disabled rules prevent automatic creation of new enabled rules that describe the same network interactions. In monitoring mode, disabled rules are not taken into account.

The application processes Interaction Control rules based on Network Integrity Control and Command Control technologies if the use of these technologies is enabled.

The following methods are provided for creating a list of Interaction Control rules:

- Automatic generation of rules in learning mode.
- Manual creation of rules.

You can configure Interaction Control rules in the **Allow rules** section of the Kaspersky Industrial CyberSecurity for Networks web interface. This section contains a table with Interaction Control rules based on Network Integrity Control and Command Control technologies. This rules table may also contain allow rules created for events.

Events registered based on Network Integrity Control and Command Control technologies are categorized as system events.

You can view Interaction Control events in the table of registered events. Events registered based on Network Integrity Control technology have the *Warning* severity level. Events registered based on Command Control technology are assigned a severity that depends on the severity level defined for the detected system command.

Learning mode for Interaction Control technologies

In Interaction Control learning mode, the application does the following:

- If use of Network Integrity Control technology is enabled, the application generates rules based on this technology. When the application detects network interactions that match disabled rules, it registers events based on Network Integrity Control technology. The event is registered using the system event type that is assigned the code 4000002601.
- If the use of Command Control technology is enabled, the application generates rules based on this technology. When the application detects system commands that match disabled rules, it registers unauthorized system command detection events based on Command Control technology. The event is registered using the system event type that is assigned the code 4000002602.

When generating rules based on Interaction Control technologies, the application adds new rules obtained from its analysis of network interactions and system commands in industrial network traffic. For these rules, the **Origin** parameter contains the **System** value. If you manually change rule settings, the **Origin** parameter will take the **User** value.

Network interactions detected during traffic analysis are checked for compliance with current Interaction Control rules. If a detected interaction does not match any rule, the application creates a new rule. In this case, an interaction detection event is not registered. When a new rule is created, the application enables it and adds values of settings based on the received data about the network interaction.

If the detected interaction only matches a disabled rule, the application registers an event based on the technology corresponding to this rule. In this case, a new rule is not created.

During the learning process, the application can optimize the list of Interaction Control rules. Optimization involves combining two or more specific rules into one general rule, or deleting specific rules if a general rule is available. Rules that satisfy the following conditions are optimized:

- The rules are enabled.
- The **Origin** parameter contains the **System** value.

- The rules are related to the same technology.

Rules are merged during optimization if the resulting general rule will correspond only to the detected network interactions and no others. For example, one Interaction Control rule was created after a system command was detected during an interaction between two devices. Then another system command was detected during an interaction between these same devices. In this case, after optimization, only one general rule will remain. It will describe both system commands detected during network interaction between these devices.

While operating in learning mode, the application periodically optimizes rules for the corresponding Interaction Control technology. The frequency of optimization is once per minute. Optimization is performed if new interactions are detected in industrial network traffic. To keep the rules table up to date, you must update rules.

After learning mode is disabled, optimization is performed one more time.

There may be a delay before the Interaction Control rules are optimized after learning mode is disabled. The length of the delay depends on the amount of data being received by the application, and may last up to three minutes. During this time, it is recommended to refrain from making any changes to rules that were generated during learning mode based on Network Integrity Control and Command Control technologies.

Interaction Control learning mode must be enabled for enough time to receive all the necessary information about network interactions. This amount of time depends on the number of devices in the industrial network and how frequently they operate and are serviced. We recommend that you enable learning mode for at least one hour. In large industrial networks, learning mode can be enabled for a period ranging from one to several days to accumulate the maximum amount of data.

Monitoring mode for Interaction Control technologies

In Interaction Control monitoring mode, the application does the following:

- If use of Network Integrity Control technology is enabled, the application checks devices' network interactions for compliance with the rules based on this technology. When the application detects network interactions for which there are no enabled rules, it registers unauthorized communication detection events based on Network Integrity Control technology. The event is registered using the system event type that is assigned the code 4000002601.

- If use of Command Control technology is enabled, the application checks devices' network interactions for compliance with the rules based on this technology. When the application detects system commands for which there are no enabled rules, it registers unauthorized system command detection events based on Command Control technology. The event is registered using the system event type that is assigned the code 4000002602.

Rules related to different technologies are applied independently of each other. Therefore, to allow use of a system command, the allow rules table must have rules created (automatically or manually) for this system command and for a network packet that transmits this command.

Selecting the technologies applied for Interaction Control

Only users with the Administrator role can manage Interaction Control technologies.

To enable or disable the use of Interaction Control technologies:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Technologies**.
3. Enable or disable the use of Interaction Control technologies by using the following toggle switches:
   - **Network Integrity Control**
   - **Command Control**
4. After a technology is enabled or disabled, wait for the toggle switch to change to the necessary position (*Enabled* or *Disabled*).

   The process may take some time, during which the toggle switch will be unavailable.
5. For each enabled technology, select the necessary Interaction Control mode. To do so, in the drop-down list on the right of the technology name, select one of the following values:
   - **Learning** – to apply the technology in learning mode.
   - **Monitoring** – to apply the technology in monitoring mode.
6. After the mode is selected, wait for the name of this mode to appear in the field of the drop-down list.

   This process may take some time, during which the drop-down list displays the *Changing* status.

Automatic generation of Interaction Control rules in learning mode

In learning mode, Kaspersky Industrial CyberSecurity for Networks automatically generates Interaction Control rules. The application creates a new rule if the detected network interaction does not match any rule in the allow rules table.

When creating a rule, the application defines the values of parameters that are received from traffic pertaining to a detected network interaction.

If a Network Integrity Control rule is being created for an interaction in which the IP address of one of the sides of communication is in a subnet known to the application, the application might not add MAC addresses detected together with this IP address to the rule settings. Detected MAC addresses for IP addresses of a subnet are added if the **Ignore MAC addresses for NIC rules** toggle is switched off in the subnet settings.

In learning mode, the application can automatically create Interaction Control rules that allow transmission of system commands for Kaspersky Industrial CyberSecurity for Nodes. These rules are needed for convenient joint use of Kaspersky Industrial CyberSecurity for Networks and Kaspersky Industrial CyberSecurity for Nodes within the integrated solution Kaspersky Industrial CyberSecurity. To automatically create rules prior to enabling learning mode, you must enable the PLC Project Integrity Check component on computers with Kaspersky Industrial CyberSecurity for Nodes installed in this same industrial network. For detailed information on enabling this component, please refer to the Help System for Kaspersky Industrial CyberSecurity for Nodes.

Viewing Interaction Control rules in the table of allow rules

Interaction Control rules are displayed in the allow rules table in the **Allow rules** section of the application web interface. Interaction Control rules include the following types:

- NIC rules based on Network Integrity Control technology.
- CC rules based on Command Control technology.

To view relevant information about Interaction Control rules in the allow rules table, you can utilize the following capabilities:

- Configure the display and order of columns in the rules table

1. In the **Allow rules** section, click the **Customize table** link to open the window for configuring how the table is displayed.

2. For the respective sides of network interactions, **Side 1** and **Side 2**, select the information to display in the table. To do so, select one of the following options from the drop-down list for each side:

   - **Address information**. The table column displays only address information representing the side of network interaction.

   - **Device names**. Instead of address information corresponding to devices known to the application, the table column displays the names of these devices. All other address information is visibly displayed (for example, ranges of addresses).

3. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.

   The following settings are available for selection:

   - **Rule ID**

     Unique ID of the rule

   - **State** (the ◐ icon)

     Current state of the rule (*Enabled* or *Disabled*).

   - **Rule type**.

     For Interaction Control rules, this indicates the technology of the rule (NIC or CC). The EVT type is indicated for rules that disable event registration.

   - **Protocols/Commands**

     For rules related to Network Integrity Control technology (NIC type) or rules that disable event registration (EVT type), this is the set of utilized protocols. For rules related to Command Control technology (CC type), this is the protocol and system commands. The protocols that are determined by the application based on the contents of network packets are italicized.

   - **Side 1**

     Device name/address information of one of the sides of network interaction. You can enable or disable the display of addresses and ports of address information by using the following settings:

     - **MAC address**
     - **IP address**
     - **Port number**

   - **Side 2**

     Device name/address information of the other side of network interaction. You can enable or disable the display of addresses and ports of address information by using the following settings:

     - **MAC address**
     - **IP address**
     - **Port number**

- **Comment**

  Additional information about the rule.

- **Created**.

  The date and time when the rule was created.

- **Changed**.

  The date and time when the rule was last modified.

- **Origin**.

  Information about the origin of the rule.

- **Rule in event**.

  The name of the Process Control rule or Intrusion Detection rule that must be indicated in the event (for EVT rules).

- **Monitoring point**

  The name of the monitoring point that must be indicated in the event (for EVT rules).

- **Event type**

  ID and title of the event type (for EVT rules).

4. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

   For the **Side 1** and **Side 2** columns, you can also change the order in which the address information is displayed for the sides of network interaction. To do so, select the value that you want to move to the left or right in the table and use the buttons containing an image of the up or down arrows.

The selected columns will be displayed in the allow rules table in the order you specified.

- Filtering based on table columns

*To filter rules by the **Rule ID**, **Rule in event**, or **Event type** column:*

1. In the **Allow rules** section, click the filtering icon in the relevant column.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values for rules that you want to include in the filter and/or exclude from the filter.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the column click the **Add condition** button and enter the condition in the opened field.

4. If you want to delete one of the created filter conditions, in the filter window of the column click the icon.

5. Click **OK**.

*To filter rules by the **State**, **Rule type**, **Origin** or **Monitoring point** column:*

1. In the **Allow rules** section, click the filtering icon in the relevant column.

   When filtering by state, rule type and origin, you can also use the corresponding buttons in the toolbar.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events.

3. Click **OK**.

*To filter rules by the **Protocols/Commands** column:*

1. In the **Allow rules** section, click the filtering icon in the **Protocols/Commands** column.

   > Filtering by the **Protocols/Commands** column is applied only for protocols. To filter rules based on the names of system commands (rules based on Command Control technology), you can use the rule search function.

   You will see a window containing the table of supported protocols displayed as a protocol stack tree. You can manage how tree elements are displayed by using the **+** and **-** buttons next to the names of protocols that contain protocols of subsequent layers.

   The table columns provide the following information:

   - **Protocol** – name of the protocol within the protocol stack tree.
   - **EtherType** – number of the next-level protocol within the Ethernet protocol (if the protocol has a defined number). It is displayed in decimal format.
   - **IP number** – number of the next-level protocol within the IP protocol (if the protocol has a defined number). It is indicated only for protocols within the IP protocol structure. It is displayed in decimal format.

2. If necessary, use the search field above the table to find relevant protocols.

3. In the list of protocols, select the check boxes opposite the protocols by which you want to filter events.

If you select or clear the check box for a protocol that contains nested protocols, the check boxes for the nested protocols are also automatically selected or cleared.

4. Click **OK**.

*To filter rules by the **Side 1** and **Side 2** columns:*

1. In the **Allow rules** section, open the **Address information** drop-down list.

   The filtering window opens.

2. Specify the necessary values in the following fields:

   - **MAC address**
   - **IP address**
   - **Port number**

3. Click **OK**.

*To filter rules by the **Created** or **Changed** column:*

1. In the **Allow rules** section, click the filtering icon in the relevant column.

   The calendar opens.

2. In the calendar, specify the date for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YYYY hh:mm:ss. If you don't need to specify the date and time of the filtering period boundary, you can choose not to select a date or you can delete the current value.

3. Click **OK**.

- Rule search

  You can find relevant allow rules by using the **Rule search** field in the **Allow rules** section.

  A search is performed in all columns except the **Rule ID**, **State**, **Rule type**, **Created**, **Changed**, **Origin** and **Monitoring point** columns.

- Resetting the defined filter and search settings

  You can reset the defined filter and search settings in the allow rules table by using the **Default filter** button in the toolbar in the **Allow rules** section. The button is displayed if search or filter settings are defined.

- Sorting rules

1. In the **Allow rules** section, click the header of the column by which you want to sort.

   You can sort the rules table based on the values of any column except the **Comment**, **Origin**, **Monitoring point** or **Event type** columns.

2. When sorting rules by the **Protocols/Commands**, **Side 1** or **Side 2** column, in the drop-down list of the column header, select the setting by which you want to sort rules:

   - In the **Protocols/Commands** column, select the sorting settings: by protocol or by system command.
   - Depending on the values selected for display in the **Side 1** or **Side 2** columns, select the sorting settings: by MAC address, by IP address, or by port number.

3. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

- Updating the rules table

Allow rules may be modified on the Server while you are viewing the rules table. For example, the rules table becomes outdated if an application user in a different connection session changes rules or if the application optimizes the list of Interaction Control rules in learning mode.

To keep the table of allow rules up to date, you can enable automatic update of rules or manually update the table. During updates, all rules are reloaded from the Server.

To enable or disable automatic update of the allow rules table:

In the **Allow rules** section, use the **Autoupdate** toggle button.

When automatic update is enabled, the allow rules table is updated every five seconds.

To manually update the allow rules table:

In the **Allow rules** section, start an update of the rules table by clicking the **Update** link (this link is displayed on the right of the **Autoupdate** toggle button if the toggle button is switched off).

The allow rules table is reloaded from the Server.

Selecting Interaction Control rules in the table of allow rules

In the allow rules table, you can select Interaction Control rules to view information or to manage these rules. When rules are selected, the details area appears in the right part of the web interface window.

Before selecting rules, you can configure the allow rules table to display Interaction Control rules in a specific order.

To select the relevant Interaction Control rules, perform one of the following actions:

- If you want to select one rule, select the check box next to the rule or use your mouse to select the rule.
- If you want to select multiple rules, select the check boxes next to the relevant rules or select the rules while holding down the **CTRL** or **SHIFT** key. When multiple rules are selected, the application checks the state of the selected rules and determines whether there are enabled and disabled rules among the selected rules.
- If you want to select all rules that satisfy the current filter and search settings, perform one of the following actions:
  - Select any rule in the table and press the key combination **CTRL+A**.
  - Select the check box in the title of the left-most column of the table.

When multiple rules are selected, the details area shows the total number of selected rules. If you selected all rules that satisfy the current filter and search settings, one of the following values appears in the details area:

- The precise number is displayed if you selected 1000 rules or less. In this case, the application checks the state of the selected rules just as with other methods for selecting multiple rules.
- If more than 1000 rules are selected, the number `1000+` is displayed. In this case, the application does not check the state of the selected rules.

The title of the left-most column of the table shows the rule selection check box. Depending on the number of selected rules, the check box can have one of the following states:

- ☐ – all rules that satisfy the current filter and search settings were not selected in the table. However, one rule or multiple rules may be selected in the table by using the check boxes next to the rules or by using the **CTRL** or **SHIFT** key.
- ☑ – all rules that satisfy the current filter and search settings were selected in the table.
- ▣ – all rules that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of the rules were cleared. This state is also retained if the check boxes were cleared for all rules selected in this way (due to the fact that the number of selected rules may change).

If all rules that satisfy the filter and search settings are selected, the number of selected rules may be automatically changed. For example, the composition of rules in the table may be changed by an application user in a different connection session or when the list of rules is optimized in learning mode. It is recommended to configure the filter and search settings in such a way that ensures that only the relevant rules end up in the selection (for example, you can filter rules by their IDs before selecting all rules).

Manually creating Interaction Control rules

You can manually create Interaction Control rules by doing the following:

- **Create a rule with initially empty values of settings or with the values from a template.**

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. In the **Allow rules** section, open the details area by clicking the **Add rule** link.

3. If you want to define the values of settings from a template, in the details area click the **Use template** button, select the necessary template in the opened window and click **Apply**.

4. In the details area, select the rule type corresponding to the relevant Interaction Control technology:

   - If you want to create a rule based on Network Integrity Control technology, click the **NIC** button.
   - If you want to create a rule based on Command Control technology, click the **CC** button.

5. In the **Protocol** field, specify the protocol for interaction between devices.

   When the **Protocol** field is selected, a window opens showing the table of supported protocols displayed as a protocol stack tree. You can manage how tree elements are displayed by using the **+** and **-** buttons next to the names of protocols that contain protocols of subsequent layers.

   If necessary, use the search field above the table to find relevant protocols.

   To specify the protocol:

   a. In the protocols table, select the protocol that you want to specify for the rule. To select the relevant protocol, click the button that is displayed in the left column of the protocols table.

      For a Network Integrity Control rule, you can select any protocol that is displayed in the table of supported protocols. For a Command Control rule, you can select only a protocol from among the supported protocols for process control.

   b. Click **OK**.

   If you select a protocol that can be identified by the application based on the contents of network packets, a notification about this appears under the **Protocol** field.

6. If Command Control technology is selected for the rule, specify the relevant system commands in the **Commands** field.

   When the **Commands** field is selected, a window opens with a list of system commands that are available for the selected protocol. To specify the commands:

   a. In the list of system commands, select the check boxes next to the commands that should be allowed. If all commands should be allowed, you can either select all check boxes or clear all check boxes for all commands.

   b. Click **OK**.

7. If necessary, enter additional information about the rule in the **Comment** field.

8. In the **Side 1** and **Side 2** settings groups, specify the editable address information for the participants (sides) of network interaction. Depending on the selected protocol (or set of protocols), address information may contain a MAC address, IP address, and/or port number.

   To autofill the address information of a side of network interaction, you can select devices that are known to the application. To do so:

a. Open the device selection window by clicking the **Specify device addresses** link.

b. In the device selection window, select the check boxes next to the devices that you want to use.

The device selection window contains a table in which you can configure the layout and order of columns, and filter, search, and sort similarly to the devices table in the **Assets** section.

c. Click **OK** in the device selection window.

9. In the details area, click **Save**.

The application checks the current list of Interaction Control rules.

10. If the Interaction Control rules include an enabled rule in which all the settings match, you will see a warning about the presence of a matching rule. In this case, close the warning and change the settings of the created rule.

11. If the Interaction Control rules include an enabled rule with more general settings, you will see a warning about the presence of a general rule. If a general rule is present, a new specific rule will not be used in the application. The warning will contain a prompt to save the new specific rule. To create a new rule with defined settings, confirm your decision in the prompt window (for example, if you want to then remove the general rule).

The new rule will be added to the allow rules table.

12. If the Interaction Control rules include enabled rules with more specific settings, you will see a warning about the presence of more specific rules. After a general rule appears, the specific rules will not be used in the application. The warning will contain a prompt to remove the specific rules. To remove specific rules, confirm your decision in the prompt window.

If the rules table contains disabled rules with more specific or matching settings, the application removes these rules from the list. The application does not show a prompt when removing these rules.

13. If there is no enabled rule allowing network interaction between devices for a new rule based on Command Control technology, you will be prompted to create the corresponding rule based on Network Integrity Control technology. In this case, you are advised to create an additional rule together with the current rule being created. To do so, confirm your decision in the prompt window and perform the necessary actions to create a new rule based on Network Integrity Control technology.

- Create a new rule based on an existing rule.

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. In the **Allow rules** section, select the rule that you want to use as the basis for creating a new rule.

3. Right-click to open the context menu.

4. In the context menu, select **Create rule based on the selected rule**.

The details area in rule editing mode will appear in the right part of the web interface window. The settings of the new rule will take the values obtained from settings of the selected rule.

5. Change the settings as necessary. To do so, complete steps 4–9 described in the procedure for creating a rule with initially empty values of settings.

- Create a rule based on an event registered for Network Integrity Control or Command Control technology.

  1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
  2. Select the **Events** section.
  3. In the table of registered events, select the event that you want to use as the basis for creating an Interaction Control rule.

     The details area appears in the right part of the web interface window.
  4. In the details area, click the **Create allow rule** button.

     The **Allow rules** section opens in the browser window. The details area in rule editing mode will appear in the right part of the web interface window. The new rule's settings will take the values received from the saved information about the event.
  5. If necessary, edit the settings of the new rule. To do so, complete steps 4–9 described in the procedure for creating a rule with initially empty values of settings. If you do not need to change the settings of the new rule, save the rule by clicking the **Save** button.

Editing Interaction Control rule settings

You can edit the settings of an enabled Interaction Control rule. You cannot edit disabled rules.

To edit the settings of an Interaction Control rule:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Allow rules** section, select the necessary NIC- or CC rule to edit its settings.

   The details area appears in the right part of the web interface window.
3. Click the **Edit** button.
4. Change the settings as necessary.

Enabling and disabling Interaction Control rules

Interaction Control rules can be either *Enabled* or *Disabled*. Rules are enabled by default after they are created.

You can disable rules that should not be used when Interaction Control technologies are operating in monitoring mode.

To change the state of Interaction Control rules:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. In the **Allow rules** section, select the Interaction Control rules whose state you want to change.

   The details area appears in the right part of the web interface window.

3. Enable or disable rules by using the **Enable** or **Disable** button. The buttons that are displayed depend on whether their corresponding operations are relevant for one or more of the selected rules.

   If all rules that satisfy the current filter and search settings are selected, and the number of selected rules is more than 1000, the application does not check the state of rules. If this is the case, the details area displays both buttons for changing the state of rules.

Deleting Interaction Control rules

You can selectively delete one or multiple Interaction Control rules. Rules that are deleted are no longer applied for Interaction Control technologies, whether in monitoring mode or learning mode.

To delete Interaction Control rules:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the **Allow rules** section.

3. In the rules table, select the Interaction Control rules that you want to delete.

   The details area appears in the right part of the web interface window.

4. Click the **Remove** button.

   A window with a confirmation prompt opens. Depending on the state of the selected rules, the prompt will suggest the following options:

   - If all selected rules are enabled, the application prompts you to delete the selected rules, disable them, or cancel the operation. This condition is not checked if all rules that satisfy the current filter and search settings are selected, and the number of selected rules is more than 1000.

   - If there are disabled rules among the selected rules or if all rules that satisfy the current filter and search settings are selected, and the number of selected rules is more than 1000, the application prompts you to delete the selected rules or cancel the operation.

5. In the prompt window, confirm deletion of the rules.

Configuring Intrusion Detection

To detect intrusions in industrial network traffic, you can use Intrusion Detection rules and additional Intrusion Detection methods based on embedded algorithms. When signs of attacks are detected in traffic, Kaspersky Industrial CyberSecurity for Networks registers events based on Intrusion Detection technology.

Intrusion Detection methods and rules can be configured when connected to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface. The list of Intrusion Detection rules is displayed in the **Intrusion Detection** section. You can change the states of Intrusion Detection methods under **Settings → Technologies**.

You can configure the settings for registering Intrusion Detection events under **Settings** → **Event types**.

You can view Intrusion Detection events in the table of registered events.

Intrusion Detection rules

An *Intrusion Detection rule* describes a traffic anomaly that could be a sign of an attack in the industrial network. The rules contain the conditions that the Intrusion Detection system uses to analyze traffic.

Intrusion Detection rules are stored on the Server and sensors.

Intrusion Detection rules are included in rule sets. A rule set includes Intrusion Detection rules grouped according to any attributes (for example, rules that contain interdependent traffic analysis conditions). The following types of rule sets may be used in the application:

- System rule sets. These rule sets are provided by Kaspersky and are intended for detecting signs of the most frequently encountered attacks or unwanted network activity. System rule sets are available immediately after the application is installed. You can update system sets of rules by installing updates.
- Custom rule sets. These rule sets are loaded into the application separately by the user. To load them, you need to use files containing data structures that define Intrusion Detection rules. These files must be in the same folder and have the RULES extension. The names of custom rule sets must match the names of the files from which these rule sets were loaded.

The application supports the application of no more than 50000 rules cumulatively in all loaded rule sets. The limit on the number of loaded rule sets is 100.

> Rules loaded from custom rule sets may contain traffic analysis conditions whereby the application will register an excessive number of events when these rules are triggered. When using rules that invoke the registration of an excessive number of events, keep in mind that they could affect the performance of the Intrusion Detection system in some cases.

Sets of Intrusion Detection rules can be either enabled or disabled. Rules from the enabled set are applied during traffic analysis if the rule-based Intrusion Detection method is enabled. If a rule set is disabled, the rules from this rule set are not applied.

When a rule set is loaded, the application verifies the rules in the rule set. If errors are detected in the verified rules, the application blocks these rules from being applied. If errors are detected in all rules of the rule set or the rule set does not contain any rules, the application disables this rule set.

For information about sets of rules and detected errors, please refer to the **Intrusion Detection** section.

When the conditions defined in a rule from an enabled rule set are detected in traffic, the application registers a rule-triggering event. Events are registered with system event types that are assigned the following codes:

- 4000003000 – for an event when a rule from a system rule set is triggered.
- 4000003001 – for an event when a rule from a custom rule set is triggered.

Custom sets of rules may contain rules that were received from other Intrusion Prevention and Detection systems. When processing these rules, the application does not perform their defined actions that would otherwise be applied to network packets (for example, the `drop` and `reject` actions). When Intrusion Detection rules are triggered in Kaspersky Industrial CyberSecurity for Networks, only event registration is performed.

The severity levels of Kaspersky Industrial CyberSecurity for Networks events correspond to the priorities in Intrusion Detection rules (see the table below).

Mapping between rule priority and event severity

Intrusion Detection rule priority	Kaspersky Industrial CyberSecurity for Networks event severity
4 or higher	Informational
2 or 3	Warning
1	Critical

Additional Intrusion Detection methods

You can apply the following additional methods for Intrusion Detection:

- **Detection of signs of falsified addresses in ARP packets**

  If detection of signs of falsified addresses in ARP packets is enabled, Kaspersky Industrial CyberSecurity for Networks scans the indicated addresses in ARP packets and detects signs of low-level man-in-the-middle (MITM) attacks. This type of attack in networks that use the ARP protocol is characterized by the presence of falsified ARP messages in traffic.

  When the application detects signs of falsified addresses in ARP packets, the application registers the events based on Intrusion Detection technology. Events are registered with system event types that are assigned the following codes:

  - 4000004001 – for detection of multiple ARP replies that are not associated with ARP requests.
  - 4000004002 – for detection of multiple ARP requests from the same MAC address to different destinations.

- **TCP protocol anomaly detection**

  If TCP protocol anomaly detection is enabled, Kaspersky Industrial CyberSecurity for Networks scans TCP segments of the data stream in supported application-level protocols.

  When it detects packets containing overlapping TCP segments with varying contents, the application registers an event based on Intrusion Detection technology. The event is registered using the system event type that is assigned the code 4000002701.

- **IP protocol anomaly detection**

If IP protocol anomaly detection is enabled, Kaspersky Industrial CyberSecurity for Networks scans fragmented IP packets.

When the application detects errors in the assembly of IP packets, it registers events for Intrusion Detection technology. Events are registered with system event types that are assigned the following codes:

- 4000005100 for detection of a data conflict when assembling an IP packet (IP fragment overlapped).
- 4000005101 for detection of an IP packet that exceeds the maximum permissible size (IP fragment overrun).
- 4000005102 for detection of an IP packet whose initial fragment is smaller than expected (IP fragment too small).
- 4000005103 for detection of mis-associated fragments of an IP packet.

You can apply additional Intrusion Detection methods regardless of the presence and state of Intrusion Detection rules. Embedded algorithms are used for the additional scan methods.

Enabling and disabling rule-based Intrusion Detection

Only users with the Administrator role can enable and disable the rule-based Intrusion Detection method.

To enable or disable the rule-based Intrusion Detection method:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Technologies**.
3. Use the **Rule-based Intrusion Detection** toggle switch to enable or disable rule-based Intrusion Detection.
4. After a method is enabled or disabled, wait for the toggle switch to change to the necessary position (*Enabled* or *Disabled*).

   This process takes some time. The toggle switch will be unavailable during this time.

Enabling and disabling additional Intrusion Detection methods

Only users with the Administrator role can enable and disable the additional Intrusion Detection methods.

To enable or disable additional Intrusion Detection methods:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Technologies**.
3. Enable or disable the use of additional Intrusion Detection methods by using the following toggle switches:
   - **ARP Spoofing Detection** – enables or disables detection of signs of falsified addresses in ARP packets.

- **TCP protocol anomaly detection** – enables or disables TCP protocol anomaly detection.
- **IP protocol anomaly detection** – enables or disables IP protocol anomaly detection.

4. After a method is enabled or disabled, wait for the toggle switch to change to the necessary position (*Enabled* or *Disabled*).

   This process takes some time. The toggle switch will be unavailable during this time.

Viewing the table containing sets of Intrusion Detection rules

The table of Intrusion Detection rule sets is displayed in the **Intrusion Detection** section of the application web interface. When viewing the table of rule sets, you can use the following functions:

- Filtering based on table columns

  *To filter the rule sets table by the **Name of rule set** column:*

  1. In the **Intrusion Detection** section, click the filtering icon in the **Name of rule set** column.

     The filtering window opens.

  2. In the **Including** and **Excluding** fields, enter the names of the rule sets that you want to include in the filter and/or exclude from the filter.
  3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the column click the **Add condition** button and enter the condition in the opened field.
  4. If you want to delete one of the created filter conditions, in the filter window of the column click the icon.
  5. Click **OK**.

  *To filter the rule sets table by the **Origin**, **State** or **Rules** column:*

  1. In the **Intrusion Detection** section, click the filtering icon in the relevant column.

     The filtering window opens.

  2. Select the check boxes opposite the values by which you want to filter events.
  3. Click **OK**.

- Search sets of rules

  You can find relevant Intrusion Detection rule sets by using the **Search rule sets** field in the **Intrusion Detection** section.

  The search is performed based on the **Name of rule set** column.

- Sorting sets of rules

1. In the **Intrusion Detection** section, click the header of the column by which you want to sort.
2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

Selecting sets of Intrusion Detection rules

In the table of Intrusion Detection rule sets, you can select the relevant sets of rules to perform actions with them.

To select the relevant sets of Intrusion Detection rules, perform one of the following actions:

- If you want to select one set of rules, select the check box next to that rule set or use your mouse to select the rule set.
- If you want to select multiple sets of rules, select the check boxes next to the relevant rule sets or select them while holding down the **CTRL** or **SHIFT** key.
- If you want to select all rule sets that satisfy the current filter and search settings, perform one of the following actions:
  - Select any rule set in the table and press the key combination **CTRL+A**.
  - Select the check box in the title of the left-most column of the table.

The title of the left-most column of the table shows the rule set selection check box. Depending on the number of selected rule sets, the check box can have one of the following states:

- ☐ – all rule sets that satisfy the current filter and search settings were not selected in the table. However, one rule set or multiple rule sets may be selected in the table by using the check boxes next to the rule sets or by using the **CTRL** or **SHIFT** key.
- ☑ – all rule sets that satisfy the current filter and search settings were selected in the table.
- ▣ – all rule sets that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of the rule sets were cleared. This state is also retained if the check boxes were cleared for all rule sets selected in this way (due to the fact that the number of selected rule sets may change).

If all rule sets that satisfy the filter and search settings are selected, the number of selected rule sets may be automatically changed. For example, the available rule sets in the table may be changed by an application user in a different connection session.

Enabling and disabling sets of Intrusion Detection rules

Sets of Intrusion Detection rules can be either *Enabled* or *Disabled*. If a set of rules is disabled, no rules in this set are used for Intrusion Detection.

Whenever you enable or disable selected rule sets on all computers that have application components installed (Server and sensors), the Intrusion Detection system is restarted. A restart is required to apply the changes.

Only users with the Administrator role can change the states of sets of Intrusion Detection rules.

To change the state of Intrusion Detection rule sets:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Intrusion Detection** section, select the sets of rules whose state you want to change.
3. Right-click to open the context menu.
4. In the context menu, select one of the following options:
   - **Enable** if you want to enable all disabled sets of rules from among the selected rule sets.
   - **Disable** if you want to disable all enabled sets of rules from among the selected rule sets.
   - **Switch the status of selected rule sets** if you want to invert the state of all selected rule sets. This option lets you quickly enable or disable selected sets of rules with different statuses on all computers that have application components installed, and the Intrusion Detection System will be restarted on all computers at the same time to apply all the changes together.

   A window with a confirmation prompt opens.
5. In the prompt window, click **OK**.

Loading and replacing custom sets of Intrusion Detection rules

You can load sets of Intrusion Detection rules from files into the application. Files containing descriptions of Intrusion Detection rules must be in the same folder and have the rules extension before you can load them into the application. The names of the files must not contain the following characters: `\ / : * ? , " < > |`.

After loading Intrusion Detection rules from a file, the rules are saved in the application as a custom set of rules. The name of a rule set matches the name of the file from which this rule set was loaded.

> When sets of rules are loaded from files, the current custom sets of rules are deleted from the table and replaced with the new ones. However, system sets of rules (whose **Origin** column shows the **System** value) are not deleted from the table.

Only users with the Administrator role can load custom sets of Intrusion Detection rules.

To load and replace custom sets of Intrusion Detection rules:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the **Intrusion Detection** section.

3. Click the **Replace user rules** link in the toolbar to open the window for selecting the folder containing Intrusion Detection rule files.

4. When the prompt window appears, click **OK**.

5. In the standard window of the browser you are using, select the folder containing the necessary files and click the button for transferring files from this folder.

   The table containing sets of rules displays the new custom sets of rules. For these sets of rules, the **Origin** column will show the **User** value. All sets of rules that have no detected errors will be enabled.

6. Check for errors in rules within the loaded sets of rules.

   Information about detected errors is displayed in the **Rules** column. The *OK* status is displayed if there are no errors. If the set of rules contains errors, you can view detailed information about them by clicking the **Details** link.

7. If necessary, change the state of rule sets (including rule sets that have the *Errors in some rules* status).

Removing custom sets of Intrusion Detection rules

You can remove all custom sets of Intrusion Detection rules that were loaded into the application from files. You cannot selectively remove individual custom sets of rules. If you want to use only some of the existing rule sets in the application, you can copy files containing these rule sets into a separate folder and replace all custom rule sets with the rule sets from this folder.

Only users with the Administrator role can delete custom sets of Intrusion Detection rules.

To delete custom sets of Intrusion Detection rules:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select the **Intrusion Detection** section.

3. Start deletion of custom sets of rules by clicking the **Delete user rules** link in the toolbar.

   A window with a confirmation prompt opens.

4. In the prompt window, click **OK**.

All custom sets of Intrusion Detection rules will be deleted from the table.

Managing logs

This section contains information about managing logs of Kaspersky Industrial CyberSecurity for Networks.

Only users with the Administrator role can manage logs of Kaspersky Industrial CyberSecurity for Networks.

Managing the settings for storing logs in the Server database

You can change the settings for storing entries of logs in the Server database.

To change the settings for storing logs in the Server database:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Deployment**.
3. Select the Server tile.

   The details area appears in the right part of the web interface window.
4. Click the **Edit** button.
5. In the **Events**, **Audit entries** and **Application messages** settings groups, configure the following settings:

   a. Use the **Space** setting to define a limit for the space occupied by stored entries. You can select the unit of measure for the defined value: **MB** or **GB**.

   When changing the value of this setting, please note the estimated maximum number of entries for the specified amount of space. You also need to keep in mind that the sum of all volume limits cannot exceed the defined maximum storage volume for the node.

   b. If necessary, use the **Storage time (days)** setting to enable a minimum storage time for entries, and specify the minimum number of days to store them.
6. Click **Save**.

Managing the settings for saving traffic in the Server database

The application can save traffic received at the moment when events are registered. Traffic is saved in the Server database when registering events for which traffic saving is enabled. The application can also save traffic in the Server database directly by requesting to load traffic using temporary traffic dump files.

The application saves traffic data in blocks. If a traffic block relates to several events (when events are registered in a short time interval), this traffic block is not duplicated in the database.

To change the settings for saving traffic in the Server database:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Deployment**.
3. Select the Server tile.

   The details area appears in the right part of the web interface window.
4. Click the **Edit** button.
5. In the **Traffic for events** settings group, use the **Space** parameter to define a limit for the space used to save traffic.

   You can select the unit of measure for the space limit: **MB** or **GB**.

When changing the value of this setting, you need to keep in mind that the sum of all volume limits cannot exceed the defined maximum storage volume for the node.

6. Click **Save**.

Enabling and disabling the user activity audit

You can enable and disable the application user activity audit.

User activity audit is enabled by default.

To enable or disable the user activity audit:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Audit**.
3. Use the **User activity audit** toggle button in the toolbar to enable or disable the user activity audit.
4. Wait for the changes to be applied. The toggle switch is unavailable until it is finished moving to the other state.

Changing the logging level for processes

If application components are installed on nodes, these nodes have running processes that may save their operating data in logs in local folders. You can manage how data is saved in logs of the following application processes:

- On a computer that performs Server functions:
  - EntityManager
  - Filter
  - KisClient
  - NetworkDumper
  - ProductServer
  - Watchdog
  - WebServer
- On a computer that performs sensor functions:
  - EntityManager
  - Filter
  - NetworkDumper

- Watchdog

For each process, you can assign one of the following logging levels:

- **Off**. Process data is not saved in the log.
- **Errors**. Data on process runtime errors is saved in the log.
- **Warning**. The log saves data from **Errors** and data requiring attention.
- **Info**. The log saves all data from the **Warning** logging level and reference information.
- **Debug**. The log saves all data covered under the **Info** logging level and all process data that may be required during the application debugging process (such as process performance data).

The logging levels may need to be changed, for example, when contacting Technical Support.

Only users with the Administrator role can change logging levels.

To change logging levels for Kaspersky Industrial CyberSecurity for Networks processes:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Logging**.
3. Change the logging levels as necessary:
   - If you want to define the same logging level for all processes on all nodes, click the column header containing the name of the necessary level.
   - If you want to define the same logging level for all processes on one node, click a cell of the column containing the name of the necessary level in the row containing the node name.
   - If you want to define a logging level for one process that is different from the logging levels defined for other processes, expand the list of processes of the relevant node in the **Nodes and processes** column and click a cell of the column containing the name of the necessary level in the row containing the process name.
4. Please wait for the changes to be applied (a progress indicator is displayed until the changes are fully applied).

Managing technologies

In Kaspersky Industrial CyberSecurity for Networks, you can enable or disable the use of technologies and the methods associated with those technologies. You can also change the operating mode of technologies and methods that are provided with this capability. Only users with the Administrator role can manage technologies.

The following technologies and methods can be enabled and disabled:

- Asset Management:
  - Device activity detection
  - Device Information Detection

- PLC Project Control
- Device vulnerability detection

- Network Control:
  - Network Integrity Control
  - Command Control
- Process Control:
  - Rule-based Process Control
  - Unknown tag detection
  - Device Discovery for Process Control
- Intrusion Detection:
  - Rule-based Intrusion Detection
  - ARP Spoofing Detection
  - IP protocol anomaly detection
  - TCP protocol anomaly detection

If a technology or method is disabled, the application does not monitor communications of devices using this technology or method. However, you can configure the settings of disabled technologies and methods (for example, add or edit rules).

The mode can be changed for the following technologies and methods:

- Device activity detection
- Command Control
- Rule-based Process Control
- Network Integrity Control

After the application is installed, all technologies and methods (except PLC Project Control and Unknown Tag Detection) are enabled by default. Learning mode is enabled by default for technologies and methods whose mode can be changed.

To change the state and/or mode of technologies and methods:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Technologies**.

   You will see a list of technologies and methods whose states and modes can be changed.

If the states or modes of technologies and methods cannot be changed at the current time, the toggle switches in the list are not available (the **No data** value is displayed in the mode selection fields). In this case, it is recommended to check the status of the kics4net service on the Server computer. If the service is not active, you must start it.

3. Use the toggle switches on the left to enable or disable the use of relevant technologies and/or methods. You can enable or disable all technologies and methods simultaneously by clicking the **Enable all** or **Disable all** links.

4. After enabling or disabling a technology or method, wait for the changes to be applied. The toggle switch is unavailable until it is finished moving to the other state.

5. For the technologies and methods that support operation in learning mode (**Device Activity Detection**, **Command Control**, **Rule-based Process Control** and **Network Integrity Control**), select the necessary mode. If you want to select the same mode for all these technologies and methods, use the **Mode** drop-down list.

   If you need to select different modes (**Learning** and **Monitoring**), use the drop-down list on the right of the name of the technology or method. In this case, the **Mode** drop-down list will show **Mixed**.

6. After selecting a mode, wait for the changes to be applied. Until the mode is applied, the drop-down list displays the *Changing* status.

Configuring the receipt of data from EPP applications

Kaspersky Industrial CyberSecurity for Networks can receive and process data received from Kaspersky applications that perform functions to protect workstations and servers. These applications are included in the Endpoint Protection Platform (EPP) and are installed to endpoint devices within the enterprise IT infrastructure.

Data transfer from EPP applications is performed by computers that have Kaspersky Endpoint Agent installed. Kaspersky Endpoint Agent is installed to workstations and servers in the enterprise IT infrastructure as a supplement to EPP applications.

The current version of Kaspersky Industrial CyberSecurity for Networks can receive and process data from the Kaspersky Endpoint Agent application included in the distribution kit of Kaspersky Industrial CyberSecurity for Nodes. Installation of Kaspersky Endpoint Agent can be performed separately or together with Kaspersky Industrial CyberSecurity for Nodes.

The maximum number of computers from which data from EPP applications can be received and processed is 1000.

Data from Kaspersky Endpoint Agent is forwarded to Kaspersky Industrial CyberSecurity for Networks through *integration servers*. Integration server functions can be performed by any node that has a Kaspersky Industrial CyberSecurity for Networks component installed (Server or sensor). For integration with Kaspersky Endpoint Agent, you need to add integration servers to the nodes that will receive data from Kaspersky Endpoint Agent.

On a Kaspersky Industrial CyberSecurity for Networks node, integration server functions are implemented by the service named kics4net-epp-proxy that facilitates integration with EPP applications. The installation package for this service is included in the distribution kit of Kaspersky Industrial CyberSecurity for Networks.

When an integration server receives data from Kaspersky Endpoint Agent, the application may do the following:

- Register events based on EPP technology (workstation and server protection events).
- Populate the device table with devices hosting installed EPP applications (and devices that have had bidirectional interactions with such devices).

- Update the device table with information about devices hosting installed EPP applications (for example, the operating system version, information on the model or developer).
- Display special icons on network map nodes indicating the availability of EPP applications and the connection states of these applications.
- On the network map, display links in which one of the sides of interaction is a device with an EPP application installed (when displaying information about such links, data received in traffic from monitoring points takes priority).

Computers hosting Kaspersky Endpoint Agent establish secure connections with integration servers over the HTTPS protocol. Connections are secured by using certificates issued by the Kaspersky Industrial CyberSecurity for Networks Server. The following certificates can be used in connections:

- Integration server certificate. This certificate is verified by the computer with Kaspersky Endpoint Agent each time a connection is being established. A connection is not established until certificate verification is successfully completed.
- Client certificate. This certificate is used to authenticate integration server clients that are computers with Kaspersky Endpoint Agent. The same client certificate can be used by multiple computers with Kaspersky Endpoint Agent. By default, an integration server does not verify certificates of clients, but you can enable client certificate verification to reinforce the security of connections.

Kaspersky Security Center is used to deliver certificates and public keys to computers with Kaspersky Endpoint Agent. This data is uploaded to Kaspersky Security Center using a communication data package, which needs to be created in Kaspersky Industrial CyberSecurity for Networks after an integration server is added.

Only users with the Administrator role can configure receipt of data from EPP applications.

Scenario for preparing to receive data from EPP applications

The scenario for preparing to receive data from EPP applications consists of the following phases:

1. **Installing EPP applications to computers of the monitored network**

   During this phase, you need to install Kaspersky applications that perform functions for protecting workstations and servers (EPP applications). EPP applications need to be installed on all computers whose data you want to receive in Kaspersky Industrial CyberSecurity for Networks. These computers must either reside outside of the industrial network (whose traffic is monitored through monitoring points) or have an additional connection to another network that includes one of the nodes that has a Kaspersky Industrial CyberSecurity for Networks component installed (for example, a connection to the Kaspersky Industrial CyberSecurity dedicated network). Kaspersky Endpoint Agent must be installed together with EPP applications.

   > The current version of Kaspersky Industrial CyberSecurity for Networks can receive and process data only from Kaspersky Industrial CyberSecurity for Nodes version 3.0 or later. You can use Kaspersky Endpoint Agent version 3.11 or later to transfer data from Kaspersky Industrial CyberSecurity for Nodes to Kaspersky Industrial CyberSecurity for Networks. For information on installing these applications, please refer to the Help Guide for the specific application.

2. **Adding integration servers for nodes of Kaspersky Industrial CyberSecurity for Networks**

This phase involves the completion of procedures for adding integration servers to nodes that computers with Kaspersky Endpoint Agent will connect to. Network interactions between nodes and these computers are possible only through network interfaces that are not being used as monitoring points. Specific network interfaces and IP addresses are not configured for integration servers because any available network interface and IP address of a computer can be used for an external connection to the integration server.

3. **Creating communication data packages for integration server clients**

   At this phase, you need to create and download communication data packages in which the application saves certificates and keys for connections between clients and integration servers. Each communication data package is an archive containing the following data:

   - Public certificate key of the integration server.
   - Certificate for integration server clients (with private key). This certificate is added if client certificate verification is enabled on the integration server. The certificate and key are saved in encrypted form with the password that was specified when the communication data package was created.

4. **Uploading integration server connection data to client computers**

   This phase is implemented by using the Kaspersky Security Center Administration Console and the Kaspersky Endpoint Agent administration plug-in. Computers with Kaspersky Endpoint Agent installed serve as clients for Kaspersky Industrial CyberSecurity for Networks integration servers. During this phase, you need to upload certificates and/or keys from communication data packages to the Kaspersky Security Center Administration Server by using the Kaspersky Endpoint Agent administration plug-in. Then, in the Kaspersky Security Center Administration Console, you need to create policies for uploading data to computers with Kaspersky Endpoint Agent. For information about working with data and creating policies, please refer to the Kaspersky Endpoint Agent documentation.

   For each integration server, you must create at least one policy containing the following data to be uploaded to the computers of clients:

   - Public certificate key of the integration server.
   - IP address for connecting to the integration server. You can indicate any of the available IP addresses of the node containing the integration server (you can view the IP addresses when connected to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface on the **Integration servers** tab under **Settings** → **Connection Servers**). Port 8081 is the default port used for the connection.
   - Certificate for integration server clients (with private key). This certificate is added if client certificate verification is enabled on the integration server.

5. **Enabling integration servers**

   This phase is completed after applying policies and uploading data to computers with Kaspersky Endpoint Agent. During this phase, you need to enable all integration servers that will receive data from EPP applications. When an integration server is enabled on a node, the kics4net-epp-proxy service is activated.

When this scenario is fulfilled, Kaspersky Industrial CyberSecurity for Networks will begin to receive and process data from EPP applications.

Adding an integration server

To add an integration server:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Connection Servers**.

3. On the **Integration servers** tab, open the details area by clicking the **Add Kaspersky Endpoint Agent integration server** link.

4. In the **Node** drop-down list, select the node with the installed application component (Server or sensor) to which you need to add an integration server.

   You can only select a node that does not yet have an added integration server.

5. If necessary, enable verification of certificates for client authentication by using the **Verify client certificates** toggle switch.

6. If you enabled client certificate verification, create one or more certificates for integration server clients. To create a certificate, click the **Create new certificate** button. If necessary, you can remove unnecessary certificates from the list by using the icon located on the right of the field containing the certificate fingerprint.

   If you created multiple client certificates, you can select the relevant certificate when creating the communication data package.

7. Click **Save**.

Creating a communication data package for integration server clients

After adding an integration server or changing its settings, you need to create and download a communication data package for clients of this server.

To create a new communication data package for integration server clients:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Connection Servers**.

3. On the **Integration servers** tab, select the server for whose clients you want to create a new communication data package.

   The details area appears in the right part of the web interface window.

4. Click the **Get communication data package for clients** button.

5. If client certificate verification is enabled for the integration server, the **Generate new communication data package** window opens. Perform the following actions:

   a. In the **Certificate for clients** drop-down list, select the relevant certificate that will be used for authentication of integration server clients.

   b. Specify the password for accessing the selected certificate. Using the defined password, the certificate will be encrypted in the communication data package of the connector.

   c. Click the **Create communication data package** button.

The Kaspersky Industrial CyberSecurity for Networks Server generates a new communication data package for clients of the selected integration server, then the browser saves the downloaded file. Depending on your browser settings, you will need to upload the contents of the new communication data package to the computers of integration server clients. These uploads are performed by using Kaspersky Security Center Administration Server policies. In the Kaspersky Security Center policies, you need to specify the IP address for connecting to the integration server (to do so, you can use one of the available IP addresses indicated in the details area of the selected integration server).

Kaspersky Security Center policies are created and configured while configuring Kaspersky Endpoint Agent integration with Kaspersky Industrial CyberSecurity for Networks. For more information about configuring integration, please refer to the Kaspersky Endpoint Agent Help Guide.

Integration servers table

The integration servers table is displayed under **Settings** → **Connection Servers** on the **Integration servers** tab. This table displays information about integration servers that were added to nodes that have application components installed.

The integration servers table contains the following information:

- **Node name** – name of the node that has the application component installed.
- **IP addresses** – list of IP addresses on all network interfaces of the node (specific network interfaces and IP addresses are not configured for integration servers because any available network interface and IP address of a computer can be used for an external connection to the integration server).
- **Requests per second** – average number of successfully processed requests coming from clients to the integration server.
- **State** – current state of the integration server.
- **Verify client certificate** – indicator of whether client certificate verification is enabled or disabled (if verification is disabled, the table cell is empty).

Enabling and disabling an integration server

Integration servers can be enabled or disabled. An integration server is disabled by default after it is created. Therefore, data from clients of this server is not processed in Kaspersky Industrial CyberSecurity for Networks.

To enable or disable an integration server:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Connection Servers**.
3. On the **Integration servers** tab, select the server that you want to enable or disable.

   The details area appears in the right part of the web interface window.
4. Click the **Enable** or **Disable** button.

Editing integration server settings

When editing integration server settings, you can replace the certificate for the integration server, and enable or disable client certificate verification and modify the list of certificates for clients.

To edit the integration server settings:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Connection Servers**.
3. On the **Integration servers** tab, select the server for whose clients you want to change the settings.

   The details area appears in the right part of the web interface window.
4. If you want to replace (issue a new) certificate for the same integration server, click the **Reissue certificate** button.

   After the integration server certificate is replaced, its old certificate becomes invalid.
5. If you want to enable or disable certificate verification for client authentication, use the **Verify client certificates** toggle switch.
6. If client certificate verification is enabled and you want to modify the list of certificates for clients, use the **Create new certificate** button and/or the icon located on the right of the field containing the certificate fingerprint.
7. Click **Save**.

If a new certificate was issued for an integration server or if new client certificates were created, you need to once again create and download a communication data package to send data about these certificates to client computers.

Removing an integration server

To remove an integration server:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Connection Servers**.
3. On the **Integration servers** tab, select the server that you want to remove.

   The details area appears in the right part of the web interface window.
4. Click the **Remove** button.

   A window with a confirmation prompt opens.
5. In the prompt window, click **OK**.

Managing connectors

This section contains information about managing connectors in Kaspersky Industrial CyberSecurity for Networks. *Connectors* are specialized application modules that facilitate the exchange of data between Kaspersky Industrial CyberSecurity for Networks and recipient systems, including Kaspersky Security Center.

You can use connectors to configure forwarding of events, application messages, or audit entries to a recipient system (for example, to a SIEM system). Connectors can also facilitate the receipt of various data from recipient systems (for example, register events based on External technology).

Maximum number of connectors in the application – no more than 20.

System types of connectors and custom types of connectors can be used in the application.

System types of connectors are embedded in the application. The following system types of connectors are provided:

- **Syslog** – for forwarding data to a Syslog server.
- **SIEM** – for forwarding data to the server of a SIEM system.
- **Email** – for forwarding data in email messages.
- **Generic** – for connecting applications that utilize the Kaspersky Industrial CyberSecurity for Networks API.

If necessary, you can add custom types of connectors that will facilitate the exchange of data between the application and other recipient systems. To add custom connector types, use the types_manager.py script located on the Server machine in the /opt/kaspersky/kics4net-connectors/sbin/ folder.

A recipient system is connected through a connector on behalf of one of the application users. It is recommended to use a separate user account for each connector. This will make it more convenient to analyze the actions that are performed through connectors based on audit entries.

The application also provides a specialized connector named the **Kaspersky Security Center Connector**. This connector facilitates interaction between the application and Kaspersky Security Center. The **Kaspersky Security Center Connector** is created in the application by default and cannot be removed. To ensure proper functioning of the connector, the capability for the application to interact with Kaspersky Security Center must be added to the Kaspersky Industrial CyberSecurity for Networks Server.

Only users with the Administrator role can manage connectors.

About forwarding events, application messages and audit entries to recipient systems

You can configure forwarding of events, application messages, or audit entries (hereinafter also referred to as "registered notifications") to a recipient system by using connectors. For the system types of connectors named **Syslog**, **SIEM** and **Email**, the capability to forward registered notifications is enabled by default. When using custom types of connectors, this capability is available depending on the settings defined for the specific type of connector.

The settings for forwarding registered notifications are configured for each connector individually. When configuring event types, you can select the relevant event types to forward via connectors. When creating a connector or changing its settings, you can enable or disable forwarding of all application messages and all audit entries through this connector.

Some types of connectors provide the capability to limit the volume of transmitted data. This limit is applied for a 24-hour period starting at 0:00 hours in the time zone of the Server. You can set a limit on the volume of transmitted data for the following system types of connectors:

- **Email**. For this type of connector, you can define the maximum number of email messages regarding new registered notifications and the maximum number of registered notifications in each message. If the maximum number of email messages has been sent, message recipients receive one more message notifying them that the maximum number has been exceeded. After this, new messages will not be sent until the end of the current day.

- **Kaspersky Security Center Connector**. For this type of connector, you can define the maximum number of registered notifications that can be forwarded. If the number of registered notifications exceeds this maximum number, the excess notifications registered before the end of the current day are not sent to Kaspersky Security Center.

Events containing information about multiple network interactions are specially forwarded as follows. Each of these events is considered as one item when forwarded through the connector. However, when it is being forwarded, the event is converted into multiple registered notifications, with each notification representing one network interaction. For this reason, the list of registered notifications for a connector may contain more notifications than defined by the setting that determines the maximum number of notifications.

The contents and order of information about registered notifications forwarded through **Syslog** and **SIEM** connectors may differ from the contents and order of information displayed on pages of the Kaspersky Industrial CyberSecurity for Networks web interface.

Email messages forwarded through an **Email** connector are generated separately for each type of registered notification. In other words, separate email messages are generated to forward events, application messages, and audit entries.

Adding a connector

Prior to adding a connector, you are advised to create a separate user account that the recipient system will use to connect to the application.

The current version of the application does not support integration with Kaspersky Unified Monitoring and Analysis Platform (KUMA) to send information about devices and risks to KUMA and use the commands to change device statuses in KUMA. To use all KUMA integration capabilities, install a more recent version of the application for which the relevant connector types are available, such as Kaspersky Industrial CyberSecurity for Networks 4.2, which has the right connector types built in.

To add a connector:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Connectors**.

3. Open the details area by clicking the **Add connector** link.

4. Specify the main settings of the connector:

   - User name that the recipient system will use to connect to the application through the connector. You must indicate the name of one of the application users.
   - Address of the node that will host the connector (for system types of connectors, this is the address of the Server computer if the connector is running on the Server node).
   - Password for accessing the connector certificate. Using the defined password, the certificate will be encrypted in the communication data package of the connector.
   - Connector name.
   - Connector type.
   - Connector description.
   - Option for forwarding application messages through the connector: **All** or **None sent**.
   - Option for forwarding audit entries through the connector: **All** or **None sent**.

5. Specify the advanced settings depending on the type of connector.

   You can configure the following settings for system types of connectors:

   - **SIEM** / **Syslog**:
     - Server address.
     - Server port.
     - Data transfer protocol.
   - **Email**:
     - Address indicated as the sender of email messages.
     - Recipient addresses of email messages.
     - Subjects of email messages for events, application messages, and audit entries.
     - Templates of text descriptions for events, application messages, audit entries, network interactions, and for entire messages containing notifications. Templates are formed by using variables.
     - Subject and text of an email message notifying when the maximum number of sent notifications is reached.
     - Maximum number of email messages sent per day.
     - Maximum number of notifications in each message. Defines the maximum number of registered notifications of one type (events, application messages, or audit entries) that can be put into one email message. If the number of registered notifications exceeds the maximum number, an additional email message is generated (within the daily limit).

6. Click **Save**.

   The new connector will appear in the connectors table. A new column with the connector name will also appear in the event types table.

At the same time, the Server generates a communication data package for the new connector. Then the browser saves the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

You will need to upload the contents of the new communication data package to the app that will use the connector.

7. Create the connector service on the Server by using the registrar.py script located on the Server computer in the /opt/kaspersky/kics4net-connectors/sbin/ folder. The script must be run with the `create` parameter (to run it, enter the following command: `sudo python3 registrar.py create`). When prompted by the script, specify the data about the connector: the name of the connector, the path to the communication data package, the connector certificate access password.

Viewing the connectors table

When viewing the connectors table, you can utilize the following functions:

- Configure the layout and order of columns displayed in the connectors table.

1. Under **Settings** → **Connectors**, click the **Customize table** link to open the window for configuring how the table is displayed.

2. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.

   The following settings are available for selection:

   - **Name**.

     Defined name of the connector.

   - **Connector ID**.

     ID assigned to the connector when it was created.

   - **Enabled**.

     Indicates whether the connector is enabled or disabled. If a connector is disabled, a connection through this connector is not possible.

   - **State**.

     Indicates the connector's registration state on the Server. The following states are available:

     - *Awaiting registration* – no connection has been established through this connector since the communication data package was created for the connector.

     - *Registered* – a successful connection was established through this connector after the communication data package was created for the connector.

     If a connector is disabled, the *Disabled* state is displayed for it regardless of the current registration state of this connector.

   - **Type**.

     Connector type.

   - **Last connection**.

     Date and time of the last connection through this connector.

   - **Changed**.

     Date and time of the last modification of the connector settings.

   - **Description**

     Defined description of the connector.

3. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

The selected columns will be displayed in the connectors table in the order you specified.

- Filtering based on table columns

*To filter connectors by the **Name** or **Connector ID** column:*

1. Under **Settings** → **Connectors**, click the filtering icon in the relevant column of the table.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values that you want to include into the filter and/or exclude from the filter.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the column click the **Add condition** button and enter the condition in the opened field.

4. If you want to delete one of the created filter conditions, in the filter window of the column click the icon.

5. Click **OK**.

*To filter connectors by the **Enabled**, **State** or **Type** column:*

1. Under **Settings** → **Connectors**, click the filtering icon in the relevant column of the table.

   When filtering based on the states or types of connectors, you can also use the corresponding buttons in the toolbar.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events. You can clear or remove all check boxes by clicking the link that is displayed in the upper part of the filter window.

3. Click **OK**.

- Search connectors

  You can find relevant connectors by using the **Search connectors** field under **Settings** → **Connectors**.

  The search is performed in the **Name**, **Description** and **Type** columns.

- Resetting the defined filter and search settings

  You can reset the defined filter and search settings in the connectors table by using the **Default filter** button in the toolbar under **Settings** → **Connectors**. The button is displayed if search or filter settings are defined.

- Sorting connectors

  1. Under **Settings** → **Connectors**, click the header of the column by which you want to sort.

  2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

  The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

Enabling and disabling connectors

Connectors can be enabled or disabled. If a connector is disabled, a connection through this connector is not possible.

To enable or disable connectors:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Connectors**.
3. In the connectors table, select the connectors that you want to enable or disable.

   The details area appears in the right part of the web interface window.
4. Click the **Enable** or **Disable** button.

   A window with a confirmation prompt opens.
5. In the prompt window, click **OK**.

Editing connector settings

To edit connector settings:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Connectors**.
3. Select the relevant connector in the connectors table.

   The details area appears in the right part of the web interface window.
4. Click the **Edit** button.
5. Change the relevant values for the main and advanced settings of the connector.
6. Click **Save**.

The changes will be displayed in the corresponding columns of the connectors table. If you changed the connector name, the new name is displayed in the column header in the event types table.

When certain settings are changed (such as the server address for the **Syslog** connector), the Server generates a new communication data package for the connector. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved communication data package.

You will need to upload the contents of the new communication data package to the app that will use the connector. Otherwise, a new connection through the connector will be impossible for this app.

Creating a new communication data package for a connector

When a connector is added, a communication data package is automatically created for this connector. If necessary, you can create a new communication data package for a connector (for example, if the configuration package from the previous communication data package has been compromised).

After a new communication data package is created, the configuration package from the old communication data package becomes invalid. For this reason, you will have to use the new communication data package the next time you connect a recipient system through the connector.

To create a new communication data package for a connector:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Connectors**.
3. In the connectors table, select the connector for which you want to create a new communication data package.

   The details area appears in the right part of the web interface window.
4. Click the **Get new communication data package** button.

   The **Generate new communication data package** window opens.
5. Specify the settings for creating the communication data package:

   - User name that the recipient system will use to connect to the application through the connector. You must indicate the name of one of the application users.

     It is recommended to specify the user name that was indicated when adding the connector. If you need to specify the name of a different user, you are advised to select an application user account that was not indicated for other connectors and is not being used to connect to the Server through the web interface.
   - Address of the node that will host the connector.
   - Password for accessing the connector certificate. Using the defined password, the certificate will be encrypted in the communication data package of the connector.
6. Click the **Create communication data package** button.

The Server generates a new communication data package for the selected connector, then the browser saves the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

You will need to upload the contents of the new communication data package to the app that will use the connector. Otherwise, a new connection through the connector will be impossible for this app.

Deleting connectors

Before removing connectors, you need to stop and remove the services of these connectors on the Server. To do this, use the registrar.py script located on the Server computer in the /opt/kaspersky/kics4net-connectors/sbin/ folder. The script must be run with the `delete` parameter (using the `sudo python3 registrar.py delete` command). When prompted by the script, specify the names of the connectors that you want to remove.

To remove connectors:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Connectors**.
3. In the connectors table, select the connectors that you want to delete.

   The details area appears in the right part of the web interface window.
4. Click the **Remove** button.

   A window with a confirmation prompt opens.
5. In the prompt window, click **OK**.

Configuring event types

In Kaspersky Industrial CyberSecurity for Networks, you can configure the types of registered events. *Event types* define the settings utilized when registering events, including their titles, descriptions, severities, and registration settings. Event types can be configured when connected to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface in the **Settings** → **Event types** section.

The table of event types contains *system event types*. These event types are created by the application during installation and cannot be deleted from the list. Various sets of system event types are used for the event registration technologies employed in the application.

Some system event types can be used as the basis for configuring *user settings of events* that will be used when registering events in specific cases. User settings can be defined for the following event types:

- Event type based on Deep Packet Inspection technology with the code 4000002900 – for registering events based on Process Control rules.
- Event type based on External technology with the code 4000005400 – for registering events using the Kaspersky Industrial CyberSecurity for Networks API.

User settings take priority when registering events. The settings defined in system event types are used if no user settings are defined.

The following settings are available for event types:

- **Code** – unique number (identifier) of the event type. In the event types table, a number is displayed together with the event title. In the table of registered events, the event type identifier is displayed in the **Event type** column.
- **Severity** – severity of the registered event.
- **Technology** – technology used for event registration.
- **Title** – contents of the event title presented as text and/or variables. System event types may utilize specific variables only for these event types (for example, the `$systemCommandShort` variable in the event type for Command Control technology) or common variables that can also be used in user settings (for example, the `$top_level_protocol` variable in the event type for Network Integrity Control technology). In the event types table, the title contents are displayed after the event type identifier. In the table of registered events, the text of the title and/or received values of variables are displayed in the **Title** column.

- **Description** – additional text that describes the event type. Like the title, a description may contain variables. This setting is not displayed in the event types table (you can view the description in the details area of the selected event type). In the table of registered events, the text of the description and/or received values of variables are displayed in the **Description** column.

- **<Recipient connector name>** – name of the connector that the application uses to forward events to the recipient system. The application sends recipient systems only those event types whose forwarding through the connector is enabled.

- **Regeneration period** – maximum period of time after which an event is allowed to be registered again. If the conditions for event registration are repeated before the specified time period elapses, a new event is not registered but the counter for the number of repeats of the previously registered event is increased and the date and time of the last occurrence of the event is updated. After this period elapses, the application will register a new event of this type when the event registration conditions are repeated. The repeat event timeout period begins when an event of this type is last registered. For example, if the defined time period is 8 hours and the conditions for registering this type of event are detected two hours after the previous event, a new event will not be registered. A new event will be registered when the event registration conditions are detected after 8 or more hours. This setting is not displayed in the event types table (you can view and configure this setting in the details area of the selected event type).

  For registered events, the event regenerate period may occur earlier than the specified period. Re-registration of an event is allowed earlier than the defined period if the *Resolved* status is assigned to the event, and if the computer performing Server functions was restarted.

- **Save traffic** – this setting enables or disables automatic saving of traffic when an event is registered. This setting is not displayed in the event types table (you can view and configure this setting in the details area of the selected event type).

  If automatic saving of traffic is disabled, you can manually load traffic some time after registration of an event of this type. When the application receives a request to load traffic, it searches network packets in traffic dump files that were temporarily created by the application. If relevant network packets are found in the traffic dump files, they are loaded after first being saved in the database.

Viewing the table of event types

When viewing the event types table, you can utilize the following functions:

- **Configure the display and order of columns in the event types table.**

1. Under **Settings** → **Event types**, click the **Customize table** link to open the window for configuring how the table is displayed.
2. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.

   The following settings are available for selection:

   - **Code and title**.

     Event type number and title contents.

   - **Severity**

     Level of severity for the event type.

   - **Technology**

     Technology for the event type.

   - **<Recipient connector name>**.

     Name of the connector that the application uses to forward events to the recipient system. If a column with a connector name is displayed in the event types table, the event types whose forwarding through this connector is enabled are emphasized in this column.
3. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

The selected columns will be displayed in the event types table in the order you specified.

- Filtering based on table columns

*To filter event types by the **Severity** or **Technology** column:*

1. Under **Settings** → **Event types**, click the filtering icon in the relevant column of the table.

   To filter by severity level or technology, you can also use the corresponding buttons in the toolbar.

   The filtering window opens.
2. Select the check boxes opposite the values by which you want to filter events. You can clear or remove all check boxes by clicking the link that is displayed in the upper part of the filter window.
3. Click **OK**.

- Searching for event types

You can find relevant event types by using the **Search event types** field under **Settings** → **Event types**.

A search is performed in all columns except the **Severity** and **Technology** columns.

- Sorting event types

1. In the **Settings** → **Event types** section, click the header of the column by which you want to sort.
2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

Selecting event types in the table

In the event types table, you can select event types to view their information or configure their settings. When event types are selected, the details area appears in the right part of the web interface window.

To select the relevant event types in the table, do one of the following:

- If you want to select one event type, select the check box next to this event type or use your mouse to select it.
- If you want to select multiple event types, select the check boxes next to the relevant event types or select them while holding down the **CTRL** or **SHIFT** key.
- If you want to select all event types that satisfy the current filter and search settings, do one of the following:
  - Select any event type in the table and press the key combination **CTRL+A**.
  - Select the check box in the title of the left-most column of the table.

When multiple event types are selected, the details area shows the total number of selected event types.

The title of the left-most column of the table shows the event type selection check box. Depending on the number of selected event types, the check box can have one of the following states:

- ☐ – all event types that satisfy the current filter and search settings were not selected in the table. However, one event type or multiple event types can be selected in the table by using the check boxes next to the event types or by using the **CTRL** or **SHIFT** key.
- ☑ – all event types that satisfy the current filter and search settings were selected in the table.
- ▣ – all event types that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of the event types were cleared.

Editing the settings of a system event type

To edit the settings of a system event type:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Event types**.

3. In the table of event types, select the event type that you want to edit. If the event type provides for registration of events with multiple severity levels, select the table row of the event type with the relevant severity level.

   The details area appears in the right part of the web interface window.

4. Click the **Edit** button.

5. Configure the editable settings, such as the event regeneration period and settings for saving traffic.

6. Click **Save**.

Configuring automatic saving of traffic for system event types

When editing event types, you can enable or disable automatic saving of traffic for events when they are registered. If saving of traffic is enabled, the network packet that invoked event registration as well as packets before and after event registration are saved in a database. The settings for saving traffic determine the number of saved network packets and time limits.

If automatic saving of traffic is disabled for an event type (and user settings enabling autosaving of traffic are not defined for this event type), you will be able to manually load traffic only after waiting some time after registration of an event of this type. In this case, the application uses traffic dump files to load traffic (these files are temporarily saved and are automatically deleted as more and more traffic is received). When traffic is loaded from these files, the database saves the specific amount of network packets that was defined by default when enabling the saving of traffic for event types.

> The application saves traffic in the database only when an event is registered. If the conditions for registering this event are repeated during the event regenerate timeout, traffic at this point in time is not saved in the database.

You can enable and configure the saving of traffic for any event types except a system event type assigned the code 4000002700. An event with the code 4000002700 is registered when there is no traffic at a monitoring point. For this reason, traffic is not expected for this type of event.

If saving of traffic is enabled for incidents (meaning for a system type of event that is assigned the code 8000000001), the application saves traffic for all embedded events of an incident when the incident is registered. The settings defined for the incident are applied when saving traffic of embedded events. However, the traffic storage settings defined directly for event types embedded in an incident take priority over the settings defined for an incident. This means that traffic for embedded events of an incident will be saved according to the settings defined for the specific types of these events. If these settings are not defined, the traffic for embedded events will be saved according to the settings defined for an incident.

To enable and configure the settings for saving traffic for an event type:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Event types**.

3. In the table of event types, select the event type that you want to edit. If the event type provides for registration of events with multiple severity levels, select the table row of the event type with the relevant severity level.

The details area appears in the right part of the web interface window.

4. Click the **Edit** button.

5. Select the **Save traffic** toggle switch to *Enabled*.

6. Configure saving of traffic before event registration. To do so, specify the necessary values in the **Packets before event** and/or **Milliseconds before event** fields. If the value is zero, the setting is not applied. If the values are defined in both of these fields, the application will save the minimum amount of packets corresponding to one of the defined values.

7. Configure the saving of traffic after event registration. To do so, specify the necessary values in the **Packets after event** and/or **Milliseconds after event** fields. If the value is zero, the setting is not applied. If the values are defined in both of these fields, the application will save the minimum amount of packets corresponding to one of the defined values.

   For certain technologies (particularly Deep Packet Inspection), fewer post-registration packets than defined by the settings for saving traffic may be saved in events. This is due to the technological specifics of traffic monitoring.

8. Click **Save**.

Configuring forwarding of events via connectors

When configuring system event types, you can specify the connectors through which Kaspersky Industrial CyberSecurity for Networks will forward registered events to recipient systems (for example, to Kaspersky Security Center). Kaspersky Industrial CyberSecurity for Networks can relay event information through multiple connectors simultaneously.

To configure forwarding of events through connectors to recipient systems:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Event types**.

3. Make sure that the event types table displays columns with the relevant connectors.

   If there is no column with the relevant connector, check the column display settings. If the connector has not been added to the list of connectors, add it.

4. In the event types table, select the event types for which you want to enable or disable forwarding via connectors.

   The details area appears in the right part of the web interface window.

5. Click the **Select connectors** button.

   The **Event recipient connectors** window opens.

6. Select the check boxes next to those connectors that you want to use to forward events to recipient systems.

7. Click **OK**.

Common variables for substituting values in Kaspersky Industrial CyberSecurity for Networks

You can use common values to substitute current values in Kaspersky Industrial CyberSecurity for Networks. You can use common variables in the following settings:

- Titles and descriptions of events in user settings for registering events (for example, in Process Control rules).
- Settings for forwarding events, application messages or audit entries via the email connector.

To insert a common variable into the entry field:

Start entering the name of the variable beginning with the $ character and choose the appropriate common variable in the list that appears.

Depending on their purpose, common variables can be used to substitute values in various settings (see the table below).

Common variables for value substitution

Variable	Purpose	Where it is used
`$communications`	Strings describing network interactions (one line for each network interaction) indicating the protocol and addresses of the network packet source and destination.	• User settings for registering events. • Settings for forwarding events through a connector.
`$dst_address`	Address of the network packet destination (depending on the data available in the protocol, this can be an IP address, port number, MAC address and/or other address data).	• User settings for registering events.
`$extra.<paramName>`	Additional variable added using the `AddEventParam` function for an external system or Lua script.	• User settings for registering events.
`$rule_max_value`	Assigned maximum value in the Process Control rule.	• User settings for registering events.
`$rule_min_value`	Assigned minimum value in the Process Control rule.	• User settings for registering events.
`$monitoring_point`	Name of the monitoring point whose traffic invoked registration of the event.	• User settings for registering events. • Settings for forwarding events through a connector.
`$occurred`	Date and time of registration.	• User settings for registering events. • Settings for forwarding events through a connector. • Settings for forwarding application messages through a connector.

		• Settings for forwarding audit entries through a connector.
`$protocol`	Name of the application-layer protocol that was being monitored when the event was registered.	• User settings for registering events.
`$src_address`	Address of the network packet source (depending on the data available in the protocol, this can be an IP address, port number, MAC address and/or other address data).	• User settings for registering events.
`$tags`	List of all names and values of tags indicated in the Process Control rule.	• User settings for registering events.
`$technology_rule`	Name of the rule in the event.	• User settings for registering events. • Settings for forwarding events through a connector.
`$top_level_protocol`	Name of the top-level protocol.	• User settings for registering events.
`$type_id`	Code of the event type, application message, or audit entry.	• User settings for registering events (the `$event_type_id` variable may also be used). • Settings for forwarding events through a connector. • Settings for forwarding application messages through a connector. • Settings for forwarding audit entries through a connector.
`$rule_values`	List of values of the Process Control rule (authorized or unauthorized).	• User settings for registering events.
`$closed`	Date and time when the *Resolved* status was assigned or the date and time of the event regeneration period (for events that are not incidents), or the date and time of registration of the last event included in the incident (for incidents).	• Settings for forwarding events through a connector.
`$count`	Number of times an event or incident was triggered.	• Settings for forwarding events through a connector.
`$description`	Description	• Settings for forwarding events through a connector. • Settings for forwarding application messages through a connector. • Settings for forwarding audit entries through a connector.

`$id`	Unique ID of the registered event, application message, or audit entry.	• Settings for forwarding events through a connector. • Settings for forwarding application messages through a connector. • Settings for forwarding audit entries through a connector.
`$message_category`	Category of transmitted data (event, application message, or audit entry).	• Settings for forwarding events through a connector. • Settings for forwarding application messages through a connector. • Settings for forwarding audit entries through a connector.
`$message_count`	Number of transmitted events, application messages or audit entries.	• Settings for forwarding events through a connector. • Settings for forwarding application messages through a connector. • Settings for forwarding audit entries through a connector.
`$messages`	Template that consists of a block containing a list of data.	• Settings for forwarding events through a connector. • Settings for forwarding application messages through a connector. • Settings for forwarding audit entries through a connector.
`$node`	Node with the installed application component that sent the data.	• Settings for forwarding application messages through a connector. • Settings for forwarding audit entries through a connector.
`$result`	Operation result in the audit entry.	• Settings for forwarding audit entries through a connector.
`$severity`	Event severity level.	• Settings for forwarding events through a connector.
`$status`	Application message status.	• Settings for forwarding application messages

		through a connector.
`$system_process`	Application process that invoked message registration.	• Settings for forwarding application messages through a connector.
`$technology`	Technology associated with the event.	• Settings for forwarding events through a connector.
`$title`	Event title, message text, or registered action.	• Settings for forwarding events through a connector. • Settings for forwarding application messages through a connector. • Settings for forwarding audit entries through a connector.
`$user`	Name of the user that performed the registered action.	• Settings for forwarding audit entries through a connector.

Managing a security policy

A *security policy* is a set of data that defines the following operational settings of the application:

- Custom sets of Intrusion Detection rules
- Allow rules for Interaction Control and for events
- Settings of devices and tags that are used for Asset Management and Process Control
- Network map display settings
- Subnet settings
- Event types settings

All other application settings are not part of a security policy and are applied separately from it. This includes the settings of nodes that have components installed, the list of application users, objects linking events and devices in the devices table, and other settings.

A security policy is stored on the Server and is automatically updated each time application settings are modified (for example, when Interaction Control rules are added).

You can export a security policy to files and import them from files. You can also clear the current security policy on the Server to delete all previously saved settings.

When exporting, importing or clearing a security policy, you can select specific sections of the policy that you want to export, import, or clear. For example, you can export only devices and allow rules.

When exporting a security policy, the application creates a file containing information about the selected application settings. To import settings, you can select a previously exported file.

Changing the contents of a security policy file may result in a malfunction of Kaspersky Industrial CyberSecurity for Networks if you import a security policy from this modified file. The application may stop performing protection functions for the industrial network.

Exporting a security policy to a file

The settings that are part of a security policy can be exported to a file. You can export the entire security policy or its individual sections.

When necessary, you can then import the relevant application settings from the file containing the saved security policy.

To export the current security policy:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface.
2. Select **Settings** → **Security policy**.
3. Click the **Export** button.

   You will see the security policy tree in which you can select the necessary sections to export.
4. Select the check boxes for the relevant sections of the security policy.
5. Click the **Export** button.
6. If it takes a long time (more than 15 seconds) to create the file, the file creation operation is transferred to the list of background operations. In this case, to download the file:

   a. Click the button in the menu of the application web interface.

   The list of background operations appears.

   b. Wait for the file creation operation to finish.

   c. Click the **Download file** button.

Your browser will save the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

Importing a security policy from a file

You can import application settings from a file containing a saved security policy. For this kind of import, you can use a file that was obtained when exporting a security policy.

When importing security policy sections, the application first clears the current contents of these sections and then imports data into these sections.

If a file contains multiple sections of a security policy, you can select the relevant sections to import.

A security policy cannot be imported if updates are currently being installed or if another import process is running.

Only users with the Administrator role can import a security policy from a file.

To import a security policy from a file:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Security policy**.
3. Click the **Import** button.

   This opens the standard browser window for selecting a file.
4. Specify the path to the security policy file.
5. Click the button for opening the file.

   After the file contents are checked, you will see a security policy tree showing the sections that can be imported.
6. Select the check boxes for the security policy sections that you want to import into the application.
7. Click the **Import** button.

The security policy import process begins. The application Server is unavailable for connections until the import process is complete. During the import process, the application web interface page displays a special section named **Application maintenance**.

Clearing the current security policy

You can clear the current settings that are part of a security policy. This can be done for the entire security policy or for some of its individual sections.

After a security policy is cleared, it will be impossible to recover some of its data even if you exported the security policy in advance. For example, after you clear a section containing device information, all the objects linking events and devices in the devices table are permanently deleted.

A security policy cannot be cleared if updates are currently being installed or if the data import process is running.

Only users with the Administrator role can clear a security policy.

To clear a security policy:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. Select **Settings** → **Security policy**.

3. Click the **Clear** button.

   You will see the security policy tree in which you can select the relevant sections to clear.

4. Select the check boxes of the security policy sections that you want to clear.

5. Click the **Clear** button.

   The security policy clearing process begins. The Application Server is unavailable for connections until the clearing process is complete. During the clearing process, the application web interface page displays a special section named **Application maintenance**.

Converting a security policy from a previous version of the application

To convert and upload the security policy that was used in the previous version of Kaspersky Industrial CyberSecurity for Networks, you can upgrade the previous version of the application.

If you want to import a file containing a saved security policy from a previous version of the application into the current version of the application, you need to convert this file by using the policy_updater.py policy conversation script. This script is located on the Server computer in the /opt/kaspersky/kics4net/sbin/ folder.

The policy_updater.py script is designed for converting security policies exported to Kaspersky Industrial CyberSecurity for Networks version 3.0.

To convert a file containing a security policy that was created in the previous version of the application:

1. Open the operating system console on the Server computer and go to the /opt/kaspersky/kics4net/sbin/ folder.

2. Enter the following command in the command line:

   ```
   python3 ./policy_updater.py -i <path to the file of the original policy> -o <path to the file of the converted policy>
   ```

   Example:

   ```
   python3 ./policy_updater.py -i /home/user1/policy_2021-09-01_12-00 -o /home/user1/policy_for_3_1
   ```

   After the config_converter tool is finished, verify that the file containing the converted security policy is located in the specified folder.

The obtained file can be imported into the current version of the application.

Using the Kaspersky Industrial CyberSecurity for Networks API

Kaspersky Industrial CyberSecurity for Networks has an application programming interface (API) that provides access to application functions for external applications (hereinafter referred to as "recipient apps").

The Kaspersky Industrial CyberSecurity for Networks distribution kit includes a package containing descriptions of specifications for representing data in requests sent to the REST API server. The *REST API server* runs on the Kaspersky Industrial CyberSecurity for Networks Server computer and processes requests by using the architectural style of interaction known as REST (Representational State Transfer). Queries to the REST API server are sent over the HTTPS protocol. You can configure the REST API server settings under **Settings** → **Connection Servers** (including to replace the default self-signed certificate with a trusted certificate).

The JSON format is used to represent data in requests and responses.

The documentation containing descriptions of requests based on the REST architectural style is published as an Online Help Guide on the Kaspersky Online Help page. This documentation serves as the Developer's Guide. The Developer's Guide also provides sample code and detailed descriptions of called elements that are available in requests sent to the REST API server.

OPEN THE DOCUMENTATION DESCRIBING REQUESTS TO THE REST API SERVER

Recipient apps can use the Kaspersky Industrial CyberSecurity for Networks API to do the following:

- Receive data on devices known to the application.
- Add, modify, and delete devices.
- Receive data on registered events.
- Send events to Kaspersky Industrial CyberSecurity for Networks (the system event type with code 4000005400 is used for registering the events).
- Receive data on tags and tag parameters.
- Subscribe to notifications about received tag values.
- Receive data on detected vulnerabilities.
- Receive application messages and audit entries.
- Receive data on allow rules.
- Enable, disable, and delete allow rules.
- Receive the following application data:
  - List of monitoring points and their parameters
  - List of supported protocol stacks and their parameters
  - List of event types and their parameters
  - Current state and operating mode of technologies
  - Application version and release dates of the installed updates

- Information about an added license key
- Application localization language

Recipient apps that utilize the Kaspersky Industrial CyberSecurity for Networks API can connect to the Application Server through connectors. Connectors use certificates for a secure connection. For each recipient app that will send requests to the REST API server, you need to create a separate connector in Kaspersky Industrial CyberSecurity for Networks.

A recipient app must use an authentication token for a connection with Kaspersky Industrial CyberSecurity for Networks. The application issues an authentication token upon request by the recipient app, and for this token it uses certificates of the connector that was created for this recipient app. An authentication token is valid for 10 hours. The recipient app can renew the authentication token by special request.

Documentation containing a description of queries for authentication token operations is published as an Online Help Guide on the Kaspersky Online Help page. This documentation serves as the Developer's Guide.

OPEN THE DOCUMENTATION DESCRIBING QUERIES FOR AUTHENTICATION TOKEN OPERATIONS

The Kaspersky Industrial CyberSecurity for Networks API provides the following options for working with recipient apps:

- Interaction based on the REST architectural style
- Interaction over the WebSocket protocol

Recipient apps can use the WebSocket protocol for interaction in the Kaspersky Industrial CyberSecurity for Networks API to create subscriptions to modified values received by the application. For example, this method of interaction lets you subscribe to notifications about the received values of a specific tag.

Securing interactions when using the Kaspersky Industrial CyberSecurity for Networks API

Recipient apps obtain access to application functions by using the Kaspersky Industrial CyberSecurity for Networks API after establishing encrypted connections over the HTTPS protocol. Connections are secured by using certificates issued by the Kaspersky Industrial CyberSecurity for Networks Server. The Server issues certificates for the connectors that are used by recipient apps to connect to the Server.

A separate certificate must be created for each recipient app. A connection can be established through a connector only by using the specific certificate that was issued by the Server and saved in the communication data package for that connector. A connection cannot be established if a recipient app uses a certificate from a different connector or different Kaspersky Industrial CyberSecurity for Networks Server, or a certificate that is used for other connections (such as a sensor certificate).

After establishing an encrypted connection, the recipient app must request an *authentication token* for the connector that will be indicated by the recipient app in requests sent to the REST API server. Before issuing an authentication token, the Server verifies the current state of the application user account that was indicated when the connector was created. The Server will not issue an authentication token if the application user account has been deleted or blocked.

An authentication token is valid for a period of 10 hours after it was issued by the Server. If a token needs to be used for a longer period, the recipient app must request a time extension before the token expires.

For information on the requests and methods provided in the Kaspersky Industrial CyberSecurity for Networks Server API, please refer to the documentation for the Kaspersky Industrial CyberSecurity for Networks API.

When the Server receives requests from the recipient app during the validity period of the authentication token, the Server verifies the existence and current access rights of the application user account that was indicated when the connector was created. A method indicated in a request from a recipient app is not executed if the user account is not found (has been deleted from the application), or if the user account does not have sufficient rights to perform the operation (the user account role does not match the performed operation).

When processing requests from recipient apps, the application uses the audit log to store information about attempts to perform the following operations:

- Receive an authentication token.
- Extend the validity period for an authentication token.
- Add a device to the devices table.
- Edit device information.
- Delete a device.
- Query the audit log (when first reading audit entries through the connector after loading the web server).

Creating and using connectors for the Kaspersky Industrial CyberSecurity for Networks API

To enable a recipient app to interact with the application by using the Kaspersky Industrial CyberSecurity for Networks API, you need to add a connector for this app. When creating a connector, you must indicate the **Generic** system type for the connector.

When adding a connector and when creating a new communication data package for this connector, the Server generates a communication data package that you need to use for the connector to work.

A communication data package is an archive containing the following files:

- certificates.pfx – encrypted file containing the Server's public certificate key and the certificate issued by the Server for the connector (with the private key). The contents of the file are encrypted with the password that was set when the connector was added or when a new communication data package was created for this connector.
- metadata.json – contains the configuration data for the connector. Data is represented in JSON format.

The listed files must be used to connect a recipient app through the connector. To decrypt the certificates.pfx file and apply the certificate and keys within it, you can use the standard methods for handling files of this format (for example, `openssl` commands). The addresses indicated in the metadata.json file are required for the connector to work and for sending requests to the REST API server.

The certificate and configuration data in the communication data package are valid until a new communication data package is created or until the connector is removed from the application.

Subscribing to notifications about tag values over the WebSocket protocol

When using the Kaspersky Industrial CyberSecurity for Networks API, a recipient app can create a subscription to notifications regarding modified values of a specific tag. The WebSocket protocol is used for creating a subscription and receiving notifications.

A subscription for a recipient app consists of the following steps:

1. **The recipient app establishes a connection with the Kaspersky Industrial CyberSecurity for Networks Server through the connector for this application using the REST API server.**

   After successfully connecting to the Server, the connector receives an authentication token. The connector uses the authentication token for all subsequent interactions with the Server in this session (specifically, for requesting its configuration from the Server).

2. **The recipient app uses WebSocket to connect and sends a request to create a subscription to notifications regarding the received values of a relevant tag.**

   The Kaspersky Industrial CyberSecurity for Networks Server receives the request and creates the subscription. A request is sent by using the appropriate functions provided by the WebSocket protocol.

3. **Kaspersky Industrial CyberSecurity for Networks detects a new tag value in traffic when reading or writing a tag.**

4. **Kaspersky Industrial CyberSecurity for Networks sends the obtained tag value to the recipient app that has an active subscription to notifications regarding the values of this tag.**

Main features of a subscription:

- After the recipient app indicates the relevant tags of Kaspersky Industrial CyberSecurity for Networks, the Server sends confirmation regarding the capability to obtain the values of those tags. The recipient app then waits to receive the values of those tags over the established connection.
- Creation and maintenance of a subscription relies on the WebSocket protocol and a connection at the same address that is used by the REST API server.
- A Kaspersky Industrial CyberSecurity for Networks Server supports no more than one active subscription for tag values. If an active subscription was already created and is being used, and you attempt to create another subscription, you will see an error regarding an excessive number of connections.
- The recipient app has the capability to close an established connection for a subscription at any time to stop receiving tag values.
- A subscription is stopped if it is intentionally closed by the recipient app or if the connection is disrupted. If the Kaspersky Industrial CyberSecurity for Networks Server was temporarily unavailable (disconnected) and tag values were not forwarded for the subscription, the recipient app must re-subscribe to the tag values after the connection is restored.

Connecting with WebSocket

To receive tags by subscription, you can use the standard functions of WebSocket as well as the SignalR Core library. Packages for working with the SignalR Core library are available for the most common programming languages: C++, C#, Java, Python, Go, and JavaScript/TypeScript.

To connect using WebSocket, you need to specify the following address:
`<publicApi address from the communication data package>/kics4net/api/ /v3/tag-values`

However, the protocol indicated in the address string depends on the functionality utilized for the connection.

If the SignalR Core library is being used, the address string begins with `https://`. For example:
`https://kics-server:8080/kics4net/api/ /v3/tag-values`

If the standard functions of WebSocket are being used, you need to replace `https` with `wss` in the address string. For example:
`wss://kics-server:8080/kics4net/api/v3/tag-values`

If an authentication token is not provided when connecting (or the provided token has not passed verification), the server returns code 401 when responding to a request to open the connection.

Creating a subscription for tag values

To create a subscription, you must make a request with the `GetTagValuesStream` method name.

Example request argument:

```
{
 "tagIdentifiers": [
 { "tagName": "Asdu_1_object_1001", "assetName": "Asset 079" },
 { "tagName": "Asdu_1_object_1003", "assetName": "Asset 079" }
 ],
 "streamConfig": {
 "samplingRateHz": 1
 }
}
```

A request argument consists of the following fields:

- `tagIdentifiers` – array of IDs of tags whose values need to be received for the subscription.
- `assetName`, `tagName` – values representing the device name and tag name (used to identify the tag whose values are needed for the subscription).
- `samplingRateHz` – tag value sampling rate (used to reduce the volume of transmitted data). If a null value is defined for the field, sampling is not performed.

If a subscription creation argument does not satisfy the requirements of the fields, an error is returned with a description of the problem.

Example error for a subscription creation argument:

```
HubException: GetTagValuesStreamRequest has validation errors:

TagIdentifiers:

The TagName field is required.

The StreamConfig field is required.
```

Confirming a subscription

When confirming a subscription, the server returns a confirmation result for each tag that matches a `tagIdentifiers` value in the request.

Example subscription confirmation:

```
{
 "confirmation": {
 "result": "ok",
 "tagIdentifier": { "tagName": "Asdu_1_object_1001", "assetName": "Asset 079" },
 "tagId": 102
 }
}
```

A response containing a subscription confirmation consists of the following fields:

- `result` – status of the tag value subscription. Possible values:
  - `ok` – subscription was successfully created.
  - `notFound` – a tag with the specified `assetName` or `tagName` was not found.
- `tagIdentifier` – tag ID equivalent to one value from the `tagIdentifiers` array of arguments of a subscription creation request.
- `tagId` – unique ID of a tag in the application. This can be used to receive information about a tag through the Kaspersky Industrial CyberSecurity for Networks API, or to identify a tag in a response containing its values.

Tag values by subscription

The application sends tag values by subscription within a fields structure. The following fields are presented at the top level of the structure:

```
{
 "value": {
 "tagId": <unique ID of the tag in the application>,
 "tagValue": "<JSON object with tag data>"
 }
}
```

Information about a new value of a tag is sent to the recipient app in JSON format. The sent data object contains the following fields:

- `n` – tag data type represented by the name from `TagStructure`.
- `ts` – time when the last update of tag values was registered. Indicated in microseconds starting on 01/01/1970.
- `dn` – transfer direction. Possible values: `r`, `w`, `rw`.
- `mp` – monitoring point ID.
- `d` – contents of tag fields.

The `d` attribute represents a dictionary in which each key is the name of a null-hierarchy tag field. Each field value has the following attributes:

- `t` – mandatory attribute indicating one of the following data types:
  - `u` – UINT64.
  - `i` – INT64.
  - `b` – BOOL.

- `d` – DOUBLE.
- `s` – UTF8 string.
- `t` – time in microseconds starting on 01/01/1970.
- `e` – ENUM. The field additionally contains the following attributes:
  - `n` – name of the ENUM type.
  - v – original value of ENUM.
  - s – string value of ENUM.
- `st` – structure.
- `un` – UNION.

- `v` – mandatory attribute indicating the tag field value.
- `n` – name of the ENUM type from `TagStructure` (only for the `e` type – ENUM).
- `s` – string value of ENUM (only for the `e` type – ENUM).

  Example:

```
- enum:
name: OpType # Name of ENUM type ('n' attribute)
data:
0: NUL # 0 is written to the 'v' attribute, NUL is written to the 's' attribute
1: PULSE_ON
2: PULSE_OFF
```

- `x` – identifies the main value of the tag.

  Format: `"x": 1`

  The `x` attribute is absent from all other fields of the tag.

- m – special marker of the tag parameter. This corresponds to the marker attribute with the following fields:
  - `q` – value of the quality attribute.
  - `ts` – timestamp status displaying its accuracy, temporary state, or reason for an error during verification.
  - `ds` – data status.
  - `o` – origin of the value or command.
  - `t` – time when the tag values were last updated (taken from traffic).
  - `ct` – cause of transmission.

  Format: `"m": "q"`

Example of a forwarded tag value in JSON format:

```
{
 "n": "TagStructure1",
 "ts": 18446744073709551616,
 "dn": "r",
 "mp": 1,
 "d":
 {
 "value":
 {
 "t": "d",
 "v": 3.1415,
 "x": 1
 },
 "quality":
 {
 "t": "s",
 "v": "good",
 "m": "q"
 },
 "mask":
 {
 "t": "u",
 "v": 18446744073709551616
 },
 "enumfield":
 {
 "t": "e",
 "n": "SwitchState",
 "v": 0,
 "s": "Off"
 },
 "strucfield":
 {
 "t": "st",
 "v":
 {
 "v1":
 {
 "t": "d",
 "v": 3.1415
 },
 "q2":
 {
 "t": "s",
 "v": "good",
 "m": "q"
 }
 }
 },
 "unionfield":
 {
 "t": "un",
 "v":
 {
 "_":
 {
 "t": "u",
 "v": 42
 },
 "low4bits":
 {
 "t": "u",
 "v": 10
 },
 "high4bits":
 {
 "t": "u",
 "v": 2
 }
 }
 }
 }
}
```

Examples of receiving tag values by subscription

Below is an example of receiving tag values by subscription using standard WebSocket functions in Python.

You must first run the following command:
`pip install websocket_client`

Example subscription using standard WebSocket functions:

```
import json, ssl, websocket

def on_message(ws, message):
 print(message)

def on_error(ws, error):
 print(f' error: {error}')

def on_close(ws):
 print("### closed ###")
```

```
def on_open(ws):
 print("connection opened and handshake received ready to send messages")

 # all sent messages must end with this character
 message_separator = chr(30)

 # setting up json as messages format
 protocol_selection_args = {
 'protocol': 'json',
 'version': 1
 }
 ws.send(json.dumps(protocol_selection_args) + message_separator)

 # creating subscription
 args = {
 'arguments': [
 {
 'tagIdentifiers': [
 {
 'tagName': 'tag_01',
 'assetName': 'asset_02'
 }
 ],
 'streamConfig': {
 'samplingRateHz': 5
 }
 }
 ],
 'invocationId': '0', # will be included in response message
 'target': 'getTagValuesStream',
 'type': 4 # must be equal to 4 for outgoing messages
 }

 ws.send(json.dumps(args) + message_separator)

def login():
 token = "you should get access token for API here"
 return token

if __name__ == "__main__":
 server_url = "wss://localhost:8091/kics4net/api/tag-values"
 auth = "Authorization: Bearer " + login()

 # for troubleshooting uncomment next line
 # websocket.enableTrace(True)
 ws = websocket.WebSocketApp(server_url,
 on_message=on_message,
 on_error=on_error,
 on_close=on_close,
 header=[auth])

 print(f'opening connection to {server_url}')
 ws.on_open = on_open
 ws.run_forever(
 # use it only if Server has self-signed certificate
 sslopt={"cert_reqs": ssl.CERT_NONE}
 )
```

Below is an example of receiving tag values by subscription using the SignalR Core library in Python.

You must first run the following command:
`pip install signalrcore`

Example subscription using the SignalR Core library:

```
import logging
from signalrcore.hub_connection_builder import HubConnectionBuilder

TOKEN = 'you should get access token for API here'
IP = '192.168.0.7'
PORT = '8080'
HUB = 'kics4net/api/v3/tag-values'

class WebsocketConnection(HubConnectionBuilder):
 def __init__(self, url: str = None, options: dict = None, verify_ssl: bool = False):
 super().__init__()
 self.with_url(url, options=options)
 self.configure_logging(logging.WARNING)
 self.with_automatic_reconnect({
 "type": "raw",
 "keep_alive_interval": 10,
 "reconnect_interval": 5,
 "max_attempts": 5
 })
 self.verify_ssl = verify_ssl

 def on_tag_stream_value(self, m):
 result.append(m)
 print(f'on_new_tag_value, {m}')

 def on_tag_strean_error(self, e):
 print(f'onError, {e}')

 def on_tag_stream_complete(self, q):
 print(f'onComplete, {q}')

 def subscribe_tags(self):
 print("connection opened and handshake received ready to send messages")

 args = {
 'tagIdentifiers': [
```

```
  {
  'tagName': 'tag_01',
  'assetName': 'asset_02'}
  ],
  'streamConfig': {
  'samplingRateHz': 5
  }
  }

  self.stream("GetTagValuesStream", [args]) \
  .subscribe({
  "next": self.on_tag_stream_value,
  "complete": self.on_tag_stream_complete,
  "error": self.on_tag_strean_error
  })

def main():
  server_url = "https://{}:{}/{}".format(IP, PORT, HUB)
  login = 'bearer {}'.format(TOKEN)

  conn = WebsocketConnection(url=server_url, options={"headers": {"authorization": login}})
  conn.build()

  logging.info(f'opening connection to {server_url}')
  conn.on_open(conn.subscribe_tags)
  conn.start()

  logging.info('closing connection')
  conn.stop()

if __name__ == '__main__':
  main()
```

Performing common tasks

This section contains a description of the common user tasks and instructions on how to perform them.

System monitoring in online mode

Kaspersky Industrial CyberSecurity for Networks displays data for monitoring the current state of the system in the **Dashboard** section of the application web interface. Data is automatically updated in online mode.

Data in the **Dashboard** section is presented as individual blocks called *widgets*. Depending on its purpose, a widget may contain an updatable value or message about the current state of the application, or provide expanded information about up-to-date data.

The **Dashboard** section may display the following widgets:

- Widgets containing information about the application and about the hardware resources of the Server and sensors:
  - **Traffic** – rate of incoming traffic. This widget can display data on all monitoring points of all nodes that have application components installed, data on monitoring points of the selected node, or data on one individual monitoring point.
  - **Processor** – processor utilization on the selected node that has an application component installed.
  - **RAM** – amount of physical RAM being used on the selected node that has an application component installed.
  - **Performance** – information about the current state of application performance. This widget can display the following values:
    - **OK** – there are no messages regarding performance issues, or all performance issues have been resolved.
    - **Non-critical malfunction** – there are messages regarding non-critical malfunctions (this is displayed until the performance issue is resolved).
    - **Operation disrupted** – there are messages regarding application performance issues (this is displayed until the performance issue is resolved).
    - **Maintenance mode** – the application is running in maintenance mode.
- **Tags** – rate of processing of tags detected by the application. This widget can display data on all monitoring points of all nodes that have application components installed, data on monitoring points of the selected node, or data on one individual monitoring point.
- **Storage** – information about the drive in the local file system on the selected node with the application component installed. On this widget, you can select the following data to be displayed:
  - **Disk usage** – percentage of time taken to process data read/write operations.
  - **Occupied on disk** – volume of occupied disk space.
  - **Read from disk** – rate of reading data from the disk.

- **Write to disk** – rate of writing data to the disk.

- **Traffic processing latency** – current delay in traffic processing from the time it arrives at a monitoring point of the node (displays the maximum delay time received from all enabled monitoring points). This widget can display data on all monitoring points of all nodes that have application components installed, or data on monitoring points of the selected node.

- **Function status** – general information about the current state of protection functions in the application. This widget can display the following values:

  - **All are enabled** – all technologies and methods designed for continual use are enabled, and all created monitoring points are enabled.

  - **Not all are enabled** – some protection functions are disabled or are enabled in learning mode, or not all monitoring points are enabled.

- **Uptime** – operating time of Kaspersky Industrial CyberSecurity for Networks. On this widget, you can select the following data to be displayed:

  - **Effective uptime** – duration of normal operation of the application (without malfunctions) since the most recent startup until the current moment.

  - **Total uptime** – operating time since the first startup of the application until the current time (includes periods of normal operation and periods when the application was running with malfunctions).

  - **Since first start of application** – total time that has elapsed since the first startup of the application until the current time (includes periods of normal operation, periods when the application was running with malfunctions, and periods when the application was not operational).

- Widgets containing information for monitoring the most significant changes in the system:

  - **Devices** – contains information about devices in the industrial network (arranged by device category).

  - **Events** – contains information about the events and incidents that have the most recent values for the date and time of last occurrence.

- **EPP application availability** – quantitative ratio of devices protected by EPP applications to devices not protected by EPP applications. The center of the pie chart displays the total number of protected and unprotected devices.

  A device is considered to be protected by an EPP application if Kaspersky Industrial CyberSecurity for Networks has information regarding fulfillment of the following conditions:

  - An EPP application is installed on the device.

  - The Real-Time Protection task is being performed for the EPP application.

  - The EPP application has an *Active* connection to the integration server.

  A device is considered to be protected by an EPP application if at least one of the listed conditions is not fulfilled. The EPP application protection check is performed for all devices in Kaspersky Industrial CyberSecurity for Networks containing the name of a Windows operating system (any version) as the installed operating system.

- Widgets without dynamically updated information. You can create widgets with user-defined contents. These widgets are called *custom* widgets. For example, you can use custom widgets to logically separate groups of widgets in the **Dashboard** section.

Widgets provide various ways to get your attention depending on incoming data. For example, widgets containing information about the application and hardware resources can automatically change color if the information requires attention (for instance, when the load on a hardware resource is nearing critical load).

Widgets display only the main information, which is dynamically updated. If you need to view more detailed information (for example, about devices with issues), you can proceed from the **Dashboard** section to other sections of the application web interface. You can switch between sections by using your mouse to select interface elements of widgets.

Adding a widget

To add a widget:

1. In the **Dashboard** section, click the **Widgets** button.

   The **Add widgets** window opens.

2. Add the necessary widget by clicking the **Add** link on the right of the widget name.

   The new widget will occupy the free space in the widget display area.

3. Click the **Close** button in the **Add widgets** window.

After adding a widget, you can configure how the widget is displayed.

Configuring how widgets are displayed

You can use the following functions to configure how widgets are displayed:

- **Moving a widget**

  1. In the **Dashboard** section, move your cursor over the upper part of the relevant widget (for example, over the widget name).

     The cursor will change to  .

  2. Drag the widget to the appropriate part of the widget display area.

- **Changing the size of a widget**

  1. In the **Dashboard** section, move your cursor over the lower-right corner of the relevant widget.
  2. Click and hold the left mouse button to set the size for the widget border.

- **Changing the settings for displaying data in a widget**

After a widget is added, the default settings are used to display data in the widget. You can change the display settings if necessary (for example, to indicate the relevant source or to select other data to display in the **Storage** widget).

To configure the widget display settings:

1. In the **Dashboard** section, use the ⚙ button in the upper-right corner of the widget to open the widget management window.
2. In the widget management menu, select the **Configure** option.

   This opens the window for configuring the display settings.
3. Configure the widget settings.

   Depending on the selected widget, the window may contain the following settings:

   - **Change name** – if the **Change name** check box is selected, you can define any name for the widget (different from the default name) in the **Widget name** field. The **Change name** setting is absent from custom widgets.
   - **Widget name** – field for entering a widget name different from the default name.
   - **Edit description** – if the **Edit description** check box is selected, you can provide any description for the widget (different from the default description) in the **Widget description** field. The **Edit description** setting is absent from custom widgets.
   - **Widget description** – field for entering a widget name different from the default name.
   - **Refresh period** – defines how frequently the displayed data is refreshed (time interval in seconds).
   - **Display** – defines the type of displayed data (for widgets that let you select which data to display).
   - **Data source** – defines the node with installed application components whose data is displayed in the widget. If the **Entire application** option is selected, the widget displays data from all nodes.
   - **Monitoring point** – defines the monitoring point of the selected node for displaying data. If the **All monitoring points** option is selected, the widget displays data for all monitoring points of the selected node.
   - **Change color based on state** – if this check box is selected, the background color of the widget automatically changes depending on the severity of the incoming data. A red background signifies critical (maximum) severity of data. If this check box is cleared, background coloring is disabled.
   - **Defined background** – defines the color of the background on the custom widget. You can choose a background color that corresponds to one of the severity levels (**Info**, **Warning**, **Critical**), or use the **Neutral** option to disable background coloring.
4. Click **OK**.

Information in the Devices widget

The **Devices** widget in the **Dashboard** section displays information about devices that are included in the list of known devices.

The widget provides the following information:

- Data on the number of devices known to the application in each category. This data is displayed as category icons in the upper part of the widget. The number of devices of the specific category is indicated under the icon of each category. If the list of devices contains devices with issues, the warning icon is displayed on the category icons of these devices.
- List of categories with devices with issues. This data is displayed in the middle part of the widget if such devices are present. The space used for displaying graphical elements is limited by the size of the widget.

Devices with issues

The application determines that a device requires attention in any of the following cases:

- The device has the *Authorized* status and a security state other than *OK*.
- The device has the *Unauthorized* status.

If there are devices with issues, the following information is displayed for each category in the list:

- Line containing the category icon, text comment, and link containing the number of devices with issues.
- Line containing the graphical elements representing the devices. This line is displayed if there is sufficient free space in the widget. The number of graphical elements in the line depends on the current size of the browser window. If there are more devices with issues than the number of graphical elements displayed in the line, the number of hidden devices is displayed on the right in the format `+<number of devices>`.

Graphical elements of devices

Graphical elements representing devices contain the following information:

- Device name.
- Device status. This is displayed as an icon if the device has the *Unauthorized* status.
- Device security state. This is displayed as a colored line on the left border of the graphical element. The color of the line corresponds to the *OK*, *Warning* or *Critical* states.

The graphical elements are displayed in the following order:

1. Devices assigned the *Unauthorized* status.
2. Devices with the *Critical* security state.
3. Devices with the *Warning* security state.

Navigating to other sections from the **Devices** widget

You can use elements of the **Devices** widget interface to navigate to the devices table and display detailed information about devices. To do so, you can utilize the following options:

- Go to the devices table and filter the table

To go to the devices table and view information about all devices in the selected category:

In the upper part of the **Devices** widget, click the icon of the relevant category.

This opens the **Devices** section containing the devices table. The table will be filtered based on the selected category of devices.

To proceed to the devices table and view information about devices that require attention and belong to a specific category:

In the list of categories containing devices with issues, click the link containing the number of devices of the relevant category (this link is displayed at the end of the line containing the category icon and text comment **with issues**).

This opens the **Devices** section containing the devices table. The table will be filtered based on the IDs of devices that require attention and belong to the specific category.

The devices table is filtered based on the IDs of those devices that were displayed in the **Devices** widget when you proceeded to the devices table. After you switch to the devices table, the filter settings are not updated. If you want to view the current number of devices with issues, you can go to the **Dashboard** section again.

To go to the devices table and view information about a device with issues:

In the **Devices** widget, click the graphical element that represents the relevant device.

This opens the **Devices** section containing the devices table. The table will be filtered based on the device ID.

To go to the devices table without changing the current table filter settings:

Click the **Show all devices** link in the **Devices** widget.

This opens the **Devices** section containing the devices table. The table will display the devices that satisfy the filter settings that were previously defined in the devices table.

- Go to the devices table and search the table

1. In the **Devices** widget, enter your search query into the **Device search** field.
2. Click the **Search** button.

   This opens the **Devices** section containing the devices table. The table will display the devices that meet the search criteria.

Information in the Events widget

The **Events** widget in the **Dashboard** section displays general information about the events and incidents that have the most recent values for the date and time of last occurrence.

The widget displays the following elements:

- Histogram of events and incidents for the selected period. This data is displayed in the upper part of the widget. The histogram shows the distribution of events and incidents based on their severity levels.
- List containing information about registered events and incidents sorted by date and time of last occurrence. This data is displayed in the middle part of the widget.

Statistics of events and incidents

On the histogram showing the distribution of events and incidents, the columns correspond to the total number of events for each time interval. Within columns, the severity of events and incidents are distinguished by color. The following colors correspond to severity levels:

- Blue. This color is used for events and incidents with the *Informational* severity level.
- Yellow. This color is used for events and incidents with the *Warning* severity level.
- Red. This color is used for events and incidents with the *Critical* severity level.

To display information about a column of the histogram, move the mouse cursor over it. A pop-up window shows the date and time of the interval as well as the number of events and incidents by severity level.

The duration of time intervals depends on the selected display period. The following periods are available for building a histogram:

- 1 hour. This period is divided into one-minute intervals.
- 12 hours, 24 hours. These periods are divided into one-hour intervals.
- 7 days. This period is divided into one-day intervals.

Selecting a period for displaying a histogram

You can select the relevant period for generating a histogram in the **Events** widget by using the following buttons:

- **1h**.
- **12h**.
- **24h**.
- **7d**.

List of events and incidents

The list of events and incidents in the **Events** widget is updated in online mode. Events and incidents with the most recent values for the date and time of last occurrence are placed at the beginning of the list.

The number of displayed elements in the list of events and incidents is limited by the size of the widget.

The following information is provided for each event or incident in the list:

- Title of the event or incident.
- Date and time of last occurrence.
- Icon designating the severity level of an event or incident: *Informational*, *Warning*, or *Critical*.

Incidents in the list are marked with the icon.

Navigating to other sections from the **Events** widget

You can use elements of the **Events** widget interface to go to the events table and display detailed information about events and incidents. To do so, you can utilize the following options:

- Go to the events table and filter the table

  You can view detailed information about an event or incident by clicking the relevant event or incident in the **Events** widget list. Doing so will open the **Events** section in which the table will be filtered based on the ID of the selected event or incident. The period ranging from the date and time of registration of the event or incident to the current moment (without indicating an end boundary for the period) will also be defined for the filter.

  If you want to proceed to the events table without changing the current table filter settings in the **Events** section, click the **Show all events** link in the **Events** widget.

- Go to the events table and search the table

  1. In the **Events** widget, enter your search query into the **Event search** field.
  2. Click the **Search** button.

     The **Events** section opens. The events table displays the events and incidents that meet the search criteria.

Removing a widget

To remove a widget:

1. In the **Dashboard** section, use the button in the upper-right corner of the widget to open the widget management window.
2. In the widget management menu, select the **Remove** option.

   A window with a confirmation prompt opens.
3. In the prompt window, confirm removal of the selected widget.

Asset Management

Kaspersky Industrial CyberSecurity for Networks lets you monitor industrial network devices that are considered to be company assets. To manage these assets, you can view the devices table in the **Assets** section of the Kaspersky Industrial CyberSecurity for Networks web interface. You can also view information about the interactions between devices and perform various actions with devices when working with the network map.

Devices table

A devices table is created for the purpose of asset management in the application. All devices in the table are considered to be known to the application.

The devices table has the following limitations on the number of elements:

- The total number of devices with the *Authorized* and *Unauthorized* statuses can be no more than 100 thousand.

  If the maximum number of devices with the *Authorized* or *Unauthorized* statuses is reached, new devices with these statuses are not added to the table. If this is the case, to add a new device to the table you need to remove one of the previously added devices.

- The number of devices with the *Archived* status can be no more than 100 thousand.

  If the maximum number of devices with the *Archived* status is reached, new devices with this status are added to the table in place of devices that have went the longest without showing any activity.

When the devices table is overfilled, the application displays the appropriate message.

The devices table contains the following information:

- **Name** – name used to represent a device in the application.
- **Device ID** – device ID assigned in Kaspersky Industrial CyberSecurity for Networks.
- **Status** – asset status that determines whether activity of the device is allowed in the industrial network. A device can have one of the following statuses:
  - *Authorized*. This status is assigned to a device for which activity is allowed in the industrial network.
  - *Unauthorized*. This status is assigned to a device for which activity is not allowed in the industrial network.
  - *Archived*. This status is assigned to a device if it is no longer being used or must not be used in the industrial network, or if the device has shown no activity and the device information has not changed in a long time (30 days or more).
- **Address information** – MAC- and/or IP addresses of the device. If a device has multiple network interfaces, you can specify the MAC- and/or IP addresses for the network interfaces of the device. Up to 64 network interfaces can be assigned for a device.
- **Category** – name of the category that determines the functional purpose of the device. Kaspersky Industrial CyberSecurity for Networks supports the following categories of devices:
  - **PLC** – programmable logic controllers.

- **IED** – intelligent electronic devices.
- **HMI / SCADA** – computers with installed software for human-machine interface (HMI) systems or SCADA systems.
- **Engineering workstation** – computers with installed software to be used by ICS engineers.
- **Server** – devices with server software installed.
- **Network device** – network equipment (for example, routers, switches).
- **Workstation** – desktop personal computers or operator workstations.
- **Mobile device** – portable electronic devices with computer functionality.
- **Laptop** – portable PCs.
- **HMI panel** – devices that use a human-machine interface to manage individual devices or operations of the industrial process.
- **Printer** – printing devices.
- **UPS** – uninterruptible power supply units connected to a computer network.
- **Network camera** – devices that perform video surveillance functions and transmit digital images.
- **Gateway** – devices that connect networks by converting various interfaces (for example, Serial/Ethernet) within networks that use a different data transfer medium and different protocols.
- **Storage system** – devices used for storing information in storage systems.
- **Firewall** – devices that perform firewall functions to inspect and block unwanted traffic.
- **Switch** – devices used for a physical connection between LAN nodes.
- **Virtual switch** – devices that logically merge physical switches, or software-implemented switches for virtualization systems.
- **Router** – devices that redirect network packets between segments of a computer network.
- **Virtual router** – devices that logically merge physical routers, or routers that utilize multiple independent routing tables.
- **Wi-Fi** – access points that provide a wireless connection for devices from Wi-Fi networks.
- **Historian server** – archived data servers.
- **Other** – devices that do not fall into the categories described above.

- **Group** – name of the group containing the device in the device group tree (contains the name of the group and the names of all its parent groups).
- **Security state** – device security state determined by the presence of events linked to the device and current vulnerabilities. The following security states are available:

- *Critical*. The device has unprocessed events with *Critical* severity or current vulnerabilities with *High* severity.
- *Warning*. The device has unprocessed events with *Warning* severity or current vulnerabilities with *Medium* severity (but there are no unprocessed events with *Critical* severity or current vulnerabilities with *High* severity).
- *OK*. All events linked to the device have been processed or have *Informational* severity. In addition, all vulnerabilities associated with the device have been switched to *Remediated* or *Accepted* state or have *Low* severity.

- **Last seen** – date and time when the last activity of the device was registered.
- **Last modified** – date and time when information about the device was last modified.
- **Created** – date and time when the device was added to the devices table.
- **OS** – name of the operating system installed on the device.
- **Network name** – name used to represent the device in the network.
- **Hardware vendor** – name of the device hardware vendor.
- **Hardware model** – name of the device model.
- **Hardware version** – device hardware version number.
- **Software name** – name of the device software.
- **Software vendor** – name of the device software vendor.
- **Software version** – device software version number.
- **Labels** – list of labels assigned to a device.
- **Vulnerabilities** – CVE IDs of vulnerabilities associated with the device (vulnerabilities detected based on device information).
- **Process Control settings** – indicator of whether there are Process Control settings defined for the device.
- **EPP application** – concise name of the EPP application installed on the device (if data from this application was received in Kaspersky Industrial CyberSecurity for Networks).
- **EPP connection** – status of the connection between the integration server and the EPP application installed on the device. The following statuses are available:
  - *Active*. Less than 24 hours have passed since the last connection between the program and the integration server.
  - *Inactive*. More than 24 hours have passed since the last connection between the program and the integration server.
  - *N/A*. The status of the connection is unknown.
- **Last connection to EPP** – date of the last connection between the integration server and the EPP application installed on the device.

Viewing the devices table

The devices table is displayed in the **Assets** section on the **Devices** tab of the application web interface. The devices table presents the main information about devices that are known to the application.

When viewing the devices table, you can use the following functions:

- Configure the display and order of columns in the devices table

  You can configure the following settings for displaying the devices table:

  - Display the CVE IDs of vulnerabilities depending on the state of vulnerabilities.
  - Contents and order of columns displayed in the table.

  To configure the device table display settings:

  1. On the **Devices** tab in the **Assets** section, click the **Customize table** link to open the window for configuring how the table is displayed.
  2. If you want to enable display of the CVE IDs of all detected vulnerabilities (regardless of the current state of the vulnerabilities), select the **Show remediated and accepted vulnerabilities** check box.

     If the check box is cleared, the table displays only vulnerabilities in *Active* state.
  3. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.
  4. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

  The selected columns will be displayed in the devices table in the order you specified.

- Filtering based on table columns

*To filter devices by the **Status**, **Category**, **Security state**, **Process Control settings**, **EPP application**, or **EPP connection** column:*

1. On the **Devices** tab in the **Assets** section, click the filtering icon in the relevant column of the table.

   When filtering by device security states, you can also use the corresponding buttons in the toolbar.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events. You can clear or remove all check boxes by clicking the link that is displayed in the upper part of the filter window.

3. Click **OK**.

*To filter devices by the **Device ID**, **OS**, **Hardware vendor**, **Hardware model**, **Hardware version**, **Software name**, **Software vendor**, **Software version** or **Network name** column:*

1. On the **Devices** tab in the **Assets** section, click the filtering icon in the relevant column of the table.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values for devices that you want to include in the filter and/or exclude from the filter.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the selected column click the **Add condition** button and enter the condition in the opened field.

4. If you want to delete one of the created filter conditions, in the filter window of the selected column click the icon.

5. Click **OK**.

*To filter devices by the **Address information** column:*

1. On the **Devices** tab in the **Assets** section, click the filtering icon in the **Address information** column.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, in the drop-down lists, select the types of addresses for devices that you want to include in the filter and/or exclude from the filter. You can select the following types of addresses:

   - **IP address**
   - **MAC address**
   - **Complex** – if you want to specify multiple addresses of different types combined by the logical operator AND. To add different types of addresses, use the **Add condition (AND)** button.

3. If you want to apply multiple filter conditions by address type combined with the logical operator OR, in the filter window click the **Add condition (OR)** button and select the relevant types of addresses.

4. If you want to delete one of the created filter conditions, in the filter window click the icon located on the right of the field containing the drop-down list.

5. Click **OK**.

*To filter devices by the **Group** column:*

1. On the **Devices** tab in the **Assets** section, click the filtering icon in the **Group** column.

   The filtering window opens.

2. Click the icon in the right part of the field for indicating the group.

   The **Select group in tree** window appears.

3. In the device group tree, select the relevant group and click the **Select** button.

   The path to the selected group will appear in the field in the filter window.

4. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window click the **Add condition (OR)** button and specify a different group in the opened field.

5. If you want to delete one of the created filter conditions, in the filter window click the icon.

   You can also disable filtering in a column by clicking the **Default filter** link that is displayed in the upper part of the filter window.

6. Click **OK**.

*To filter devices by the **Last seen**, **Last modified** or **Created** column:*

1. On the **Devices** tab in the **Assets** section, click the filtering icon in the relevant column of the table.

   The calendar opens.

2. In the calendar, specify the date and time for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YY hh:mm:ss.

3. Click **OK**.

*To filter devices by the **Labels** column:*

1. On the **Devices** tab in the **Assets** section, click the filtering icon in the **Labels** column.

   The filtering window opens.

2. Enter one or multiple labels combined with the logical operator AND.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window click the **Add condition (OR)** button and enter the relevant labels (multiple labels in this condition will also be combined by the logical operator AND).

4. If you want to delete unnecessary labels in the filter window, you can do the following:

   - Use the × icon next to the names of labels to delete the unnecessary labels.
   - Delete one of the created filter conditions by using the icon located on the right of the field.

   You can also disable filtering in a column by clicking the **Default filter** link that is displayed in the upper part of the filter window.

5. Click **OK**.

*To filter devices by the **Vulnerabilities** column:*

1. On the **Devices** tab in the **Assets** section, click the filtering icon in the **Vulnerabilities** column.

The filtering window opens.

2. If you want to define the settings for filtering devices with vulnerabilities, leave the **Exclude devices with vulnerabilities** toggle in the *Disabled* position and configure the settings by using the following management elements:

   - **CVE** – lets you enter the CVE ID for displaying devices with this vulnerability.
   - **CVSS score** – lets you define a range of values of CVSS scores for displaying devices with vulnerabilities whose score is within the specified range.
   - **State** – groups buttons for enabling and disabling filtering based on the states of vulnerabilities (the buttons are displayed if the **Show remediated and accepted vulnerabilities** check box is selected in the devices table display settings).

3. If you want to display only devices that have no vulnerabilities, switch the **Exclude devices with vulnerabilities** toggle to *Enabled*.

4. Click **OK**.

- Device search

  You can find relevant devices by using the **Device search** field on the **Devices** in the **Assets** section.

  A search is performed in all columns except the following columns: **Device IDs**, **Status**, **Category**, **Security state**, **Last seen**, **Last modified**, **Created**, **Process Control settings**, **EPP connection**, and **Last connection to EPP**. The search is also performed in the values of custom fields for devices.

- Resetting the defined filter and search settings

  You can reset the defined filter and search settings in the device table by using the **Default filter** button in the toolbar on the **Devices** tab in the **Assets** section. The button is displayed if search or filter settings are defined.

- Sorting devices

1. On the **Devices** tab in the **Assets** section, click the header of the column by which you want to sort.
2. When sorting devices by the **Address information** column, in the drop-down list of the column header select the setting by which you want to sort devices.

   Depending on the values selected for display in the **Address information** column, you can select one of the following options:

   - **IP address**
   - **MAC address**
3. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

- Updating the devices table

Device information could be changed on the Server while you are viewing the devices table (for example, it could be changed by another user who is connected to the Server).

To keep the devices table up to date, you can enable automatic update of the table.

To enable or disable automatic update of the devices table:

In the toolbar on the **Devices** tab in the **Assets** section, use the **Autoupdate** toggle button.

Viewing subnets for asset management

Kaspersky Industrial CyberSecurity for Networks monitors only those IP addresses of devices that belong to subnets from the list of subnets known to the application.

By default, the application has a standard list of subnets that are most frequently used at enterprises. Users with the Administrator role can generate a list of known subnets while taking into account the specific addressing of devices within the network of your organization. If Kaspersky Industrial CyberSecurity for Networks receives data from EPP applications, the application can use this data to automatically add subnets to the list of subnets.

The application checks the detected IP addresses against the list of known subnets and can do the following depending on whether the IP addresses belong to specific types of subnets:

- Add a device with its detected IP address to the devices table and monitor the activity of this device.
- Display a device with its detected IP address on the network map as its corresponding type of node (known device, unknown device, or WAN node).
- Display a network map link in which one of the sides of interaction is a device with a detected IP address.

- Verify the interaction of a device with a detected IP address based on defined rules (Interaction Control rules, Intrusion Detection rules, and correlation rules).
- Ignore the activity of a device with a detected IP address.

You can view information about subnets on the **Subnets** tab in the **Assets** section.

When viewing information about subnets, you can utilize the following functions:

- Configure the layout and order of columns in the subnets table.

  1. On the **Subnets** tab in the **Assets** section, click the **Customize table** link to open the window for configuring how the table is displayed.
  2. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.

     The following settings are available for selection:

     - **Subnet** – subnet address in Classless Inter-Domain Routing (CIDR) format: `<base address of subnet>/<number of bits in mask>`. The addresses of subnets are displayed as a tree that shows the nesting hierarchy of subnets.
     - **Type** – subnet type that determines its purpose. The following types are provided:
       - **Private, IT** – subnet for devices serving as information technology (IT) resources, such as file servers.
       - **Private, OT** – subnet for devices related to operating technologies (OT), such as PLCs.
       - **Private, DMZ** – subnet for devices residing within a network segment of a demilitarized zone (DMZ), such as servers that handle requests from external networks.
       - **Public** – subnet that is considered to be an external (global) network for devices in other types of subnets. IP addresses from this subnet are represented by a WAN node on the network map.
       - **Link-local** – subnet for network interactions within one segment of the local area network (not routed).
     - **Range** – range of IP addresses in the subnet.
     - **Ignore MAC addresses** – indicates whether detected MAC addresses are skipped when creating allow rules for network interactions involving IP addresses from the subnet. If this option is enabled, the MAC addresses detected together with IP addresses from the subnet will not be added to Network Integrity Control rules in learning mode.
     - **Automatically add subnets** – indicates whether or not nested subnets are automatically added based on data received from EPP applications. If this mode is enabled, the application adds nested subnets based on data received from EPP applications.
  3. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

  The selected columns will be displayed in the subnets table in the order you specified.

- Filtering based on table columns

  If necessary, you can filter subnets by the **Type** or **Ignore MAC address** columns.

  To filter subnets:

  1. On the **Subnets** tab in the **Assets** section, click the filtering icon in the **Type**, **Ignore MAC address** or **Automatically add subnets** column.

     When filtering by type, you can also use the **Types** drop-down list in the toolbar.

     The filtering window opens.

  2. Select the check boxes opposite the values by which you want to filter events.

  3. Click **OK**.

- Searching subnets

  You can find relevant subnets by using the **Search subnets** field on the **Subnets** tab in the **Assets** section.

  The search is performed based on the **Subnet** column.

- Resetting the defined filter and search settings

  You can reset the defined filter and search settings in the subnets table by using the **Default filter** button in the toolbar on the **Subnets** tab in the **Assets** section. The button is displayed if search or filter settings are defined.

- Sorting subnets

  1. On the **Subnets** tab in the **Assets** section, click the header of the column by which you want to sort.

     You can filter the subnets table based on the values of any column except the **Range** column.

  2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

  The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

Selecting devices in the devices table

In the devices table, you can select devices to view their information and manage these devices. When devices are selected, the details area appears in the right part of the web interface window.

To select relevant devices in the table:

- If you want to select one device, select the check box next to the device or use your mouse to select the device.

- If you want to select multiple devices, select the check boxes next to the relevant devices or select them by holding down the **CTRL** or **SHIFT** key.
- If you want to select all devices that satisfy the current filter and search settings, perform one of the following actions:
  - Select any device in the table and press the key combination **CTRL+A**.
  - Select the check box in the title of the left-most column of the table.

When more than one device is selected, the details area shows the quantitative distribution of the selected devices by category. If there are devices with various categories among the selected devices, you can exclude devices from one of the categories. To do so, you need to clear the check box next to the name of this category.

The title of the left-most column of the table shows the device selection check box. Depending on the number of selected devices, the check box can have one of the following states:

- ☐ – all assets that satisfy the current filter and search settings were not selected in the table. However, one device or multiple devices may be selected in the table by using the check boxes next to the devices or by using the **CTRL** or **SHIFT** key.
- ☑ – all assets that satisfy the current filter and search settings were selected in the table.
- ▣ – all assets that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of the assets were cleared. This state is also retained if the check boxes were cleared for all devices selected in this way (due to the fact that the number of selected devices may change).

If all devices that satisfy the filter and search settings are selected, the number of selected devices may be automatically changed. For example, the composition of devices in the table may be changed by an application user in a different connection session or when devices are automatically added. It is recommended to configure the filter and search settings in such a way that ensures that only the relevant devices end up in the selection (for example, you can filter devices by their IDs before selecting all devices).

Selecting subnets in the subnets table

In the subnets table, you can select subnets to view their information and manage these subnets. When a subnet is selected, the details area appears in the right part of the web interface window.

To select relevant subnets in the table:

- If you want to select one subnet, select the check box next to the subnet or click on the subnet.
- If you want to select multiple subnets, select the check boxes next to the relevant subnets or select them while holding down the **CTRL** or **SHIFT** key.
- If you want to select all subnets that satisfy the current filter and search settings, do one of the following:
  - Select any subnet in the table and press the key combination **CTRL+A**.
  - Select the check box in the title of the left-most column of the table.

The title of the left-most column of the table shows the subnet selection check box. Depending on the number of selected subnets, the check box can have one of the following states:

- ☐ – all subnets that satisfy the current filter and search settings were not selected in the table. However, one subnet or multiple subnets may be selected in the table by using the check boxes next to the subnets or by using the **CTRL** or **SHIFT** key and your mouse.
- ☑ – all subnets that satisfy the current filter and search settings were selected in the table.
- ▣ – all subnets that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of the subnets were cleared. This state is also retained if the check boxes were cleared for all subnets selected in this way (due to the fact that the number of selected subnets may change).

If all subnets that satisfy the filter and search settings are selected, the number of selected subnets may be automatically changed. For example, the available subnets in the table may be changed by an application user in a different connection session. You are advised to configure the filtering and search settings so that you only see the relevant subnets in the selection.

Viewing device information

Detailed information about a device includes information from the device table, and the following fields (if values are available for these fields):

- **Router** – indicator of a routing device.

  If the router indicator is not determined automatically, it must be manually set (for example, for a device that performs functions of a network switch between industrial network segments). This is particularly relevant if PLCs and a computer with a SCADA system interacting with these PLCs are located in different segments. In this case, the application will be able to automatically add all devices detected in a segment with these PLCs to the devices table.

- **Additional information** – additional information about a device specified by an application user (for example, a description of the device deployment location).
- **Custom fields** – set of non-standard device information defined by an application user (for example, categories and classes of device protection). Up to 16 custom fields may be specified for a device.
- **Dynamic fields** – set of expanded device information detected in traffic when the device information detection method is being employed. This field is displayed if expanded information was detected by the application.
- **Kaspersky Endpoint Agent** – information about the Kaspersky Endpoint Agent application installed on the device.
- **EPP application** – information about the installed application that performs functions for protecting workstations and servers (EPP application).

If Process Control settings are defined for a device, they are displayed in a separate settings block.

To view device information:

On the **Devices** tab in the **Assets** section, select the relevant device.

The details area appears in the right part of the web interface window. The details area displays all data that has defined values. Information for which automatic updates are disabled is marked by the icon.

Automatically adding and updating devices

The application can automatically add devices to the table and update information about devices. To automatically add and update devices in Kaspersky Industrial CyberSecurity for Networks, you must enable the following asset management methods:

- Device activity detection When using this method, the application adds newly detected devices to the table based on the obtained MAC- and/or IP addresses of the devices. If the application detects activity of an already known device, it may change its status depending on the current asset management mode.

- Device Information Detection When using this method, the application updates information about known devices based on data received from traffic or from EPP applications. Based on data received from traffic, the application updates the information for which automatic updates are enabled in the device settings (this is enabled by default until an application user manually changes a value). If device information detection is disabled, the application does not update or augment available device information based on data received from traffic or from EPP applications.

When adding a device, the application assigns a device name based on the default template: **Device <value of the internal device counter>**. The value of the internal counter in the device name may differ from the device ID that is displayed in the **Device ID** column.

Using device information detection, the application can update a device name after receiving the following information:

- Device model name.

- Network name used to represent the device on the network (the network name of the device takes priority during an update).

The application can automatically update information related to the vendors of network equipment based on the MAC addresses of devices. To identify vendors based on MAC addresses, the application compares the MAC addresses of devices with the address ranges that are registered in the public database of the international Institute of Electrical and Electronics Engineers (IEEE). If a network equipment vendor is identified by MAC address, the application uses the same vendor name that is presented in the IEEE database.

After the application is installed, it uses a copy of the IEEE database containing information about MAC addresses and vendors that was up to date when the current version of the application was released. You can keep the local copy of the IEEE database up to date by installing updates.

Automatically changing the statuses of devices

When monitoring the activity of devices in the industrial network, the application can automatically assign statuses to detected devices based on the obtained MAC- and/or IP addresses of devices. Statuses are assigned depending on the current asset management mode.

In learning mode, the application assigns the *Authorized* status to all detected devices (this includes new devices as well as devices that were previously added to the devices table). The status of a detected device is not changed if the *Unauthorized* status was previously assigned to the device.

In monitoring mode, the assigned status depends on whether the device that showed activity is known or unknown to the application. In this mode, statuses are assigned according to the following rules:

- If a device is new (not present in the devices table when it is detected), the *Unauthorized* status is assigned to this device.
- If the device is in the devices table and has the *Authorized* or *Unauthorized* status, the status is not changed.
- If the device is in the devices table with the *Archived* status, the *Unauthorized* status is assigned to this device.

By default, if a device with the *Authorized* status has not shown any activity in over 30 days and the device information has not changed during this time, the *Archived* status is assigned to this device. You can disable automatic status changes when manually changing the status of a device (for example, to prevent the *Authorized* status from automatically changing to the *Archived* status for rarely connected devices).

When devices with the *Unauthorized* status appear in the devices table, you need to determine whether all of these devices are required for industrial process support. After making this determination, it is recommended to manually assign one of the following statuses to each device:

- *Authorized* – if the device is required for industrial process support.
- *Archived* – if the device should not be used in the industrial network.

> Instead of assigning the *Archived* status, you can delete the device. However, all information specified for the device will also be deleted. If a deleted device is detected again, the application will provide only the information that has been received since the device was re-added to the devices table (the date and time of the first detection of the device is also updated).

Device group tree

The device group tree is intended for arranging devices according to their purpose, location, or any other attribute. Devices can be arranged into groups either manually (for example, to designate the location of devices within the facility's industrial structure) or automatically (based on the subnets of device IP addresses, according to the device category, or by vendor).

If a device was not added to any of the groups, this device is assigned to the top level of the group tree hierarchy. By default, devices that are automatically added to the table are not put into groups.

Only users with the Administrator role can put devices into groups.

You can find out which devices belong to groups when viewing the devices table. Paths to groups are indicated in the **Group** column. Device groups are also displayed on the network map. However, devices that are in these groups might not be displayed if they do not satisfy the settings for filtering objects on the network map.

Monitoring read and write of PLC projects

Kaspersky Industrial CyberSecurity for Networks can monitor industrial network traffic for information about PLC projects and compare this information with previously received information about PLC projects.

A PLC project is a microprogram written for a PLC. A PLC project is stored in PLC memory and is run as part of the industrial process that uses the PLC. A PLC project may consist of blocks that are individually transmitted and received over the network when the project is read or written.

Information about a PLC project/block may be received by the application when it detects operations for reading a project/block from a PLC or writing a project/block to a PLC. The obtained information is saved in Kaspersky Industrial CyberSecurity for Networks. The next time it detects a project/block write or read operation, the application compares the received information about the project/block with the saved information. If the received information about a project/block does not match the latest saved information about that project/block (including when there is no saved information), the application registers the corresponding event.

Receiving information about PLC projects is supported for the following types of devices:

- Schneider Electric Modicon: M580, M340
- Siemens SIMATIC S7-300, S7-400

You do not need to add Process Control settings for devices to monitor read/write of PLC projects. Read/write of PLC projects is monitored for all detected devices of the listed types.

For each device, the application saves no more than 100 different variants of PLC projects. If a PLC project is transmitted or received by individual blocks, up to 100 different variants of each block are saved.

If the maximum number of saved PLC projects (or PLC project blocks with the same name) has been reached for a device, the application saves a newly detected project/block in place of the oldest project/block.

When monitoring read/write of PLC projects, the application registers events based on Asset Management technology. Events are registered with system event types that are assigned the following codes:

- Codes of event types when a PLC project/block is read:
  - 4000005200 – for a detected read of an unknown block of a project from a PLC (if there is no saved information about this block).
  - 4000005201 – for a detected read of a known block of a project from a PLC (if there is saved information about this block but the obtained information does not match the latest saved information about this block).
  - 4000005204 – for a detected read of an unknown project from a PLC (if there is no saved information about this project).
  - 4000005205 – for a detected read of a known project from a PLC (if there is saved information about this project but the obtained information does not match the latest saved information about this project).
- Codes of event types when a PLC project/block is written:
  - 4000005202 – for a detected write of a new block of a project to a PLC (if there is no saved information about this block).
  - 4000005203 – for a detected write of a known block of a project to a PLC (if there is saved information about this block but the obtained information does not match the latest saved information about this block).
  - 4000005206 – for a detected write of a new project to a PLC (if there is no saved information about this project).

- 4000005207 – for a detected write of a known project to a PLC (if there is saved information about this project but the obtained information does not match the latest saved information about this project).

You can configure the available parameters for event types under **Settings → Event types**.

You can view information about registered events when connected to the Server through the web interface.

Viewing events associated with devices

You can view events associated with devices. Events are loaded by automatically applying a filter based on the IDs of devices using the values of the MAC- and IP addresses specified for the devices.

In the events table, the application shows events whose **Source** or **Destination** columns contain the MAC- or IP addresses of selected devices.

Events can be loaded if no more than 200 devices are selected.

To view events associated with devices:

1. Select the **Assets** section.
2. On the **Devices** tab, select the devices for which you want to view events.

   The details area appears in the right part of the web interface window.
3. Depending on which events you want to load, click one of the following buttons (the buttons are unavailable if more than 200 devices are selected):

   - **Show events** – if you want to view events with any status.
   - **Show unprocessed events** – if you want to view events with the *New* or *In progress* status.

   The **Events** section opens. The events table will apply a filter based on the IDs of devices. The list of device IDs defined for event filtering is displayed in the **Device IDs** field in the toolbar. If you loaded events by using the **Show unprocessed events** button, events will also be filtered by the **Status** column.

Exporting devices to a file

You can export information about devices to files of the following formats:

- CSV

  When exporting a file in this format, the file saves information from the columns currently displayed in the table, and the additional fields and Process Control settings in the information about devices.
- JSON

  When exporting a file in this format, the file saves all available information about devices, including service information from the database (such as information about events associated with the devices). The file can be used to upload detailed device data to other systems.

You can export information for all devices that satisfy the current filter and search settings, or selectively for devices displayed in the table.

To export information about all devices that satisfy the current filter and search settings:

1. Select the **Assets** section.

2. Click the **Export** link in the toolbar on the **Devices** tab to open the menu for selecting the format of the saved file.

3. In the opened window, select the relevant file format option: **file in CSV format** or **file in JSON format**.

4. If the **file in CSV format** option is selected in the menu, you will be prompted to select an option for saving Process Control settings and tags associated with devices. If you want to save Process Control settings and tags in the file, select the **Including Process Control settings and tags** check box and click **Export**.

   The file creation process starts.

5. If it takes a long time (more than 15 seconds) to create the file, the file creation operation is transferred to the list of background operations. In this case, to download the file:

   a. Click the button in the menu of the application web interface.

      The list of background operations appears.

   b. Wait for the file creation operation to finish.

   c. Click the **Download file** button.

Your browser will save the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

To export information about selected devices:

1. Select the **Assets** section.

2. On the **Devices** tab, select the devices whose information you want to export to a file.

3. Right-click to open the context menu of one of the selected devices.

4. In the context menu, select the option showing the necessary file format for the export (to **CSV file** or **to JSON file**).

5. If the File in CSV format option is selected in the menu for the export, you will be prompted to select an option for saving Process Control settings and tags associated with devices. If you want to save Process Control settings and tags in the file, select the **Including Process Control settings and tags** check box and click **Export**.

   The file creation process starts. If it takes a long time (more than 15 seconds) to create the file, perform the necessary actions for step 5 as described in the procedure for exporting information about all devices.

Exporting subnets to a file

You can export information about subnets to a JSON file. This file saves the main information about subnets regardless of which columns are currently displayed in the subnets table.

You can export information for all subnets that satisfy the current filter and search settings, or selectively for subnets displayed in the table.

To export information about all subnets that satisfy the current filter and search settings:

1. Select the **Assets** section.
2. Click the **Export** link in the toolbar on the **Subnets** tab to open the menu for selecting the format of the saved file.
3. In the opened menu, select **file in JSON format**.

   The file creation process starts.
4. If it takes a long time (more than 15 seconds) to create the file, the file creation operation is transferred to the list of background operations. In this case, to download the file:

   a. Click the button in the menu of the application web interface.

   The list of background operations appears.

   b. Wait for the file creation operation to finish.

   c. Click the **Download file** button.

Your browser will save the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

To export information about selected subnets:

1. Select the **Assets** section.
2. On the **Subnets** tab, select the subnets whose information you want to export to a file.

   After you select subnets, the details area opens in the right part of the web interface window.
3. Click the part of the **Export to** button indicating the **JSON file** format.

   The file creation process starts. If it takes a long time (more than 15 seconds) to create the file, perform the necessary actions for step 4 as described in the procedure for exporting information about all devices.

Working with the network map

The network map is a visual representation of monitored communications between industrial network devices. You can use the network map to view information about communication between devices during various time periods.

The following objects may be displayed on the network map:

- Nodes. These objects designate the sources and destinations of network packets.
- Device groups. These objects correspond to groups in the device group tree. Groups contain nodes that represent the devices and child groups embedded in those groups.
- Links. These objects represent connections between nodes.

Nodes and links appear on the network map based on data received from traffic or from EPP applications for a specific time interval. Device groups are continually displayed.

If necessary, you can filter nodes and links. By default, the network map displays objects in online mode with a defined filtering period of one hour.

Objects with issues are visually distinguished on the network map. The application considers the following to be objects with issues:

- Node associated with unprocessed events that have the *Warning* or *Critical* severity, or node that represents a device with the *Unauthorized* status.
- Link associated with events that have the *Warning* or *Critical* severity. Events registered during the defined object filtering period are taken into account. However, the current status of events is not taken into account.
- Group that contains devices with issues, or whose nodes have links with issues. This includes objects within the group and within any child group of all nesting levels.

Nodes on the network map

Nodes on the network map can be of the following types:

- A device that is known to the application (a device). This type of node represents a device that is listed in the devices table.
- A device that is unknown to the application. This type of node represents a device with a unique IP address or MAC address that is not in the devices table. Such a node may appear on the network map, for example, if network packets are sent using the `ping` command to the address of a non-existent device. Nodes of unknown devices are displayed individually if their total number does not exceed 100 (according to the current filter settings on the network map). If the number of nodes exceeds this limit, one consolidated node of unknown devices is displayed.
- WAN. This type of node represents devices of a Wide Area Network with which industrial network devices connect. WAN devices are any devices whose IP addresses belong only to **Public** subnets known to the application.

Displayed information on nodes representing devices

The following information is displayed for nodes representing devices when the network map is maximized:

- Assigned device name.
- Device category icon.
- IP address of the device (If an IP address is not assigned, the MAC address is displayed).
- Various icons depending on fulfillment of the following conditions:
  - if the router indicator has been set for the device.
  - if an EPP application is installed on the device (the color of the icon depends on the connection state).
  - if the device has the *Archived* status.
- The thick line on the left border of a node has one of the following colors depending on the device's security state:
  - Green signifies the *OK* security state.

- Yellow signifies the *Warning* security state.
- Red signifies the *Critical* security state.

If a device has the *Unauthorized* status or has a security state different from the *OK* state, the node has a red background.

Information displayed on nodes representing unknown devices

The following is displayed for nodes representing unknown devices when the network map is maximized:

- If a node represents one unknown device, the IP address or MAC address of the device is displayed. For a consolidated node of unknown devices (a node that combines more than 100 unknown devices), **Unknown devices** is displayed.
- Icon for an unknown device and its status .

Nodes representing devices that are unknown to the application have a gray background.

Displayed information on WAN nodes

The following is displayed for WAN nodes when the network map scale is maximized:

- Node name: **WAN**.
- WAN node icon.

Groups of devices on the network map

Groups from the device group tree may be displayed in collapsed or expanded states on the network map. Collapsed groups are displayed as icons similar to nodes. Expanded groups are displayed as windows containing their embedded nodes and other groups.

Displayed information on collapsed groups

If a group is collapsed, the following is displayed when the network map scale is maximized:

- Group name.
- Number of devices that satisfy the current filter settings on the network map. This number includes devices within the group and within its child groups in all nesting levels.
- Number of child groups in all nesting levels.

If a group contains devices or links with issues (including in child groups of any nesting level), the border of this group is colored red.

Displayed information on expanded groups

The window of an expanded group contains a title with the group name and an area for displaying objects. The group window displays the devices included in this group, and the child groups of the next nesting level. Of the devices included in the group, only the devices that meet the current filter settings on the network map are displayed.

If a group contains devices or links with issues (including in child groups of any nesting level), the window has a red background.

Collapsing and expanding groups

If a group is collapsed, you can expand it by double-clicking the icon of the group. If a group is expanded, you can collapse it by double-clicking the header of this group's window or by clicking the button in the header.

To simultaneously expand multiple collapsed groups:

1. On the network map, select multiple collapsed groups by performing one of the following actions:
   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant groups.
   - Hold down the **CTRL** key and use your mouse to select the relevant collapsed groups.
2. Click the button in the toolbar located in the left part of the network map display area (the button is available if at least one collapsed group is selected).

To simultaneously collapse all expanded groups:

Click the button in the toolbar located in the left part of the network map display area (the button is available if at least one group is expanded).

Links on the network map

Links on the network map are identified based on detected network packets in which the source and destination addresses can be correlated to the addresses of nodes.

Each link shows two sides of communication. A side of communication in a link may be one of the following objects on the network map:

- One of the following types of nodes:
  - Device that is known to the application.
  - Device that is unknown to the application.
  - Consolidated node of unknown devices – if the link shows communication with one or more unknown devices of this node.
  - WAN node – if the link shows communication in which the source of network packets is a WAN device (the IP address belongs only to **Public** networks that are known to the application).
- Collapsed group, if the link shows communication with one or more devices in this group.

Depending on the severity of events registered when communications are detected, the link may have the following colors:

- Gray – the communication did not cause event registration, or only events with the *Informational* severity level were registered.
- Red – the communication caused the registration of events with the *Warning* or *Critical* severity level.

Events registered during the defined object filtering period are taken into account for links. However, the current status of events is not taken into account.

The application saves connection data in the database on the Server. The total volume of saved entries cannot exceed the defined limit. If the volume exceeds the defined limit, the application automatically deletes 10% of the oldest entries. You can set a maximum volume limit for the network map when configuring data storage settings on the Server node.

Viewing details about objects

Detailed information about objects presented on the network map are displayed in the details area. To display detailed information, you can use your mouse to select an object (if you want to view information about a group, you must first collapse the group).

The following information is displayed for nodes:

- If a node represents a known device, the details area displays the same information that is displayed in the devices table.
- If a node represents one unknown device, the details area displays the MAC address and/or IP address of the device.
- If a consolidated node of unknown devices is selected, the following information is displayed:
  - Number of nodes combined by this node under the current filter settings.
  - **IP addresses** – number of IP addresses of unknown devices and the first 100 IP addresses. This section is displayed if there are nodes with IP addresses among the nodes of unknown devices.
  - **MAC addresses** – number of MAC addresses of unknown devices and the first 100 MAC addresses. This section is displayed if there are nodes with MAC addresses among the nodes of unknown devices.
- If a WAN node is selected, the following information is displayed:
  - **Exclude defined addresses** indicates that all devices whose addresses are included in the listed subnets are excluded from the device group.
  - **Subnets** – section containing a list of known subnets indicated as **Public** (external networks).

The following information is displayed for groups:

- Number of devices and groups within the selected group and its child groups of all nesting levels.
- Path to the group in the device group tree. If a group is in the top level of the hierarchy, **Top-level group** is displayed.
- Information about the number of objects with issues within the selected group and its child groups of all nesting levels. If there are no such objects, the *OK* security state is displayed.

The following information is displayed for links:

- **Severity** – icon corresponding to the maximum importance level of events associated with the link. If no event is associated with the link, **No events** is displayed. Events registered during the defined object filtering period are taken into account. However, the current status of events is not taken into account.

- Sections containing basic information about the first and second sides of communication:

  - If the side of communication is a node of a known device or a node of an unknown device, the section displays the name or address of the device/device, category, and address information (for a known device, address information is provided only for those network interfaces that were used during the communication).

  - If the side of communication is a collapsed group, the section displays the name of the group and the number of devices and child groups within it.

  - If the side of communication is a consolidated node of unknown devices, the section displays the **Unknown devices** node name and the number of nodes combined within this node.

- If one of the sides of communication is a collapsed group, you will see the number of links that are designated by the selected link:

  - **Total links** – total number of links with devices of the collapsed group.

  - List showing the quantitative distribution of links based on the severity of their associated events (including the number of links not associated with any event). Next to list items are links for viewing detailed information about the items. You can click the **To devices** link to go to the **Devices** tab in the **Assets** section and filter devices associated with links. You can click the **To events** link to go to the **Events** section and filter events associated with links.

- **Protocols** – section containing a list of protocols used for communication. The volume of transmitted data calculated for detected network packets is specified for each protocol. This section is not displayed if one of the sides of communication is a consolidated node of unknown devices.

Changing the network map scale

The network map can be displayed in a scale of 1–100%. The current scale value is displayed in the toolbar located in the left part of the network map display area.

To change the scale of the network map:

Use the mouse wheel or the **+** and **–** buttons located in the toolbar next to the current scale value.

Reducing the scale of the network map reduces the amount of information that is displayed in nodes and collapsed groups.

If the display scale is less than 25%, icons and text information are not displayed in nodes and collapsed groups. The appearance of nodes and collapsed groups may change as follows:

- On a node representing a device that is known to the application (device), the upper-right corner displays the device status as a triangle in one of the following colors:

  - Green signifies that the device has the *Authorized* status.

  - Red signifies that the device has the *Unauthorized* status.

- Gray signifies that the device has the *Archived* status.

- A thick black line on the left border of the node appears on the WAN node.

- On a collapsed group, the upper-right corner displays a triangle indicating the presence of objects with issues. The triangle has one of the following colors:

  - Green means that the group does not contain objects with issues.

  - Red means that the group contains objects with issues.

Positioning the network map

If necessary, you can change the positioning of the network map manually or automatically. Automatic positioning lets you move the network map and change its scale in such a way to display all nodes that satisfy the defined filter settings, and all expanded groups.

To manually position the network map:

1. Position the mouse cursor over any part of the network map that is not occupied by objects.

2. Click and hold the left mouse button to drag the network map image.

To automatically position the network map:

Click the  button in the toolbar located in the left part of the network map display area.

The positioning and scale of the network map will change to display all nodes and expanded groups.

Pinning and unpinning nodes and groups

By default, nodes and collapsed groups are not pinned on the network map. Unpinned nodes and collapsed groups may be automatically arranged for optimal display of other objects.

Nodes and groups are pinned when their location is changed manually or when automatically arranged. You can also pin the current location of displayed objects without moving them.

To pin and unpin objects without moving them, you can use the following interface elements:

- Buttons in the toolbar located in the left part of the network map display area. You can use the and buttons to pin and unpin all nodes and groups displayed on the network map (including nodes in expanded groups).

- Buttons in the expanded group's window header. You can use the and buttons to pin and unpin only nodes and groups in the window of the expanded group (but not in windows of nested groups).

Buttons are available if the network map contains objects to which the corresponding actions can be applied.

After the location of a node or collapsed group is pinned, the icon appears in the upper-right corner of this element (if the network map has a scale of less than 25%). You can also use this icon to unpin the object.

The location of a pinned node or pinned group is retained. If a pinned node disappears from the network map (for example, after a filter is applied), this node will be displayed in the same location the next time it appears.

Manually changing the location of nodes and groups

You can manually change the location of nodes and groups on the network map by using the arrangement method that is most convenient for you.

After their arrangement, nodes and groups are locked (pinned) in their new location. If necessary, you can unpin these objects.

Objects that are included in groups can be moved only within the windows of these groups.

To change the location of nodes and/or collapsed groups:

1. On the network map, select one or multiple objects representing nodes and/or collapsed groups.

   To select multiple nodes and/or collapsed groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

2. Use your mouse to drag the selected objects to the necessary location.

After they are moved, nodes and collapsed groups will remain pinned. The icon appears in these objects.

To change the location of an expanded group:

Move the cursor over the expanded group's window title, left-click and drag the window to the necessary location.

Automatic arrangement of nodes and groups

For optimal arrangement of objects on the network map, you can use algorithms to automatically change the location (arrangement) of nodes and groups. The following algorithms are provided:

- Radial arrangement.
- Grid-aligned arrangement.

You can use automatic arrangement algorithms for the following objects:

- All displayed nodes and groups at the top level of the hierarchy within the group tree. Automatic arrangement is performed by using the (radial arrangement) button and (grid-aligned arrangement) button in the toolbar located in the left part of the network map display area.
- All displayed nodes and groups within the expanded group. Automatic arrangement is performed by using the (radial arrangement) button and (grid-aligned arrangement) button in the expanded group's window header.
- Only selected nodes and collapsed groups. Before performing automatic arrangement, you need to select at least three nodes and/or collapsed groups within the expanded group or at the top level of the hierarchy. To select multiple objects, you can use the mouse to select a rectangular area containing the relevant objects

while holding down the **SHIFT** key, or select the relevant objects with the mouse while holding down the **CTRL** key. Automatic arrangement is performed by using the (radial arrangement) button and (grid-aligned arrangement) button in the toolbar located in the left part of the network map display area.

After automatic arrangement, nodes and groups are locked (pinned) in their new location. The icon appears in these objects. If necessary, you can unpin these objects.

Filtering objects on the network map

To limit the number of nodes and links displayed on the network map, you can use the following functions:

- Functions for complex filtering of nodes and links:
  - **Filtering using a period on the time scale**

To filter nodes and links, you can choose the relevant period of time on the time scale. The time scale is displayed in the lower part of the **Network map** section.

The time scale contains the following items:

- Time scale start date and time.
- Periods when events with the *Critical* and *Warning* severity levels were registered. These periods are displayed as red strips in the lower part of the time scale. The periods are not displayed if a duration of more than seven days is defined for the time scale.
- Filtering period. This period is displayed as a yellow band lined with buttons for moving the boundaries.
- Chart of the volume of traffic processed by the application. The chart is not displayed if a duration of more than seven days is defined for the time scale.
- End of the time scale. Depending on the arrangement of the filtering period, the end of the time scale is displayed as a date and time (if the date and time are defined) or as a **Now** link.

The following types of filtering periods are provided:

- Period correlated to the current moment. The right-side boundary of this period corresponds to the time scale boundary designating the current moment in time.
- Period not correlated to the current moment. This type of period may be arranged in any part of the time scale.

To configure object filtering by a period correlated to the current moment:

1. Click the **Now** button on the right of the time scale. This button is not displayed if the period is already correlated to the current moment.
2. If it is necessary to specify a different period duration, perform one of the following actions:
   - Move the left border of the yellow band of the period to the necessary position (the maximum duration of the period is 7 days).
   - Open the configuration window by using the button above the yellow band of the period, select the **Anchor to boundary** check box, select the necessary duration (**Hour**, **Day**, **7 days**), and click **OK**.

The network map shows only those nodes and links for which communications were detected since the beginning of the specified period up to the current moment.

To configure filtering by a period not correlated to the current moment:

1. If the necessary period is not within the time scale, change the values of the date and time for the start and/or end of the time scale:
   a. To change the data and time of the start of the time scale, open the window by clicking the link in the left part of the time scale and select one of the following options:
      - **Day**
      - **7 days**

- **Month**
- **Specify a date**. For this option, specify a date and time in the opened field.

b. To change the date and time of the end of the time scale, open the window by clicking the link in the right part of the time scale and select one of the following options:

- **Now**
- **Specify a date**. For this option, specify a date and time in the opened field.

2. Specify the necessary period. To do so, do one of the following:

- Use the mouse to move the period to the relevant place on the time scale.
- Move one or both of the borders of the yellow band of the period to the necessary part of the time scale (the maximum duration of the period is 7 days).
- Open the configuration window by using the button above the yellow band of the period, select the necessary duration (**Hour**, **Day**, **7 days**), and click **OK**.

3. If a period is automatically anchored to the current moment (when you move the period to the right-most position, the **Now** button on the right of the time scale is no longer displayed), disable automatic anchoring of the period to the time scale boundary. To do so, open the configuration window by using the button above the yellow band of the period, clear the **Anchor to boundary** check box, and click **OK**.

- Filtering by registered events

You can configure the network map to show the nodes and links whose information is saved in events associated with the selected nodes.

The capability to filter by event is available if no more than 200 nodes on the network map are selected. You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

You can use the following methods to filter by event:

- Initial filtering by event. This method is applied if you need to filter objects based on events associated only with the selected nodes.
- Additional filtering by event. This method is applied if initial filtering by event has already been performed (for example, when switching to the network map from the events table) and you need to also filter events associated with additionally selected nodes from the list of nodes displayed on the network map.

To display nodes and links using initial filtering by event:

1. On the network map, select one or multiple objects representing nodes and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.

2. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.

3. Click the **Filter by events** button.

   The network map displays only those nodes and links whose information is contained in events associated with the selected nodes. The toolbar located above the network map will show a list containing the IDs of events (IDs are listed in the order in which their associated events were detected).

To add nodes and links to the displayed objects by using additional filtering by event:

1. Make sure that initial filtering by event has been performed. To do so, check for the availability of a list containing event IDs in the toolbar located above the network map.

2. Among the nodes displayed on the network map, select the nodes for which you want to add associated events to the filter.

   The details area appears in the right part of the web interface window.

3. Click the **Add filtering for events** button.

The network map will additionally display the nodes and links whose information is contained in events associated with the selected nodes. The IDs of detected events are added to the list containing IDs in the toolbar.

- Functions for filtering nodes:
  - Filtering by device status

    1. In the toolbar located above the network map, open the **Device statuses** drop-down list.

       You will see a list containing the names of statuses for devices that are known to the application (**Unauthorized**, **Authorized**, **Archived**), and the **Unknown device** status for devices that are unknown to the application.

    2. In the drop-down list, select the check boxes for the statuses of devices that need to be displayed on the network map.

    3. Click **OK**.

    The network map displays only those nodes that represent devices with the selected statuses.

  - Filtering by device security state

    1. In the toolbar located above the network map, open the **Device states** drop-down list.

       You will see a list containing the names of security states for devices (**OK**, **Warning**, **Critical**).

    2. In the drop-down list, select the check boxes for the security states of nodes that need to be displayed on the network map.

    3. Click **OK**.

    The network map displays only those nodes that represent devices with the selected security states.

  - Filtering by device category

    1. In the toolbar located above the network map, open the **Device categories** drop-down list.

       You will see a list containing the names of categories for known devices, as well as individual categories for unknown devices and WAN nodes.

    2. In the drop-down list, select the check boxes for those categories of devices that need to be displayed on the network map.

    3. Click **OK**.

    The network map displays only those nodes that represent the selected categories of devices.

  - Enabling and disabling the display of nodes associated with filtered nodes

After filtering nodes, the network map displays only those nodes that satisfy the defined filter settings. In addition, for a node to be displayed on the network map, it must have a connection (link) with another displayed node. If the defined filter settings cause the network map to not display all nodes with which a node has interacted, this node is also not displayed on the network map. Filtering is applied similarly for nodes that are part of a consolidated node of unknown devices: if the network map does not display all nodes with which a node of an unknown device has interacted, this node is removed from the list of nodes within the consolidated node of unknown devices.

If necessary, you can enable the network map to display all nodes associated with filtered nodes. Together with nodes that satisfy the defined node filter settings, the network map will also display all nodes with which interactions have occurred (irrespective of the defined filter settings).

For example, if node filtering by **PLC** category is enabled and you have enabled the display of linked nodes, the network map will display all nodes that have communicated with **PLC** category devices. If the display of linked nodes is disabled, the network map will display nodes of only those **PLC** category devices that have communicated with each other.

To enable or disable the display of nodes associated with filtered nodes:

Use the **Linked devices** toggle button in the toolbar located above the network map.

- Functions for filtering links:
  - Filtering based on event severity

    1. In the toolbar located above the network map, open the **Link severity levels** drop-down list.

       You will see a list containing the names of the severity levels of events (**Informational**, **Warning**, **Critical**), as well as the **No events** item that lets you filter connections for which no events have been registered.

    2. In the drop-down list, select the check boxes for those severity levels by which you want to filter links.

    3. Click **OK**.

    The network map displays only those links associated with events that have the selected severity levels.

  - Filtering by communication protocols

1. In the toolbar located above the network map, open the **Protocols** drop-down list.

   You will see a window containing the table of supported protocols displayed as a protocol stack tree. You can manage how tree elements are displayed by using the **+** and **-** buttons next to the names of protocols that contain protocols of subsequent layers.

   The table columns provide the following information:

   - **Protocol** – name of the protocol within the protocol stack tree.
   - **EtherType** – number of the next-level protocol within the Ethernet protocol (if the protocol has a defined number). It is displayed in decimal format.
   - **IP number** – number of the next-level protocol within the IP protocol (if the protocol has a defined number). It is indicated only for protocols within the IP protocol structure. It is displayed in decimal format.

2. If necessary, use the search field above the table to find relevant protocols.
3. In the list of protocols, select the check boxes opposite the protocols by which you want to filter events.

   If you select or clear the check box for a protocol that contains nested protocols, the check boxes for the nested protocols are also automatically selected or cleared.

4. Click **OK**.

The network map displays only those links in which the selected protocols were used.

- Filtering based on the OSI model layers

You can filter links based on the levels of communications corresponding to the layers of the OSI (Open Systems Interconnection) model for the network protocol stack.

To filter links on the network map based on the layers of the OSI network model:

1. In the toolbar located above the network map, open the **OSI model layers** drop-down list.

   You will see a list containing the names of OSI model layers:

   - **Data Link**. This layer includes the communication links in which MAC addresses were used to communicate with devices.
   - **Network**. This layer includes links in which IP addresses were used to communicate with devices.

2. In the drop-down list, select the check boxes for those OSI model layers whose links need to be displayed on the network map.
3. Click **OK**.

The network map displays only those links that are associated with the selected OSI model layer.

- Resetting the filter settings

You can reset the defined settings for filtering nodes and links to their default state.

To reset the defined filter settings on the network map:

In the toolbar located above the network map, click the **Default filter** button (this button is displayed if filter settings have been defined).

The network map will display all nodes and links for which communications were detected during the currently defined period.

Saving and loading network map display settings

The application lets you save the current network map display settings. A set of saved display settings is called a *view*. You can use views to apply their saved settings on the network map (for example, to quickly restore the display settings after making some changes, or to work with the network map on a different computer).

When a network map view is saved, the following display settings are saved:

- Scale
- Network map positioning
- Location of pinned nodes and groups
- Filtering of nodes and links

The application can save and use no more than 10 groups of settings providing different network map views.

Only users with the Administrator role can manage the list of network map views (including saving the current display settings). However, users with the Administrator role and users with the Operator role can both access the list of views and apply the saved groups of settings.

When working with network map views, you can use the following functions:

- **Adding a new view while saving the current network map display settings**

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, configure the network map display settings.
3. Open the **Configure network map views** window by clicking the **Manage views** link.
4. Click **Add**.
5. Type the view name in the entry field.

   You can use letters, numerals, a space, and the following special characters: `! @ # № $ % ^ & ( ) [ ] { } ' , . - _`.

   A view name must meet the following requirements:

   - Must begin and end with any permitted character except a space.
   - Must contain 100 characters or less.
   - Must not match the name of a different view (not case-sensitive).
6. Click the ✓ icon on the right of the entry field.

- Updating a view while saving the current network map display settings

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, configure the network map display settings.
3. Open the **Configure network map views** window by clicking the **Manage views** link.
4. Select the view in which you want to save the current network map display settings.
5. Click the **Overwrite** button.

   A window with a confirmation prompt opens.
6. In the prompt window, confirm that you want to save the current settings in the selected view.

- Renaming a network map view

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, open the **Configure network map views** window by clicking the **Manage views** link.
3. Select the view that you want to rename.
4. Click the icon on the right of the current view name.
5. In the entry field, enter the new name of the view.

   You can use letters, numerals, a space, and the following special characters: `! @ # № $ % ^ & ( ) [ ] { } ' , . - _`.

   A view name must meet the following requirements:

   - Must begin and end with any permitted character except a space.
   - Must contain 100 characters or less.
   - Must not match the name of a different view (not case-sensitive).
6. Click the icon on the right of the entry field.

- Deleting a network map view

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
2. In the **Network map** section, open the **Configure network map views** window by clicking the **Manage views** link.
3. Select the view that you want to delete.
4. Click the **Remove** button.

   A window with a confirmation prompt opens.
5. In the prompt window, confirm deletion of the selected view.

- Applying saved view settings on the network map

1. In the **Network map** section, open the **Configure network map views** window by clicking the **Manage views** link.
2. Select the relevant view in the list.
3. Click the **Apply** button.

   A window with a confirmation prompt opens.
4. In the prompt window, confirm application of the view.

Searching nodes on the network map

You can search nodes on the network map based on information about these nodes. This search will involve all nodes that meet the current filter settings, including those located in collapsed groups or outside of the displayed part of the network map.

For nodes representing known devices, the search is performed in all columns of the devices table except the following columns: **Status**, **Security state**, **Last seen**, **Last modified**, and **Created**. The search is also performed in the values of custom fields for devices.

To find the relevant nodes on the network map:

In the **Network map** section, enter your search query into the **Search nodes** field. The search is initiated as you type characters in the search field.

If nodes that satisfy the search query are found, the contours of these nodes are highlighted in yellow. The contours of collapsed groups in which nodes were found are highlighted in the same way. However, the right part of the **Search nodes** field will display the following items:

- Sequence number of the currently selected object (node or collapsed group containing the found nodes) among the search results.
- Total number of found objects (nodes and/or collapsed groups containing the found nodes).

  The number of nodes in collapsed groups is not taken into account in the total number of found objects. If you want the nodes in groups to also be taken into account in the search results, expand the collapsed groups.

- Arrows for moving between found objects. Arrow movements proceed in alphabetical order of the names of found objects. When moving to the next object, the network map is automatically positioned to display this object.

Viewing events associated with nodes of known devices

For nodes representing known devices on the network map, you can view the events associated with these devices. When events are loaded, they are automatically filtered based on the IDs of devices using the values of the MAC- and IP addresses specified for the devices.

The capability to load events is available if no more than 200 nodes on the network map are selected. You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

To view events associated with devices:

1. On the network map, select one or multiple objects representing nodes of known devices and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

- Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
- Hold down the **CTRL** key and use your mouse to select the relevant objects.

The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.

2. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.
3. Depending on which events you want to load, click one of the following buttons (the buttons are unavailable if the total number of devices in the selection exceeds 200):
   - **Show events** – if you want to view events with any status.
   - **Show unprocessed events** – if you want to view events with the *New* or *In progress* status.

The **Events** section opens. The events table will apply a filter based on the IDs of devices corresponding to the selected nodes on the network map (the **Device IDs** field appears in the toolbar). If you loaded events by using the **Show unprocessed events** button, events are additionally filtered by the **Status** column.

Viewing events associated with a link

You can view the events associated with links on the network map. When events are loaded, they are automatically filtered based on the IDs of events associated with the link, and based on the time period.

You can use the following methods to load events associated with links:

- Load events associated with a selected link. This method can be used for any link except links with the consolidated node of unknown devices.
- Load events associated with links to nodes in a collapsed group.

The application loads no more than 200 events associated with a link. If there are more events, the events with the highest severity and with the latest time of occurrence are selected first.

To view events associated with a link:

1. On the network map, select a link (except a link in which one of the sides of communication is a consolidated node of unknown devices).

   The details area appears in the right part of the web interface window.
2. Depending on which events you want to load, click one of the following buttons (the buttons are available if there are events associated with the link):
   - **Show events** – if you want to view events with any status.
   - **Show unprocessed events** – if you want to view events with the *New* or *In progress* status.
3. If more than 200 events associated with the link were registered during the time period defined on the network map, you will see a warning about the large number of events. In the prompt window, confirm whether you want to load events with the highest severity levels.

The **Events** section opens. The events table will apply a filter based on the IDs of events and the time period defined on the network map. If you loaded events by using the **Show unprocessed events** button, events are additionally filtered by the **Status** column.

To view events associated with links of nodes in collapsed groups:

1. On the network map, select the link showing interactions with nodes in the collapsed group.

   The details area appears in the right part of the web interface window. The **Total links: <number>** settings group contains a list of the maximum severities of events in links to nodes of the collapsed group. For each severity level, the number of links with this severity is displayed. Only the severities of links to nodes of the collapsed group are shown. If there are links that are not associated with any event, **No events** is displayed with the number of such links.

2. Load events by using the **To events** link in the row containing the relevant severity.

   You can load the following events:

   - For the **Critical** severity level, events associated with links that have **Critical** severity are loaded.
   - For the **Warning** severity level, events associated with links that have a **Warning** or **Critical** severity are loaded.
   - For the **Informational** severity level, events associated with links that have an **Informational**, **Warning** or **Critical** severity are loaded.

3. If more than 200 events associated with links that have the selected severities were registered during the time period defined on the network map, you will see a warning about the large number of events. In the prompt window, confirm whether you want to load events with the highest severity levels.

The **Events** section opens. The events table will apply a filter based on the IDs of events and the time period defined on the network map.

Viewing information in the devices table for selected nodes

For nodes representing known devices on the network map, you can view information in the devices table. The devices table automatically applies a filter based on the IDs of known devices.

The capability to load information is available if no more than 200 nodes representing known devices are selected. You can select the relevant nodes individually or as part of collapsed groups that include the relevant devices. When a collapsed group is selected, all devices in the child groups of any nesting level are also included in the device selection.

To view information about devices in the devices table:

1. On the network map, select one or multiple objects representing nodes of known devices and/or collapsed groups.

   To select multiple nodes and/or groups, do one of the following:

   - Hold down the **SHIFT** key and use your mouse to select a rectangular area containing the relevant objects.
   - Hold down the **CTRL** key and use your mouse to select the relevant objects.

   The details area appears in the right part of the web interface window. The details area shows the total number of selected nodes and groups while also showing the quantitative distribution of selected objects by type.

2. If the selected objects belong to different types or categories of devices, you can exclude certain types of objects (for example, nodes of devices that are unknown to the application) or categories (for example, PLC). To do so, clear the check box next to the name of the category or type.

3. Depending on the number of selected objects, click the **Show device** or **Show devices** button (the **Show devices** button is not available if the total number of known devices in the selection exceeds 200).

The **Assets** section opens. The devices table on the **Devices** tab will apply a filter based on the IDs of devices corresponding to the selected nodes on the network map.

Viewing information in the devices table for a selected link

For links on the network map, you can view information about known devices involved in communications. Proceed to the devices table to load information. The devices table automatically applies a filter based on the IDs of known devices.

You can view information in the devices table only for links to nodes in collapsed groups.

The application loads no more than 200 devices associated with links to nodes in collapsed groups. If there are more devices, the devices associated with links with the highest severity are selected first.

To view information about devices associated with links to nodes in collapsed groups:

1. On the network map, select the link showing interactions with nodes in the collapsed group.

   The details area appears in the right part of the web interface window. The **Total links: <number>** settings group contains a list of the maximum severities of events in links to nodes of the collapsed group. For each severity level, the number of links with this severity is displayed. Only the severities of links to nodes of the collapsed group are shown. If there are links that are not associated with any event, **No events** is displayed with the number of such links.

2. Load device information by using the **To devices** link in the row containing the relevant severity.

   You can load the following device information:

   - For the **Critical** severity level, you can load information about devices associated with links that have **Critical** severity.
   - For the **Warning** severity level, you can load information about devices associated with links that have a **Warning** or **Critical** severity.
   - For the **Informational** severity level, you can load information about devices associated with links that have **Informational**, **Warning**, or **Critical** severity.
   - For the **No events** severity level, you can load information about devices associated with links that have any severity.

3. If the total number of known devices in the selection exceeds 200, you will see a warning about the large number of devices. In the prompt window, confirm whether you want to load devices associated with links that have the highest severity levels.

The **Assets** section opens. The devices table on the **Devices** tab will apply a filter based on the IDs of devices.

Monitoring events and incidents

When analyzing industrial network traffic, the application registers events and incidents.

An *event* in Kaspersky Industrial CyberSecurity for Networks is a record containing information about the detection of certain changes or conditions in industrial network traffic requiring the attention of an ICS security officer. Events are registered and transmitted to the Kaspersky Industrial CyberSecurity for Networks Server. The Server processes received events and saves them in a database.

An *incident* is a special type of event that is registered when a certain sequence of events is received. Incidents group events that have certain common traits or that are associated with the same process.

The application registers incidents based on event correlation rules. An *event correlation rule* describes the conditions for checking the sequences of events. When the application detects a sequence of events matching the rule conditions, it registers an incident that indicates the name of the triggered rule. Incidents are registered using the system event type that is assigned the code 8000000001.

Event correlation rules are embedded in the application and are applied regardless of the security policy.

After installation, the application uses the default event correlation rules. To improve the effectiveness of rules, Kaspersky experts regularly update the databases containing the sets of rules. You can update correlation rules by installing updates.

The Kaspersky Industrial CyberSecurity for Networks Server registers events and incidents according to the settings defined for registering event types. You can configure these settings in the Event types section (for all event types) and when configuring Process Control rules (only for events that are registered when Process Control rules are triggered).

To reduce the number of frequently recurring events that do not require attention from the operator, you can create allow rules for events. Events that satisfy allow rules are not registered. For example, you can use an allow rule to temporarily disable registration of all events from a specific monitoring point. You can view allow rules for events in the **Allow rules** section. The EVT type is indicated for these rules.

The application saves events and incidents in the database on the Server. The total volume of saved entries cannot exceed the defined limit. If the volume exceeds the defined limit, the application automatically deletes 10% of the oldest entries. If the minimum storage time limit is enabled and the application deletes entries whose storage time is less than the defined limit, a corresponding message will appear in the application message log. You can configure the settings for storing events and incidents.

Database files are saved on the Server in the DBMS folders. Deleting or modifying any file in these folders may cause a disruption in application performance.

You can view information about events and incidents in the following sections of the Kaspersky Industrial CyberSecurity for Networks web interface:

- The **Dashboard** section displays general information about the latest events and incidents registered by the application.
- The **Events** section displays detailed information about events and incidents and provides the capability to download information from the Server database for any period.

Event severity levels

Events and incidents in Kaspersky Industrial CyberSecurity for Networks are classified according to the following severity levels:

- *Informational* (marked with the icon).

  Informational events and incidents contain reference information. These events usually do not require an immediate response.

- *Warning* (marked with the icon).

  Warnings and incidents contain information that requires attention. These events may require a response.

- *Critical* (marked with the icon).

  Critical events and incidents contain information that may have a critical impact on the industrial process. These events require an immediate response.

You can define severity levels for custom event types. The severity levels for system event types (including events in incidents) are assigned by the application automatically.

Event registration technologies

Kaspersky Industrial CyberSecurity for Networks registers events based on one of the following technologies:

- *Deep Packet Inspection* (DPI)

  This technology is used to register events associated with process violations (for example, an event where the specified temperature was exceeded).

- *Network Integrity Control* (NIC)

  This technology is used to register events associated with industrial network integrity or the security of communications (for example, an event for the detection of communications between devices in the industrial network over a protocol that is new for those devices).

- *Intrusion Detection* (IDS)

  This technology is used to register events associated with the detection of traffic anomalies that are signs of an attack (for example, an event for the detection of signs of ARP spoofing).

- *Command Control* (CC)

  This technology is used to register events associated with the detection of system commands for devices in traffic (for example, an event for the detection of an unauthorized system command).

- *External* (EXT)

  This technology is used for incidents and events that are received by Kaspersky Industrial CyberSecurity for Networks from recipient systems using Kaspersky Industrial CyberSecurity for Networks API methods.

- *Asset Management* (AM).

  This technology is used to register events associated with the detection of device information in traffic or in data received from EPP applications (for example, an event for the detection of a new IP address for a device).

- *Endpoint Protection Platform* (EPP).

  This technology is used to register events associated with threats detected by Kaspersky applications that perform functions to protect workstations and servers (for example, a malware detection event).

Event statuses

Statuses of events and incidents enable the application to show the progression of information processing by the ICS security officer.

The following statuses can be assigned to events and incidents:

- *New* (marked with the icon).

  This status is assigned to all events and incidents when they are registered in Kaspersky Industrial CyberSecurity for Networks.

- *In progress* (marked with the icon).

  You can assign this status to events and incidents that are currently being processed (in progress), for example, when investigating the reasons for registration of these events and incidents.

- *Resolved* (marked with the icon).

  You can assign this status to events and incidents that have already been processed (for example, investigation of the reasons for their registration is complete).

  > After the *Resolved* status is assigned, events and incidents with this status are not taken into account by the application when determining the security states of devices displayed in the devices table and on the network map.

The statuses of events and incidents are changed manually. You can sequentially assign statuses in order from the *New* status to the *Resolved* status (however, you are not required to assign the intermediate *In progress* status). After the status of an event or incident is changed, you cannot assign the previous status to it.

Table of registered events

You can view the table of registered events and incidents in the **Events** section of the application web interface.

By default, the table of registered events and incidents is updated in online mode. The beginning of the table displays the events and incidents with the latest dates and times when last visible.

> The date and time when the event or incident was last visible may differ from the date and time of its registration (the date and time of registration is displayed in the **Start** column). For an event, the date and time when last visible may be updated during the event regeneration period for this type of event. For an incident, the date and time when last visible is updated according to the date and time of last occurrence of the events that are part of the incident.

You can perform the following operations when working with the table of events and incidents:

- Manage the display of events and incidents
- Filter events
- Event search

- Sort events
- Configure the table of registered events
- View event details
- Change the statuses of events
- View event information in the devices table
- View the nodes and links of events on the network map
- Add markers
- Copy events to a text editor
- Export events to file
- Load traffic of events

The settings for displaying the events table (for example, the filter settings) are automatically saved for the current application user. The saved settings are applied the next time this user connects to the Server, provided that the connection is used by the same computer, browser, and operating system user account.

Selecting events in the events table

In the events table, you can select events and incidents to view their information and to work with these events and incidents. When events and incidents are selected, the details area appears in the right part of the web interface window.

To find relevant events and/or incidents, do one of the following:

- If you want to select one event or incident, select the check box next to this event or incident or use your mouse to select it.
- If you want to select multiple events and/or incidents, select the check boxes next to the relevant events and/or incidents or select them while holding down the **CTRL** or **SHIFT** key. When multiple events and/or incidents are selected, the application checks their status and determines if there are events and/or incidents with the *New*, *In progress* or *Resolved* statuses among those selected.
- If you want to select all events and incidents that satisfy the current filter and search settings, perform one of the following actions:
  - Select any event or incident in the table and press the key combination **CTRL+A**.
  - Select the check box in the title of the left-most column of the table.

When multiple events and/or incidents are selected, the details area displays the total number of selected elements. However, embedded elements of collapsed incidents (events and other incidents) are not taken into account.

If you selected all events and incidents that satisfy the current filter and search settings, embedded elements of collapsed incidents are included in the total number of selected elements. The details area displays one of the following values:

- If 1000 or less events and incidents are selected, the precise number is displayed. In this case, the application checks the statuses of the selected events and incidents just as with other multiple selection methods.
- If more than 1000 events and incidents are selected, the number `1000+` is displayed. In this case, the application does not check the statuses of the selected events and incidents.

The title of the left-most column of the table shows a check box for the selection of events and incidents. Depending on the number of selected items in the table, the check box can have one of the following states:

- ☐ – all events and incidents that satisfy the current filter and search settings were not selected in the table. However, one event/incident or multiple events and/or incidents may be selected in the table by using the check boxes next to the events and incidents or by using the **CTRL** or **SHIFT** key.
- ☑ – all events and incidents that satisfy the current filter and search settings were selected in the table.
- ▣ – all events and incidents that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of them were cleared. This state is also retained if the check boxes were cleared for all events and incidents selected in this way (due to the fact that the number of selected events and incidents may change).

If all events and incidents that satisfy the filter and search settings are selected, the number of selected elements may be automatically changed. For example, this may happen if new events or incidents are registered. It is recommended to configure the filter and search settings in such a way that ensures that only the relevant elements end up in the selection (for example, you can filter events by their IDs before selecting all events and incidents).

Viewing events included in an incident

For viewing events included in incidents, the following modes are provided in the events table:

- Simple viewing mode. In this mode, the events table displays all events without consideration of how events are nested in incidents.
- Tree display mode. In this mode, incidents are displayed as tree structures that can be collapsed or expanded using the ⊞ and ⊟ buttons next to the headers of incidents.

You can change the display mode when configuring the events table.

Filtering events

To limit the number of events and incidents displayed in the events table, you can use the following functions:

- Filtering based on standard periods

When filtering based on a standard period, the events table is updated in online mode.

To configure filtering of events and incidents based on a standard period:

1. In the **Events** section, perform one of the following actions:
   - Open the **Period** drop-down list.
   - Click the filtering icon in the **Last seen** column.
2. In the drop-down list, select one of the standard periods:
   - **Last hour**
   - **Last 12 hours**
   - **Last 24 hours**.
   - **Last 48 hours**
3. If table updates are disabled, in the opened window confirm that you agree to resume table updates.

The table will display events and incidents for the period you specified.

- Filtering based on a specified period

When filtering by a defined period, the table will no longer be updated. The table will display only the events and incidents whose date and time of last occurrence are within the specified period.

To configure filtering of events and incidents based on a specified period:

1. In the **Events** section, perform one of the following actions:
   - Open the **Period** drop-down list.
   - Click the filtering icon in the **Last seen** column.
2. In the drop-down list, select **Specify a period**.
3. If table updates are enabled, in the opened window confirm that you agree to suspend table updates.

   The start and end date and time of the filtering period are displayed on the right of the drop-down list.
4. Click the date of the start or end of the period.

   The calendar opens.
5. In the calendar, specify the date for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YYYY hh:mm:ss. If you don't need to specify the date and time of the filtering period end boundary, you can choose not to select a date or you can delete the current value.
6. Click **OK**.

The events table will display events and incidents for the period you specified.

- Filtering based on table columns

You can configure filtering of events and incidents based on the values in all columns except the **End**, **Title**, and **Description** columns.

*To filter the events table by the **Start** column:*

1. In the **Events** section, click the filtering icon in the **Start** column.

   The calendar opens.

2. In the calendar, specify the date for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YYYY hh:mm:ss. If you don't need to specify the date and time of the filtering period boundary, you can choose not to select a date or you can delete the current value.

3. Click **OK**.

*To filter the events table by the **Severity**, **Technology**, **Status**, **Monitoring point** or **Marker** column:*

1. In the **Events** section, click the filtering icon in the relevant column.

   When filtering by severity level or technology, you can also use the corresponding buttons in the toolbar.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events. You can select the **All** check box to select all values in the **Marker** and **Technology** columns.

3. Click **OK**.

*To filter the events table by the **Source** or **Destination** column:*

1. In the **Events** section, click the filtering icon in the relevant column.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, in the drop-down lists, select the types of address blocks that you want to include in the filter and/or exclude from the filter. You can select the following types of address blocks:

   - **IP address**
   - **Port number**
   - **MAC address**
   - **Application-level address**
   - **VLAN ID**
   - **Complex** – if you want to specify multiple address blocks of different types combined by the logical operator AND. To add different types of address blocks, use the **Add condition (AND)** button.

3. If you want to apply multiple filter conditions by address block type combined with the logical operator OR, in the filter window click the **Add condition (OR)** button and select the relevant types of addresses.

4. If you want to delete one of the created filter conditions, in the filter window click the × icon located on the right of the field containing the drop-down list.

5. Click **OK**.

*To filter the events table by the **Protocol** column:*

1. In the **Events** section, click the filtering icon in the **Protocol** column.

   You will see a window containing the table of supported protocols displayed as a protocol stack tree. You can manage how tree elements are displayed by using the **+** and **-** buttons next to the names of protocols that contain protocols of subsequent layers.

   The table columns provide the following information:

   - **Protocol** – name of the protocol within the protocol stack tree.
   - **EtherType** – number of the next-level protocol within the Ethernet protocol (if the protocol has a defined number). It is displayed in decimal format.
   - **IP number** – number of the next-level protocol within the IP protocol (if the protocol has a defined number). It is indicated only for protocols within the IP protocol structure. It is displayed in decimal format.

2. If necessary, use the search field above the table to find relevant protocols.
3. In the list of protocols, select the check boxes opposite the protocols by which you want to filter events.

   If you select or clear the check box for a protocol that contains nested protocols, the check boxes for the nested protocols are also automatically selected or cleared.

4. Click **OK**.

*To filter the events table by the **Total appearances**, **ID**, **Triggered rule** or **Event type** column:*

1. In the **Events** section, click the filtering icon in the relevant column.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values for events and incidents that you want to include in the filter and/or exclude from the filter.
3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the selected column click the **Add condition** button and enter the condition in the opened field.
4. If you want to delete one of the created filter conditions, in the filter window of the selected column click the icon.
5. Click **OK**.

- Filtering based on the values in table cells

You can filter the events table by the values in cells of any column except the following columns: **Start**, **Last seen**, **Title**, **Description** and **End**.

To filter the table based on the values of settings in table cells:

1. Select the **Events** section.
2. In the events table, select the check box next to the event or incident whose setting you want to use as a filter.

   If you want to select multiple events and/or incidents, select the check boxes next to the events and/or incidents whose settings you want to use as a filter. You can also select multiple events and/or incidents by holding down the **CTRL** or **SHIFT** key.

   The details area appears in the right part of the web interface window. If multiple events and/or incidents are selected, the details area displays the total number of selected elements.
3. In the events table, move your mouse cursor over a cell of the relevant column of one of the selected events or incidents.
4. Right-click to open the context menu.
5. In the context menu, select one of the following options:

   - **Show all events with this setting**, if one event or incident is selected.
   - **Show all events with these settings**, if multiple events and/or incidents are selected.

   The **Show all events with this setting** or **Show all events with these settings** options are not available for selection if it is impossible to filter by column values.

The table of registered events displays the events and incidents that have values in that same column matching the values of the selected events and/or incidents.

When filtering the events table in tree display mode, incidents that meet the filtering criteria may be presented in the following variants:

- Displayed with all nested elements
- Displayed only with the nested elements that also meet the defined filtering criteria

You can select the relevant display option for incidents by using the **Show embedded events when filtering** check box when configuring the table.

Searching events

You can search events and incidents in the events table.

The search is performed in the columns containing characters (letters and/or numerals), except the **Start**, **Last seen**, **End** and **Total appearances** columns.

To find relevant events and incidents:

In the **Events** section, enter your search query into the **Event search** field. The search is initiated as you type characters in the search field.

The table displays the events and incidents that meet the search criteria.

When performing a search in tree display mode, incidents that meet the filtering criteria may be presented in the following variants:

- Displayed with all nested elements
- Only with the nested elements that also meet the search criteria

You can select the relevant display option for incidents by using the **Show embedded events when filtering** check box when configuring the table.

Resetting the defined filter and search settings in the events table

You can reset the defined filter and search settings in the events table to their default state.

To reset the defined filter and search settings in the events table:

In the toolbar in the **Events** section, click the **Default filter** button (this button is displayed if the filter and/or search settings are defined).

Sorting events

You can sort events and incidents displayed in the **Events** section of the application web interface. You can sort by the values of any column except the **Description** column.

By default, table rows are sorted by the **Last seen** column in descending order of the dates and times when events last occurred. If the default sorting scheme is changed, the application stops updating events in the table.

To sort events and incidents:

1. In the **Events** section, click the header of the column by which you want to sort.
2. When sorting events by the **Destination** or **Source** column, in the drop-down list of the column header, select the address of the destination or source by which you want to sort.

   Depending on the values selected for display in these columns, you can select one of the following options:

   - **IP address**
   - **Port number**
   - **MAC address**
   - **VLAN ID**
   - **Application-level address**
3. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

4. If table updates are enabled, in the opened window confirm that you agree to suspend table updates.

The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons showing the current sorting order: in ascending order or descending order of values.

Configuring the table of registered events

You can configure the following settings for displaying the events table:

- Display of the information panel.
- Display of events included in incidents.
- Contents and order of columns displayed in the table.

To configure the events table display settings:

1. In the **Events** section, click the **Customize table** link to open the window for configuring how the table is displayed.
2. If you want to enable display of the information panel showing the number of events with the *New* and *In progress* statuses, select the **Display information panel** check box.
3. In the **Display embedded lists** settings group, select the relevant mode for displaying events included in incidents:
   - **Flat**. In this mode, the events table displays all events without consideration of how events are nested in incidents.
   - **Tree**. In this mode, incidents are displayed as a tree of embedded events and other incidents. If you want the nested elements of incidents to be displayed regardless of the current filter and search settings, select the **Show embedded events when filtering** check box.
4. In the **Displayed table columns** settings group, select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.

   The following settings are available for viewing:

   - **Start**

     For an event that is not an incident – date and time of event registration. For an incident – date and time of registration of the first event included in the incident. In the table, you can view the date together with the time, or just the date or time by itself. To choose the information to display, select the check boxes opposite the **Date** and/or **Time** settings.

   - **Last seen**

     For an event that is not an incident, this is the date and time when the event last occurred. It may contain the date and time of event registration, or the date and time when the event regenerate counter value increased if the conditions for event registration were repeated during the event regenerate timeout. The value of the regenerate counter is displayed in the **Total appearances** column. For an incident, this is the latest date and time of last occurrence of events that are part of the incident. Just like with the **Start** column, you can view the date together with the time, or just the date or time by itself.

   - **Title**

     Header defined for the event type.

- **Severity**

  This icon corresponds to the severity level of an event or incident.

- **Source**

  Address of the source of network packets (the abbreviated names for display in table cells are specified in parentheses):

  - **IP address**
  - **Port number (P)**
  - **MAC address**
  - **VLAN ID (VID)**
  - **Application-level address**

- **Destination**

  Address of the destination of network packets (the abbreviated names for display in table cells are specified in parentheses):

  - **IP address**
  - **Port number (P)**
  - **MAC address**
  - **VLAN ID (VID)**
  - **Application-level address**

- **Protocol**

  Application layer protocol that was being monitored when the application registered the event.

- **Technology**

  This icon corresponds to the technology that was used to register the event.

- **Total appearances**

  For an event that is not an incident, this is the value of the regenerate counter after the event is registered within the event regenerate timeout. A value greater than 1 means that the conditions for event registration were repeated N – 1 times. The value 1 is displayed for the incident in this column.

- **ID**

  Unique ID of the registered event or incident.

- **Status**

  This icon corresponds to the status of an event or incident.

- **Description**

  Description specified for the event type.

- **End**

For an event that is not an incident, this is the date and time when the *Resolved* status was assigned, or the date and time of the event regenerate timeout. For an incident, this is the latest date and time of the end of events that are part of the incident. Just like with the **Start** column, you can view the date together with the time, or just the date or time by itself.

- **Triggered rule**

  For an event that is not an incident, this is the name of the Process Control rule or Intrusion Detection rule whose triggering caused the registration of the event. For an incident, this is the name of the correlation rule whose triggering caused the registration of the incident.

- **Monitoring point**

  Monitoring point whose traffic invoked registration of the event.

- **Event type**

  Numerical code assigned to the event type.

- **Marker**

  This is a selection of icons that you can set for any event or incident so that you can easily find events and incidents based on a criterion that is not in the table.

5. If you want to change the order in which columns are displayed, select the name of the column that you want to move to the left or right in the table and use the buttons containing an image of the up or down arrows.

   For the **Start**, **Last seen** and **End** columns, you can also change the order in which the date and time are displayed. For the **Source** and **Destination** columns, you can change the order of the addresses of the senders and recipients of network packets. To do so, select the value that you want to move to the left or right in the table and use the buttons containing an image of the up or down arrows.

The selected columns will be displayed in the **Events** section in the table in the order you specified.

Viewing event details

Detailed information about events and incidents is displayed in the details area in the **Events** section of the application web interface.

To view the details of an event or incident:

In the **Events** section, select the relevant event or incident.

The right part of the web interface window will show the details area, which displays detailed information about the selected event or incident.

Viewing information about devices associated with events

You can view information about devices associated with events in the devices table. When data is loaded, it is automatically filtered based on the IDs of known devices using the values of the MAC- and IP addresses specified in events.

To view information about devices in the devices table:

1. Select the **Events** section.

2. In the events table, select the events and/or incidents for which you want to view device information.

The details area appears in the right part of the web interface window.

3. Click the **Show devices** button.

   The **Show devices** button is not available if there are no incidents among the selected events and the number of selected events exceeds 200.

4. If the total number of selected events (including events of the selected incidents) exceeds 200, you will see a warning about the large number of events. In the prompt window, confirm whether you want to load devices associated with the first 200 events from those selected.

5. If the total number of devices associated with the selected events exceeds 200, you will see a warning about the large number of devices. In the prompt window, confirm whether you want to load the first 200 devices associated with the selected events.

The **Assets** section opens. The devices table on the **Devices** tab will be filtered based on the IDs of devices corresponding to the selected events.

Switching to the network map to display event information

You can configure the network map to display nodes and links based on information saved in events. The nodes displayed on the network map are determined by the address information of the sources and destinations of network packets in the selected events. The displayed links are filtered based on the time of communications, beginning with the date and time of registration of the first event among the list of selected events.

The capability to display nodes and links on the network map is available if no more than 200 events are selected in the events table (including among the selected incidents).

To configure the network map to display nodes and links based on information in events:

1. Select the **Events** section.

2. In the events table, select the events and/or incidents for which you want to display nodes and links on the network map.

   The details area appears in the right part of the web interface window.

3. Click the **Show on network map** button (this button is unavailable if there are more than 200 events selected).

The **Network map** section opens. The network map displays nodes and links based on information in the selected events (initial filtering by event will be applied). If you select an incident in which events are still being added, the network map will also display nodes and links based on information in the new events.

Changing the statuses of events

You can change the following statuses of events and incidents:

- *New*. This status can be changed to the *In progress* or *Resolved* status.
- *In progress*. This status can be changed to the *Resolved* status.

The *Resolved* status cannot be changed.

To change the status of events or incidents:

1. Select the **Events** section.
2. In the events table, select the events and/or incidents whose status you want to change.

   The details area appears in the right part of the web interface window.
3. Use the **In progress** or **Resolved** buttons to assign the relevant status to events and/or incidents. These buttons are unavailable in the following cases:

   - The **In progress** button is unavailable if the selected items do not include events or incidents with the *New* status.
   - The **Resolved** button is unavailable if the selected items do not include events or incidents with the *New* or *In progress* status.

   > If all events and incidents that satisfy the current filter and search settings are selected, and the number of selected items is more than 1000, the application does not check their statuses. In this case, the **In progress** and **Resolved** buttons are both available. However, the **In progress** button can be used to assign the *In progress* only to events and incidents that have the *New* status.

   A window with a confirmation prompt opens.
4. In the prompt window, click **OK**.

Creating allow rules for events

If you need to disable registration of events with specific indicators (for example, all events from a monitoring point), you can create allow rules for events.

Only users with the Administrator role can create allow rules for events.

You can use the following capabilities to create allow rules for events:

- **Create a rule with initially empty values of settings or with the values from a template.**

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. In the **Allow rules** section, open the details area by clicking the **Add rule** link.

3. If you want to define the values of settings from a template, in the details area click the **Use template** button, select the necessary template in the opened window and click **Apply**.

4. In the details area, click **EVT**.

5. In the **Protocol** field, specify the protocol that will be indicated in events.

   When the **Protocol** field is selected, a window opens showing the table of supported protocols displayed as a protocol stack tree. You can manage how tree elements are displayed by using the **+** and **-** buttons next to the names of protocols that contain protocols of subsequent layers.

   If necessary, use the search field above the table to find relevant protocols.

   To specify the protocol:

   a. In the protocols table, select the protocol that you want to specify for the rule. To select the relevant protocol, click the button that is displayed in the left column of the protocols table.

   b. Click **OK**.

   If you select a protocol that can be identified by the application based on the contents of network packets, a notification about this appears under the **Protocol** field.

6. If necessary, enter additional information about the rule in the **Comment** field.

7. In the **Side 1** and **Side 2** settings groups, specify the editable address information for the participants (sides) of network interaction. Depending on the selected protocol (or set of protocols), address information may contain a MAC address, IP address, and/or port number.

   To autofill the address information of a side of network interaction, you can select devices that are known to the application. To do so:

   a. Open the device selection window by clicking the **Specify device addresses** link.

   b. In the device selection window, select the check boxes next to the devices that you want to use.

      The device selection window contains a table in which you can configure the layout and order of columns, and filter, search, and sort similarly to the devices table in the **Assets** section.

   c. Click **OK** in the device selection window.

8. In the **Event type** field, specify the event type whose numerical code is indicated in events.

   Selecting the **Event type** field opens a window containing a list of event types that may be indicated in allow rules. If necessary, use the search field above the list to find the relevant event type. To specify the event type, select it in the list and click **Apply**.

9. In the **Monitoring point** field, specify the monitoring point name that is indicated in events.

   Selecting the **Monitoring point** field opens a window containing a list of all monitoring points on all nodes that have application components installed. If necessary, use the search field above the list to find the name of the relevant monitoring point. To specify the monitoring point name, select it in the list and click **Apply**.

10. In the **Rule in event** field, enter the name (or part of the name) that is indicated as the triggered rule in events.

11. In the details area, click **Save**.

    The new rule will be added to the allow rules table.

- Create a new rule based on an existing rule.

  1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
  2. In the **Allow rules** section, select the rule that you want to use as the basis for creating a new rule.
  3. Right-click to open the context menu.
  4. In the context menu, select **Create rule based on the selected rule**.

     The details area in rule editing mode will appear in the right part of the web interface window. The settings of the new rule will take the values obtained from settings of the selected rule.
  5. Change the settings as necessary. To do so, complete steps 4–11 described in the procedure for creating a rule with initially empty values of settings.

- Creating a rule based on a registered event

  1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.
  2. Select the **Events** section.
  3. In the table of registered events, select the event that you want to use as the basis for creating the allow rule for events.

     The details area appears in the right part of the web interface window.
  4. In the details area, click the **Create allow rule** button.

     The **Allow rules** section opens in the browser window. The details area in rule editing mode will appear in the right part of the web interface window. The new rule's settings will take the values received from the saved information about the event.
  5. If necessary, edit the settings of the new rule. To do so, complete steps 4–11 described in the procedure for creating a rule with initially empty values of settings. If you do not need to change the settings of the new rule, save the rule by clicking the **Save** button.

Setting markers

You can assign specific markers to events and incidents in the **Events** section of the application web interface.

A *marker* is an icon that lets you easily find events and incidents based on a criterion that is absent from the table.

To set a marker for an event or incident:

1. In the **Events** section, left-click to open the context menu in the cell of the **Marker** column for the row containing the relevant event or incident.
2. In the context menu, select the marker that you want to set for this event or incident.

   You can select one of the seven markers provided in the application. You choose the purpose of each marker on your own.
3. If you need to remove a marker, select **No marker** in the context menu.

Copying events to a text editor

You can copy information about the events and incidents displayed in the events table to any text editor. The information is copied from the columns that are currently displayed in the table.

The capability to copy is available if no more than 200 events and incidents are selected.

To copy events and/or incidents to a text editor:

1. Select the **Events** section.
2. In the events table, select the events and/or incidents whose information you want to copy to a text editor.

   The details area appears in the right part of the web interface window.
3. Right-click to display the context menu of one of the selected events.
4. In the context menu, select one of the following options:

   - **Copy details of the event** if one event or incident is selected.
   - **Copy details of the selected events** if multiple events and/or incidents are selected.
5. Open any text editor.
6. Paste it into the text editor window (for example, by pressing the key combination **CTRL+V**).

The copied event details can be edited in the text editor. Information about multiple events will be separated by an empty line.

Exporting events to a file

When connected to the Server through the web interface, you can export information about events (and incidents) to files of the following formats:

- CSV

  When exporting a file in this format, the file saves information from the columns currently displayed in the table.
- JSON

When exporting a file in this format, the file saves all available information about events, including service information from the database (such as information about devices associated with the events). The file can be used to upload detailed event data to other systems.

You can perform an export to CSV and JSON files for all events that satisfy the current filter and search settings, or selectively for events displayed in the table.

To export information about all events that satisfy the current filter and search settings:

1. Select the **Events** section.
2. Click the **Export** link in the toolbar to open the menu for selecting the format of the saved file.
3. In the opened window, select the relevant file format option: **file in CSV format** or **file in JSON format**.

   The file creation process starts.
4. If it takes a long time (more than 15 seconds) to create the file, the file creation operation is transferred to the list of background operations. In this case, to download the file:

   a. Click the button in the menu of the application web interface.

   The list of background operations appears.

   b. Wait for the file creation operation to finish.

   c. Click the **Download file** button.

Your browser will save the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

To export information about selected events:

1. Select the **Events** section.
2. In the events table, select the events whose information you want to export to a file.

   After you select events, the details area opens in the right part of the web interface window.
3. Click the relevant part of the **Export to:** button indicating the necessary file format: **CSV file or JSON file**.

   The file creation process starts. If it takes a long time (more than 15 seconds) to create the file, perform the necessary actions for step 4 as described in the procedure for exporting information about all events.

Loading traffic for events

When viewing the events table, you can load traffic associated with registered events and/or incidents. Traffic is loaded into a PCAP file (when one event is selected) or into a ZIP archive containing PCAP files (when multiple events or incidents are selected).

The capability to load traffic is available if no more than 200 events are selected in the events table (including events within incidents).

Traffic for events is loaded from the application database. The database saves traffic only when registering events for which traffic saving is enabled. The application can also save traffic in the database directly by requesting to load traffic using traffic dump files. These files are intended for temporarily saving traffic and are automatically deleted as more and more traffic is received from the industrial network (the frequency of file deletion depends on the amount of traffic received and the defined application data storage settings). To ensure that traffic is loaded, it is recommended to enable the saving of traffic for the relevant event types and configure the settings for saving traffic in the database in accordance with the rate of traffic and registration of events.

To load a traffic file for events and/or incidents:

1. Select the **Events** section.
2. In the events table, select the events and/or incidents whose traffic you want to load.

   The details area appears in the right part of the web interface window.
3. Depending on the number of selected elements, click the **Load traffic for the event** or **Load traffic for the selected events** button.
4. If it takes a long time (more than 15 seconds) to create the file, the file creation operation is transferred to the list of background operations. In this case, to download the file:

   a. Click the button in the menu of the application web interface.

      The list of background operations appears.

   b. Wait for the file creation operation to finish.

   c. Click the **Download file** button.

Your browser will save the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

Monitoring vulnerabilities of devices

Kaspersky Industrial CyberSecurity for Networks can detect vulnerabilities in monitored industrial network devices. A *vulnerability* is a defect or flaw in device hardware or software that a hacker could exploit to impact the operation of an information system or to gain unauthorized access to information.

The application detects vulnerabilities by analyzing available information about devices. The relevant information utilized to find a known vulnerability of a device is compared to specific fields in the *database of known vulnerabilities*. The database of known vulnerabilities is built in to the application. This database is created by Kaspersky experts who fill it with information about the latest or most frequently encountered vulnerabilities of devices in industrial networks.

The database of known vulnerabilities contains descriptions of vulnerabilities and descriptions of the devices affected by these vulnerabilities. This database also contains system security recommendations in the form of text or links to publicly available resources. Descriptions and recommendations from various sources are uploaded to the database of known vulnerabilities. These sources may be the manufacturers of devices or software, or various organizations specializing in industrial security. Descriptions and recommendations in the database are provided in English.

After the application is installed, the initial preconfigured database of known vulnerabilities is used. You can keep the database up to date by installing updates.

Kaspersky Industrial CyberSecurity for Networks compares available device information with the specific fields in the database of known vulnerabilities that describe devices affected by vulnerabilities. For example, available information about software versions on devices may be used for the comparison. When a data match is identified, the application registers a device vulnerability detection event, then downloads information about this vulnerability from the database of known vulnerabilities.

The application uploads information about detected vulnerabilities to the database of detected vulnerabilities on the Server. The contents of this database are displayed in the vulnerabilities table when connected to the Server through the web interface. The total volume of saved entries in the known vulnerabilities database cannot exceed the defined limit. If the volume exceeds the defined limit, the application automatically deletes 10% of the oldest entries. You can set a maximum volume limit for detected vulnerabilities when configuring data storage settings on the Server node.

The main parameter used to identify a vulnerability in the application database is the identification number assigned to this vulnerability in the list of Common Vulnerabilities and Exposures (CVE). This identification number is known as a *CVE ID*.

You can view information about the vulnerabilities of devices on the Server web interface page in the following sections:

- **Vulnerabilities** – displays detailed information about all vulnerabilities detected by the application.
- **Assets** – on the **Devices** tab, displays lists of CVE IDs of detected vulnerabilities in the **Vulnerabilities** column and in the details area of the selected device.

Scenario for implementing the continuous vulnerability management process

Using asset management and vulnerability detection functionality, you can implement continuous (cyclical) management of vulnerabilities in industrial network devices. For vulnerability management purposes, Kaspersky Industrial CyberSecurity for Networks provides information on detected vulnerabilities that you can use to take the appropriate measures to remediate vulnerabilities and mitigate risks. The continuity of the vulnerability management process is ensured through automatic updates of information about devices and vulnerabilities in the application.

The scenario for implementing the continuous vulnerability management process consists of the following stages:

1. **Inventory of devices and tracking of device information**

   This stage is implemented by using the device activity detection and device information detection methods (these methods must be enabled). During this stage, the application automatically detects new devices and updates the device information. For all information that defines the classification and operating specifications of devices (such as information about the device model and software version), you must enable autoupdate in the settings of devices. If autoupdate of this information cannot be completed for some reason, this information should be manually updated.

2. **Scanning devices for vulnerabilities**

This stage is implemented by using the vulnerability detection method (this method must be enabled). Scanning is performed based on available device information. A scan is started automatically after the application's database of known vulnerabilities is updated or after the addition/modification of device information that is used for comparison with fields in the database (for example, after information about the device model and software version is saved).

3. **Assessment of detected vulnerabilities and classification of risks**

   Each detected vulnerability is given a score denoting its severity according to the Common Vulnerability Scoring System (CVSS). Depending on the numerical value of this score, a vulnerability may have a severity of *Low* (score of 0.0–3.9), *Medium* (4.0–6.9) or *High* (7.0–10.0). The severities of detected vulnerabilities affect the security states of their associated devices (just like unresolved events associated with these devices).

   You can classify the risks of exploitation of detected vulnerabilities based on their severities and scores, and on other factors related to the operational specifications of the devices. If the risk associated with the exploitation of a vulnerability is assessed as negligible, this vulnerability can be switched from the *Active* state (the default state of a vulnerability after it is detected) to the *Accepted* state. For example, this would be advisable if the conditions for vulnerability exploitation cannot be reproduced. All vulnerabilities that require some additional actions should be left in the *Active* state.

4. **Remediate vulnerabilities and mitigate risks**

   During this stage, you need to eliminate active vulnerabilities or mitigate the risks associated with their exploitation. Actions toward remediating vulnerabilities and mitigating risks may include acquisition, verification, and installation of the necessary patches or updates for devices, organizational measures (such as isolating vulnerable devices from external networks), or replacement of vulnerable devices.

   You can obtain information about the recommended actions by viewing information about the detected vulnerabilities. Recommendations for protecting your system are provided in the form of text or links to publicly available resources.

   > Actions toward remediating vulnerabilities and mitigating risks are performed without the involvement of Kaspersky Industrial CyberSecurity for Networks.

5. **Verification that vulnerabilities have been remediated**

   This stage is similar to the stage involving scanning devices for vulnerabilities. When device information is changed, the application automatically switches the device's associated vulnerability from the *Active* state to the *Remediated* state if the device information no longer matches the database fields that describe a vulnerability with the same CVE ID (for example, after changing information about the device software version). The *Remediated* state is also assigned to vulnerabilities that no longer have a description in the database of known vulnerabilities (if the description is deleted from the database after updates are loaded). If devices with vulnerabilities are removed from the device table, their associated vulnerabilities are also deleted from the database of detected vulnerabilities on the Server.

   If information about a vulnerability-related device has not changed (for example, risks were mitigated by isolating the vulnerable device from external networks), you can manually switch this vulnerability from the *Active* state to the *Accepted* state.

6. **Returning devices to the OK security state**

   When a vulnerability event is registered, the security state of the device for which a vulnerability was detected changes. The device security state changes depending on the severity level of the event.

   The device returns to the **OK** security state after the *Resolved* status is assigned to all events that are related to the vulnerabilities of this device. After the vulnerability is switched to the *Remediated* or *Accepted* state, the application automatically assigns *Resolved* status to the corresponding events. Likewise, if you assigned the *Resolved* status to a vulnerability detection event that is in the *Active* state, the vulnerability is switched to the *Accepted* state.

Device information used to check for vulnerabilities

Just like when verifying that vulnerabilities have been remediated, when checking devices for vulnerabilities the application utilizes the following device information:

- **Hardware vendor**.
- **Hardware model**.
- **Hardware version**.
- **Software vendor**.
- **Software name**.
- **Software version**.

The application compares this information with the descriptions of devices in the corresponding fields of the database of known vulnerabilities. In the database, descriptions of devices are stored in the CPE (Common Platform Enumeration) language format. The application compares the information with these descriptions by automatically converting the information into the CPE language format.

For each vulnerability, the contents of matching descriptions are provided in the details area in the **Matched CPE** section. Depending on which type of device information matched the description of a device in the database, the **Matched CPE** section may display the following information:

- **Hardware CPE code**, **Hardware description** – if the device information **Hardware vendor**, **Hardware model** and **Hardware version** matched descriptions in the database.
- **Software CPE code**, **Software description** – if the device information **Software vendor**, **Software name** and **Software version** matched descriptions in the database.

Viewing devices with detected vulnerabilities

The devices table displays the CVE IDs of vulnerabilities that are currently in the *Active* state (information about vulnerabilities in other states is not displayed in the devices table). CVE IDs are displayed in the **Vulnerabilities** column and in the details area when a device is selected. You can use the CVE ID to open a window containing details about the vulnerability.

To designate the severity levels of the vulnerabilities, CVE IDs may have one of the following colors:

- Red designates a vulnerability with *High* severity.
- Yellow designates a vulnerability with *Medium* severity.
- Blue designates a vulnerability with *Low* severity.

By default, the **Vulnerabilities** column displays the CVE IDs of vulnerabilities in the *Active* state with any CVSS scores. Within cells, CVE IDs are sorted in descending order of their scores.

When viewing the devices table, you can configure the settings for filtering, sorting, or searching for devices based on CVE IDs of vulnerabilities.

Viewing the vulnerabilities table

The vulnerabilities table is displayed in the **Vulnerabilities** section of the application web interface. The table may display information about vulnerabilities in an *Active* state and vulnerabilities in either a *Remediated* or *Accepted* state.

When viewing the vulnerabilities table, you can use the following functions:

- **Configure the display and order of columns in the vulnerabilities table.**

1. In the **Vulnerabilities** section, click the **Customize table** link to open the window for configuring how the table is displayed.

2. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.

   The following settings are available for selection:

   - **CVE**.

     CVE ID of the detected vulnerability.

   - **Device group**.

     Name of the group containing the device with the detected vulnerability (contains the name of the group and the names of all its parent groups).

   - **Device**

     Device name.

   - **CVSS score**.

     Assessment of the severity of the vulnerability according to the Common Vulnerability Scoring System (CVSS). The severity of the vulnerability is designated by a numerical score. Depending on the severity, the score may have one of the following colors:

     - Red designates a vulnerability with *High* severity.
     - Yellow designates a vulnerability with *Medium* severity.
     - Blue designates a vulnerability with *Low* severity.

     For vulnerabilities in the *Active* state, the score is brightly colored. If a vulnerability is switched to the *Remediated* or *Accepted* state, its score is faintly colored.

   - **State**.

     Current state of the vulnerability. The following states are available:

     - *Active* is the automatically set state of a vulnerability when it is first detected (and when it is detected again after the vulnerability was in the *Remediated* state). You can also manually switch a vulnerability to the *Active* state from the *Accepted* state.
     - *Remediated* is the automatically set state of a vulnerability if the device information no longer matches database fields that describe a vulnerability with the same CVE (including if the vulnerability description has been removed from the database of known vulnerabilities).
     - *Accepted*. A vulnerability can be manually switched to this state from the *Active* state if the risk associated with exploitation of this vulnerability is considered to be negligible or mitigated by organizational measures.

   - **Published**.

     Date and time when information about the vulnerability was published by the hardware or software vendor (VendorAdvisory).

   - **First detected**.

     Date and time when the vulnerability was first detected based on device information.

- **Last detected**.

  Date and time when the vulnerability was last detected based on device information.

- **Attack conditions**.

  Description of the attack conditions.

- **Impact**.

  Description of the potential effects from exploitation of the vulnerability.

- **Matched CPE**.

  Descriptions of devices stored in the database of known vulnerabilities. These are descriptions that match device information in the devices table. Descriptions are provided in CPE language format (**Hardware CPE code** / **Software CPE code**) and in text format (**Hardware description** / **Software description**).

- **Vector**.

  Record of metrics used to calculate a CVSS vulnerability score.

- **Description**

  Text description of the vulnerability from the database of known vulnerabilities.

- **Origin**.

  Name of the source of the information uploaded to the database of known vulnerabilities.

3. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

The selected columns will be displayed in the vulnerabilities table in the order you specified.

- Filtering based on standard periods

In the **Vulnerabilities** section, perform one of the following actions:

- Open the **Detection period** drop-down list in the toolbar.
- Click the filtering icon in the **Last detected** column.

1. In the drop-down list, select one of the standard periods:

   - **Last 24 hours**.
   - **Last week**.
   - **Last month**.
   - **Last year**.

The table will display vulnerabilities for the period you specified.

- Filtering based on a specified period

In the **Vulnerabilities** section, perform one of the following actions:

- Open the **Detection period** drop-down list in the toolbar.
- Click the filtering icon in the **Last detected** column.

1. In the drop-down list, select **Specify a period**.

   The start and end date and time of the filtering period are displayed on the right of the drop-down list.

2. Click the date of the start or end of the period.

   The calendar opens.

3. In the calendar, specify the date for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YYYY hh:mm:ss. If you don't need to specify the date and time of the filtering period end boundary, you can choose not to select a date or you can delete the current value.
4. Click **OK**.

The table will display vulnerabilities for the period you specified.

- Filtering based on table columns

*To filter vulnerabilities by the **CVE**, **Device**, **Attack conditions**, **Impact**, **Vector** or **Matched CPE** column:*

1. In the **Vulnerabilities** section, click the filtering icon in the relevant column of the table.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values for vulnerabilities that you want to include in the filter and/or exclude from the filter.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the selected column click the **Add condition** button and enter the condition in the opened field.

4. If you want to delete one of the created filter conditions, in the filter window of the selected column click the icon.

5. Click **OK**.

*To filter vulnerabilities by the **CVSS score** or **State** column:*

1. In the **Vulnerabilities** section, click the filtering icon in the relevant column of the table.

   When filtering by CVSS score or state, you can also use the corresponding buttons in the toolbar.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events. You can clear or remove all check boxes by clicking the link that is displayed in the upper part of the filter window.

3. Click **OK**.

*To filter vulnerabilities by the **Device group** column:*

1. In the **Vulnerabilities** section, click the filtering icon in the **Device group** column.

   The filtering window opens.

2. Click the icon in the right part of the field to indicate the group.

   The **Select group in tree** window appears.

3. In the device group tree, select the relevant group and click the **Select** button.

   The path to the selected group will appear in the field in the filter window.

4. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window click the **Add condition (OR)** button and specify a different group in the opened field.

5. If you want to delete one of the created filter conditions, in the filter window click the icon.

6. Click **OK**.

*To filter vulnerabilities by the **Published** or **First detected** column:*

1. In the **Vulnerabilities** section, click the filtering icon in the relevant column of the table.

   The calendar opens.

2. In the calendar, specify the date and time for the start and end boundaries of the filtering period. To do so, select a date in the calendar (the current time will be indicated) or manually enter the value in the format DD-MM-YY hh:mm:ss.

3. Click **OK**.

*To filter vulnerabilities by the **Origin** column:*

1. In the **Vulnerabilities** section, click the filtering icon in the **Origin** column.

   The filtering window opens.

2. Select the check boxes opposite the values by which you want to filter events. You can filter and sort the presented values by using the input field and the **Origin** link in the upper part of the filter window.

3. Click **OK**.

- **Vulnerability Scan**

  You can find relevant vulnerabilities by using the **Vulnerability Scan** field in the **Vulnerabilities** section.

  A search is performed in all columns except the **CVSS score**, **State**, **Published**, **First detected**, **Last detected** and **Origin** columns.

- **Resetting the defined filter and search settings**

  You can reset the defined filter and search settings in the vulnerabilities table by using the **Default filter** button in the toolbar in the **Vulnerabilities** section. The button is displayed if search or filter settings are defined.

- **Sorting vulnerabilities**

  You can sort vulnerabilities displayed in the vulnerabilities table. You can sort by the values of any column except the **Description** column.

  To sort vulnerabilities:

  1. In the **Vulnerabilities** section, click the header of the column by which you want to sort.

  2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

     The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

Choosing vulnerabilities in the vulnerabilities table

In the vulnerabilities table, you can select vulnerabilities to view their information and manage these vulnerabilities. When vulnerabilities are selected, the details area appears in the right part of the web interface window.

To select the relevant vulnerabilities in the table, perform one of the following actions:

- If you want to select one vulnerability, select the check box next to the vulnerability or click on the vulnerability.

- If you want to select multiple vulnerabilities, select the check boxes next to the relevant vulnerabilities or select them while holding down the **CTRL** or **SHIFT** key. When multiple vulnerabilities are selected, the application checks the state of the selected vulnerabilities and determines whether there are remediated and accepted vulnerabilities among the selected vulnerabilities.

- If you want to select all vulnerabilities that satisfy the current filter and search settings, perform one of the following actions:

  - Select any vulnerability in the table and press the key combination **CTRL+A**.

  - Select the check box in the title of the left-most column of the table.

When multiple vulnerabilities are selected, the details area shows the total number of selected vulnerabilities. If you selected all vulnerabilities that satisfy the current filter and search settings, one of the following values appears in the details area:

- The precise number is displayed if you selected 2000 vulnerabilities or fewer. In this case, the application checks the state of the selected vulnerabilities just as with other methods for selecting multiple vulnerabilities.

- If more than 2000 vulnerabilities are selected, the number `2000+` is displayed. In this case, the application does not check the state of the selected vulnerabilities.

The title of the left-most column of the table shows the vulnerability selection check box. Depending on the number of selected vulnerabilities, the check box can have one of the following states:

- ☐ – all vulnerabilities that satisfy the current filter and search settings were not selected in the table. However, one vulnerability or multiple vulnerabilities may be selected in the table by using the check boxes next to the vulnerabilities or by using the **CTRL** or **SHIFT** key.

- ☑ – all vulnerabilities that satisfy the current filter and search settings were selected in the table.

- ▣ – all vulnerabilities that satisfy the current filter and search settings were selected in the table, but then the check boxes for some of the vulnerabilities were cleared. This state is also retained if the check boxes were cleared for all vulnerabilities selected in this way (due to the fact that the number of selected vulnerabilities may change).

If all vulnerabilities that satisfy the filter and search settings are selected, the number of selected vulnerabilities may be automatically changed. For example, as a result of the user's actions during another connection session or when new vulnerabilities are discovered. We recommend that you configure filtering and search parameters so that you only see the desired vulnerabilities in the selection.

Viewing vulnerability information

Detailed information about a vulnerability includes information from the vulnerabilities table, and the following fields:

- **Mitigations** – recommendations on remediating the vulnerability (for example, which software version should be installed on the device).

- **Links** – links to publicly available resources containing additional information about the vulnerability.

- **CVE history** – dates of identification, confirmation, and publication of the vulnerability in publicly available sources.

- **Events** – list of events associated with the vulnerability (if there are more than 10 events, the number of undisplayed events is shown under the list).
- **Other devices with this vulnerability** – list of devices in which this vulnerability was detected (if there are more than 10 devices, the number of undisplayed devices is shown under the list).

*To view information about a vulnerability in the **Vulnerabilities** section:*

Select the relevant vulnerability in the vulnerabilities table.

In the right part of the web interface window, you will see the details area containing detailed information about the vulnerability.

*To view information about a vulnerability on the **Devices** tab in the **Assets** section:*

Click the CVE ID of the vulnerability in the **Vulnerabilities** column or in the details area of the device with the vulnerability.

You will see a window containing detailed information about the vulnerability.

Automatically changing the states of vulnerabilities

The application can automatically switch the states of detected vulnerabilities from the *Active* state to the *Remediated* state, and vice versa.

A vulnerability is switched to the *Remediated* state in one of the following cases:

- Device information no longer matches the fields that describe a vulnerability with the same CVE ID in the database of known vulnerabilities (for example, after changing the version of software on the device).
- The description of the vulnerability was deleted from the database of known vulnerabilities (after downloading updates).

A vulnerability is automatically returned to the *Active* state if a vulnerability with the same CVE ID is detected again on the same device.

Manually changing the states of vulnerabilities

When working in the **Vulnerabilities** section, you can manually switch vulnerabilities from the *Active* state to the *Accepted* state, and vice versa. When working in the **Assets** section, you can switch vulnerabilities only from the *Active* state to the *Accepted* state.

You can also switch a vulnerability from the *Active* state to the *Accepted* state when the *Resolved* status is assigned to events that are associated with this vulnerability (for example, a vulnerability detection event). In addition, the *Resolved* status will also be assigned to all other events that are connected to this vulnerability.

To manually change the state of a vulnerability:

1. Open the details area or the window containing detailed information about the vulnerability.
2. Depending on which state you want to assign to the vulnerability, click one of the following buttons:

- **Accepted** – if you want to switch the vulnerability from the *Active* state to the *Accepted* state.
- **Active** – if you want to switch the vulnerability from the *Accepted* state back to the *Active* state.

A window with a confirmation prompt opens.

3. Click **OK**.

Viewing information about devices with a detected vulnerability

If a vulnerability was detected in multiple devices, you can view information about these devices in the devices table.

To view information about one of the devices with the detected vulnerability:

1. Open the details area or the window containing detailed information about the vulnerability.
2. In the **Other devices with this vulnerability** block, click the row containing the name of the relevant device.

The **Assets** section opens. Filtering by device ID will be applied on the **Devices** tab.

To view information about all devices with a detected vulnerability:

1. Open the details area or the window containing detailed information about the vulnerability.
2. Click the **Go to device table** link in the **Other devices with this vulnerability** block to proceed to the devices table.

The **Assets** section opens. The **Devices** tab will be filtered based on the CVE ID of the vulnerability.

Viewing events associated with a vulnerability

When monitoring vulnerabilities, the application registers events based on Asset Management technology. Events are registered with system event types that are assigned the following codes:

- 4000005300 – device vulnerability detected for the first time or a vulnerability had been previously switched to the *Remediated* state (for example, if modified device information once again matches a device description in a vulnerability with the same CVE ID).
- 4000005303 – changes detected in a vulnerability that did not impact its current state (for example, if additional recommendations on system protection were added when the database of known vulnerabilities was updated).

You can view events associated with a vulnerability in the events table.

To view information about one of the events associated with a detected vulnerability:

1. Open the details area or the window containing detailed information about the vulnerability.
2. In the **Events** block, click the row containing the header of the relevant event.

The **Events** section opens. The events table will be filtered based on the ID of the selected event.

To view information about all events associated with a detected vulnerability:

1. Open the details area or the window containing detailed information about the vulnerability.
2. Click the **Go to event table** link in the **Events** block to proceed to the events table.

   The **Events** section opens. The events table will be filtered based on the IDs of events associated with the vulnerability.

Exporting vulnerabilities to a file

You can export information about vulnerabilities to a CSV file. The information is exported from the columns that are currently displayed in the table.

To export information about vulnerabilities:

1. Select the **Vulnerabilities** section.
2. In the vulnerabilities table, select the vulnerabilities whose information you want to export to a file.

   > To export information about all vulnerabilities that satisfy the current filter and search settings, you can select all vulnerabilities in the table or use the **Export** link in the toolbar of the **Vulnerabilities** section. Clicking the **Export** link immediately starts the process for generating a CSV file.

   After you select vulnerabilities, the details area opens in the right part of the web interface window.
3. Depending on the number of selected elements, click the **Export vulnerability** or **Export selected vulnerabilities** button.
4. If it takes a long time (more than 15 seconds) to create the file, the file creation operation is transferred to the list of background operations. In this case, to download the file:

   a. Click the button in the menu of the application web interface.

   The list of background operations appears.

   b. Wait for the file creation operation to finish.

   c. Click the **Download file** button.

Your browser will save the downloaded file. Depending on your browser settings, your screen may show a window in which you can change the path and name of the saved file.

Deep Packet Inspection

Kaspersky Industrial CyberSecurity for Networks lets you monitor an industrial process by providing you with information about the process parameters and system commands transmitted in industrial network traffic. The application tracks this data for devices that are displayed in the devices table and that have defined Process Control settings.

You can view the monitored tags and existing Process Control rules on the Server web interface page in the **Process control** section. The Process Control settings for devices are available when you select the corresponding devices in the **Assets** section and **Network map** section.

Monitoring process parameter values

Kaspersky Industrial CyberSecurity for Networks can display the values of process parameters (tags) in online mode.

To display these values, you must add the relevant tags to the application. You can add tags when configuring Process Control.

The application does not save the tag values displayed in online mode. The names and values of tags may be saved in events registered based on Deep Packet Inspection technology (the tag values received when the event is registered are saved in the event). To save the names and values of tags, the variable $tags must be present in the settings of event types.

To view the values of process parameters:

Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface and select the **Tags** tab in the **Process Control** section.

The browser window will display a table containing the tags and their current values. The following tag parameters show values that are modified on the fly:

- **Value**.
- **Main value data type**.
- **Structural values**.
- **Read/Write**.
- **Received**.
- **Timestamp**.
- **Timestamp status**.
- **Data status**.
- **Originator**.
- **Cause of transmission**.
- **Origin**.

To monitor the values of tags, you can utilize all the functions that are available when viewing the tags table.

Settings of tags

The settings of tags utilized for process control are displayed in the tags table and in the details area when a tag is selected.

Depending on which columns are selected for display, the tags table may show the following settings:

- **Device group** – name of the group containing the device associated with the tag (contains the name of the group and the names of all its parent groups in the device group tree).
- **Device** – name of the device associated with the tag.
- **Protocol** – name of the protocol used to transmit the tag.
- **Tag name** – defined name of the tag.
- **Value** – tag value that is modified on the fly during operations.
- **Unit of measure** – unit of measurement for the process parameter represented by the tag.
- **Data type** – type of tag data.
- **Main value data type** – type of data of the main value within the tag field structure.
- **Read/Write** – direction of transmission when a tag value was received (R when reading from the device, W when writing to a device, and RW for both directions).
- **Received** – date and time when the tag value was last received by the application.
- **Timestamp** – date and time when the tag value (received from traffic) was last modified or updated.
- **Timestamp status** – current status for the date and time when the tag value was last modified or updated.
- **Data status** – current status of the received tag value.
- **Originator** – name of the source from which the tag value was received or the command was sent.
- **Cause of transmission** – reason for modification or transmission of the tag value (received from traffic).
- **Favorites** – indicator of whether the tag was added to the favorites list.
- **Description** – additional information about the tag.
- **Tag address** – physical address of the tag in the device memory.
- **Tag ID** – sequential number of the tag. A tag ID is assigned automatically.
- **Scalable tag** – indicator of the tag scaling within the range of minimums and maximums for input and output values.
- **Input (minimum)** – minimum boundary of the input value.
- **Input (maximum)** – maximum boundary of the input value.
- **Output (minimum)** – minimum boundary of the output value.
- **Output (maximum)** – maximum boundary of the output value.
- **Structural values** – list of names and values of all tag fields. List items are separated by a comma and space (for example: `field1: <value1>, field2: <value2>`). The names of nested fields are generated from the names of all parent fields and the name of the actual field, separated by colons (for example: `parent1:parent2:field: <value>`). String values must be enclosed in quotation marks.

- **Origin** – information about the source of tag creation.

The details area for the selected tag may also display other settings determined by the device and protocol (for example: **Block number** and **Memory area**).

The types of frames comprising application service data units (ASDU) are supported for Deep Packet Inspection on devices that interact over protocols of the IEC 60870-5-104 and IEC 60870-5-101 standards. For information on the supported ASDU types identification in these protocols, please refer to the Appendices.

Viewing the tags table

The tags table is displayed on the **Tags** tab in the **Process Control** section of the application web interface. The table provides the general parameters of tags and of the devices associated with the tags.

When viewing the tags table, you can use the following functions:

- **Configure the display and order of columns in the tags table**

  1. On the **Tags** tab, in the **Process Control** section, click the **Customize table** link to open the window for configuring how the table is displayed.
  2. Select the check boxes opposite the settings that you want to view in the table. You must select at least one setting.
  3. If you want to change the order in which columns are displayed, select the name of the column that needs to be moved to the left or right in the table and use the buttons containing an image of the up or down arrows.

  The selected columns will be displayed in the tags table in the order you specified.

- **Filtering based on table columns**

You can filter the tags table based on the values of the **Device group**, **Device**, **Protocol**, **Tag name**, **Unit of measure**, **Favorites** and **Tag ID** columns.

*To filter tags by the **Device**, **Tag name**, **Unit of measure** or **Tag ID** column:*

1. On the **Tags** tab in the **Process Control** section, click the filtering icon in the relevant column of the table.

   The filtering window opens.

2. In the **Including** and **Excluding** fields, enter the values for tags that you want to include in the filter and/or exclude from the filter.

3. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window of the selected column click the **Add condition** button and enter the condition in the opened field.

4. If you want to delete one of the created filter conditions, in the filter window of the selected column click the icon.

5. Click **OK**.

*To filter tags by the **Device group** column:*

1. On the **Tags** tab, in the **Process Control** section, click the filtering icon in the **Device group** column.

   The filtering window opens.

2. Click the icon in the right part of the field for indicating the device group.

   The **Select group in tree** window appears.

3. In the device group tree, select the relevant group and click the **Select** button.

   The path to the selected group will appear in the field in the filter window.

4. If you want to apply multiple filter conditions combined by the logical operator OR, in the filter window click the **Add condition (OR)** button and specify a different group in the opened field.

5. If you want to delete one of the created filter conditions, in the filter window click the icon.

6. Click **OK**.

*To filter tags by the **Protocol** column:*

1. On the **Tags** tab, in the **Process Control** section, click the filtering icon in the **Protocol** column.

   The filtering window opens.

2. In the **Protocols** field, choose the relevant protocol from the supported application-layer protocols. To do so, start entering the name of the protocol and select the relevant protocol from the drop-down list (the list of suitable protocols is automatically expanded when the value in the **Protocols** field is changed).

   You can sort the opened list of protocols by clicking the **Sort** link.

3. If you want add another protocol, click the **Add protocol** button and specify the other protocol in the opened field.

4. If you want to delete one of the specified protocols, click the icon in the filter window. You can also delete all specified protocols by clicking the **Default filter** link in the filter window.

5. Click **OK**.

*To filter tags by the **Favorites** column:*

1. On the **Tags** tab, in the **Process Control** section, click the filtering icon in the **Favorites** column.
   To filter by the **Favorites** column, you can also use the **Displayed tags** drop-down list in the toolbar.
   The filtering window opens.
2. Select one of the following options:
   - **Only from favorites list** – to display only tags with **Yes** indicated in the **Favorites** column.
   - **No favorites** – to display only tags with **No** indicated in the **Favorites** column.
3. Click **OK**.

- Searching tags

  You can find relevant tags by using the **Search tags** field on the **Tags** tab in the **Process control** section.

  The search is performed on the **Device group**, **Device**, **Protocol**, **Tag name**, **Unit of measure**, **Favorites**, **Description**, **Tag address** and **Tag ID** columns.

- Resetting the defined filter and search settings

  You can reset the defined filter and search settings in the tags table by using the **Default filter** button in the toolbar on the **Tags** tab in the **Process control** section. The button is displayed if search or filter settings are defined.

- Sorting tags

  You can sort the tags table based on the values of the **Device group**, **Device**, **Protocol**, **Tag name**, **Unit of measure**, **Favorites** and **Origin** columns.

  To sort tags:

  1. On the **Tags** tab in the **Process Control** section, click the header of the column by which you want to sort.
  2. If you need to sort the table based on multiple columns, press the **SHIFT** key and hold it down while clicking the headers of the columns by which you want to sort.

  The table will be sorted by the selected column. When sorting by multiple columns, the rows of the table are sorted according to the sequence of column selection. Next to the headers of columns used for sorting, you will see icons displaying the current sorting order: in ascending order or descending order of values.

Viewing information about devices associated with tags

You can view information about devices associated with tags in the devices table. The devices table is automatically filtered based on the IDs of devices that are indicated in tags.

Information can be loaded if no more than 200 tags are selected.

To view information about devices in the devices table:

1. Select the **Process Control** section.
2. On the **Tags** tab, select the tags for which you want to view information about devices.

   The details area appears in the right part of the web interface window.
3. Click **Show device** (if one tag is selected) or **Show devices** (if multiple tags are selected).

   The **Show devices** button is not available if the number of selected tags exceeds 200.

The **Assets** section opens. The **Devices** tab will be filtered based on the IDs of devices associated with the selected tags.

Detecting default passwords when connecting to devices

When monitoring the communications of process control devices, Kaspersky Industrial CyberSecurity for Networks can determine when default passwords are used. If a connection is made to a device using a password that is set as the default password for the particular type of device, the application registers the corresponding event. To register default password detection events, the application uses the system event type for the detection of system commands.

Kaspersky Industrial CyberSecurity for Networks detects default passwords in the following cases:

- An attempt to use a default password was successful or the result of that attempt was not determined. In this case, an event is registered for the detection of the DEFAULT PASSWORD ENTRY system command.
- A new password matching the default password is set. In this case, an event is registered for the detection of the DEFAULT PASSWORD SET system command.
- The default password is received when reading the connection account credentials from a device. In this case, an event is registered for the detection of the DEFAULT PASSWORD READ or DEFAULT PASSWORD READ WITH TYPE system command (if the password details indicate its type, which determines the operations that can be performed with the device using this password).

Detection of default passwords is supported for certain types of devices and application-level protocols (see the table below).

Supported devices and protocols with default passwords

Devices	Protocols	System commands
ABB Relion series: RED670, REL670, RET670	ABB SPA-Bus	DEFAULT PASSWORD ENTRY DEFAULT PASSWORD SET
BECKHOFF CX series	BECKHOFF ADS/AMS	DEFAULT PASSWORD ENTRY DEFAULT PASSWORD READ DEFAULT PASSWORD SET
Emerson ControlWave series	Emerson ControlWave Designer	DEFAULT PASSWORD ENTRY
General Electric Multilin series: B30, C60	Modbus TCP	DEFAULT PASSWORD ENTRY DEFAULT PASSWORD READ DEFAULT PASSWORD READ WITH TYPE DEFAULT PASSWORD SET

Mitsubishi System Q E71	Mitsubishi MELSEC System Q	DEFAULT PASSWORD SET
Schneider Electric Modicon: M580, M340	Modbus TCP	DEFAULT PASSWORD READ WITH TYPE
Siemens SIMATIC S7-200, S7-300, S7-400	Siemens Industrial Ethernet Siemens S7comm	DEFAULT PASSWORD ENTRY DEFAULT PASSWORD READ
Siemens SIMATIC S7-1200, S7-1500	Siemens Industrial Ethernet Siemens S7comm-plus	DEFAULT PASSWORD ENTRY DEFAULT PASSWORD READ DEFAULT PASSWORD SET
Prosoft-Systems Regul R500, PLC with a runtime system for CODESYS V3	CODESYS V3 Gateway	DEFAULT PASSWORD ENTRY DEFAULT PASSWORD READ DEFAULT PASSWORD SET
EKRA 200 series	Modbus TCP for EKRA 200 series devices	DEFAULT PASSWORD READ DEFAULT PASSWORD SET
EKRA BE2502, BE2704 series	ABB SPA-Bus	DEFAULT PASSWORD ENTRY DEFAULT PASSWORD SET

To register default password detection events, the following conditions must be met:

- Interaction Control is enabled in monitoring mode and Command Control technology is applied.
- The allow rules table does not contain any rules for Command Control technology that allow system commands with default passwords. For example, the application may automatically create these rules in Interaction Control learning mode. If these rules are present in the allow rules table, you are advised to disable them.
- For the relevant devices, tracking of system commands with default passwords is enabled.

Detecting security issues in encryption protocols

If encryption protocols (such as SSL/TLS or SSH) are being used in an industrial network, Kaspersky Industrial CyberSecurity for Networks can detect various security issues in network interactions using these protocols. The application registers the appropriate event when detecting a security issue. The system event type for the detection of system commands is used to register these events.

The application registers events when it detects the following security issues in an encryption protocol:

- Use of an outdated version of an encryption protocol (DEPRECATED PROTOCOL VERSION).
- Use of a weak encryption algorithm (WEAK CIPHER TYPE).
- Use of an expired certificate (OUTDATED CERTIFICATE).
- Use of a self-signed certificate (SELF-SIGNED CERTIFICATE).

The list of detected security issues depends on the specific encryption protocol.

After installation, the application uses the original protocol processing modules that support a limited number of encryption protocols. You can update protocol processing modules by installing updates.

You do not need to add Process Control settings for devices to detect security issues in encryption protocols. The application analyzes the encryption protocols in all detected interactions.

To register security issue detection events, the following conditions must be met:

- Interaction Control is enabled in monitoring mode and Command Control technology is applied.
- The allow rules table does not contain any rules for Command Control technology that block the registration of events regarding security issues in encryption protocols. For example, the application may automatically create these rules in Interaction Control learning mode. If these rules are present in the allow rules table, you are advised to disable them.

Managing the application through Kaspersky Security Center

This section contains information about configuring interaction between the application and Kaspersky Security Center, and information about using Kaspersky Security Center functions for working with Kaspersky Industrial CyberSecurity for Networks. You can use Kaspersky Security Center to do the following:

- Add a license key to Kaspersky Industrial CyberSecurity for Networks.
- Download updates for application modules and databases to Kaspersky Industrial CyberSecurity for Networks.
- View Kaspersky Industrial CyberSecurity for Networks events in the Kaspersky Security Center Administration Console.
- Monitor the ICS security state in the Administration Console or in a SCADA system.
- Remotely connect to the Kaspersky Industrial CyberSecurity for Networks Server computer.
- Use Single Sign-On technology for authentication of Kaspersky Security Center 13.2 Web Console users when they connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface.
- Utilize the newly expanded capabilities for centralized monitoring of systems with Kaspersky Industrial CyberSecurity for Networks in the Kaspersky Security Center 13.2 Web Console (when using the Kaspersky Industrial CyberSecurity for Networks Administration web plug-in).

To enable interaction between Kaspersky Industrial CyberSecurity for Networks and Kaspersky Security Center, the following conditions must be fulfilled:

- The functionality for application interaction with Kaspersky Security Center was added during installation of the Kaspersky Industrial CyberSecurity for Networks Server.
- In Kaspersky Industrial CyberSecurity for Networks, the functionality for interaction with Kaspersky Security Center has been enabled and configured.
- The Kaspersky Industrial CyberSecurity for Networks Administration Plug-in for Kaspersky Security Center is installed in Kaspersky Security Center.
- The Kaspersky Industrial CyberSecurity for Networks Administration web plug-in is installed in the Kaspersky Security Center 13.2 Web Console (to implement the newly expanded capabilities for centralized monitoring of systems with Kaspersky Industrial CyberSecurity for Networks).
- The computer on which the Kaspersky Industrial CyberSecurity for Networks Server is installed is included in the Kaspersky Security Center administration group (in the **Managed devices** group or its subgroup). For detailed information on moving managed devices to administration groups, please refer to the Kaspersky Security Center Help system.

Enabling and configuring interaction with Kaspersky Security Center

After the functionality for interaction with Kaspersky Security Center is added to the application, this functionality is disabled by default.

To enable and configure the functionality for application interaction with Kaspersky Security Center:

1. Connect to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface using the Administrator account.

2. Select **Settings** → **Kaspersky Security Center**.

3. Use the **Enabled** toggle button to enable interaction with Kaspersky Security Center.

4. In the **Connector settings** block, configure the settings of the **Kaspersky Security Center Connector**:

   - IP address / network name of the computer hosting the Kaspersky Security Center Administration Server.
   - SSL port for the connection.
   - Maximum number of relayed events per day, starting at 0:00 hours in the time zone of the Kaspersky Industrial CyberSecurity for Networks Server.

5. In the **Plug-in for Kaspersky Security Center Web Console** block, configure the settings for connections from the Kaspersky Security Center Web Console:

   - Kaspersky Industrial CyberSecurity for Networks user name that will be indicated in audit log entries when actions are registered from the Kaspersky Security Center Web Console.
   - IP address / network name of the web server.
   - IP address of the REST API server.

6. Click the **Apply** button.

Adding a license key to Kaspersky Industrial CyberSecurity for Networks from Kaspersky Security Center

You can add a license key to Kaspersky Industrial CyberSecurity for Networks by using the functionality for automatic distribution of license keys to Kaspersky Security Center. A license key received in this way is processed in Kaspersky Industrial CyberSecurity for Networks the same as a license key that is added manually in the application.

To distribute a license key, you need to first add it to the Kaspersky Security Center Administration Server repository. You can add a license key to the Administration Server repository from a license key file.

Automatic distribution of a license key is possible if the computer hosting the Kaspersky Industrial CyberSecurity for Networks Server is in the administration group in the **Managed devices** folder within the Kaspersky Security Center Administration Console tree. If the computer hosting the Kaspersky Industrial CyberSecurity for Networks Server is not in the administration group, you need to add it.

For detailed information about licensing managed applications in Kaspersky Security Center and for descriptions of the actions required for automatic distribution of keys, please refer to the Kaspersky Security Center Help system.

Receiving updates from the Kaspersky Security Center Administration Server

You can use the Kaspersky Security Center Administration Server as the source of updates for databases and application modules of Kaspersky Industrial CyberSecurity for Networks. This method of receiving updates may be required if, for example, you need to download updates from Kaspersky servers when the computer hosting the Kaspersky Industrial CyberSecurity for Networks Server has no Internet access.

To use the Kaspersky Security Center Administration Server as the source of updates for application modules and databases of Kaspersky Industrial CyberSecurity for Networks:

1. In the Kaspersky Security Center Administration Console, create and configure the "Download updates to the Administration Server repository" task.

   For detailed information on creating and using the "Download updates to the Administration Server repository" task, please refer to the Kaspersky Security Center Help system.

2. Select the Kaspersky Security Center Administration Server as the source of updates when manually running an update and/or when configuring automatic updates.

Monitoring events via Kaspersky Security Center

In Kaspersky Security Center, information about events of Kaspersky Industrial CyberSecurity for Networks is displayed in the following columns of the events table:

- **Time** means the Kaspersky Industrial CyberSecurity for Networks event registration time in the time zone of the computer where Kaspersky Security Center is installed.
- **Device** means the name of the managed device in Kaspersky Security Center (the computer on which Kaspersky Industrial CyberSecurity for Networks Server is installed).
- **Event** means the name of the Kaspersky Security Center event type defined for events of Kaspersky Industrial CyberSecurity for Networks.
- **Description** means the title and brief description of the Kaspersky Industrial CyberSecurity for Networks event.
- **Group** is the name of the administration group that contains the computer hosting the Kaspersky Industrial CyberSecurity for Networks Server in the **Managed devices** folder in the Kaspersky Security Center Administration Console tree.
- **Application** means the application name (Kaspersky Industrial CyberSecurity for Networks).
- **Version number** means the application version number.
- **Severity** means the importance level of the event based on how importance is typified by Kaspersky Security Center.
- **Registered** means the time at which the event was registered in the Kaspersky Security Center database.

You can configure the contents of fields displayed in the events table. For descriptions of how to add or remove fields in the tables, please refer to the Kaspersky Security Center Help system.

The parameter values of events relayed from Kaspersky Industrial CyberSecurity for Networks are displayed according to the localization settings of Kaspersky Industrial CyberSecurity for Networks. The localization language of Kaspersky Security Center is disregarded for these parameters.

If a Kaspersky Industrial CyberSecurity for Networks event contains information about multiple network interactions, this event is converted into separate items of the Kaspersky Security Center events table. This way, individual events are created in Kaspersky Security Center for each network interaction specified in a Kaspersky Industrial CyberSecurity for Networks event.

To have events of Kaspersky Industrial CyberSecurity for Networks displayed in the Kaspersky Security Center events table:

1. Make sure that the required components are installed in Kaspersky Industrial CyberSecurity for Networks and Kaspersky Security Center.

2. Make sure that the port used for connecting to the computer hosting Kaspersky Security Center is open and accessible on the computer hosting the Kaspersky Industrial CyberSecurity for Networks Server.

3. In the Kaspersky Industrial CyberSecurity for Networks Administration Plug-in for Kaspersky Security Center, configure the receipt of the relevant event types for all event severity levels. For detailed information on configuring the receipt of Kaspersky Security Center events, please refer to the Kaspersky Security Center Help system.

4. In Kaspersky Industrial CyberSecurity for Networks, configure forwarding of events through the **Kaspersky Security Center Connector**.

   When the specific event types are registered in Kaspersky Industrial CyberSecurity for Networks, these events will also be displayed in the Kaspersky Security Center events table.

Event types in Kaspersky Security Center for Kaspersky Industrial CyberSecurity for Networks events

A fixed set of event types are used for receiving events of Kaspersky Industrial CyberSecurity for Networks in Kaspersky Security Center. The event types in Kaspersky Security Center correspond to the specific event types in Kaspersky Industrial CyberSecurity for Networks and can be registered as Kaspersky Security Center incidents depending on the severities of the events (see the figure below).

Event types in Kaspersky Security Center for receiving events of Kaspersky Industrial CyberSecurity for Networks

Displayed name of the event type	Code of the event type in Kaspersky Security Center	Registration as a Kaspersky Security Center incident	Corresponding event type code in Kaspersky Industrial CyberSecurity for Networks
Maximum number of reported events has been reached	32769	yes, with the *Warning* severity level	–
Test event (DPI)	32770	no	4000000001
Test event (NIC)	32771	no	4000000002
Test event (IDS)	32772	no	4000000003
Test event (AM)	32773	no	4000000004
Unauthorized network interaction detected	32774	no	4000002601
System command detected	32775	Only events with the *Critical* severity level	4000002602
No traffic at monitoring point	32776	no	4000002700
TCP protocol anomaly detected: content substitution in overlapping TCP segments	32777	yes	4000002701
Process Control rule violation	32778	Only events with the *Critical* severity level	4000002900
Intrusion Detection rule from the system set of rules was triggered	32779	no	4000003000
Intrusion Detection rule from the custom set of rules was triggered	32780	no	4000003001
Symptoms of ARP spoofing detected in ARP	32781	yes	4000004001

replies			
Symptoms of ARP spoofing detected in ARP requests	32782	yes	4000004002
New device detected in network	32783	yes	4000005003
New device settings detected	32784	no	4000005004
IP address conflict detected	32785	yes	4000005005
Activity detected from device with Archived status	32786	no	4000005006
New IP address of device detected	32787	yes	4000005007
New MAC address of device detected	32788	yes	4000005010
MAC address added to device	32789	no	4000005008
IP address added to device	32790	no	4000005009
PLC Project Control: detected read of unknown block from PLC	32791	no	4000005200
PLC Project Control: detected read of known block from PLC	32792	no	4000005201
PLC Project Control: detected write of new block to PLC	32793	no	4000005202
PLC Project Control: detected write of known block to PLC	32794	no	4000005203
PLC Project Control: detected read of unknown project from PLC	32795	no	4000005204
PLC Project Control: detected read of known project from PLC	32796	no	4000005205
PLC Project Control: detected write of new project to PLC	32897	no	4000005206
PLC Project Control: detected write of known project to PLC	32898	no	4000005207
IP protocol anomaly detected: data conflict when assembling IP packet	32899	yes	4000005100
IP protocol anomaly detected: fragmented IP packet size exceeded	32800	yes	4000005101
IP protocol anomaly detected: the size of the initial fragment of the IP packet is less than expected	32801	yes	4000005102
IP protocol anomaly detected: mis-associated fragments	32802	yes	4000005103
Vulnerability detected	32803	Only events with the *Critical* severity level	4000005300
Vulnerability information was modified	32804	no	4000005303
Correlation rule event registered	32805	Only events with the *Critical* severity level	8000000001
Event from an external system	32806	yes	4000005400
EPP application triggered	32807	yes	4000005500
Different MAC address of device detected in data received from EPP application	32808	yes	4000005011
New address information of device detected in data received from EPP application	32809	yes	4000005012
Conflict detected in device addresses after data received from EPP application	32810	yes	4000005013
Subset added based on data from EPP application	32811	yes	4000005014

Correspondence of Kaspersky Security Center event severity levels

Severity of events in Kaspersky Security Center correspond to the importance levels of Kaspersky Industrial CyberSecurity for Networks events (see the table below).

Correspondence between event severities

Kaspersky Security Center event severities	Kaspersky Industrial CyberSecurity for Networks event severity
Informational message	Informational
Warning	Warning
Critical event	Critical

Monitoring the ICS security state: Kaspersky Security Center and SCADA

Kaspersky Industrial CyberSecurity for Networks can relay data about the ICS security state to Kaspersky Security Center. To transmit data to Kaspersky Industrial CyberSecurity for Networks and Kaspersky Security Center, the required components must be installed.

If the transmission of ICS security state data to Kaspersky Security Center has been configured, you can configure the SCADA system to receive the corresponding information from Kaspersky Security Center.

Viewing the ICS security state in Kaspersky Security Center

To view the ICS security state in Kaspersky Security Center:

1. Open the Kaspersky Security Center Administration Console.

2. In the Kaspersky Security Center Administration Console tree, in the **Managed devices** folder, select the administration group containing the computer on which the Kaspersky Industrial CyberSecurity for Networks Server is installed.

   Information about the computer status will be displayed in the section for working with the selected object, which appears on the right in the workspace of the selected group.

3. If the section for working with the selected object does not appear, open it by using the right border of the table containing the list of managed devices.

The computer status of the Kaspersky Industrial CyberSecurity for Networks Server corresponds to the ICS security state. The security state of the ICS is determined based on the presence of unprocessed incidents of Kaspersky Security Center. Kaspersky Security Center incidents are registered when certain event types of Kaspersky Industrial CyberSecurity for Networks are received.

The color of the icon of the Kaspersky Industrial CyberSecurity for Networks Server computer corresponds to one of the following ICS security states:

- Red color: *Critical* status. There are unprocessed incidents of Kaspersky Security Center. This status is displayed if the **Unprocessed incidents detected** condition is enabled for the selected administration group in the list of conditions of the *Critical* status (enabled by default).

- Yellow color: *Warning* status. There are unprocessed incidents of Kaspersky Security Center. This status is displayed if the **Unprocessed incidents detected** condition is enabled for the selected administration group in

the list of conditions of the *Warning* status (and if this condition is disabled for the *Critical* status).

- Green color: *OK* status. There are no unprocessed incidents of Kaspersky Security Center.

A green icon with the *OK* status may be displayed even if there are unprocessed incidents of Kaspersky Security Center. This is possible if the **Unprocessed incidents detected** condition is disabled for the selected administration group in the lists of conditions for the *Warning* and *Critical* statuses. To correctly display the ICS security state, you must enable the specified condition in the list of conditions for at least one of the *Warning* or *Critical* statuses.

Viewing the ICS security state via SCADA system

To configure a SCADA system to receive and display the ICS security state:

1. Install Kaspersky Security Gateway on the computer hosting Kaspersky Security Center.

   You can find detailed information on installing and configuring Kaspersky Security Gateway in the *Kaspersky Security Gateway Administrator's Guide*.

2. In the SCADA system, create a control element that reflects the state of the computer with Kaspersky Industrial CyberSecurity for Networks.

3. Configure the created control element to receive data over the OPC DA 2.0 or IEC 60870-5-104 protocol.

   Instructions on configuring the control element are provided in the *Kaspersky Security Gateway Administrator's Guide*.

Connecting to the Server computer from Kaspersky Security Center

You can remotely connect to the Kaspersky Industrial CyberSecurity for Networks Server computer from the Kaspersky Security Center Administration Console. The Virtual Network Computing (VNC) remote desktop access system is used to make the connection.

To connect, you must install and configure the following VNC components:

- VNC server. It is installed on the computer that performs functions of the Kaspersky Industrial CyberSecurity for Networks Server. When configuring the VNC server, you need to set a password for the VNC connection. If a firewall is enabled on the computer, you also need to open the ports for the VNC and SSH protocols.

- VNC client. It is installed on the computer that has the Kaspersky Security Center Administration Console.

To gain access to the Kaspersky Industrial CyberSecurity for Networks Server computer from Kaspersky Security Center:

1. Open the Kaspersky Security Center Administration Console.

2. In the Kaspersky Security Center Administration Console tree, in the **Managed devices** folder, select the administration group containing the computer on which the Kaspersky Industrial CyberSecurity for Networks Server is installed.

3. In the workspace on the **Devices** tab, select the computer hosting the Kaspersky Industrial CyberSecurity for Networks Server, and select **External tools** → **VNC** in the context menu of the computer.

By default, the VNC tool is absent from the list of external tools. To add the tool, in the context menu of the computer, select **External tools → Configure external tools**. In the **External tools** window, click the **Add** button and specify the following values of settings:

- In the **Tool name** field, enter any name for the tool (for example, `VNC`).
- In the **Executable file name** field, enter the full path to the executable file of the VNC client (for example, `C:\Program Files\TightVNC\tvnviewer.exe`).
- In the **Working directory** field, enter the full path to the working folder of the VNC client (for example, `C:\Program Files\TightVNC\`).
- In the **Command line** field, enter the following value: `<A>:<P>`.
- Select the **Create tunnel for TCP port specified below** check box and enter the number of the VNC port on the VNC server (for example, if the VNC server uses screen :3, enter the VNC port number `5903`).

4. After the external VNC tool is started, a password prompt window appears. Enter the password for the VNC connection.

The opened window displays the desktop of the computer on which the Kaspersky Industrial CyberSecurity for Networks Server is installed.

Centrally monitoring systems with Kaspersky Industrial CyberSecurity for Networks from the Kaspersky Security Center Web Console

The Kaspersky Security Center 13.2 Web Console (hereinafter also referred to as "the Web Console") provides expanded capabilities for centrally monitoring the security state of information systems running Kaspersky Industrial CyberSecurity for Networks. These expanded capabilities are available when using the Kaspersky Industrial CyberSecurity for Networks Administration web plug-in (hereinafter also referred to as "the web plug-in") in the Web Console. To use the web plug-in, it must be installed on the computer that has the Kaspersky Security Center Web Console installed.

After installing and configuring the web plug-in, you can do the following in the Web Console:

- Monitor systems controlled by Kaspersky Industrial CyberSecurity for Networks and the Kaspersky Industrial CyberSecurity for Networks Servers by using web widgets designed only for working with Kaspersky Industrial CyberSecurity for Networks.
- Search devices and events in the databases of selected Servers of Kaspersky Industrial CyberSecurity for Networks using various filtering criteria.
- Map components and groups of components of Kaspersky Industrial CyberSecurity for Networks on geographic, schematic or other images to arrange objects based on their location.
- Group components of Kaspersky Industrial CyberSecurity for Networks into organizational units (hereinafter also referred to as "sites") that logically delimit the areas of control and/or deployment of Kaspersky Industrial CyberSecurity for Networks.

When using the functions listed above, you can quickly switch from the Web Console to connect to the necessary Servers of Kaspersky Industrial CyberSecurity for Networks through the web interface. If Single Sign-On technology is in use, users who were created in Kaspersky Industrial CyberSecurity for Networks do not have to enter their account credentials when connecting to a Kaspersky Industrial CyberSecurity for Networks Server. Users who have logged in to the Web Console can also complete authentication.

About the Kaspersky Industrial CyberSecurity for Networks Administration web plug-in

The Kaspersky Industrial CyberSecurity for Networks Administration web plug-in facilitates interaction between the application and the Kaspersky Security Center 13.2 Web Console.

The web plug-in is not installed in the Web Console by default. In contrast to the Management Plug-in for the Kaspersky Security Center Administration Console, which is installed on the administrator's workstation, the web plug-in must be installed on the computer that has the Kaspersky Security Center Web Console installed. The functionality of the web plug-in is available to all administrators that have access to the Web Console in a browser.

You can view the list of installed web plug-ins in the Web Console interface: **Console settings** → **Web plug-ins**.

Installing the web plug-in

You can install the web plug-in by using any of the following methods:

- Install the web plug-in from the list of available distribution packages in the Web Console.

  To install the web plug-in, select the web plug-in distribution package in the Web Console interface: **Console settings** → **Web plug-ins**. The list of available distribution packages is updated automatically after new versions of Kaspersky applications are released.

- Download the distribution package to the Web Console from an external source.

  To install the web plug-in, add the ZIP archive of the web plug-in distribution package in the Web Console interface: **Console settings** → **Web plug-ins**. The distribution package of the web plug-in can be downloaded from the Kaspersky website, for example. For a local version of the application, you also need to download a text file containing a signature.

- Download the distribution package from the list of available distribution packages, plug-ins and patches for Kaspersky Security Center.

  To install the web plug-in, select the web plug-in distribution package in the Web Console interface: **Operations** → **Kaspersky applications** → **Current application versions**. The list of available distribution packages is updated automatically after new versions of Kaspersky applications are released.

Updating the web plug-in

If a new version of the web plug-in becomes available, the Web Console displays the *Updates are available for utilized plug-ins* notification. You can proceed to update the web plug-in version from this Web Console notification. You can also manually check for new web plug-in updates in the Web Console interface (**Console settings** → **Web plug-ins**). The previous version of the web plug-in will be automatically removed during the update.

When the web plug-in is updated, existing components (such as the added widgets or map images) are saved. The new settings of components that implement new functions of Kaspersky Industrial CyberSecurity for Networks will have the default values.

You can update the web plug-in by using any of the following methods:

- Update the web plug-in in the list of web plug-ins in online mode.

To update the web plug-in, select the distribution package of the Kaspersky Industrial CyberSecurity for Networks web plug-in in the Web Console interface and start the update (**Console settings → Web plug-ins**). The Web Console checks for available updates on Kaspersky servers and downloads the relevant updates.

- Update the web plug-in from a file.

  To update the web plug-in, select the ZIP-archive of the distribution package for the Kaspersky Industrial CyberSecurity for Networks web plug-in in the Web Console interface: **Console settings → Web plug-ins**. The distribution package of the web plug-in can be downloaded from the Kaspersky website, for example. For a local version of the application, you also need to download a text file containing a signature.

  You can only update the web plug-in to a more recent version. The web plug-in cannot be updated to an older version.

Scenario for Single Sign-On (SSO) technology usage preparations

When working in combination with Kaspersky Security Center, you can use Single Sign-On (SSO) technology. This enables users that already logged in to the Kaspersky Security Center Web Console to also successfully complete authentication when connecting to the Kaspersky Industrial CyberSecurity for Networks Server through the web interface. This means that any user accounts that are allowed to work with the Kaspersky Security Center Web Console (including Active Directory users) can connect to the Server using their own account credentials.

Single Sign-On technology is available for use with Kaspersky Industrial CyberSecurity for Networks in the Kaspersky Security Center version 13.2 Web Console.

The Single Sign-On (SSO) technology usage preparations scenario consists of the following steps:

1. **Verifying and fulfilling the required conditions for interaction between Kaspersky Industrial CyberSecurity for Networks and Kaspersky Security Center**

   At this step, you need to verify fulfillment of all conditions for interaction between Kaspersky Industrial CyberSecurity for Networks and Kaspersky Security Center. If any of the conditions is not fulfilled, ensure that they get fulfilled. For example, if the functionality for interacting with Kaspersky Security Center is not configured in Kaspersky Industrial CyberSecurity for Networks, enable and configure this functionality.

2. **Enabling and configuring the Kaspersky Security Center Web Console Identity and Access Manager (IAM) component**

   This stage involves the completion of procedures for installing and configuring the Identity and Access Manager component in the Kaspersky Security Center Web Console. For detailed information about installing and configuring this component, please refer to the Kaspersky Security Center Help System.

   When configuring the IAM component, it is recommended to specify the DNS name of the computer as the network name of the device only if the computer is accessible by this name from the Kaspersky Industrial CyberSecurity for Networks Server computer. If it is accessible only by IP address, specify this IP address instead of the DNS name.

3. **Registering the Kaspersky Industrial CyberSecurity for Networks Server as a client for the IAM component**

   At this step, the IAM component detects Kaspersky Industrial CyberSecurity for Networks Servers that are prepared for registration as clients for this component. You need to accept the request for Server registration after it is detected. Detected and registered clients of the IAM component are displayed in a table that you can open in the Kaspersky Security Center Web Console under **Console settings → Integration → Identity and Access Manager**. To register Servers, open the table by clicking the **Settings** link in the section containing information about registered clients, select the check boxes next to the relevant Servers, and click **Approve**.

   After you have confirmed registration of the IAM component client, you need to wait for the preparation process to finish. When synchronization between the IAM component and the client is completed, the ready status will be displayed for this client. If the status has not changed, click the **Update** button.

The IAM component needs some time to detect clients and synchronize with them. Depending on the workload of the Kaspersky Security Center Administration Server and the Kaspersky Industrial CyberSecurity for Networks Server, it may take up to 15 minutes to complete these actions.

4. **Preparing users with access permissions for connecting to Kaspersky Industrial CyberSecurity for Networks**

   At this step, you need to grant access permissions to Kaspersky Security Center users corresponding to the Administrator and Operator roles of Kaspersky Industrial CyberSecurity for Networks. For this purpose, you can use existing user accounts or new accounts of users and groups that were created specifically for granting only these permissions.

When this scenario is fulfilled, Kaspersky Industrial CyberSecurity for Networks will have the capability to connect to the Server through the web interface using the account credentials of Kaspersky Security Center users. To do so, you can use the **Kaspersky Security Center user** button on the account credentials input page for the Kaspersky Industrial CyberSecurity for Networks web interface.

Granting Kaspersky Security Center users the access rights corresponding to their user roles in Kaspersky Industrial CyberSecurity for Networks

To utilize Single Sign-On technology and perform specific actions in the Web Console, Kaspersky Security Center users must be granted the access permissions corresponding to their user roles in Kaspersky Industrial CyberSecurity for Networks. You can grant these permissions after the file containing the configuration of the rights-based access control model (RBAC) for Kaspersky Industrial CyberSecurity for Networks has been uploaded to the Kaspersky Security Center Administration Server.

The configuration is loaded automatically after installation of the Kaspersky Industrial CyberSecurity for Networks Administration web plug-in. If the configuration was uploaded to the Administration Server, the file named KICS4NET_<file version number>.conf was saved in the folder %ProgramData%\KasperskyLab\adminkit\1093\dat\rbac\. If the specified folder does not contain the file named KICS4NET_<file version number>.conf, create and configure the "Download updates to the Administration Server repository" task. For detailed information on creating and using the "Download updates to the Administration Server repository" task, please refer to the Kaspersky Security Center Help system. You can select the Kaspersky update servers as the source of updates.

After loading the RBAC configuration for Kaspersky Industrial CyberSecurity for Networks, Kaspersky Security Center will provide the capability to assign users the permissions corresponding to the Administrator and Operator roles of Kaspersky Industrial CyberSecurity for Networks.

User roles in Kaspersky Industrial CyberSecurity for Networks have the following corresponding access rights in Kaspersky Security Center from the functional scope of **Kaspersky Industrial CyberSecurity for Networks: General functions**:

- **Read** – corresponds to the Operator role.
- **Write** – corresponds to the Administrator role.

Together with these rights, users must also be assigned all rights from the functional scope of the **Kaspersky Security Center Administration Server: General functions: Basic functionality** (this functional scope includes the rights to **Read**, **Write**, **Execute** and **Perform operations on device selections**).

For detailed information about managing user accounts and assigning rights, please refer to the Kaspersky Security Center Help System.

Web widgets for monitoring systems and Servers of Kaspersky Industrial CyberSecurity for Networks

You can use web widgets to monitor systems controlled by Kaspersky Industrial CyberSecurity for Networks and the Servers of Kaspersky Industrial CyberSecurity for Networks. The Kaspersky Security Center Web Console displays web widgets in the Dashboard (under **Monitoring and reports → Dashboard**). By default, the Dashboard does not show web widgets for Kaspersky Industrial CyberSecurity for Networks. You can add the necessary web widgets after installation of the Kaspersky Industrial CyberSecurity for Networks Administration web plug-in.

Web widgets let you show the following information in the Dashboard:

- Statuses of KICS for Networks.
- Critical events of KICS for Networks.
- Devices with issues in KICS for Networks.
- Up-to-date events of KICS for Networks.
- KICS for Networks deployment map.
- Information about KICS for Networks Servers.

Web widgets for Kaspersky Industrial CyberSecurity for Networks are included in the **Other** category in the list of available web widgets of the Web Console.

The information displayed in web widgets is automatically updated every 1–2 minutes. If no data is received from a Server after two minutes, out-of-date data in web widgets is hidden. If necessary, you can manually update the displayed information by using the relevant options in the web widget menu.

Web widget for Statuses in KICS for Networks

The **Statuses in KICS for Networks** web widget for the Web Console displays the ratio of current statuses assigned to Servers of Kaspersky Industrial CyberSecurity for Networks. Information is provided only for relevant statuses (if there are no Servers with a specific status, this status is not displayed in the web widget).

The following statuses are available for Servers in the web widget:

- *Critical*.

  This status is assigned to a Server if at least one of the following conditions is fulfilled:

  - The Server has messages about disruption of application operation.
  - The Server database has unresolved events with *Critical* severity.
  - There are devices with the *Unauthorized* status.
  - The license key expired.

- *Warning*.

This status is assigned to a Server if none of the conditions for assigning the *Critical* status are fulfilled, but at least one of the following conditions is fulfilled:

- The Server has messages about non-critical malfunctions.
- The Server database has unresolved events with *Warning* severity.
- The license key will expire in less than 14 days.

- *OK*.

  This status is assigned to a Server in all other cases (if the Server is accessible and data is being received for processing).

- *Maintenance*.

  This status is assigned to a Server if the application is currently under maintenance (for example, when importing a security policy).

If the status of a Server cannot be determined, the *Unknown* status is displayed for this Server.

By default, the web widget displays status information for all Servers in Kaspersky Security Center administration groups. If data is not received from a Server after two minutes, the out-of-date information is no longer displayed in the web widget. If necessary, you can use the web widget settings menu to select the Servers whose data should be displayed in the web widget.

Web widget for Critical events of KICS for Networks

The **Critical events of KICS for Networks** web widget for the Web Console displays the ratio of unresolved events with *Critical* severity on Servers of Kaspersky Industrial CyberSecurity for Networks. For each Server whose database contains unresolved events with *Critical* severity, the web widget shows the quantity of these events.

> The different coloring of data presented in the web widget does not have any relation to the severity of events. Colors on the web widget chart are used only to visually distinguish events of different Servers.

By default, the web widget displays information based on the data received by the Web Console from all Servers in Kaspersky Security Center administration groups. If data is not received from a Server after two minutes, the out-of-date information is no longer displayed in the web widget. If necessary, you can use the web widget settings menu to select the Servers whose data should be displayed in the web widget.

Web widget for Devices with issues in KICS for Networks

The **Devices with issues in KICS for Networks** web widget for the Web Console displays information about devices that were detected by Kaspersky Industrial CyberSecurity for Networks applications and have issues that require attention. A device requires attention (designated as "with issues") in any of the following cases:

- The security state of the device differs from *OK*.
- The device has the *Unauthorized* status.

If there are devices with issues, the web widget contains the following information:

- Number of devices with issues (in each device category). This data is displayed in the upper part of the web widget under the icons of device categories. The number of displayed categories depends on the free space in the widget. If there are more categories to display, you can open a window containing all categories by clicking the **Show all** icon.

- List of categories of devices with issues. This data is displayed in the middle part of the widget. The following information is displayed for each category in the list:

  - Line containing the category icon and comment. The end of the line provides a link containing the number of devices with issues.

  - Line containing the graphical elements representing the devices. This line is displayed if there is sufficient free space in the widget. If there are more devices with issues than the number of graphical elements displayed in the line, the number of hidden devices is displayed on the right in the format `+<number of devices>`.

By default, the web widget displays information based on the data received by the Web Console from all Servers in Kaspersky Security Center administration groups. If data is not received from a Server after two minutes, the out-of-date information is no longer displayed in the web widget. If necessary, you can use the web widget settings menu to select the Servers whose data should be displayed in the web widget.

Graphical elements of devices

Graphical elements representing devices contain the following information:

- Device name.

- Device status. This is displayed as an icon if the device has the *Unauthorized* status.

- Device security state. This is displayed as a colored line on the left border of the graphical element. The color of the line corresponds to the *OK*, *Warning* or *Critical* states.

The graphical elements are displayed in the following order:

1. Devices assigned the *Unauthorized* status.

2. Devices with the *Critical* security state.

3. Devices with the *Warning* security state.

Navigating from the web widget

You can use elements of the web widget interface to display detailed information about devices. To do so, you can utilize the following options:

- **Display information about the selected device in the devices table on the Server web interface page.**

In the **Devices with issues in KICS for Networks** web widget, click the graphical element that represents the relevant device.

The Kaspersky Industrial CyberSecurity for Networks Server web interface page opens on a new tab in the browser window. The name of the opened tab will be the Server name that was defined during initial configuration of the application after installation.

If Single Sign-On technology is in use and the Web Console user has the permissions to connect to this Server, access to the Server web interface will be granted without prompting the user for their user account credentials.

On the Server web interface page, the **Devices** section automatically opens to show the devices table. The table will be filtered based on the device ID.

- **Display information about devices of the selected category in the search results table in the Web Console.**

  To display information about all devices of the selected category:

  In the upper part of the **Devices with issues in KICS for Networks** web widget, click the icon of the relevant category.

  The **KICS for Networks → Search** section of the Web Console opens to display a table of device search results. The table will be filtered based on the following criteria:

  - Selected category of devices
  - All Servers whose data is taken into account in the web widget

  To display information about all devices that require attention and belong to a specific category:

  In the list of categories containing devices with issues, click the link containing the number of devices of the relevant category.

  The **KICS for Networks → Search** section of the Web Console opens to display a table of device search results. The table will be filtered based on the following criteria:

  - Selected category of devices
  - All Servers whose data is taken into account in the web widget
  - Indicator of devices with issues

- **Display information about all devices in the search results table in the Web Console.**

  Click the **Show all devices** link in the **Devices with issues in KICS for Networks** web widget.

  The **KICS for Networks → Search** section of the Web Console opens to display a table of device search results. The table will be filtered for all Servers whose data is taken into account in the web widget.

Web widget for Up-to-date events of KICS for Networks

The **Up-to-date events of KICS for Networks** web widget for the Web Console displays general information about Kaspersky Industrial CyberSecurity for Networks events that have the most recent values for the date and time of last occurrence.

The web widget contains the following information:

- Histogram of events for the selected period. This data is displayed in the upper part of the web widget. The histogram shows the distribution of events by severity.
- List of registered events. This data is displayed in the middle part of the web widget. Events are sorted by date and time of last occurrence.

By default, the web widget displays information based on the data received by the Web Console from all Servers in Kaspersky Security Center administration groups. If data is not received from a Server after two minutes, the out-of-date information is no longer displayed in the web widget. If necessary, you can use the web widget settings menu to select the Servers whose data should be displayed in the web widget.

Histogram of events

On the histogram showing the distribution of events, the bars correspond to the total number of events for each time interval. Within bars, the severity of events is distinguished by color. The following colors correspond to severity levels:

- Blue designates events that have *Informational* severity.
- Yellow designates events that have *Warning* severity.
- Red designates events that have *Critical* severity.

When you move the mouse cursor over a bar of the histogram, you will see a pop-up window showing the number of events by severity level.

The duration of time intervals depends on the selected display period. To build the relevant histogram, you can select one of the following periods from the web widget menu:

- 1 hour. This period is divided into one-minute intervals.
- 12 hours, 24 hours. These periods are divided into one-hour intervals.
- 7 days. This period is divided into 12-hour intervals.

Instead of the names of specific time periods, the web widget menu may display internal codes for fetching commands if the patch that fixes this specific error has not been installed in the Kaspersky Security Center 13.2 Web Console.

List of events

The number of displayed elements in the list of events is limited by the size of the web widget.

The following information is provided for each event:

- Event title

- Severity: *Informational*, *Warning*, or *Critical*
- Name of the computer hosting the Kaspersky Industrial CyberSecurity for Networks Server

Navigating from the web widget

You can use elements of the web widget interface to display detailed information about events. To do so, you can utilize the following options:

- **Display information about the selected event in the events table on the Server web interface page.**

  Click the relevant event in the **Up-to-date events of KICS for Networks** web widget.

  The Kaspersky Industrial CyberSecurity for Networks Server web interface page opens on a new tab in the browser window. The name of the opened tab will be the Server name that was defined during initial configuration of the application after installation.

  If Single Sign-On technology is in use and the Web Console user has the permissions to connect to this Server, access to the Server web interface will be granted without prompting the user for their user account credentials.

  On the Server web interface page, the **Events** section automatically opens to show the events table. The table will be filtered based on the ID of the selected event. The period ranging from the date and time of registration of the event to the current moment (without indicating an end boundary for the period) will also be defined for the filter.

- **Display information about all events for the selected period in the search results table in the Web Console.**

  Click the **Show all events** link in the **Up-to-date events of KICS for Networks** web widget.

  The **KICS for Networks** → **Search** section of the Web Console opens to display a table of event search results. The table will be filtered based on the following criteria:

  - Currently selected period for building a histogram in the web widget
  - All Servers whose data is taken into account in the web widget

Web widget for KICS for Networks deployment map

The **KICS for Networks deployment map** web widget for the Web Console displays a map depicting the geographic distribution of sites in which Kaspersky Industrial CyberSecurity for Networks components are grouped. The web widget uses a smaller copy of the main map that is available in the **KICS for Networks** → **Map** section of the Web Console.

Sites on the map are designated by icons whose color depends on the statuses of the sites. The following statuses are available for sites:

- *Critical*.

  This status is assigned to a site if it contains at least one Server with the *Critical* status.

- *Warning*.

This status is assigned to a site if it contains at least one Server with the *Warning* status and does not contain Servers with the *Critical* or *Unknown* status.

- *OK*.

  This status is assigned to a site if it contains at least one Server with the *OK* status and does not contain Servers with the *Critical*, *Warning*, *Unknown* or *Maintenance* status.

- *Maintenance*.

  This status is assigned to a site if it contains at least one Server with the *Maintenance* status and does not contain Servers with the *Critical*, *Warning* or *Unknown* status.

- *Muted*.

  This status is assigned to a site if it contains only Servers with the *Muted* status.

- *Unknown*.

  This status is assigned to a site if it contains at least one Server with the *Unknown* status and does not contain Servers with the *Critical* status.

- *No Servers*.

  This status is assigned to a site if it does not contain any Servers.

You can proceed to the main map in the **KICS for Networks** → **Map** section of the Web Console by clicking any part of the map except the icons of sites.

You can proceed to a site map by clicking the icon of this site in the web widget.

Web widget for Information about KICS for Networks Servers

The **Information about KICS for Networks Servers** web widget for the Web Console displays general information about the current state of Kaspersky Industrial CyberSecurity for Networks Servers.

The following information is provided for each Server:

- **Server name** – name used to represent the Server in Kaspersky Security Center (device name in the administration group).
- **Functions** – information about the current state of protection functions in Kaspersky Industrial CyberSecurity for Networks. The following values are possible:
  - **All ON** – all technologies and methods designed for continual use are enabled, and all created monitoring points are enabled.
  - **Not all ON** – some protection functions are disabled or are enabled in learning mode, or not all monitoring points are enabled.
- **Status** – current status of the Server.
- **Application message** – last application message or additional status information.

By default, the web widget displays information based on the data received by the Web Console from all Servers in Kaspersky Security Center administration groups. If necessary, you can use the web widget settings menu to select the Servers whose data should be displayed in the web widget.

You can click the link containing a Server name to open the web interface page of the selected Server in Kaspersky Industrial CyberSecurity for Networks. The name of the opened browser tab will be the Server name that was defined during initial configuration of the application after installation.

If Single Sign-On technology is in use and the Web Console user has the permissions to connect to this Server, access to the Server web interface will be granted without prompting the user for their user account credentials.

Searching devices and events in the databases of Kaspersky Industrial CyberSecurity for Networks Servers

In the Kaspersky Security Center Web Console, you can create requests to receive specific selections of devices and events by using the Kaspersky Industrial CyberSecurity for Networks web plug-in. Based on these requests, a search is performed directly in the databases of Kaspersky Industrial CyberSecurity for Networks Servers. This is the main distinction between the web plug-in capabilities and the search functionality provided by the standard tools for receiving selections of devices and events in the Web Console (for example, under **Devices → Device selections** and **Monitoring and reports → Event selections**). When using the standard tools in the Web Console, the search for devices and events is performed in the Administration Server database.

The **KICS for Networks → Search** section of the Web Console is used to configure the settings of search requests sent to Servers of Kaspersky Industrial CyberSecurity for Networks and to display the search results. Search requests for devices must be formulated separately from search requests for events.

Servers of Kaspersky Industrial CyberSecurity for Networks process the search requests and provide information for those requests with the following limitations:

- The number of returned items that match the search request (devices or events) from each Server cannot be more than 200.
- They provide only the information that can actually be searched. For example, device search results will contain the MAC- and IP addresses of devices but will not contain information about the device models and manufacturers.

In any case, when you need to obtain complete information about any found devices or events, you can go to the web interface page of the Server by using the interface elements under **KICS for Networks → Search**. The Server web interface page automatically opens the corresponding section (**Devices** or **Events**), which will be filtered based on the criteria of the search request or the obtained results.

Configuring the device search settings

You can manually configure the device search settings or use automatically applied filtering criteria when navigating directly from the **Devices with issues in KICS for Networks** web widget.

To manually configure these settings, you need to open the **Devices** tab in the search request details area.

*To open the **Devices** tab in the search request details area:*

1. Go to the **KICS for Networks → Search** section of the Web Console.
2. Do one of the following:

- If a search request was not created during the current session and this section is not displaying a search results table, click the **Find events or devices** button.
- If a search request was created in the current session and this section is displaying a search results table, click the **Search** button in the toolbar.

  The **Search** button displays the number of filtering criteria (defined settings) of the current search request.

3. In the search request details area, go to the **Devices** tab.

After configuring the settings, you can start searching for devices in the databases of Servers by using the **Find** button.

You can configure the following settings in a device search request:

- **Name** – name used to represent the device in the devices table of the Kaspersky Industrial CyberSecurity for Networks Server. The complete name must be specified.
- **Servers** – names used to represent the Servers in Kaspersky Security Center (device names in administration groups).
- **Addresses** – MAC- and/or IP addresses of devices. Complete addresses must be provided.
- **Statuses** – device statuses that determine whether activity of the devices is allowed in the industrial network.
- **Security states** – device security states that are determined by the severity of registered events linked to the device and current vulnerabilities.
- **Categories** – names of the categories that determine the functional purpose of devices.
- **With issues** – indicates whether a device has issues requiring attention.

You can clear the defined settings in a search request by clicking the **Reset filters** button.

Configuring the event search settings

You can manually configure the event search settings or use automatically applied filtering criteria when navigating directly from the **Up-to-date events of KICS for Networks** web widget.

To manually configure these settings, you need to open the **Events** tab in the search request details area.

*To open the **Events** tab in the search request details area:*

1. Go to the **KICS for Networks** → **Search** section of the Web Console.
2. Do one of the following:
   - If a search request was not created during the current session and this section is not displaying a search results table, click the **Find events or devices** button.
   - If a search request was created in the current session and this section is displaying a search results table, click the **Search** button in the toolbar.

     The **Search** button displays the number of filtering criteria (defined settings) of the current search request.

3. In the search request details area, go to the **Events** tab.

After configuring the settings, you can start searching for events in the databases of Servers by using the **Find** button.

You can configure the following settings in an event search request:

- **Title** – title defined for the event type in Kaspersky Industrial CyberSecurity for Networks. The complete title must be specified.
- **Servers** – names used to represent the Servers in Kaspersky Security Center (device names in administration groups).
- **Last seen** – period for filtering events by date and time of last appearance.
- **Source** – address information (MAC/IP addresses or port numbers) of the senders of network packets.
- **Destination** – address information (MAC/IP addresses or port numbers) of the recipients of network packets.
- **Technologies** – icons and names of technologies that were used to register the events.
- **Severity** – icons and names of the severity levels of events.

You can clear the defined settings in a search request by clicking the **Reset filters** button.

Viewing the search results table

The search results table for devices or events is displayed in the **KICS for Networks** → **Search** section of the Web Console. The table shows only the data that can be used to perform a device search or event search. Any found items are grouped based on their respective Servers.

When viewing the table, you can utilize the following functions:

- Filtering search results

  To filter the search results table, you can utilize the following interface elements in the toolbar:

  - **Security states**.

    This filter is available in the results table for device searches. You can use the filter buttons to hide some of the found devices depending on their security states.

  - **Severity**

    This filter is available in the results table for event searches. You can use the filter buttons to hide some of the found events depending on their severity.

  - **Technologies**.

    This filter is available in the results table for event searches. You can use the filter buttons to hide some of the found events depending on the technologies that were used to register them.

  - **Servers**.

    This drop-down list lets you select specific Servers for displaying search results.

- Updating search results

  Information about devices or events could be changed on the Servers while you are viewing the search results table. The **Last updated** field displays the date and time when the results were last loaded.

  You can repeat a search request to update the results by clicking the **Update** button in the toolbar.

- Displaying information on Server web interface pages

  Do one of the following:

  - To receive detailed information about one of the found items, open the web interface page of the corresponding Server by clicking the link containing the device name or the event title.
  - To receive information about all the found items that meet the search request criteria, open the web interface page of the corresponding Server by clicking the **Go to Server** link.

  The Kaspersky Industrial CyberSecurity for Networks Server web interface page opens on a new tab in the browser window. The name of the opened tab will be the Server name that was defined during initial configuration of the application after installation.

  If Single Sign-On technology is in use and the Web Console user has the permissions to connect to this Server, access to the Server web interface will be granted without prompting the user for their user account credentials.

  On the Server web interface page, the relevant section automatically opens to show the devices table or events table. The table will be filtered based on the corresponding criteria.

Mapping components of Kaspersky Industrial CyberSecurity for Networks

The web plug-in lets you create maps depicting the deployment of Servers and sensors of Kaspersky Industrial CyberSecurity for Networks in the Kaspersky Security Center Web Console. You can use maps to arrange these items based on their geographic location and to monitor their state in a view that is convenient for you.

The **KICS for Networks** → **Map** section of the Web Console is designed for working with maps. This section displays the following maps (only one map can be selected at one time):

- Main map. This map depicts the various sites (organizational units used to group components of Kaspersky Industrial CyberSecurity for Networks). Servers and sensors are not displayed at this level.
- Site maps. Each site map contains the application components (Servers and sensors) that are included in this particular site.

On maps, sites and application components are represented by icons containing the names of these objects. Long names are abbreviated to their first characters.

Background images can be displayed in various scales. To manage the display scale, you can use the toolbar located in the upper part of the **KICS for Networks** → **Map** section of the Web Console.

After navigating from the main map to a site map, you can return to the main map by using the arrow button.

Only Kaspersky Security Center users who have been granted the access permissions for the Administrator role in Kaspersky Industrial CyberSecurity for Networks can create maps and arrange objects on those maps. When configuration is complete, users with access permissions for the Operator role can track the state of objects by using the maps in the Web Console under **KICS for Networks** → **Map** and in the **KICS for Networks deployment map** web widget.

Generating a list of sites for the main map

When working with the main map in the **KICS for Networks** → **Map** section of the Web Console, you can generate a list of sites that will be used to delimit the zones of control and/or deployment of Kaspersky Industrial CyberSecurity for Networks. You can add relevant Servers and perform operations with these Servers and their sensors within sites.

The maximum number of sites is 100.

A list of sites can be generated only by Kaspersky Security Center users who have been granted access permissions corresponding to the Administrator role in Kaspersky Industrial CyberSecurity for Networks.

You can use the following functions to generate a list of sites:

- **Adding a site**

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.
2. Select **KICS for Networks** → **Map**.
3. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.
4. Click **Add**.

   A window for entering the site name appears.
5. Enter the site name.

   You can use letters, numerals, a space, and the following special characters: `! @ # № $ % ^ & ( ) [ ] { } ' , . - _`.

   The site name must meet the following requirements:

   - Must begin and end with any permitted character except a space.
   - Must contain 255 characters or less.
   - Must not match the name of another site.

   The **Sites** window will show a line containing the name of the new site.
6. If a line containing the site name has not appeared in the list, this could be due to an applied filter based on site status. If this is the case, enable the display of all sites by clicking the **All statuses** button or enable the display of sites without Servers by clicking the **No Servers** button.
7. Add the site to the main map. To do so, move your cursor over the line containing the site name and click the button.
8. Move the site icon to the necessary place on the map.

- Renaming a site

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.
2. Select **KICS for Networks → Map**.
3. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.
4. If a line containing the name of the relevant site is not displayed in the list, this could be due to an applied filter based on site status. If this is the case, enable the display of all sites by clicking the **All statuses** button or click the button containing the name of the status that was assigned to the relevant site.
5. Move your cursor over the line containing the site name and click the button.

   A window for entering the site name appears.
6. Enter the site name.

   You can use letters, numerals, a space, and the following special characters: `! @ # № $ % ^ & ( ) [ ] { } ' , . - _`.

   The site name must meet the following requirements:

   - Must begin and end with any permitted character except a space.
   - Must contain 255 characters or less.
   - Must not match the name of another site.

- Deleting a site

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.
2. Select **KICS for Networks → Map**.
3. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.
4. If a line containing the name of the relevant site is not displayed in the list, this could be due to an applied filter based on site status. If this is the case, enable the display of all sites by clicking the **All statuses** button or click the button containing the name of the status that was assigned to the relevant site.
5. Move your cursor over the line containing the site name and click the button.
6. In the confirmation prompt window, click **OK**.

Changing the background image of a map

After a map is created, the map uses the default background image. You can change the background image to any image of your choosing. For example, you can use the image of a geographic map of any territory for the main map, and you can upload equipment deployment schematics of workshops and work areas for site maps.

For a map background, you can use images uploaded from JPG or PNG files. The maximum size of an uploaded file is 50 MB. The minimum size of an image in an uploaded file is 600x600 pixels. After a new image is uploaded, the old image is deleted and the positions of all objects on the map are cleared.

The background image on maps can be changed only by Kaspersky Security Center users who have been granted access permissions corresponding to the Administrator role in Kaspersky Industrial CyberSecurity for Networks.

To change the background image for the main map:

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.
2. Select **KICS for Networks** → **Map**.
3. Click the **Replace image** button.

   You will see a window prompting you to drag the image file or select a file.
4. Use any convenient method to upload the file.

To change the background image for a site map:

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.
2. Select **KICS for Networks** → **Map**.
3. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.
4. Click the line containing the name of the relevant site.

   The site map opens.
5. Click the **Replace image** button.

   You will see a window prompting you to drag the image file or select a file.
6. Use any convenient method to upload the file.

Generating lists of Servers within sites

On the maps of created sites under **KICS for Networks** → **Map** in the Web Console, you need to generate lists of Servers residing at these sites based on the delimited zones of control and/or deployment of Kaspersky Industrial CyberSecurity for Networks. Any Servers residing at sites also include the sensors that are associated with these Servers.

Each Kaspersky Industrial CyberSecurity for Networks Server can be included in only one site. Any Server that was not added to a site will remain on the **Outside of sites** list until it is included in a site.

Lists of Servers at sites can be generated only by Kaspersky Security Center users who have been granted access permissions corresponding to the Administrator role in Kaspersky Industrial CyberSecurity for Networks.

You can use the following functions to generate a list of Servers:

- Adding a Server to a site

  1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.
  2. Select **KICS for Networks** → **Map**.
  3. Click the **Show list of sites** button.

     The **Sites** window will appear in the right part of the section.
  4. Click the line containing the name of the relevant site.

     The site map opens.
  5. Click the **Show list of Servers** button.

     A window containing the site name will appear in the right part of the section.
  6. Select the **Outside of sites** tab.
  7. If a line containing the relevant Server is not displayed in the list, this could be due to an applied filter based on Server status. If this is the case, enable the display of all Servers by clicking the **All statuses** button or click the button containing the name of the status that was assigned to the relevant Server.
  8. Move your cursor over the line containing the Server name and click the + button.

     The Server line will no longer be displayed on the **Outside of sites** tab.
  9. Select the **In site** tab.
  10. If a line containing an added Server is not displayed in the list, this could be due to an applied filter based on Server status. If this is the case, enable the display of all Servers by clicking the **All statuses** button or click the button containing the name of the status that was assigned to the Server.
  11. Add the Server to the site map. To do so, move your cursor over the line containing the Server name and click the button.

      After this operation is performed, the brightness of the icon in the button changes.
  12. If there are sensors associated with the Server and you want to enable the display of these sensors, expand the **Sensors** list and add them by using the buttons.
  13. Move the icons of objects to their proper positions on the map.

- Removing a Server from a site

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.
2. Select **KICS for Networks** → **Map**.
3. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.
4. Click the line containing the name of the relevant site.

   The site map opens.
5. Click the **Show list of Servers** button.

   A window containing the site name will appear in the right part of the section.
6. Select the **In site** tab.
7. If a line containing the relevant Server is not displayed in the list, this could be due to an applied filter based on Server status. If this is the case, enable the display of all Servers by clicking the **All statuses** button or click the button containing the name of the status that was assigned to the relevant Server.
8. Move your cursor over the line containing the Server name and click the × button.

   The Server will appear on the **Outside of sites** tab.

Managing the arrangement of objects on maps

In the **KICS for Networks** → **Map** section of the Web Console, sites and components of Kaspersky Industrial CyberSecurity for Networks are represented by icons on maps.

The arrangement of objects on maps can be managed only by Kaspersky Security Center users who have been granted access permissions corresponding to the Administrator role in Kaspersky Industrial CyberSecurity for Networks.

You can move the icons of objects to their necessary locations on maps. However, all icons on a map must be displayed separately without completely overlaying each other.

If necessary, you can disable the display of an irrelevant object on a map. After being disabled from the display, an object is not deleted from the list of map objects. You can re-enable the display of this object at a later time.

To enable or disable the display of a site on the main map:

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.
2. Select **KICS for Networks** → **Map**.
3. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.

4. If a line containing the name of the relevant site is not displayed in the list, this could be due to an applied filter based on site status. If this is the case, enable the display of all sites by clicking the **All statuses** button or click the button containing the name of the status that was assigned to the relevant site.

5. Move your cursor over the line containing the site name and click the button.

   After this operation is performed, the brightness of the icon in the button changes.

To enable or disable the display of a Server or sensor on the site map:

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.

2. Select **KICS for Networks** → **Map**.

3. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.

4. Click the line containing the name of the relevant site.

   The site map opens.

5. Click the **Show list of Servers** button.

   A window containing the site name will appear in the right part of the section.

6. Select the **In site** tab.

7. If a line containing the relevant Server is not displayed in the list, this could be due to an applied filter based on Server status. If this is the case, enable the display of all Servers by clicking the **All statuses** button or click the button containing the name of the status that was assigned to the relevant Server.

8. If there are sensors associated with the Server and you want to enable or disable the display of these sensors, expand the **Sensors** list in the line containing the name of the relevant Server.

9. Move your cursor over the line containing the name of the relevant Server or sensor and click the button.

   When you enable the display of a Server, this simultaneously enables the display of all sensors associated with this Server.

   After this operation is performed, the brightness of the icon in the button changes.

Muting a Server in the Web Console

If the Kaspersky Security Center Web Console is receiving data from multiple Servers of Kaspersky Industrial CyberSecurity for Networks and data from a specific Server does not require monitoring for a certain period of time (for example, during preventative maintenance and adjustment operations in the ICS), you can exclude this Server from monitoring ("mute" the Server). After you mute a Server, the Web Console will stop receiving data from this Server and will assign the *Muted* status to it. However, the Kaspersky Security Center Administration Server will continue receiving and saving data from this Server (including events).

The Server will remain muted until you re-enable monitoring for this Server ("unmute" the Server).

Servers can be muted and unmuted only by Kaspersky Security Center users who have been granted access permissions corresponding to the Administrator role in Kaspersky Industrial CyberSecurity for Networks.

To mute or unmute a Server:

1. Log in to the Kaspersky Security Center Web Console using an account that has Administrator privileges in Kaspersky Industrial CyberSecurity for Networks.

2. Select **KICS for Networks** → **Map**.

3. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.

4. Click the line containing the name of the relevant site.

   The site map opens.

5. Click the **Show list of Servers** button.

   A window containing the site name will appear in the right part of the section.

6. Click the line containing the name of the relevant Server.

   A window containing detailed information about the Server will appear in the right part of the section.

7. If you want to mute the Server, click the **Mute** button. If the Server was already muted and you want to unmute it, click the **Unmute** button.

8. In the confirmation prompt window, click **OK**.

Viewing information about Servers on maps

The statuses of Kaspersky Industrial CyberSecurity for Networks Servers affect the colors of the displayed icons for Servers and the icons of sites on maps in the **KICS for Networks** → **Map** section of the Web Console. If icons of sensors are displayed on a site map, the colors of these icons depend on the current state of the nodes containing the sensors. This lets you keep track of the statuses of Kaspersky Industrial CyberSecurity for Networks components based on the colors of icons representing the objects on maps.

If necessary, you can view detailed information about each Server. The detailed information window provides the main data on the current state of the Server, information about installed updates of application modules and databases, data on hardware resource usage, and license key details.

To view detailed information about a Server:

1. Select **KICS for Networks** → **Map**.

2. Click the **Show list of sites** button.

   The **Sites** window will appear in the right part of the section.

3. Click the line containing the name of the relevant site.

   The site map opens.

4. Click the **Show list of Servers** button.

   A window containing the site name will appear in the right part of the section.

5. Click the line containing the name of the relevant Server.

   A window containing detailed information about the Server will appear in the right part of the section.

6. If you want to go to the web interface page of the Server, click the **Go to Server** button.

The browser will open a tab showing the Server name that was defined during initial configuration of the application after installation.

Troubleshooting

This section contains a description of possible problems in the operation of Kaspersky Industrial CyberSecurity for Networks and methods for resolving them.

The application cannot be installed due to an unavailable repository for DNF

Problem

When installing the application on a computer running the CentOS operating system, you see a message stating that the repository for the DNF software package manager is not available. Application installation is interrupted.

Solution

The application cannot be installed if the repositories containing the installation packages for the operating system are unavailable (or incorrectly configured) in the DNF software package manager. To install the application, unavailable repositories must be disabled.

To disable unavailable repositories and install the application:

1. Load the list of all connected repositories of the DNF package manager. To do so, open the operating system console and type the following command in the command line:

   ```
   dnf repolist
   ```

2. Find the unavailable repositories on the list and disable them. To disable a repository, type the following command in the command line:

   ```
   sudo dnf config-manager --set-disabled <repository name>
   ```

3. Reinstall the application with the same installation settings.

An application component cannot be installed on a selected node

Problem

During centralized installation of application components, there is a message stating that a node is unavailable for component installation due to failure to connect over the SSH protocol. The component is not installed on this node.

Solution

Centralized installation of an application component is impossible if the address information or network name of the computer was changed after configuring access over the SSH protocol on the node where the component will be installed. To centrally install the application component, you must restore access to the remote computer over the SSH protocol.

To restore access over the SSH protocol and install the application component:

1. On the computer from which the centralized installation of application components is performed, update the key used for connecting to the node over the SSH protocol. To do so, sign in to the system using the account credentials of the user account used to install the application, and enter the following command in the operating system console:

   ```
   sudo ssh-keygen -R <node IP address>
   ```

2. Reinstall the application with the same installation settings. During reinstallation, make sure that there is no message stating that the node is unavailable for component installation.

Application problems detected

Problem

When connected to the Server through the web interface, the upper part of the application web interface menu displays a red icon next to the button.

Solution

This state of Kaspersky Industrial CyberSecurity for Networks signifies that one of the application processes is malfunctioning.

To restore operation of the application:

1. Wait 20-30 seconds.

   The application may resume normal operation automatically. If the application resumes normal operation, the red icon will no longer be displayed.

2. If the malfunction persists, please contact Kaspersky Technical Support. Be prepared to submit process logs of Kaspersky Industrial CyberSecurity for Networks and other system data when requested by Technical Support representatives. Process logs are located in the folders that are listed in the Folders for storing application data section. Root privileges in the operating system are required for providing access to logs.

New application message

Problem

A new application message appears in the **Settings** → **Application messages** section.

Messages requiring attention are indicated by a red or yellow icon next to the button in the web interface menu. If the icon is displayed, this means that there is a message regarding disruption of application operation or about a non-critical malfunction, and this problem has not been resolved. To view information, you can go to the **Settings** → **Application messages** section by using the button when a red or yellow icon is displayed next to this button.

Solution

An application message means that some event occurred in the application.

Read the concise information in the message under **Settings** → **Application messages**. Based on this information, you can make a decision on the necessary actions.

The next steps depend on the message status. The following statuses are available for messages:

- *Normal operation* – in most cases, the message does not require a response. However, there may be situations requiring additional clarification of the circumstances. For example, this may be necessary when you receive a message about the successful application of a security policy when you do not know why this action was taken.
- *State unknown*, *Malfunction* – if the message just recently appeared, wait 20–30 seconds and check the current state of the application.
- *Moderate malfunction*, *Critical malfunction* or *Fatal malfunction* – the application is malfunctioning. If the issue could not be resolved, please contact Kaspersky Technical Support. Be prepared to submit process logs of Kaspersky Industrial CyberSecurity for Networks and other system data when requested by Technical Support representatives. Process logs are located in the folders that are listed in the Folders for storing application data section. Root privileges in the operating system are required for providing access to logs.

Not enough free space on hard drive

Problem

There is not enough free space on the computer hard drive where the Application Server or sensor is installed.

Solution

The computer must meet the hardware and software requirements to ensure proper functioning of application components.

For the application to function correctly:

1. On the hard drive of the computer, free up sufficient space to satisfy the minimum free disk space requirements.
2. Restart the services supporting operation of application components.

An error occurs when enabling a monitoring point

Problem

After switching a monitoring point to *Enabled*, it has an *Error* state. As a result, the node associated with this monitoring point is switched to the *Operation disrupted* state. The list of notifications about application operating issues also shows a message regarding disrupted operation due to detected issues at the monitoring point.

Solution

The *Error* state at the monitoring point may be associated with an unsupported operational state of a network interface. For successful completion of a scan when a monitoring point is enabled, the network interface must have the *UP* operational state. Other states of a network interface (for example, *UNKNOWN*) will switch the monitoring point to the *Error* state due to possible issues when receiving or processing network packets.

You can use the `ip link` command to check the current operational state of a network interface on a node computer. Information about the current operational state is displayed in the string containing the name of the interface in the following format: `state <state>`. The most likely operational states on a problematic network interface are as follows:

- *DOWN*. In this case, you can switch the interface to the *UP* operational state by using the following command:

  ```
  sudo ip link set <interface name> up
  ```

- *UNKNOWN*. This operational state may be due to an incorrectly added interface. For example, network interfaces that were added by default on a VMware™ virtual machine may operate in the *UNKNOWN* state. In this case, it is recommended to re-add (create) a network interface with the correct settings by using the corresponding resources for managing network interfaces.

After switching a network interface to the *UP* state, check the state of the monitoring point that was added to this network interface. If the monitoring point is still in the *Error* state, disable and then re-enable this monitoring point.

No traffic at monitoring point

Problem

The application has registered an event whose description contains the following text: `No traffic at monitoring point`. The event description includes the duration of the absence of traffic, the name of the monitoring point, and the network interface that is not receiving traffic.

Solution

For traffic to arrive at the monitoring point, the following conditions must be met:

- The monitoring point is enabled and its current state is *OK*.
- On the network interface of the monitoring point, the network cable is connected to the Ethernet port.
- The rate of incoming traffic is more than 0 bps at the network interface of the monitoring point.

You can view information about monitoring points and network interfaces when connected to the Server through the web interface in the **Settings** → **Deployment** section.

If the displayed rate of incoming traffic is 0 bps at the network interface of the monitoring point, verify that the following conditions are met:

- The network interface of the monitoring point is correctly configured in the operating system.
- When the network interface is connected to the industrial network switch, transmission of mirrored traffic through the connection port (SPAN) must be correctly configured on the network switch.

Traffic is not being loaded for events or incidents

Problem

Cannot load traffic for the selected events and/or incidents. The events table either does not display the tools for loading traffic (for example, the **Load traffic for the event** button is missing from the details area when one event is selected), or displays the message `No traffic for the selected events` (when attempting to load traffic).

Solution

Saved traffic for the selected events and/or incidents may be missing for one of the following reasons:

- The traffic was not saved.
- The traffic was deleted from the database.

The application saves traffic during event registration if the saving of traffic is enabled for the specific type of event. By default, saving of traffic is disabled for all event types. You can enable and configure the saving of traffic for relevant event types.

The application deletes saved traffic for registered events when one of the traffic storage limits is reached (for example, upon reaching the maximum volume of saved traffic in the database). Traffic packets that were saved before other packets are deleted from the database. If saved traffic is deleted too quickly and you do not have time to load it for relevant events, you can increase the maximum values of traffic storage settings.

Preventative maintenance and adjustment operations on the ICS

Problem

Preventative maintenance and adjustment operations on the ICS can create a large number of important and critical events in Kaspersky Industrial CyberSecurity for Networks.

Solution

While conducting preventive maintenance and adjustment operations, you can select one of the following options for resolving this problem:

- Leave all monitoring points enabled on the Server and on application sensors. In this case, when viewing information about events and interactions of devices, take into account the time and list of preventive maintenance and adjustment operations to be conducted.
- Disable the monitoring points that receive traffic from industrial network segments where preventative maintenance and adjustment operations will be conducted. For example, if the work will be conducted in only one shop, you can disable the monitoring point that receives traffic from this shop and leave all other monitoring points enabled.
- Disable all monitoring points on all nodes that have application components installed. You can select this option if preventative maintenance and adjustment operations are to be conducted throughout the entire industrial

network.

If you have disabled monitoring points, to resume control of the protected ICS you need to re-enable the monitoring points immediately after completion of preventative maintenance and adjustment operations.

Bear in mind that intruders may attempt to gain unauthorized access to the network during maintenance and commissioning operations on the ICS. Follow the security regulations and procedures in place at your enterprise when deciding to disable monitoring points.

If the composition or settings of the industrial network equipment were changed while conducting preventative maintenance and adjustment operations (for example, MAC addresses and IP addresses were changed), make the appropriate changes for Process Control, Interaction Control, and Asset Management.

Unexpected system restart

Problem

Unexpected restart of a computer hosting a component of Kaspersky Industrial CyberSecurity for Networks.

Solution

Wait for the computer reboot to finish. After the computer has restarted, the following states of Kaspersky Industrial CyberSecurity for Networks are possible:

- Kaspersky Industrial CyberSecurity for Networks has resumed normal operation.

  The application is operating normally.

- Normal operation of Kaspersky Industrial CyberSecurity for Networks has not resumed.

  The application informs of detected operating issues.

If the malfunction persists, restart the services that support operation of application components. If the problem is not resolved after the restart, please contact Kaspersky Technical Support. Be prepared to submit process logs of Kaspersky Industrial CyberSecurity for Networks and other system data when requested by Technical Support representatives. Process logs are located in the folders that are listed in the Folders for storing application data section. Root privileges in the operating system are required for providing access to logs.

After the Kaspersky Security Center Administration Server is reinstalled, Network Agent cannot be synchronized

Problem

If the settings from a backup copy were not restored after reinstalling the Kaspersky Security Center Administration Server, the Kaspersky Security Center Administration Console does not show the computer on which Kaspersky Industrial CyberSecurity for Networks is installed.

Solution

To restore synchronization of Network Agent, you can restore the settings of the Kaspersky Security Center Administration Server by using the klbackup utility. The klbackup tool is included in the Kaspersky Security Center distribution package. For detailed information on backup copying and restoring the settings of the Kaspersky Security Center Administration Server, please refer to the Kaspersky Security Center Help system.

If for some reason it is not possible to restore the settings of the Kaspersky Security Center Administration Server using the klbackup utility, you can restore synchronization of Network Agent by using the klmover utility that is included in Network Agent.

To use the klmover utility to restore synchronization of Network Agent:

1. On the computer that performs functions of the Kaspersky Industrial CyberSecurity for Networks Server, open the operating system console and go to the folder /opt/kaspersky/klnagent64/bin/.

2. Enter the following command in the command line:

   `sudo ./klmover -address <IP address or computer name>`

   where `<IP address or computer name>` is the IP address or name of the computer with Kaspersky Security Center.

3. After the klmover utility finishes, check the connection of Network Agent to the Kaspersky Security Center Administration Server. To do so, type the following command in the command line:

   `sudo ./klnagchk`

   The screen will display information about the connection to the Administration Server.

After Network Agent synchronization is successfully restored, the Kaspersky Security Center Administration Console will show the computer on which Kaspersky Industrial CyberSecurity for Networks is installed.

Unable to connect to the Server through the web interface

Problem

When attempting to connect to the Server, the Kaspersky Industrial CyberSecurity for Networks web interface page does not load.

Solution

Possible situations:

- There is no network access to the Kaspersky Industrial CyberSecurity for Networks Server computer that has the web server installed. Check the connection with the computer based on the specified Server name (for example, using the `ping` command).

- Incorrect data has been entered into the browser address bar. Enter the IP address or computer name of the Server that was specified for the web server under **Settings** → **Connection Servers**. If the default port 443 is set, you do not have to specify the port number. If a different port number is set, enter the full address `https://<Server name>:<port>` in the address bar.

- JavaScript is disabled in the browser. A message about this is displayed on the connection failure warning page. In the browser settings, enable the execution of JavaScript and refresh the page.

- Access to the Server computer is blocked by the firewall. Properly configure the firewall that is being used.

When connecting to the Server, the browser displays a certificate warning

Problem

When attempting to connect to a computer that has a Kaspersky Industrial CyberSecurity for Networks component installed, the browser displays a warning that the security certificate or the connection being established is not trusted. The contents of the warning depend on the specific browser being used.

Solution

The warning means that a self-signed certificate is being used on the web server. To obtain and use a trusted certificate, you need to contact the administrator.

You can temporarily use a self-signed certificate to connect to the Server (for example, when testing the operation of Kaspersky Industrial CyberSecurity for Networks). When using a self-signed certificate, in the browser warning window select the option that lets you continue connecting. After connecting to the Server, the browser window will display a warning message about the certificate. The text of the message depends on the specific browser being used.

To continually use a certificate, you can add a trusted certificate for the web server under **Settings** → **Connection Servers**.

Contacting Technical Support

This section describes the ways to get technical support and the terms on which it is available.

How to get technical support

If you cannot find a solution to your issue in the application documentation or in other sources of information about Kaspersky Industrial CyberSecurity for Networks, we recommend that you contact Technical Support. Our Technical Support experts will answer your questions about installing and using Kaspersky Industrial CyberSecurity for Networks.

Kaspersky provides support for Kaspersky Industrial CyberSecurity for Networks during the application's life cycle (please refer to the application life cycle page). Before contacting Technical Support, please read the technical support rules.

You can contact Technical Support experts in one of the following ways:

- visit Technical Support website ;
- Send a request to Kaspersky Technical Support through the Kaspersky CompanyAccount portal.

Technical Support via Kaspersky CompanyAccount

Kaspersky CompanyAccount is a portal for organizations that use Kaspersky applications. The Kaspersky CompanyAccount portal is designed to facilitate interaction between users and Kaspersky experts via online requests. The Kaspersky CompanyAccount portal lets you monitor the progress of electronic request processing by Kaspersky experts and store a history of electronic requests.

You can register all of your organization's employees under a single account on Kaspersky CompanyAccount. A single user account lets you centrally manage electronic requests from registered employees to Kaspersky and also manage the privileges of these employees via Kaspersky CompanyAccount.

The Kaspersky CompanyAccount portal is available in the following languages:

- English
- Spanish
- Italian
- German
- Polish
- Portuguese
- Russian
- French

- Japanese

To learn more about Kaspersky CompanyAccount, visit the Technical Support website.

Collecting information for Technical Support

Kaspersky Technical Support experts may request your logs from Kaspersky Industrial CyberSecurity for Networks and other system data.

Logs are located on computers that have components of Kaspersky Industrial CyberSecurity for Networks installed. Information about the folders used for storing logs is provided in the Folders for storing application data section.

Root privileges in the operating system are required for providing access to logs.

Kaspersky Technical Support experts may also request additional data on the application components. This data can be obtaining by using the application components centralized installation script named kics4net-deploy-<application version number>.bundle.sh or by locally running the kics4net-gather-artefacts.sh script, which is located on the computer with the installed application component in the /opt/kaspersky/kics4net/sbin/ folder.

To get information about application components by using the kics4net-deploy-<application version>.bundle.sh script:

1. On the computer from which the centralized installation of application components was performed, go to the folder containing the saved files from the distribution kit of Kaspersky Industrial CyberSecurity for Networks.

2. Enter the command for running the centralized installation script with the `gather-artefacts` parameter:

   `bash kics4net-deploy-<application version number>.bundle.sh --gather-artefacts -<parameter> <folder name>`

   where:

   - `<parameter>` – determines the data acquisition mode.

     The following parameters are provided:

     - `a` – receive all data.
     - `c` – receive data on certificates.
     - `i` – receive data on the Intrusion Detection configuration.
     - `t` – receive traffic dump files.

   - `<folder name>` – name of the folder used for copying archived data files.

     Example:
     `bash kics4net-deploy-<application version number>.bundle.sh --gather-artefacts -a /tmp/data_for_support`

3. In the `SSH password` and `BECOME password` prompts, enter the password for the user account that was used to run the installation of application components.

Wait for completion of the script kics4net-deploy-<application version number>.bundle.sh. Upon successful completion, files will be created in the specified folder.

To obtain data on the application component installed on a computer by using the kics4net-gather-artefacts.sh script:

1. Log in to the system using the account credentials of a user account with root privileges.

2. Go to the /opt/kaspersky/kics4net/sbin/ folder and enter the following command for running the script to receive data on an application component:

   `bash kics4net-gather-artefacts.sh -<parameter> <folder name>`

   where:

   - `<parameter>` – determines the data acquisition mode.

     The following parameters are provided:

     - `a` – receive all data.
     - `c` – receive data on certificates.
     - `i` – receive data on the Intrusion Detection configuration.
     - `t` – receive traffic dump files.

   - `<folder name>` – name of the folder used for copying archived data files.

     Example:
     `bash kics4net-gather-artefacts.sh -a /tmp/data_for_support`

Wait for the kics4net-gather-artefacts.sh script to finish. Upon successful completion, files will be created in the specified folder.

Sources of information about the application

On the Kaspersky Industrial CyberSecurity for Networks page, you can view general information about the application, its functions and features.

The Online Help Guide contains information on administration of Kaspersky Industrial CyberSecurity for Networks. The Online Help Guide also provides information about the application's capabilities that users can utilize to accomplish common tasks.

Online Help includes documentation for the Kaspersky Industrial CyberSecurity for Networks API. This documentation serves as the Developer's Guide for the Kaspersky Industrial CyberSecurity for Networks API. In the Kaspersky Industrial CyberSecurity for Networks API Developer's Guide, you can find information on performing the following tasks:

- Preparing to use Kaspersky Industrial CyberSecurity for Networks API.
- Handling requests for receiving data from Kaspersky Industrial CyberSecurity for Networks and for sending data to the application.

If you cannot find a solution to an issue on your own, please contact Kaspersky Technical Support.

Appendices

This section provides information that complements the main document text with examples, reference information, and additional data.

Steps to fix the CVE-2024-23836 vulnerability in the Intrusion Detection System

When using the rule-based Intrusion Detection method, the Intrusion Detection System, which is susceptible to the CVE-2024-23836 vulnerability, operates on the nodes with the application components installed. Following the recommendations of the Intrusion Detection System vendor, to quickly fix the specified vulnerability in Kaspersky Industrial CyberSecurity for Networks, disable the SMTP and HTTP protocol processing modules for the intrusion detection rules. The module disabling procedure must be performed on all nodes with the application components installed (Server and sensors).

To disable the SMTP and HTTP protocol processing modules on a node:

1. Open the operating system console.
2. Open the configuration file for the Filter process. To do so, enter the following command:

   ```
   sudo mcedit /var/opt/kaspersky/kics4net/config/Filter.json
   ```

3. Go to the "additionalSuricataArguments" settings section.
4. Add a trailing character `,` (comma) at the end of the line with the last section parameter and below it add the following lines:

   ```
   "--set",
   "app-layer.protocols.smtp.enabled=no",
   "--set",
   "app-layer.protocols.http.enabled=no"
   ```

   Example contents of this section:

   ```
   "additionalSuricataArguments" :
   [
   "--set",
   "runmode=autofp",
   "--set",
   "autofp-scheduler=hash",
   "--set",
   "vars.address-groups.SCAN_HOSTS=0.0.0.0",
   "--set",
   "vars.address-groups.BRUTE_HOSTS=0.0.0.0",
   "--set",
   "app-layer.protocols.smtp.enabled=no",
   "--set",
   "app-layer.protocols.http.enabled=no"
   ]
   ```

5. Save and close the configuration file.
6. Restart the application service. To do so, enter the following command:

   ```
   sudo systemctl restart kics4net.service
   ```

Migrating CentOS Linux 8 to CentOS Stream 8

At the end of 2021, Red Hat® is discontinuing support for the CentOS Linux 8 operating system. This means that security updates will no longer be released for CentOS Linux 8 in 2022. In other words, computers and applications running CentOS Linux 8 (including Kaspersky Industrial CyberSecurity for Networks) will not be fully protected against new types of threats and attack techniques.

Red Hat is advising CentOS Linux 8 users to migrate to the CentOS Stream 8 operating system. Kaspersky Industrial CyberSecurity for Networks is compatible with CentOS Stream 8.

You can migrate CentOS Linux 8 to CentOS Stream 8 either before or after installation of Kaspersky Industrial CyberSecurity for Networks components. Migration of the operating system is performed locally on each computer where a Kaspersky Industrial CyberSecurity for Networks component is installed or will be installed.

To migrate CentOS Linux 8 to CentOS Stream 8:

1. Open the operating system console.
2. Update all packages and libraries of the CentOS Linux 8 operating system. To do so, enter the following command:

   ```
   sudo dnf update
   ```

3. Install the centos-release-stream package for access to CentOS Stream repositories. To do so, enter the following command:

   ```
   sudo dnf install centos-release-stream
   ```

4. Change the default repository to the CentOS Stream repository. To do so, enter the following command:

   ```
   sudo dnf swap centos-{linux,stream}-repos
   ```

5. Synchronize the installed packages and libraries from the new default repository. To do so, enter the following command:

   ```
   sudo dnf distro-sync
   ```

6. Restart the operating system. To do so, enter the following command:

   ```
   sudo reboot
   ```

Configuring time synchronization via the NTP and PTP protocols

The time on nodes that have Kaspersky Industrial CyberSecurity for Networks components installed must be synchronized with a common source of time used by industrial network devices. For synchronization purposes, you can use the standard protocols known as Network Time Protocol (NTP) and Precision Time Protocol (PTP).

On the Server node, you must configure time synchronization regardless of how this component was installed (after centralized installation as well as after local installation).

On nodes hosting installed sensors, you must configure time synchronization in the following cases:

- Automatic time synchronization between the Server and sensors was not enabled during centralized installation of Kaspersky Industrial CyberSecurity for Networks.

- The sensor was installed locally using the kics4net-install.sh script.

The steps required for configuring time synchronization may differ depending on the version of the operating system and the specific protocol.

- Configuring time synchronization via the NTP protocol in CentOS

  1. Open the operating system console.
  2. Check the status of the standard time synchronization service known as chrony. To do so, enter the following command:

     ```
     systemctl status chronyd
     ```

  3. If the service is not found, enter the following commands to add the package and enable the service:

     ```
     sudo dnf install chrony
     sudo systemctl enable chronyd
     sudo systemctl start chronyd
     ```

  4. Open the service configuration file. To do so, enter the following command:

     ```
     sudo mcedit /etc/chrony.conf
     ```

  5. Specify the NTP servers that will be used for time synchronization. To specify the server, you only need to add the following string:

     ```
     server <server name or IP address> iburst
     ```

  6. Save and close the configuration file.
  7. Restart the service. To do so, enter the following command:

     ```
     sudo systemctl restart chronyd
     ```

  8. Verify that the specified NTP servers are on the list of synchronization sources. To do so, enter the following command:

     ```
     chronyc sources
     ```

- Configuring time synchronization via the PTP protocol in CentOS

1. Open the operating system console.
2. Check whether the linuxptp package is installed. To do so, enter the following command:

   ```
   dnf list installed
   ```

3. If the linuxptp package is not installed, enter the following commands to add the package and enable the ptp4l time synchronization service:

   ```
   sudo dnf install linuxptp
   sudo systemctl enable ptp4l
   sudo systemctl start ptp4l
   ```

4. Open the service configuration file. To do so, enter the following command:

   ```
   sudo mcedit /etc/ptp4l.conf
   ```

5. Enter `1` for the `slaveOnly` parameter.
6. Save and close the configuration file.
7. Open the file containing the general settings for the service. To do so, enter the following command:

   ```
   sudo mcedit /etc/sysconfig/ptp4l
   ```

8. In the `OPTIONS` string, specify the parameters as follows:

   ```
   OPTIONS="-f <configuration file> -i <interface name> -S -s"
   ```

   where:

   - `-f <configuration file>` – default name and full path of the configuration file.
   - `-i <interface name>` – name of the network interface that is used for time synchronization.
   - `-S` – enables use of software-based timestamps. You can skip this switch if you want to use hardware-based timestamps. However, first make sure that the equipment supports this capability.
   - `-s` – enables subordinate time synchronization.

   Example `OPTIONS` string:

   ```
   OPTIONS="-f /etc/ptp4l.conf -i eth0 -S -s"
   ```

9. Save and close the general settings file.
10. Allow use of ports 319 and 320 in the firewall. To do so, enter the following commands:

    ```
    sudo firewall-cmd --permanent --add-port=319/udp
    sudo firewall-cmd --permanent --add-port=320/udp
    ```

11. Restart the firewall service. To do so, enter the following command:

    ```
    sudo systemctl restart firewalld
    ```

12. Restart the time synchronization service. To do so, enter the following command:

    ```
    sudo systemctl restart ptp4l
    ```

Supported ASDU types identification in protocols of the IEC 60870-5-104 and IEC 60870-5-101 standards

This section presents the ASDU types identification that are supported in Kaspersky Industrial CyberSecurity for Networks (see the table below). The listed types of frames are processed during Deep Packet Inspection on devices that interact over protocols of the IEC 60870-5-104 and IEC 60870-5-101 standards.

Types of frames in protocols of the IEC 60870-5-104 and IEC 60870-5-101 standards

Frame type ID	Operation	Description	Type of main value / system commands
1. Process information in the monitoring direction			
<1>	M_SP_NA	Single-point information	0 – OFF, 1 – ON
<2>	M_SP_TA	Single-point information (with time tag)	0 – OFF, 1 – ON
<3>	M_DP_NA	Double-point information	0 – Indeterminate or intermediate, 1 – OFF, 2 – ON, 3 – Indeterminate
<4>	M_DP_TA	Double-point information (with time tag)	0 – Indeterminate or intermediate, 1 – OFF, 2 – ON, 3 – Indeterminate
<5>	M_ST_NA	Step position information	-64 … +64
<6>	M_ST_TA	Step position information (with time tag)	-64 … +64
<7>	M_BO_NA	Bitstring of 32 bit	unsigned int32
<8>	M_BO_TA	Bitstring of 32 bit (with time tag)	unsigned int32
<9>	M_ME_NA	Measured value, normalized value	float
<10>	M_ME_TA	Measured value, normalized value (with time tag)	float
<11>	M_ME_NB	Measured value, scaled value	float
<12>	M_ME_TB	Measured value, scaled value (with time tag)	float
<13>	M_ME_NC	Measured value, short floating point number	float
<14>	M_ME_TC	Measured value, short floating point number (with time tag)	float
<15>	M_IT_NA	Integrated total	int32
<16>	M_IT_TA	Integrated total (with time tag)	int32
<17>	M_EP_TA	Event of protection equipment (with time tag)	0 – Indeterminate, 1 – OFF, 2 – ON, 3 – Indeterminate
<18>	M_EP_TB	Packed start events of protection equipment (with time tag)	Set of bits in accordance with the standard
<19>	M_EP_TC	Packed output circuit information of protection equipment (with time tag)	Set of bits in accordance with the standard
<20>	M_PS_NA	Packed single-point information with status change detection	unsigned int16
<21>	M_ME_ND	Measured value, normalized value without quality descriptor	float
<30>	M_SP_TB	Single-point information (with time tag CP56Time2a)	0 – OFF, 1 – ON
<31>	M_DP_TB	Double-point information (with time tag CP56Time2a)	0 – Indeterminate or intermediate, 1 – OFF, 2 – ON, 3 – Indeterminate
<32>	M_ST_TB	Step position information (with time tag CP56Time2a)	-64 … +64
<33>	M_BO_TB	Bitstring of 32 bit (with time tag CP56Time2a)	unsigned int32
<34>	M_ME_TD	Measured value, normalized value (with time tag CP56Time2a)	float

<35>	M_ME_TE	Measured value, scaled value (with time tag CP56Time2a)	float
<36>	M_ME_TF	Measured value, short floating point number (with time tag CP56Time2a)	float
<37>	M_IT_TB	Integrated totals (with time tag CP56Time2a)	int32
<38>	M_EP_TD	Event of protection equipment (with time tag CP56Time2a)	0 – Indeterminate, 1 – OFF, 2 – ON, 3 – Indeterminate
<39>	M_EP_TE	Packed start events of protection equipment (with time tag CP56Time2a)	Set of bits in accordance with the standard
<40>	M_EP_TF	Packed output circuit information of protection equipment (with time tag CP56Time2a)	Set of bits in accordance with the standard
2. Process information in the control direction			
<45>	C_SC_NA	Single command	0 – OFF, 1 – ON
<46>	C_DC_NA	Double command	0 – Unallowed, 1 – OFF, 2 – ON, 3 – Unallowed
<47>	C_RC_NA	Regulating step command	0 – Unallowed, 1 – Next step UP, 2 – Next step DOWN, 3 – Unallowed
<48>	C_SE_NA	Setpoint command, normalized value	float
<49>	C_SE_NB	Setpoint command, scaled value	float
<50>	C_SE_NC	Setpoint command, short floating point number	float
<51>	C_BO_NA	Bitstring of 32 bit	int32
<58>	C_SC_TA	Single command (with time tag CP56Time2a)	0 – OFF, 1 – ON
<59>	C_DC_TA	Double command (with time tag CP56Time2a)	0 – Unallowed, 1 – OFF, 2 – ON, 3 – Unallowed
<60>	C_RC_TA	Regulating step command (with time tag CP56Time2a)	0 – Unallowed, 1 – Next step UP, 2 – Next step DOWN, 3 – Unallowed
<61>	C_SE_TA	Setpoint command, normalized value (with time tag CP56Time2a)	float
<62>	C_SE_TB	Setpoint command, scaled value (with time tag CP56Time2a)	float
<63>	C_SE_TC	Setpoint command, short floating point number (with time tag CP56Time2a)	float
<64>	C_BO_TA	Bitstring of 32 bit (with time tag CP56Time2a)	int32
3. System information in the monitoring direction			
<70>	M_EI_NA	End of initialization	END OF INITIALIZATION system command
4. System information in the control direction			
<100>	C_IC_NA	Interrogation command	INTERROGATION system command
<101>	C_CI_NA	Counter interrogation command	COUNTER INTERROGATION system command
<102>	C_RD_NA	Read command	READ system command
<103>	C_CS_NA	Clock synchronization command	CLOCK SYNCHRONIZATION system command
<104>	C_TS_NA	Test command	TEST system command
<105>	C_RP_NA	Reset process command	RESET PROCESS ACTIVATION / RESET PROCESS CONFIRMATION system commands
<106>	C_CD_NA	Delay acquisition command	DELAY ACQUISITION system command
<107>	C_TS_TA	Test command (with time tag CP56Time2a)	TEST WITH TIME TAG system command
5. Parameters in the control direction			
<110>	P_ME_NA	Parameter of measured value, normalized value	float
<111>	P_ME_NB	Parameter of measured value, scaled value	float
<112>	P_ME_NC	Parameter of measured value, short floating point number	float
<113>	P_AC_NA	Parameter activation	PARAMETER ACTIVATION system command

6. File transfer			
<120>	F_FR_NA	File ready	Not processed
<121>	F_SR_NA	Section ready	Not processed
<122>	F_SC_NA	Call directory, select file, call file, call section	CALL DIRECTORY, SELECT FILE, CALL FILE, CALL SELECTION system command
<123>	F_LS_NA	Last section, last segment	Not processed
<124>	F_AF_NA	ACK file, ACK section	Not processed
<125>	F_SG_NA	Segment	Not processed
<126>	F_DR_TA	Directory	Not processed

Sending Kaspersky Industrial CyberSecurity for Networks events to SIEM systems

In Kaspersky Industrial CyberSecurity for Networks, you can use a connector to send data to a SIEM system server. After you add a connector, you need to configure forwarding of events through this connector.

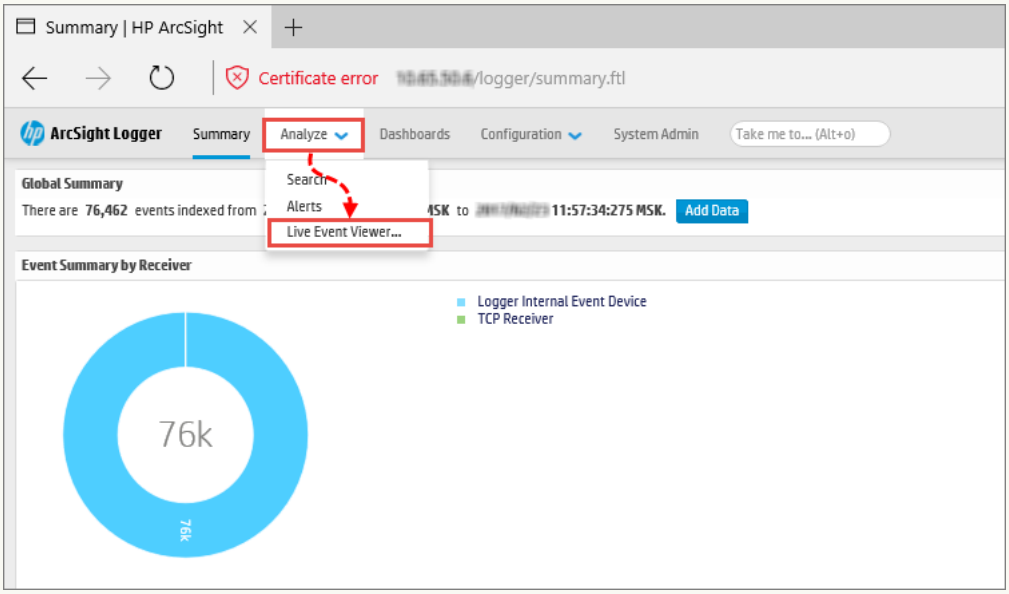
The contents and order in which information is displayed about events forwarded to a SIEM system may differ from the data displayed in the **Events** section of the Kaspersky Industrial CyberSecurity for Networks Server web interface.

- Verifying event forwarding using an HP ArcSight system (as an example)

1. Make sure that a channel is configured for receiving messages from Kaspersky Industrial CyberSecurity for Networks using the standard tools of the HP ArcSight system.

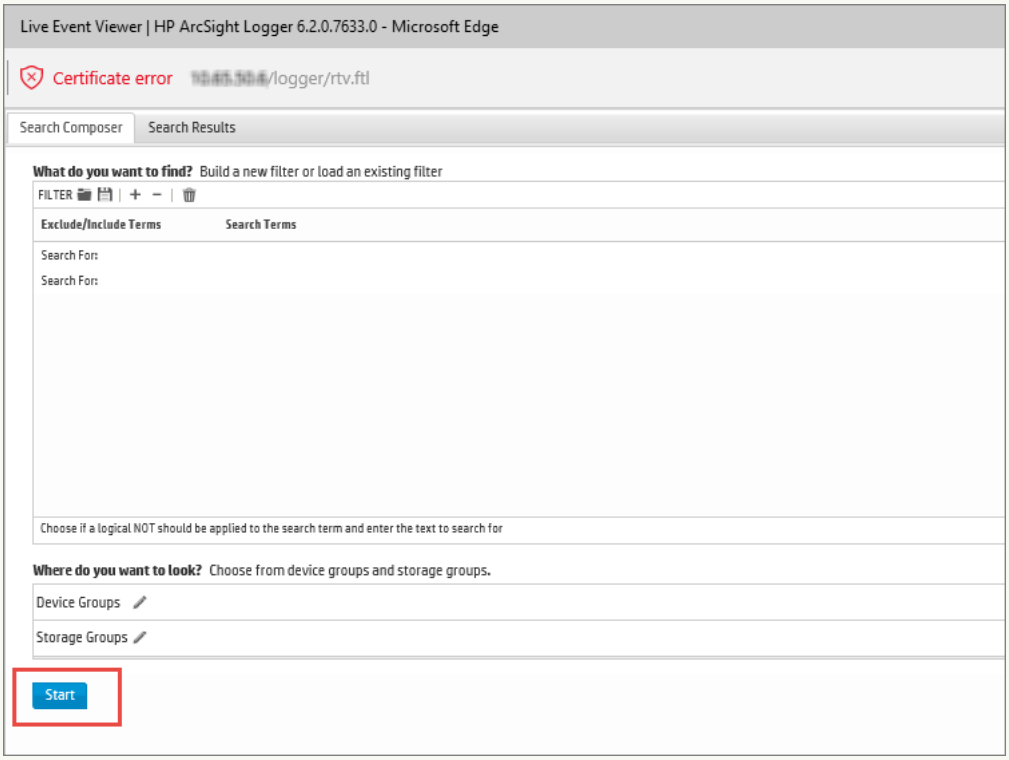
2. Open your browser and enter the address of your HP ArcSight system.

3. Log in to your user account and go to **Analyze** → **Live Event Viewer** (see the figure below).



Opening the **Live Event Viewer** section in the HP ArcSight system

4. Click the **Start** button (see the figure below).



Starting **Live Event Viewer** in the HP ArcSight system

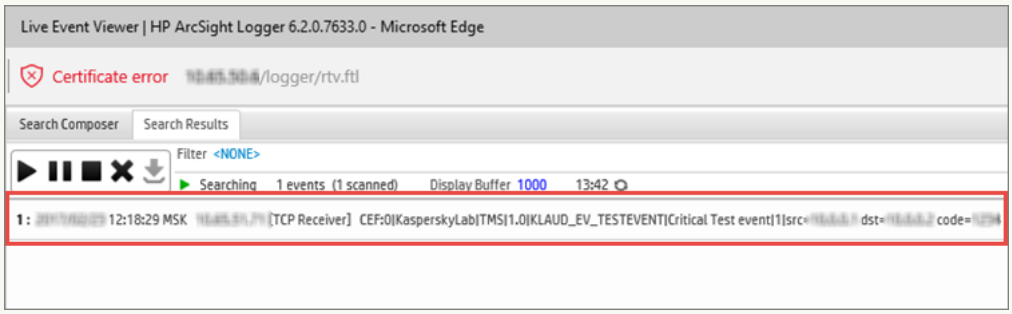
5. Open the command line interface and enter the following command to connect to the server over the Telnet protocol:

   ```
   telnet <ArcSight server address> <port>
   ```

6. Send a test message in CEF format:

```
CEF:0|KasperskyLab|TMS|1.0|KLAUD_EV_TESTEVENT|Critical Test event|1|src=10.0.0.1
dst=10.0.0.2 code=1234
```

If there is a connection with the HP ArcSight system, the **Live Event Viewer** section will show an event whose contents match the message that was sent (see the figure below).



Verifying operation results

- Format of messages forwarded to a SIEM system

The application transmits data to a SIEM system in CEF 20 format. The internal `EventMessage` structure is used when transmitting data.

Received messages are not converted to the system log protocol format.

Format of the EventMessage structure

The table below provides data in the following columns:

- EventMessage — field name in a message.
- Event — corresponding field of the event in Kaspersky Industrial CyberSecurity for Networks or a specific value.
- Description — field description.

EventMessage	Event	Description
dateTime	Start	Date and time (with precision down to the millisecond) when the event-triggering network packet was captured.
hostname	Kaspersky Industrial CyberSecurity for Networks Server address	Address of the Kaspersky Industrial CyberSecurity for Networks Server.
cefVersion	0	CEF version number.
deviceVendor	Kaspersky Lab	Vendor.
deviceProduct	Kaspersky Industrial CyberSecurity for Networks	Product name.
deviceVersion	Example: 3.0.0.472.	Version of Kaspersky Industrial CyberSecurity for Networks.
signatureId	Event type	Event type ID.
name	Title	Event description.
severity	Event severity level: • 10 – Critical • 5 – Warning • 0 – Informational	Event severity level. Values from 0 to 10, where 10 is the most severe event.
extension	Indicated in the Extension Fields table	Determined individually for each type of message.

Date and time is sent in the following format: `YYYY-MM-DD T hh:mm:ss.ms Z`. Example: 2021-04-01T22:14:15.030Z — time of the event, which occurred on April 01, 2021 at 22 hours, 14 minutes, 15 seconds, and 030 milliseconds.

Contents of Extension Fields

The table below provides data in the following columns:

- Extension — field name in a message.
- Related events — events in which the specific field is sent.
- Description — field description.

Extension	Related events	Description

cnt	Common fields of events	Counter of the number of times an event is repeated after the event is registered.
dmac	Common fields of events	Destination MAC address.
dpt	Common fields of events	Destination port.
dst	Common fields of events	Destination IP address.
end	Common fields of events	Event end time.
smac	Common fields of events	Source MAC address.
spt	Common fields of events	Source port.
src	Common fields of events	Source IP address.
start	Common fields of events	Event registration time.
technology	Common fields of events	Technology that was used to register the event.
triggeredRule	Common fields of events	Triggered rule.
protocol	Common fields of events	Protocol.
vlanId	Common fields of events	VLAN ID.
monitoringPoint	Common fields of events	Monitoring point whose traffic invoked registration of the event.
sourceIndustrialAddress	Common fields of events	Application-level address for the source.
destinationIndustrialAddress	Common fields of events	Application-level address for the destination.
eventIdentifier	Common fields of events	Event ID.
noTrafficDuration	No traffic at monitoring point	Period of no traffic.
tagId	Invalid tag type	Tag ID.
expectedTagType	Invalid tag type	Expected data type of tag.
actualTagType	Invalid tag type	Actual data type of tag.
ruleName	• Process Control rule violation • Intrusion Detection rule from the system set of rules was triggered	Rule name.
tags	Process Control rule violation	Tags.
msg	Intrusion Detection rule from the system set of rules was triggered	Message.
substitutedIpAddress	• Signs of ARP spoofing detected in ARP replies • Signs of ARP spoofing detected in ARP requests	IP address of the source of network packets.
targetIpAddress	• Signs of ARP spoofing detected in ARP replies • Signs of ARP spoofing detected in ARP requests	IP address of the destination of network packets.
attackStartTimestamp	• Signs of ARP spoofing detected in ARP replies • Signs of ARP spoofing detected in ARP requests	Start time of the activity showing signs of an attack.
ownerMac	• IP address conflict detected • New IP address detected • New device detected • New information received	MAC address of owner.

	• Traffic detected from MAC address • MAC address added to device • IP address added to device	
ownerIp	• New device detected • MAC address added to device • IP address added to device • IP address conflict detected • New MAC address detected	IP address of owner.
challengerMac	IP address conflict detected	MAC address of challenger.
newIpAddress	New IP address detected	New IP address.
newMacAddress	New MAC address detected	New MAC address.
oldIpAddress	New IP address detected	Old IP address.
assetName	New device detected	Device name.

Device settings

The table below provides data on the settings of devices.

If one or two devices were identified for a detected interaction, Kaspersky Industrial CyberSecurity for Networks also sends known information about one or two devices to the SIEM system.

If multiple devices were identified for a detected interaction, the message is duplicated with different address information and different device settings (if the devices are different).

Extension	Device setting
srcAssetName	Name of the source device.
srcVendor	Vendor of the source device.
srcOS	Operating system of the source device.
srcNetworkName	Network name of the source device.
srcModel	Model of the source device.
dstAssetName	Name of the destination device.
dstVendor	Vendor of the destination device.
dstOS	Operating system of the destination device.
dstNetworkName	Network name of the destination device.
dstModel	Model of the destination device.

Files for importing a universal project

You can use a universal-format project to import Process Control configurations for devices and tags into Kaspersky Industrial CyberSecurity for Networks. A universal project can be imported by using text files with delimiters (CSV files). CSV format is a text format for presentation of table data.

You can create data files using any method of your choice (for example, from SCADA systems). To import your created files into the application, you need to pack the files into a ZIP archive.

The set of files used for importing a universal project may consist of the following CSV files:

- devices.csv. Contains descriptions of devices and connections.

  A *connection* is a named link between a device, a set of device protocols, and a set of device tags relayed through such protocols.

- connections.csv. Contains descriptions of connection protocols.
- variables.csv. Contains descriptions of variables and tags for connections.
- enums.csv. Contains descriptions of enumerations for the IEC 61850 standard.
- datasets.csv. Contains descriptions of data sets for the IEC 61850 standard.
- iec61850_mms_reports.csv. Contains descriptions of reports for the IEC 61850: MMS protocol.

When using data files, consider the following specifics:

- Data files must have UTF-8 encoding.
- The list of tags in the variables.csv file has the "connection" grouping attribute.
- You can specify several different protocols and addresses for one connection in the connections.csv file.
- A protocol can have one or several addresses.
- One device can have several connections with different sets of tags.

Rows containing the parameter values in the enums.csv and datasets.csv files are filled out only when describing enumerations and data sets for MMS and GOOSE protocols of the IEC 61850 standard. For other protocols, the enums.csv and datasets.csv files can contain only header rows. Please note that the enums.csv and datasets.csv files must be included in the set of files used for the import.

When data files are imported, only the values of the specified parameters are considered. Parameters whose values are not specified are omitted. If the data file is missing strings to which a different file from the set of data files contains references, the relevant strings are omitted during import.

File with descriptions of devices: devices.csv

The file with descriptions of devices contains an enumeration of devices, their types, and connection IDs. A connection ID specified in the device description file is used in the connections and protocols description file for purposes of linking with tags and protocols.

If you use different protocols with different sets of tags, you have to use several connections for one device. Connection IDs in each row of the devices.csv file have to be unique.

The file should begin with header strings containing the data needed for file processing. An example of header strings of the devices.csv file is provided below.

Example:

```
'Devices
```

```
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Device;Type;Connection
```

Header strings of the devices.csv file contain the following values:

- `Devices`

  The name of the CSV file is specified in this string. `Devices` – the name of the device description file. The data file name corresponds to the file purpose and is defined for each file in the set.

- `Format Version;KICS Importer Version`

  This string specifies the version of the file format and the version of the tool using which the file was created. Specify the value V1.0.0.0 for the parameter `Format version`. It is then recommended to specify the name and version of the tool that was used to create the CSV file.

- `Field separator: ; Decimal separator: . Text quotes: " Var name separator: .`

  Use this string to specify the separators used in the data file:

  - `Field separator: ;`
  - `Decimal separator: .`
  - line terminator: `Text quotes: "`
  - field separator in tag name: `Var name separator: .`

- `Device;Type;Connection`

  This string contains the names of columns with data. Data in the file should be arranged according to the following order of columns:

  - `Device` – device name.
  - `Type` – device type code. The following codes are used:
    - 0 – SIEMENS SIMATIC S7-300
    - 1 – SIEMENS SIMATIC S7-400
    - 2 – SCHNEIDER ELECTRIC MOMENTUM
    - 3 – SCHNEIDER ELECTRIC M340
    - 4 – MITSUBISHI SYSTEM Q
    - 5 – ALLEN-BRADLEY CONTROL LOGIX 5000
    - 6 – SIEMENS SIPROTEC
    - 7 – IEC 61850 GOOSE, MMS device
    - 8 – IEC 60870-5-104 device
    - 9 – ABB RELION 670
    - 10 – GENERAL ELECTRIC RX3I

- 11 – SIEMENS SIMATIC S7-1500
- 12 – IEC 61850 SAMPLED VALUES device
- 13 – SIEMENS SIPROTEC 6MD66
- 14 – SIEMENS SIPROTEC 7SS52
- 15 – SIEMENS SIPROTEC 7UM62
- 16 – SIEMENS SIPROTEC 7SA52
- 17 – SIEMENS SIPROTEC 7SJ64
- 18 – SIEMENS SIPROTEC 7UT63
- 19 – GENERAL ELECTRIC MULTILIN B30
- 20 – GENERAL ELECTRIC MULTILIN C60
- 21 – EMERSON DELTAV
- 22 – SCHNEIDER ELECTRIC M580
- 23 – RELEMATIKA TOR 300
- 24 – EKRA 200 series
- 25 – EKRA BE2704 / BE2502
- 26 – OMRON CJ2M
- 27 – ABB AC 800M
- 28 – YOKOGAWA CENTUM
- 29 – CODESYS V3 based device
- 30 – DNP3 device
- 31 – OPC UA server
- 32 – ABB AC 700F
- 33 – SIEMENS SIMATIC S7-1200
- 34 – OPC DA server
- 35 – BECKHOFF CX series
- 36 – PROSOFT-SYSTEMS REGUL R500
- 37 – EMERSON CONTROLWAVE
- 38 – IEC 60870-5-101 device

- 39 – MOXA NPORT IA 5000 series
- 40 – I/O device
- 41 – ABB RELION REF615
- 42 – SIEMENS SIMATIC S7-200
- 43 – MODBUS TCP device
- 44 – SCHNEIDER ELECTRIC SEPAM 80 NPP
- 45 – YOKOGAWA PROSAFE-RS
- 46 – SCHNEIDER ELECTRIC FOXBORO FCP280 / FCP270
- 47 – HONEYWELL CONTROLEDGE 900 series
- 48 – HONEYWELL EXPERION C300
- 49 – SCHNEIDER ELECTRIC MICOM C264
- 50 – UMAS device
- 51 – TASE.2 server
- 52 – PROFINET device
- 53 – DIRECTLOGIC
- 54 – Server with encryption support
- 55 – BACNET device
- 56 – SCHNEIDER ELECTRIC P545
- 57 – YCU/ELC
- 58 – FEU device
- 59 – Generic IED
- 60 – Generic Gateway
- 61 – Generic PLC
- 62 – VALMET DNA device
- 63 – COS device
- 64 – OWEN PLC100 series
- 65 – CODESYS V2 based device.

- `Connection` is the connection ID from the connections.csv file containing a description of connections and protocols.

The header strings are followed by the file body containing the values of parameters (device name, device type code, connection ID). An example of the devices.csv file is provided below.

Example:

```
'Devices
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Device;Type;Connection
"ms_plc";4;"ms_plc"
"mc_SysQ";8;"mc_SysQ"
```

File with descriptions of connections and protocols: connections.csv

The protocol description file contains descriptions of protocols for each connection.

The file should begin with header strings containing the data needed for file processing. An example of header strings of the connections.csv file is provided below.

Example:

```
'Connections

'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0

'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .

'Connection;Protocol;Address
```

The first three header strings are identical to the header strings in the devices.csv file.

The string `Connection;Protocol;Address` contains the names of columns with data:

- `Connection` – connection ID for description files.
- `Protocol` – code of the application-level protocol. The following protocol codes are used:
  - 0 – MODBUS TCP
  - 1 – SIEMENS S7COMM over TCP
  - 2 – SIEMENS S7COMM over INDUSTRIAL ETHERNET
  - 3 – MITSUBISHI MELSEC SYSTEM Q
  - 4 – ALLEN-BRADLEY ETHERNET/IP
  - 5 – IEC 61850 MMS
  - 6 – IEC 61850 GOOSE
  - 7 – IEC 60870-5-104
  - 8 – GENERAL ELECTRIC SRTP
  - 9 – IEC 61850 SAMPLED VALUES
  - 10 – SIEMENS S7COMMPLUS over TCP

- 11 – EMERSON DELTAV
- 12 – OMRON FINS over UDP
- 13 – MMS for ABB AC 800M
- 14 – YOKOGAWA VNET/IP
- 15 – CODESYS V3 GATEWAY over TCP
- 16 – DNP3
- 17 – OMRON FINS over TCP
- 18 – OPC UA BINARY
- 19 – DMS for ABB AC 700F
- 20 – OPC DA
- 21 – OMRON FINS over ETHERNET/IP
- 22 – CODESYS V3 GATEWAY over UDP
- 23 – BECKHOFF ADS/AMS
- 24 – IEC 60870-5-101
- 25 – FOXBORO FCP280 / FCP270 INTERACTION
- 26 – EMERSON CONTROLWAVE DATA EXCHANGE
- 27 – HONEYWELL CONTROLEDGE 900 INTERACTION
- 28 – WMI INTERACTION
- 29 – HONEYWELL EXPERION INTERACTION
- 30 – MiCOM C264 INTERACTION
- 31 – SCHNEIDER ELECTRIC UMAS
- 32 – TASE.2
- 33 – PROFINET IO
- 34 – DIRECTLOGIC INTERACTION
- 35 – BACNET
- 36 – YARD
- 37 – COS
- 38 – IPU-FEU INTERACTION

- 39 – VALMET DNA INTERACTION
- 40 – CODESYS V2.

- `Address` – a string containing the full network address of the device, which is specific to the given protocol.

Example:
Connection with the Schneider Momentum controller (one IP address):
```
"Barline1";0;"IP-Address=192.168.0.7;Port=502"
```

Connection with the Mitsubishi System Q controller (one IP address, two ports):
```
"Station1";3;"IP-Address=192.168.0.8;Port=5001 Network=0;Station=0;PC=255"
"Station1";3;"IP-Address=192.168.0.8;Port=5002 Network=0;Station=0;PC=255"
```

Connection with the redundant Siemens S7-400 controller, two controllers (two IP addresses, one set of tags):
```
"S7$Program";1;"IP-Address=192.168.0.21;Port=102;Rack=0;Slot=2"
"S7$Program";1;"IP-Address=192.168.0.22;Port=102;Rack=0;Slot=2"
```

The connection with the Siemens S7-400 controller uses two protocols: S7Comm over the TCP/IP stack, and S7Comm over the Industrial Ethernet network (one set of tags):
```
"S7$Program";1;"IP-Address=192.168.0.21;Port=102;Rack=0;Slot=2"
"S7$Program";2;"MAC=00:01:02:03:04:05;Rack=0;Slot=2"
```

The header strings are followed by the file body containing the values of parameters (connection ID, application-level protocol code, full network address of the device). An example of the connections.csv file is provided below.

Example:
```
'Connections
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Connection;Protocol;Address
"ms_plc";3;"IP-Address=192.168.0.77;Port=1025"
"mc_SysQ";7;"IP-Address=192.168.0.77;Port=2404;Asdu=555"
```

The format of the device network address in the file connections.csv depends on the type of protocol used.

Example:
The following address formats can be used for protocols supported by Kaspersky Industrial CyberSecurity for Networks:

- MODBUS TCP:
  `"IP-Address=192.168.0.7;Port=502"`
- SIEMENS S7COMM over TCP:
  `"IP-Address=192.168.0.7;Port=502;Rack=0;Slot=2"`
- SIEMENS S7COMM over INDUSTRIAL ETHERNET:
  `"MAC=00:01:02:03:04:05;Rack=0;Slot=2"`
- MITSUBISHI MELSEC SYSTEM Q:
  `"IP-Address=192.168.0.7;Port=502;Network=0;Station=0;PC=255"`
- ALLEN-BRADLEY ETHERNET/IP:
  `"IP-Address=192.168.0.7;Port=44818"`
- IEC 61850 MMS:
  `"IP-Address=192.168.0.7;Port=502;Domains=IED_0009CTRL,IED_0009PROT;Vendor=SIEMENS;Model=Siprotec-6MD66x"`
- IEC 61850 GOOSE:
  `"Domains=IED_0009CTRL,IED_0009PROT;Vendor=SIEMENS;Model=Siprotec-6MD66x"`

- IEC 60870-5-104:
  `"IP-Address=192.168.0.7;Port=104;Asdu=2"`
- GENERAL ELECTRIC SRTP:
  `"IP-Address=192.168.0.50;Port=18245"`
- IEC 61850 SAMPLED VALUES:
  `"MAC=00:01:02:03:04:05;Domains=IED_TRANSFORMER1;Vendor=TMW;Model=IED"`
- SIEMENS S7COMMPLUS over TCP:
  `"IP-Address=192.168.0.22;Port=102"`
- EMERSON DELTAV:
  `"IP-Address=192.168.0.38;Port=18507"`
- OMRON FINS over UDP:
  `"IP-Address=192.168.0.1;Port=9600"`
- MMS for ABB AC 800M:
  `"IP-Address=192.168.0.60;Port=102"`
- YOKOGAWA VNET/IP:
  `"IP-Address=192.168.0.4;Port=5313"`
- CODESYS V3 GATEWAY over TCP:
  `"IP-Address=192.168.0.4;Port=11740"`
- DNP3:
  `"IP-Address=192.168.1.10;Port=20000"`
- OMRON FINS over TCP:
  `"IP-Address=192.168.0.1;Port=9600"`
- OPC UA BINARY:
  `"IP-Address=192.168.0.213;Port=49320"`
- DMS for ABB AC 700F:

File with descriptions of tags and variables: variables.csv

The variables and tags description file contains enumerations of tags, their parameters, and connections with which the tags are linked.

The file should begin with header strings containing the data needed for file processing. An example of header strings of the variables.csv file is provided below.

Example

```
'Variables
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'ID;Varname;Connection;Address;Datatype;Length;InLo;InHi;OutLo;OutHi;Description;EngUnits;EnumName
```

The first three header strings are identical to the header strings in the devices.csv file.

The string `ID;Varname;Connection;Address;Datatype;Length;InLo;InHi;OutLo;OutHi;Description;EngUnits;E` contains the names of columns with data:

- `Id` – unique numerical ID of the tag.

  The tag ID is needed to create links to the tag in the datasets.csv file.

- `Varname` – full name of the tag (for example, `Drain.8450PT00058.value20`).

- `Connection` – ID of the connection with which the tag is linked.

- `Address` – address of the tag in string form.

  The address depends on the type of the protocol with which the tag is linked (for example, for the S7comm protocol the address value is `M2.7`, `DB575:82.0`, and for the Modbus TCP protocol the address value is `400537`, `123`, `300001`).

- `Datatype` – numerical code of the tag data type. The following codes are used:

  - 0 – BOOL
  - 1 – INT8
  - 2 – UINT8
  - 3 – INT16
  - 4 – UINT16
  - 5 – INT32
  - 6 – UINT32
  - 7 – INT64
  - 8 – UINT64
  - 9 – FLOAT

- 10 – DOUBLE
- 11 – STRING
- 12 – ENUM
- 13 – BOOL ARRAY
- 14 – UNSPECIFIED

- `Length` – string length in bytes for a tag of the string type.
- `InLo;InHi;OutLo;OutHi` – parameters for scaling the tag value.

  If the values of all parameters for scaling the tag value are equal to zero, scaling of the tag value is not used. If numerical values of parameters are specified, the following formula is used to calculate the tag value: TagValue = OutLo + (TagValue – InLo) * (OutHi – OutLo) / (InHi – InLo), where TagValue is the tag value.
- `Description` – tag description (for example, "Steam pressure at the output of Boiler No. 1").
- `EngUnits` – units of measurement of the physical quantity corresponding to the tag (for example, m/s, J).
- `EnumName` – name of the enumeration from the enums.csv file, which defines the value of the tag.

  The `EnumName` field can be filled for tags with data types ENUM, INT*, or UINT*. The `EnumName` field contains a link to the enumeration from the enums.csv file.

  Example:
  The `EnumName` field in the variables.csv file:
  `EnumName = "OnOffSwitch"`
  Description of the enumeration in the enums.csv file:
  `"OnOffSwitch"; 0; " On "`
  `"OnOffSwitch"; 1; " Off "`

The header strings are followed by the file body containing the values of parameters (for example, tag ID, tag name, or connection ID). An example of the variables.csv file is provided below.

Example:

```
'Variables
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'ID;Varname;Connection;Address;Datatype;Length;InLo;InHi;OutLo;OutHi;Description;EngUnits;EnumName
5;"System.mitsub_n.ms_plc.Bit01";"ms_plc";"W0";4;0;0;0;0;0;"System.mitsub_n.ms_plc.Bit01";"";""
6;"System.mitsub_n.ms_plc.Register01";"ms_plc";"W20";9;0;0;0;0;0;"System.mitsub_n.ms_plc.Register01";"";""
1;"systemQ.Bit01";"mc_SysQ";"10";0;0;0;0;0;0;"systemQ.Bit01";"";""
```

The structure of the tag address in the `Address` field depends on the protocol used.

The following structure addresses are used for the supported protocols:

- MODBUS TCP: integer (for example, addresses of discrete inputs: from 100001).
- SIEMENS S7COMM over TCP and S7COMM over INDUSTRIAL ETHERNET: string in the format `[Area][ByteAddress].[BitAddress]`.

  If the condition `MemArea=DataBlocks` is satisfied, the address is supplemented with the number of the data block. The string changes to `[DB17]:[ByteAddress].[BitAddress]`, where:

  - `Area` – the enumeration of codes of memory areas according to the protocol standard: M, I, O, DB, C, T.
  - `ByteAddress` – the byte address represented by an integer.

    - `BitAddress` – the bit address inside the byte, which is represented by an integer.

- MITSUBISHI MELSEC SYSTEM Q: a string in the format `[Area][Address]`, where:

    - `Area` – the enumeration of codes of memory areas according to the protocol specification: SM, SD, M, L, F, V, D, TS, TC, TN, SS, SC, SN, CS, CC, CN, S, Z, R, X, Y, B, W, SB, SW, DX, DY, ZR.

    - `Address` – the address value. The address is an integer in the range that depends on the data area.

- ALLEN-BRADLEY ETHERNET/IP: a string with the tag name.

- IEC 61850 MMS and GOOSE: per the IEC 61850 standard – a string of the format `DOMAIN=Domain;LN=LnName;CO=CoName;DA=FullTagName;CDC=CdcName;LNCDC=LNClassName`, where:

    - `DOMAIN` – a parameter that includes the device name and the logical device name.

    - `LN` – logical node name.

    - `CO` – functional constraint name.

    - `DA` – tag name.

    - `CDC` – attribute common data class name.

    - `LNCDC` – logical node common data class name.

- IEC 60870-5-104 and IEC 60870-5-101: a string in the format `[ASDU]:[Address]`, where:

    - `ASDU` – ASDU number represented by an integer.

    - `Address` – InformationObject number represented by an integer.

- GENERAL ELECTRIC SRTP: string in the format `[Area][ByteAddress].[BitAddress]`, where:

    - `Area` – the enumeration of codes of memory areas according to the protocol standard: I, Q, T, M, G, AI, AQ, R, P, L, W.

    - `ByteAddress` – the byte address represented by an integer.

    - `BitAddress` – the bit address inside the byte, which is represented by an integer.

- SIEMENS S7COMMPLUS over TCP: string in the format `LID=LidValue;RID=RidValue`, where `LidValue` and `RidValue` are internal identifiers of a tag in the TiaPortal project.

- EMERSON DELTAV: a string with the tag name.

- OMRON FINS over UDP, OMRON FINS over TCP and OMRON FINS over ETHERNET/IP: string in the format `[Area][ByteAddress].[BitAddress]`, where:

    - `Area` – enumeration of codes of memory areas according to the protocol standard: A, CIO, C, CS, D, DR, E, H, IR, TK, T, TS, W.

    - `ByteAddress` – the byte address represented by an integer.

    - `BitAddress` – the bit address inside the byte, which is represented by an integer.

- YOKOGAWA VNET/IP: a string with the tag name.
- DNP3: string in the format `[GROUP]:[INDEX]`, where:
  - `GROUP` is the specific group.
  - `INDEX` is the specific index.
- DMS for ABB AC 700F: integer.
- MMS for ABB AC 800M: string in the format `[Application]:[POUInstance].[VarOffset]`, where:
  - `Application` is the name of the application.
  - `POUInstance` is the POU instance.
  - `VarOffset` is the variable offset.
- CODESYS V3 GATEWAY over TCP and CODESYS V3 GATEWAY over UDP: string with the tag name.
- OPC UA BINARY: a string with the tag name.
- OPC DA: a string with the tag name.
- EMERSON CONTROLWAVE DATA EXCHANGE: a string in the format `[MSD_VERSION]:[MSD]`, where:
  - `MSD_VERSION` is an integer in the range of 0–65535 that is used for comparing versions of projects/tags in the PLC and SCADA system.
  - `MSD` is the tag ID represented by an integer in the range of 0–65535.
- FOXBORO FCP280 / FCP270 INTERACTION: string containing the tag name.
- HONEYWELL EXPERION INTERACTION: string in the format `[BLOCK_ID]:[SUBBLOCK_ID]:[PROPERTY_ID]`, where:
  - `BLOCK_ID` is the sequence number of the PLC program block represented by an integer in the range of 0–65535.
  - `SUBBLOCK_ID` is the sequence number of the PLC program subblock represented by an integer in the range of 0–65535.
  - `PROPERTY_ID` is the sequence number of the PLC program block parameter represented by an integer in the range of 0–65535.
- DIRECTLOGIC INTERACTION: string in the format `[Area][ByteAddress].[BitAddress]`, where:
  - `Area` is the enumeration of memory area codes according to the protocol specification: X, Y, C, S, T, CT, GX, GY, V, P, SP, B, PB.
  - `ByteAddress` – the byte address represented by an integer.
  - `BitAddress` – the bit address inside the byte, which is represented by an integer.
- BACNET: string in the format `[OBJECT_TYPE]:[OBJECT_ID]`, where:

- `OBJECT_TYPE` is the type of object according to the protocol specification.
- `OBJECT_ID` is the sequence number of the object represented by an integer in the range of 0–4194303.

- PROFINET IO: string in the format `[IO]:[SubSlot]:[Index]:[Offset].[BitAddress]`, where:
  - `IO` is the variable direction (input, output).
  - `SubSlot` is the number of the subslot represented by an integer.
  - `Index` is the tag index represented by an integer.
  - `Offset` is the tag byte address represented by an integer.
  - `BitAddress` is the bit address inside the byte, which is represented by an integer (used only for tags that have the bool data type).

  In addition, to correctly load the protocol parameters, you must specify the GSDML file for the specific device.

- YARD: string in the format `[Controller Address]:[Index]:[Size]:[Config]:[MessageType]`, where:
  - `Controller Address` – address of the object controller represented by a hexadecimal integer.
  - `Index` – bit tag index represented by an integer.
  - `Size` – bit size represented by an integer.
  - `Config` – position of the jumpers on the object controller represented by a hexadecimal integer.
  - `MessageType` – type of message (`Order` or `Status`).

  In addition, to correctly load the protocol parameters, you must specify the configuration file for the specific device.

- COS: string in the format `[Object ID]:[Variable ID]`, where:
  - `Object ID` – object identifier represented by an integer.
  - `Variable ID` – variable identifier represented by an integer.

  In addition, to correctly load the protocol parameters, you must specify the configuration file for the station.

- VALMET DNA INTERACTION: string containing the tag name.

An example of the tag address string for the MMS and GOOSE protocols is provided below.

Example:
```
DOMAIN=IED009PROT1;LN=LLN0;CO=DC;DA=NamPlt.configRev;CDC=LPL;LNCDC=LLN0
```

File with descriptions of enumerations: enums.csv

The enumerations description file contains all elements of all enumerations used in the current set of data files for the IEC 61850 standard.

The file should begin with header strings containing the data needed for file processing. An example of header strings of the enums.csv file is provided below.

```
Example:
'Enums
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Connection;EnumName;IntValue;TextValue
```

The first three header strings are identical to the header strings in the devices.csv file.

The string `Connection;EnumName;IntValue;TextValue` contains names of columns with data:

- `Connection` – the ID of the connection to which this element belongs.
- `EnumName` – the name of the enumeration.
- `IntValue` – the numerical value of the enumeration.
- `TextValue` – a text description corresponding to the numerical value of enumeration.

The header strings are followed by the file body containing the parameter values (connection ID, name of enumeration, numerical value of enumeration, text description). An example of the enums.csv file is provided below.

```
Example:
'Enums
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Connection;EnumName;IntValue;TextValue
"AA1J1Q01A2";"Beh";1;"on"
"AA1J1Q01A2";"Beh";2;"blocked"
"AA1J1Q01A2";"Beh";3;"test"
"AA1J1Q01A2";"Beh";4;"test/blocked"
"AA1J1Q01A2";"Beh";5;"off"
```

File with descriptions of data sets (tag sets): datasets.csv

The file with descriptions of data sets (tag sets) contains the parameters of data sets for IEC 61850 standard protocols.

The file should begin with header strings containing the data needed for file processing. An example of header strings of the datasets.csv file is provided below.

```
Example:
'Datasets
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Connection;DatasetName;Deprecated;ItemName
```

The first three header strings are identical to the header strings in the devices.csv file.

The string `Connection;DatasetName;Deprecated;ItemName` contains the names of columns with data:

- `Connection` – the ID of the connection to which the datasets.csv file belongs.
- `DatasetName` – the name of the data set.

- `Deprecated` – unused data (zero value).
- `ItemName` – full name of the device model element. This can be the final name of a tag or the name of the top branch of the tree.

The header strings are followed by the file body containing the parameter values (connection ID, name of the data set, unused value, and name of the device model element). An example of the datasets.csv file is provided below.

Example:

```
'Datasets
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Connection;DatasetName;Deprecated;ItemName
"S7UTDZD";"S7UTDZDPROT/LLN0$DataSet";0;"S7UTDZDPROT/PTRC1$ST$Tr"
"S7UTDZD";"S7UTDZDPROT/LLN0$DataSet";0;"S7UTDZDMEAS/M1_MMXU1$MX$A$phsA"
```

File with descriptions of MMS protocol reports: iec61850_mms_reports.csv

The file with descriptions of MMS protocol reports contains the parameters for the Reports service of the IEC 61850: MMS protocol.

The file should begin with header strings containing the data needed for file processing. An example of header strings of the iec61850_mms_reports.csv file is provided below.

Example:

```
'Reports
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Connection;ReportName;ReportId;DataSetName;IsBuffered
```

The first three header strings are identical to the header strings in the devices.csv file.

The string `Connection;ReportName;ReportId;DataSetName;IsBuffered` contains the names of columns with data:

- `Connection` – ID of the connection associated with the string of settings in the file iec61850_mms_reports.csv.
- `ReportName` – name of the report.
- `ReportId` – ID of the report.
- `DataSetName` – name of the data set associated with this report.
- `IsBuffered` – indicates whether or not the report is buffered. It takes the `Buffered` or `Unbuffered` value.

The header strings are followed by the file body containing the parameter values (connection ID, report name, report ID, name of the data set for the report, and the buffer indicator). An example of the iec61850_mms_reports.csv file is provided below.

Example:

```
'Reports
'Format Version V1.0.0.0;KICS Importer Version V1.0.0.0
'Field separator: ; Decimal separator: . Text quotes: " Var name separator: .
'Connection;ReportName;ReportId;DataSetName;IsBuffered
"IED24151LD";"IED24151LD/LLN0$BR$brcbST01";"brcbST01";"IED24151LD/LLN0$DSList";"Buffered"
"IED24151LD";"IED24151LD/LLN0$RP$urcbMX01";"urcbMX01";"IED24151LD/LLN0$MXList";"Unbuffered"
```

System event types in Kaspersky Industrial CyberSecurity for Networks

In Kaspersky Industrial CyberSecurity for Networks, events are registered by using the system event types that are automatically created during installation of the application.

Each event type corresponds to a specific event registration technology.

System event types based on Deep Packet Inspection technology

This section provides a description of system event types associated with Deep Packet Inspection technology (see the table below).

System event types based on Deep Packet Inspection technology (DPI)

Code	Title of event type	Severity	Registration conditions
4000002900	$technology_rule	*Critical*	Process Control rule was triggered. The following variables are used in the title and description of system event type: • $technology_rule – name of the rule. • $tags – received values of tags whose conditions are defined in the rule. The user settings defined in the triggered Process Control rule are used for the title, description, and severity in a registered event.
4000000001	Test event (DPI)	*Informational*	A test network packet was detected.

System event types based on Command Control technology

This section provides a description of a system event type associated with Command Control technology (see the table below).

System event type based on Command Control technology (CC)

Code	Title of event type	Severity	Registration conditions
4000002602	$systemCommandShort	Determined by the importance level of the system command	A monitored system command was detected (and there is no enabled Interaction Control rule for the system command). The following variables are used in the title and description of an event type: • $systemCommandShort – brief description of the detected system command. • $systemCommandFull – detailed description of the detected system command. • $attackTechniques – list of possible techniques from the MITRE ATT&CK Knowledge Base that could be employed by cybercriminals for attacks using this system command.

System event types based on Network Integrity Control technology

This section provides a description of system event types associated with Network Integrity Control technology (see the table below).

System event types based on Network Integrity Control technology (NIC)

Code	Title of event type	Severity	Registration conditions
4000002601	Unauthorized network interaction detected ($top_level_protocol)	*Warning*	A network interaction that is not specified in an enabled Interaction Control rule was detected. The following variables are used in the title and description of an event type: • $top_level_protocol – name of the top-level protocol. • $protocol – name of the application-level protocol.
4000002700	No traffic at the monitoring point named $monitoringPoint	*Warning*	The network interface linked to the monitoring point has not received traffic in more than 15 seconds. The following variables are used in the title and description of an event type: • $monitoringPoint – name of the monitoring point. • $interface – name of the network interface that is linked to the monitoring point. • $duration – amount of time during which there was no traffic (in seconds).
4000000002	Test event (NIC)	*Informational*	A test network packet was detected (when Network Integrity Control is enabled).

System event types based on Intrusion Detection technology

This section provides a description of system event types associated with Intrusion Detection technology (see the table below).

System event types based on Intrusion Detection (IDS) technology

Code	Title of event type	Severity	Registration conditions
4000003000	Rule from the $fileName set (system set of rules) was triggered	Determined based on the rule priority	An Intrusion Detection rule in the system set of rules was triggered (the rule set is in active state). The following variables are used in the title and description of an event type: • $fileName – name of the rule set. • $category – class of the rule. • $ruleName – name of the rule. • $severity – priority of the rule. • $signature_id – rule ID (sid).
4000003001	A rule from the $fileName set (custom set of rules) was triggered.	Determined based on the rule priority	An Intrusion Detection rule in the custom set of rules was triggered (the rule set is in active state). The following variables are used in the title and description of an event type: • $fileName – name of the rule set. • $category – class of the rule. • $ruleName – name of the rule.

			• $severity – priority of the rule. • $signature_id – rule ID (sid).
4000004001	Symptoms of ARP spoofing detected in ARP replies	*Critical*	Signs of falsified addresses in ARP packets detected: multiple ARP replies that are not associated with ARP requests. The following variables are used in an event type description: • $senderIp – substituted IP address. • $targetIp – IP address of the target node. • $attackStartTimestamp – time when the first ARP reply was detected.
4000004002	Symptoms of ARP spoofing detected in ARP requests	*Critical*	Signs of falsified addresses in ARP packets detected: multiple ARP requests from the same MAC address to different destinations. The following variables are used in an event type description: • $senderIp – substituted IP address. • $targetIp – IP address of the target node. • $attackStartTimestamp – time when the first ARP reply was detected.
4000005100	IP protocol anomaly detected: data conflict when assembling IP packet	*Critical*	IP protocol anomaly detected: data does not match when overlaying fragments of an IP packet.
4000005101	IP protocol anomaly detected: fragmented IP packet size exceeded	*Critical*	An IP protocol anomaly was detected: the actual total size of a fragmented IP packet after assembly exceeds the acceptable limit.
4000005102	IP protocol anomaly detected: the size of the initial fragment of the IP packet is less than expected	*Critical*	An IP protocol anomaly was detected: the size of the initial fragment of an IP packet is less than the minimum permissible value.
4000005103	IP protocol anomaly detected: mis-associated fragments	*Warning*	An IP protocol anomaly was detected: fragments of an assembled IP packet contain conflicting data on the length of the fragmented packet.
4000002701	TCP protocol anomaly detected: content substitution in overlapping TCP segments	*Critical*	TCP protocol anomaly detected: packets contain overlapping TCP segments with varying contents.
4000000003	Test event (IDS)	*Informational*	A test network packet was detected (with rule-based Intrusion Detection enabled).

System event types based on Asset Management technology

This section provides a description of system event types associated with Asset Management technology (see the table below).

System event types based on Asset Management technology (AM)

Code	Title of event type	Severity	Registration conditions
4000005003	Detected new device with the address $owner_ip_or_mac	*Critical*	Asset Management monitoring mode resulted in the automatic addition of a new device based on a detected IP address or MAC address that has not been specified for other devices in the table. The following variables are used in the title and description of an event type: • $owner_ip_or_mac – IP or MAC address of the device. • $asset_name – assigned name of the device. • $assigned_mac – assigned MAC address (if defined).

			• $owner_ip – assigned IP address (if defined). • $asset_id – ID of the device.
4000005004	Received new information about device with the address $owner_ip_or_mac	*Informational*	Asset Management monitoring mode resulted in the automatic update of device information based on data obtained from traffic. The following variables are used in the title and description of an event type: • $owner_ip_or_mac – IP or MAC address of the device. • $asset_name – name of the device. • $updated_params – list of updated information. • $asset_id – ID of the device.
4000005005	IP address $owner_ip conflict detected	*Critical*	In Asset Management monitoring mode, the application detected the use of an IP address by a different device than the device for which this IP address was specified. The following variables are used in the title and description of an event type: • $owner_ip – IP address. • $challenger_asset_name – name of the device that used the IP address. • $challenger_mac – MAC address of the device that used the IP address. • $asset_name – name of the device in whose settings the IP address was specified. • $owner_mac – MAC address of the device in whose settings the IP address was specified. • $challenger_ips_list – list of other IP addresses of the device that used the IP address. • $asset_id – ID of the device in whose settings the IP address was specified. • $challenger_id. – ID of the device that used the IP address.
4000005006	Detected traffic from address $owner_ip_or_mac, which is assigned to a device with the Archived status	*Critical*	In Asset Management monitoring mode or based on data received from an EPP application, activity was detected from a device that was assigned the *Archived* status. The following variables are used in the title and description of an event type: • $owner_ip_or_mac – IP or MAC address of the device. • $asset_name – name of the device. • $last_seen_timestamp – date and time when the device was last seen in the network. • $asset_id – ID of the device.
4000005007	A new IP address $new_ip_addr was detected for the device with MAC address $owner_mac	*Critical*	In Asset Management monitoring mode, a new IP address used by a device was detected. The following variables are used in the title and description of an event type: • $new_ip_addr – detected IP address. • $owner_mac – MAC address of the device. • $asset_name – name of the device. • $owner_ips_list – list of other IP addresses of the device.

			• $asset_id – ID of the device.
4000005008	MAC address $owner_mac was added to the device with IP address $owner_ip	*Informational*	Asset Management monitoring mode resulted in the automatic addition of a MAC address for a network interface for which only an IP address was specified (the device had the *Unauthorized* or *Archived* status). The following variables are used in the title and description of an event type: • $owner_mac – detected MAC address of the device. • $owner_ip – IP address of the device. • $asset_name – name of the device. • $asset_id – ID of the device.
4000005009	IP address $owner_ip was added to the device with MAC address $owner_mac	*Informational*	Asset Management monitoring mode resulted in the automatic addition of an IP address for a network interface for which only a MAC address was specified (the device had the *Unauthorized* or *Archived* status). The following variables are used in the title and description of an event type: • $owner_ip – detected IP address of the device. • $owner_mac – MAC address of the device. • $asset_name – name of the device. • $asset_id – ID of the device.
4000005010	Detected new MAC address $new_mac_addr for device with the IP address $owner_ip	*Critical*	Asset Management monitoring mode resulted in the detection of a new MAC address used by a device (autoupdate of address information is disabled for the device). The following variables are used in the title and description of an event type: • $new_mac_addr – detected MAC address. • $owner_ip – IP address of the device. • $asset_name – name of the device. • $asset_id – ID of the device.
4000005011	Change of MAC address $owner_mac to $challenger_mac detected in device information received from EPP application	*Critical*	The MAC address of a device was updated according to data received from an EPP application. The following variables are used in the title and description of an event type: • $owner_mac – old MAC address of the device. • $challenger_mac – new MAC address of the device. • $asset_name – name of the device. • $asset_id – ID of the device.
4000005012	New address information of device $asset_name detected in data received from EPP application	*Critical*	New address information of a device was detected in data received from an EPP application. This type of event is registered if a change in device address information was not processed by the application as an event with code 4000005009 or 4000005010. The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $unaccepted_epp_addresses – address information. • $asset_id – ID of the device.

4000005013	Conflict detected in addresses of devices $conflicted_epp_assets after data received from EPP application	*Critical*	Based on data received from an EPP application, a conflict was detected in the addresses of multiple devices in Kaspersky Industrial CyberSecurity for Networks. According to data from the EPP application, the addresses belong to the same device. The following variables are used in the title and description of an event type: • $conflicted_epp_assets – devices with conflicting addresses detected. • $unaccepted_epp_addresses – addresses that belong to the same device.
4000005014	Subnet $subnet_mask added based on data from EPP application	*Critical*	After data was received from an EPP application, a new subnet was automatically added to the list of known subnets. The following variables are used in the title and description of an event type: • $subnet_mask – subnet address. • $subnet_type – subnet type.
4000005200	PLC Project Control: detected read of unknown block from PLC $asset_name	*Critical*	PLC Project Control read/write monitoring resulted in a detected read of an unknown block of a project from a PLC (if there is no saved information about this block). The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $block_name – name of the block. • $saved_date_time – date and time when the operation was detected.
4000005201	PLC Project Control: detected read of known block from PLC $asset_name	*Critical*	PLC Project Control read/write monitoring resulted in a detected read of a known block of a project from a PLC (if there is saved information about this block but the received information does not match the latest saved information about this block). The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $block_name – name of the block. • $saved_date_time – date and time when the block was saved in the application.
4000005202	PLC Project Control: detected write of new block to PLC $asset_name	*Critical*	PLC Project Control read/write monitoring resulted in a detected write of an unknown block of a project from a PLC (if there is no saved information about this block). The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $block_name – name of the block. • $saved_date_time – date and time when the operation was detected.
4000005203	PLC Project Control: detected write of known block to PLC $asset_name	*Critical*	PLC Project Control read/write monitoring resulted in a detected write of a known block of a project from a PLC (if there is saved information about this block but the received information does not match the latest saved information about this block). The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $block_name – name of the block.

			• $saved_date_time – date and time when the block was saved in the application.
4000005204	PLC Project Control: detected read of unknown project from PLC $asset_name	*Critical*	PLC Project Control read/write monitoring resulted in a detected read of an unknown project from a PLC (if there is no saved information about this project). The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $saved_date_time – date and time when the operation was detected.
4000005205	PLC Project Control: detected read of known project from PLC $asset_name	*Critical*	PLC Project Control read/write monitoring resulted in a detected read of a known project from a PLC (if there is saved information about this project but the received information does not match the latest saved information about this project). The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $saved_date_time – date and time when the project was saved in the application.
4000005206	PLC Project Control: detected write of new project to PLC $asset_name	*Critical*	PLC Project Control read/write monitoring resulted in a detected write of a new project to a PLC (if there is no saved information about this project). The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $saved_date_time – date and time when the operation was detected.
4000005207	PLC Project Control: detected write of known project to PLC $asset_name	*Critical*	PLC Project Control read/write monitoring resulted in a detected write of a known project to a PLC (if there is saved information about this project but the received information does not match the latest saved information about this project). The following variables are used in the title and description of an event type: • $asset_name – name of the device. • $saved_date_time – date and time when the project was saved in the application.
4000005300	Detected vulnerability $cve_id	*Critical*	Device vulnerability detected for the first time or a vulnerability had been previously switched to the *Remediated* state (for example, if modified device information once again matches a device description in a vulnerability with the same CVE ID). The following variables are used in the title and description of an event type: • $cve_id – vulnerability identification number. • $cve_desc – vulnerability description. • $cve_mitigation – mitigations from vulnerability database.
4000005303	Modified information about vulnerability $cve_id	*Critical*	Changes detected in a vulnerability that did not impact its current state (for example, if additional recommendations on system protection were added when the database of known vulnerabilities was updated). The following variables are used in the title and description of an event type: • $cve_id – vulnerability identification number. • $cve_desc – vulnerability description.

			• $cve_updated_params – modified information.
4000000004	Test event (AM)	*Informational*	A test network packet was detected (with the device activity detection method enabled).

System event types based on External technology

This section provides a description of system event types associated with External technology (see the table below).

System event types based on External technology (EXT)

Code	Title of event type	Severity	Registration conditions
8000000001	Incident	Determined by the importance level of the correlation rule	A sequence of events satisfying the conditions of a correlation rule was detected. When an event is registered, the incident receives a title and description from the correlation rule.
4000005400	Event from an external system	Determined by the external system	An event was received from an external system using the Kaspersky Industrial CyberSecurity for Networks API. When an event is registered, the contents of the title and description are determined by the external system.

System event types based on Endpoint Protection Platform

This section provides a description of a system event type associated with Endpoint Protection Platform (see the table below).

System event type based on Endpoint Protection Platform (EPP)

Code	Title of event type	Severity	Registration conditions
4000005500	EPP application triggered ($verdict, mode: $mode)	Critical	The integration server received data indicating that the EPP application was triggered by a possibly infected object or potential threat. The following variables are used in the title and description of an event type: • $verdict – threat name • $mode – processing mode • $epp_event_description – obtained data, which may additionally contain an IP address, web address, email address or object type.

Glossary

Account role

Set of access rights that determine the actions available to a user when connected to the Server through the web interface. Kaspersky Industrial CyberSecurity for Networks provides the Administrator role and the Operator role.

ARP spoofing

A technique used by criminals to conduct a "man-in-the-middle" attack on networks that use ARP (Address Resolution Protocol).

Asset Management

Technology for registering events associated with the detection of device information in traffic or in data received from EPP applications (for example, an event for the detection of activity from a previously unknown device).

Command Control

Technology for registering events associated with the detection of system commands for devices in traffic (for example, detection of an unauthorized system command).

CVE

Acronym for Common Vulnerabilities and Exposures. Database of publicly known vulnerabilities and information security risks. Vulnerabilities are assigned identification numbers in the format CVE-<year>-<number>.

Dedicated Kaspersky Industrial CyberSecurity network

A computer network consisting of computers designed for running applications that are part of the Kaspersky Industrial CyberSecurity solution, and the network equipment that enables interaction between computers. The dedicated network must not be accessible from other networks.

Deep Packet Inspection

Technology for registering events associated with process violations (for example, the set temperature value has been exceeded).

Device

Device that is connected to a computer network and is identified by address information that can be saved in Kaspersky Industrial CyberSecurity for Networks (for example, programmable logic controller, remote terminal, or intelligent electronic device).

Device vulnerability

A defect in device hardware or software that can be exploited by a hacker to impact the operation of the information system or to gain unauthorized access to information.

Endpoint Protection Platform (EPP)

An integrated system providing comprehensive Endpoint Protection (such as mobile devices, computers or laptops) by using various security technologies. An example of an Endpoint Protection Platform is the application known as Kaspersky Endpoint Security for Business.

EPP application

An application that is included in the Endpoint Protection Platform (EPP). EPP applications are installed to endpoint devices within an enterprise IT infrastructure (such as mobile devices, computers or laptops). One example of an EPP application is Kaspersky Endpoint Security for Windows included in the EPP solution known as Kaspersky Endpoint Security for Business.

Event

Record containing information requiring the attention of an ICS security officer. Kaspersky Industrial CyberSecurity for Networks saves registered events in the database. To view registered events, you need to connect to the Server through the web interface. If necessary, you can configure transmission of events to Kaspersky Security Center and recipient systems.

Event correlation rule

Set of conditions for checking sequences of events in Kaspersky Industrial CyberSecurity for Networks. When Kaspersky Industrial CyberSecurity for Networks detects a sequence of events that meet the conditions of an event correlation rule, the application registers an incident.

Event type

Defined set of parameters for registering events in Kaspersky Industrial CyberSecurity for Networks. A unique number (event type code) is assigned to each event type.

External

Technology for registering incidents and events that are received by Kaspersky Industrial CyberSecurity for Networks from recipient systems using Kaspersky Industrial CyberSecurity for Networks API methods.

ICS

Abbreviation for Industrial Control System. A package of hardware and software designed to automate control of process equipment at industrial enterprises.

Incident

In Kaspersky Industrial CyberSecurity for Networks, an incident is an event that is registered when a specific sequence of events is received. Incidents group events that have certain common traits or that are associated with the same process. Kaspersky Industrial CyberSecurity for Networks registers incidents based on event correlation rules.

Industrial network

Computing network that links the nodes of an automated Industrial Control System of an industrial enterprise.

Intelligent electronic device (IED)

A set of devices that ensure timely disconnection of faulty power facilities from the power system, and that perform the necessary actions to ensure normal operation of the power system in automated or semi-automated operating modes.

Interaction Control rule

A description of authorized communications for industrial network devices. When Kaspersky Industrial CyberSecurity for Networks detects network interaction that satisfies an enabled Interaction Control rule, the application does not register an event.

Intrusion Detection

Technology for registering events associated with the detection of traffic anomalies that are signs of an attack (for example, detection of signs of ARP spoofing).

Intrusion Detection rule

A set of conditions used by the Intrusion Detection system to analyze traffic. The rule describes a traffic anomaly that could be a sign of an attack in the industrial network.

Kaspersky Industrial CyberSecurity for Networks Sensor

Kaspersky Industrial CyberSecurity for Networks component. A sensor is installed on a separate computer (not on the computer that performs functions of the Kaspersky Industrial CyberSecurity for Networks Server). A sensor receives and analyzes data from computer networks that are connected to the network interfaces of the sensor's computer. To receive and analyze industrial network traffic, monitoring points must be added to the network interfaces. A sensor forwards the data analysis results to the Server.

Kaspersky Industrial CyberSecurity for Networks Server

Kaspersky Industrial CyberSecurity for Networks component. The Server receives data, processes it, and provides it to users of the application. The Server can receive data from sensors or independently obtain and analyze data from computer networks that are connected to the network interfaces of the Server computer.

Link on the network map

Object on the network map depicting interaction between nodes represented by a line between those nodes.

Monitoring point

A point where incoming data is received. It is added to the network interface of a node hosting the Server or sensor of Kaspersky Industrial CyberSecurity for Networks, and is used for receiving a copy of industrial network traffic (for example, from a network switch port configured to transmit mirrored traffic).

Network Integrity Control

Technology for registering events associated with industrial network integrity or the security of communications (for example, detection of communication between devices over an unauthorized protocol).

Network map

Model that visually represents detected communications between devices. The network map contains the following objects: nodes representing devices, device groups, and links between nodes/device groups.

Node

Computer on which a Kaspersky Industrial CyberSecurity for Networks Server or sensor is installed, or an object on the network map representing one or multiple devices.

PLC project

Microprogram written for a PLC. It is stored in PLC memory and is run as part of the industrial process that uses the PLC. A PLC project may consist of blocks that are individually transmitted and received over the network when the project is read or written.

Process Control rule

A set of conditions for tag values. When the conditions of a Process Control rule are fulfilled, Kaspersky Industrial CyberSecurity for Networks registers an event.

Programmable Logic Controller (PLC)

Industrial controller used to automate enterprise processes.

SCADA

Abbreviation for Supervisory Control And Data Acquisition. A software suite that enables the operator to control industrial processes in real time.

Security policy

Set of data that determines the operational settings of Kaspersky Industrial CyberSecurity for Networks.

SIEM

Abbreviation for Security Information and Event Management. This is a solution for managing information and events in an organization's security system.

Single Sign-On (SSO) technology

Mechanism that allows a user to access multiple software resources using the same user account.

System command

Data block in industrial network traffic containing the device management command (for example, START PLC) or system message related to device operation (for example, REQUEST NOT FOUND).

Tag

Variable that contains the value of a specific process parameter such as temperature.

Information about third-party code

Information about third-party code is contained in the file named legal_notices.txt in the application installation folder.

Trademark notices

Registered trademarks and service marks are the property of their respective owners.

Adobe, Flash are either registered trademarks or trademarks of Adobe in the United States and/or other countries.

BACnet is a registered trademark of the American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc.

iPad, iPhone, Mac, Mac OS, macOS, and OS X are trademarks of Apple Inc.

AXIS and AXIS COMMUNICATIONS are registered trademarks or trademark applications of Axis AB in various jurisdictions.

BitTorrent is a trademark of BitTorrent, Inc.

Cisco, Cisco AnyConnect, AnyConnect, IOS, Jabber, and Snort are registered trademarks or trademarks of Cisco Systems, Inc. and/or its affiliates in the United States and certain other countries.

Radmin is a registered trademark of Famatech.

FreeBSD is a registered trademark of The FreeBSD Foundation.

General Electric and Multilin are registered trademarks of General Electric Company.

Google, Android, Chrome, Google Chrome, and Nexus are trademarks of Google LLC.

HL7 is the registered trademark of Health Level Seven International and its use of the trademark does not constitute endorsement by HL7.

Hitachi is a trademark of Hitachi, Ltd.

Intel, Atom, and Core are trademarks of Intel Corporation in the United States and/or other countries.

IBM and DB2 are trademarks of International Business Machines Corporation, registered in many jurisdictions worldwide.

Node.js is a trademark of Joyent, Inc.

Linux is the registered trademark of Linus Torvalds in the United States and other countries.

OpenAPI is a trademark of The Linux Foundation.

Microsoft, Active Directory, ActiveX, AppLocker, BizTalk, Microsoft Edge, SQL Server, Visual Basic, Visual FoxPro, Windows, Windows Server, Windows Vista, and Windows XP are trademarks of the Microsoft group of companies.

CVE is a registered trademark of The MITRE Corporation.

MOXA is a registered trademark of Moxa Inc.

Mozilla and Firefox are trademarks of the Mozilla Foundation in the United States and other countries.

DICOM is the registered trademark of the National Electrical Manufacturers Association for its Standards publications relating to digital communications of medical information.

ONVIF is a trademark of ONVIF, Inc.

OpenVPN is a registered trademark of OpenVPN, Inc.

Oracle, Java, JavaScript, and Solaris are registered trademarks of Oracle and/or its affiliates.

Python is a trademark or registered trademark of the Python Software Foundation.

Red Hat, Ansible, and CentOS are trademarks or registered trademarks of Red Hat, Inc. or its subsidiaries in the United States and other countries.

Remote Utilities is a registered trademark of Remote Utilities LLC in the United States and/or other countries.

The Trademark BlackBerry is owned by Research In Motion Limited and is registered in the United States and may be pending or registered in other countries.

Schneider Electric is a trademark of Schneider Electric.

Siemens, Simatic, and WinCC are registered trademarks of Siemens AG.

OpenWRT is a trademark of Software Freedom Conservancy (SFC). Kaspersky Industrial CyberSecurity for Networks is not affiliated with OpenWrt.

Dameware is trademark of SolarWinds Worldwide, LLC, registered in the United States and other countries.

VMware is a registered trademark or trademark of VMware, Inc. in the United States and/or other jurisdictions.

VxWorks is a registered trademark (®) or service mark (SM) of Wind River Systems, Inc. This product is not affiliated with, endorsed, sponsored, supported by the owners of the third-party trademark mentioned herein.
